

Review of the genus *Hypostomus* Lacépède, 1803 from Southern Brazil, with descriptions of three new species (Pisces, Siluriformes, Loricariidae)

by

Roberto E. REIS*, Claude WEBER** & Luiz R. MALABARBA*

With 31 figures

ABSTRACT

The South Brazilian species of the loricariid catfish genus *Hypostomus* Lacépède, 1803 are reviewed. Eight species were found in the area: *H. aspilogaster* (Cope, 1894), *H. commersonii* Valenciennes, 1840, *H. luteus* (Godoy, 1980), *H. regani* (Ihering, 1905), *H. cf. ternetzi* (Boulenger, 1895), *H. isbrueckeri* sp. n., *H. roseopunctatus* sp. n., and *H. uruguayensis* sp. n. *Hypostomus luteomaculatus* (Devincenzi & Teague, 1942) is synonymized with *H. regani*. Lectotypes are designated for *H. aspilogaster*, *H. limosus* (Eigenmann & Eigenmann, 1888), and *H. regani*. A key, descriptions and illustrations are provided for all species included.

RESUMO

É feita uma revisão das espécies do gênero *Hypostomus* Lacépède, 1803 (Loricariidae) do sul do Brasil. Oito espécies foram encontradas na área: *H. aspilogaster* (Cope, 1894), *H. commersonii* Valenciennes, 1840, *H. luteus* (Godoy, 1980), *H. regani* (Ihering, 1905), *H. ternetzi* (Boulenger, 1895), *H. isbrueckeri* sp. n., *H. roseopunctatus* sp. n., e *H. uruguayensis* sp. n. *Hypostomus luteomaculatus* (Devincenzi & Teague, 1942) é considerada sinônimo de *H. regani*. Lectótipos são designados para

* Museu de Ciências, Pontifícia Universidade Católica do Rio Grande do Sul, Caixa Postal 1429, 90620 Porto Alegre, Brazil.

** Département d'herpétoologie et d'ichtyologie, Muséum d'Histoire naturelle, case postale 434, CH-1211 Genève 6, Suisse.

H. aspilogaster, *H. limosus* (Eigenmann & Eigenmann, 1888) e *H. regani*. São apresentadas uma chave, descrições e ilustrações de todas as espécies.

INTRODUCTION

The genus *Hypostomus* Lacépède, 1803 is one of the most diverse and complex groups of South American freshwater catfishes. Like most other Neotropical groups studied in the past two centuries, the species of *Hypostomus* have been only briefly and incompletely described, and the available descriptions are often useless for species identification. This, allied to a very limited knowledge of general distribution patterns in South

