

referred, with some doubt, to the genus *Mauisaurus* of Dr. Hector, founded upon a Saurian from the Cretaceous formation of New Zealand. He gave it the name of *Mauisaurus Gardneri* in honour of its discoverer. A small heap of pebbles was found in the neighbourhood of the ribs; and it was supposed that these had been contained in the stomach of the animal.

MISCELLANEOUS.

Note on the Femoral Brushes of the Mantidæ.

By Prof. J. WOOD-MASON.

SINCE the abstract* of my paper on these structures and their use was published, I have been enabled to consult M. Stål's memoir† entitled "*Orthoptera quædam Africana*;" and I find that I have been anticipated as to the discovery—the brushes, or rather the setulose eminences which I call brushes, being thus described in a footnote to p. 382 of the work cited:—"In latere interiore femorum anticorum *Mantodeorum* adest apicem versus prope marginem inferiorem spatium parvum leviter convexum, oblongum, dense brevissimeque setulosum." M. Stål makes no suggestion as to the possible use of the brushes to the insects; but I have ascertained‡ that they are exclusively used for keeping the eyes and ocelli in a functional condition, and that they are present in the young when these quit the egg.

A full account of my observations and experiments on numerous living specimens belonging to several genera (*Schizocephala*, *Pseudomantis*, *Hierodula*, &c.) will be given in my paper.

Calcutta, Dec. 22, 1876.

On the Development of the Antennæ in the Pectinicorn Mantidæ.

By Prof. J. WOOD-MASON.

The author shows that, down to the last change of skin but one, no difference is to be detected between the two sexes of *Gongylus gongylodes*, either in the form or in the proportional length of the antennæ, which in both male and female are identically the same simple and setaceous structures, consisting of two distinct basilar segments followed by a multitude of very short and ill-defined flagellar ones, but that shortly after this event these appendages in the male begin to thicken throughout that portion of their length which in the perfect insect is bipectinated, so as eventually to acquire a compressed spindle-shaped form; that this thickening is the outward manifestation of the growth going on beneath the
