

Mystery Fever at Fort Bragg

From the New York Sun
November 13, 1942

Civilian volunteers will be called as guinea pigs to help determine the origin of a mysterious, although just now dormant, disease in an American Army camp, the Southern Medical Association was told today.

Lieut. Col. Worth P. Daniels of Fort Bragg, N. C., said that forty soldiers there had been stricken by a strange rash-accompanied fever. There were no deaths.

He said a mosquito known as *Aedes aegypti* was among suspects listed as transmitters of the disease. Some of these were fed on two men during the early phase of their illness and an attempt is to be made to transmit the disease by these mosquitoes for observation.

Lieut. Col. Daniels said since September there had been no cases of the disease, which had been called pre-tibial fever because the rash occurs on the front of the legs.

He said the fever lasted about five days and was accompanied by low respiratory manifestations, pain in the forehead and behind the eyes, backache, reduction in white blood cells, enlargement of the spleen and the rash.