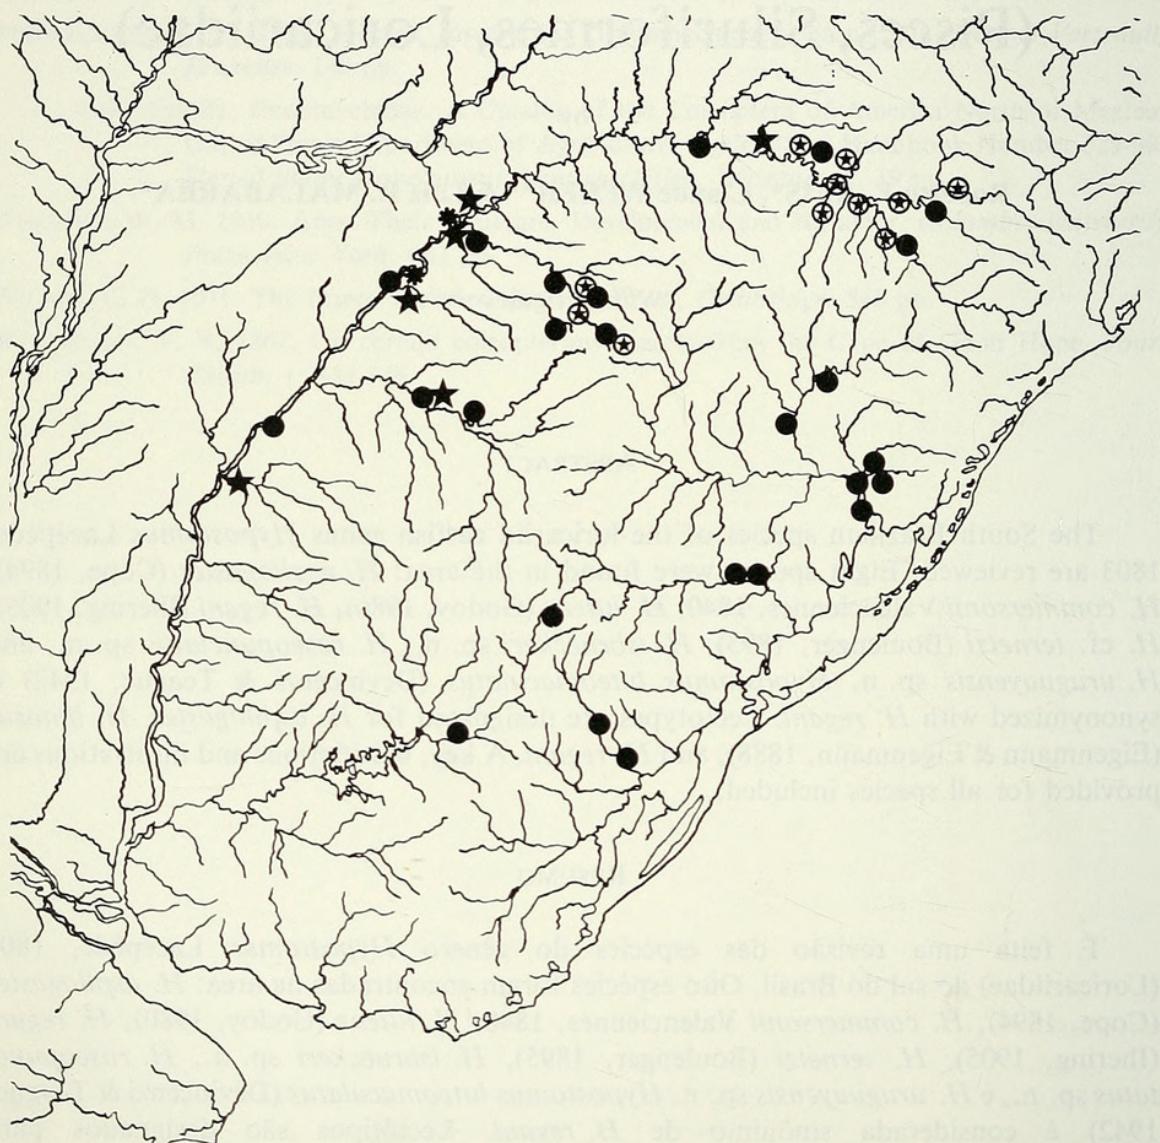

FIG. 1.

Localities of specimens examined: black circle: *H. commersonii*; circled star: *H. isbrueckeri* sp. n.; asterisk: *H. ternetzi*; star: *H. uruguayensis* sp. n. Some symbols represent more than one lot or locality.

American rivers, has resulted in a proliferation of misidentifications in the literature. This can be exemplified in the laguna dos Patos system in Rio Grande do Sul, as will be discussed below.

In this work we present a taxonomic review of the species of the genus *Hypostomus* from Southern Brazil, chiefly the Rio Grande do Sul State. This geopolitical area comprises mainly two hydrographic systems (Figs 1, 2), viz. most of the laguna dos Patos system, with the Jacui river as its main tributary, and the upper and middle parts of the rio Uruguay basin. We believe that regional revisions of diverse and complex groups of freshwater fishes such as *Hypostomus* are an efficient way, and often the only practicable one, to solve problems at the specific level, as was successfully done by BOESEMAN (1968) with *Hypostomus* from Surinam, WEBER (1985, 1986 and 1987) with *Hypostomus* from Paraguay, NIJSSEN & ISBRÜCKER (1983) with *Corydoras* from Colombia, NIJSSEN & ISBRÜCKER (1986) with *Corydoras* from Peru and Ecuador, among others.

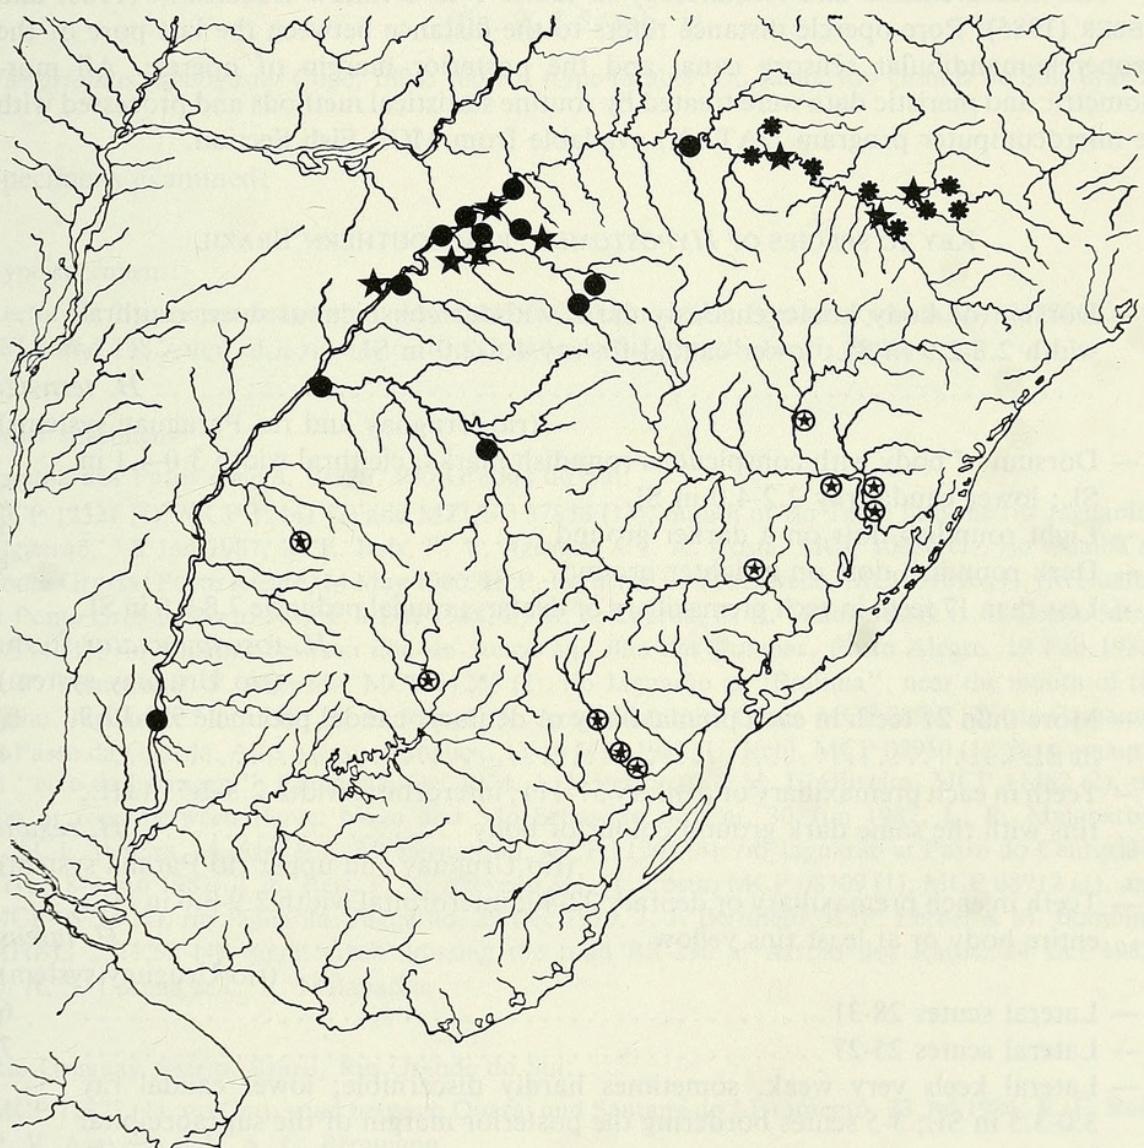

FIG. 2.

Locality of specimens examined: black circle: *H. regani*; circled star: *H. aspilogaster*; asterisk: *H. luteus*; star: *H. roseopunctatus* sp. n. Some symbols represent more than one lot or locality.

METHODS

Specimens examined in this study belong to the fish collections of the Academy of Natural Sciences of Philadelphia, Philadelphia (ANSP); British Museum (Natural History), London (BMNH); Facultad de Humanidades y Ciencias, Montevideo (FHCM); Museu de Ciências da Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre (MCP); Museum of Comparative Zoology, Cambridge (MCZ); Muséum d'Histoire naturelle de Genève, Genève (MHNG); Museo de Historia Natural de Montevideo, Montevideo (MHNM); Muséum national d'Histoire naturelle, Paris (MNHN); Museu de Zoologia da Universidade de São Paulo, São Paulo (MZUSP); National Museum of Natural History, Washington (USNM); and Zoologisches Museum Berlin, Berlin (ZMB). Other abbreviations are: L1 and L2, lower and upper confidence limits; SD, standard deviation; and SL, standard length.

The measurements and terminology in tables 1 to 8 follow BOESEMAN (1968) and WEBER (1985). Pore-opercle distance refers to the distance between the last pore of the preopercle-mandibular sensory canal and the posterior margin of opercle. All morphometric and meristic data were treated by routine statistical methods and processed with the microcomputer program DATAx, available from MCP Fish Section.

KEY TO SPECIES OF *HYPOSTOMUS* FROM SOUTHERN BRAZIL

- 1 — Dorsum of body homogeneously dark, without conspicuous dots; cleithral width 2.8-2.9 in SL; lower caudal-fin ray 1.8-2.0 in SL *H. ternetzi*
(rio Uruguay and rio Paraguay systems)
- 1' — Dorsum of body with conspicuous roundish marks; cleithral width 3.0-4.1 in SL; lower caudal ray 2.2-4.0 in SL 2
- 2 — Light roundish dots on a darker ground 3
- 2' — Dark roundish dots on a lighter ground 5
- 3 — Less than 17 teeth in each premaxillary or dentary; caudal peduncle 7.8-9.0 in SL *H. roseopunctatus* sp. n.
(rio Uruguay system)
- 3' — More than 21 teeth in each premaxillary or dentary; caudal peduncle 9.0-10.9 in SL 4
- 4 — Teeth in each premaxillary or dentary 57-111; interorbital width 2.3-2.7 in HL; fins with the same dark ground colour of body *H. regani*
(rio Uruguay and upper rio Paraná system)
- 4' — Teeth in each premaxillary or dentary 22-40; interorbital width 2.9-3.6 in HL; entire body or at least fins yellow *H. luteus*
(rio Uruguay system)
- 5 — Lateral scutes 28-31 6
- 5' — Lateral scutes 25-27 7
- 6 — Lateral keels very weak, sometimes hardly discernible; lower caudal ray 3.0-3.5 in SL; 3-5 scutes bordering the posterior margin of the supraoccipital bone *H. aspilogaster*
(rio Uruguay and rio Jacui systems)
- 6' — Lateral keels strong, sometimes very rough; lower caudal ray 2.5-2.9 in SL; 1-2 scutes bordering the posterior margin of the supraoccipital bone

- *H. commersonii*
 (rio Uruguay and rio Jacui systems)
- 7 — Upper caudal ray equal or longer than head length, 2.2-3.0 in SL; margin of caudal fin strongly concave, with big conspicuous darker dots and never with an yellow band *H. uruguensis* sp. n.
 (rio Uruguay system)
- 7' — Upper caudal ray shorter than head length, 3.4-4.1 in SL; margin of caudal fin truncated to slightly concave, homogeneously dark, often with an yellow (whitish in alcohol preserved specimens) distal band on mature males
 *H. isbrueckeri* sp. n.
 (rio Uruguay system)

Hypostomus aspilogaster (Cope)

(fig. 2, 3-5; tab. 1)

Plecostomus aspilogaster Cope, 1894: 100-101 (type-locality: rio Jacui, Rio Grande do Sul, Brazil).

Specimens examined:

Type-specimens:

Lectotype (by present designation) ANSP 21781 (203.7 mm SL); Paralectotypes ANSP 21782 (120.9, 187.3 and 148.7 mm SL), rio Jacui, Rio Grande do Sul, Brazil, H. H. Smith.

Other specimens:

Laguna dos Patos system, Brazil, Rio Grande do Sul:

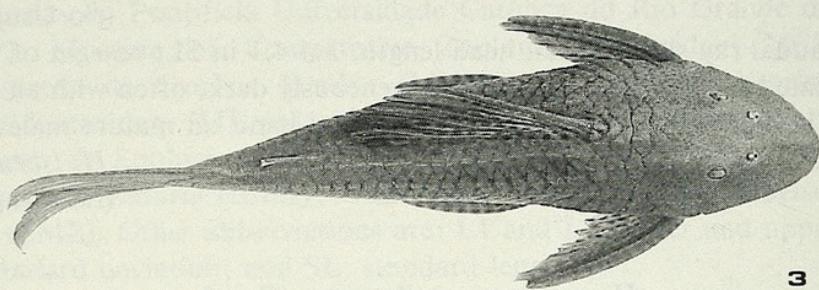

MCP 12321 (1), MCP 12141 (7) and MZUSP 37858 (13), mouth of rio Telho into the rio Jaguarão, Jaguarão, 7-8 Jan 1987, R. E. Reis, P. V. Azevedo & I. A. Costa. MCP 10886 (1), rio Guaiba at Ponta Grossa, Porto Alegre, 14 May 1986, E. P. Lerner & P. V. Azevedo. MCP 09696 (9), rio Guaiba at Ponta Grossa, Porto Alegre, 1 Dec 1983, Z. M. S. Lucena, L. R. Malabarba & I. A. Costa. MCP 10884 (1), rio Guaiba, between ilha do Junco and ilha das Pombas, Porto Alegre, 19 Feb 1986, E. P. Lerner & P. V. Azevedo. MCP 11258 (2), rio Jaguarão at "Prainha", near the mouth of rio Telho, Jaguarão, 7 Jan 1987, R. E. Reis, P. V. Azevedo & I. A. Costa. MCP 08995 (2), rio Camaquã at Passo da Guarda, Alto Alegre, Canguçu, 13-14 May 1982, U. Kehl. MCP 08950 (1), rio Camaquã at "eixo da barragem", Camaquã, Oct 1974, J. J. Bertoletti & M. F. Oliveira. MCP 11482 (2), rio Cai at road between Pareci Novo and São Sebastião do Cai, 30 Jun 1987, L. R. Malabarba, E. H. L. Pereira, M. Ries & L. M. Bernardini. MCP 11265 (4), rio Jaguarão at Passo do Centurião, Erval, 8-9 Jan 1987, R. E. Reis, P. V. Azevedo & I. A. Costa. MCP 08709 (1), MCP 08712 (1), and MCP 08715 (1), rio Jaguarão, Jaguarão, 29 Dec 1975, J. J. Bertoletti, E. P. Lerner & M. Bombim. MHNG 2311.52 (4), small creek crossing the road BR-290 at Arroio dos Ratos, 24 Oct 1982, C. A. S. Lucena & L. R. Malabarba.

Rio Uruguay system, Brazil, Rio Grande do Sul:

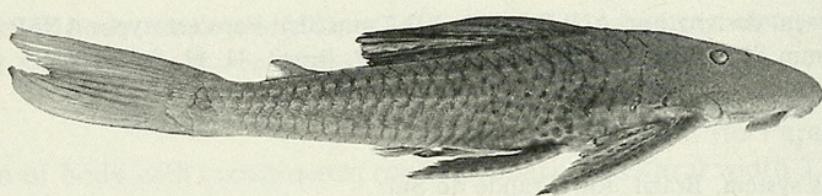

MCP 10877 (1), rio Cati, road between Quarai and Santana do Livramento, 23 Jul 1986, R. E. Reis, P. V. Azevedo & L. A. C. Bergmann.

Uruguay:

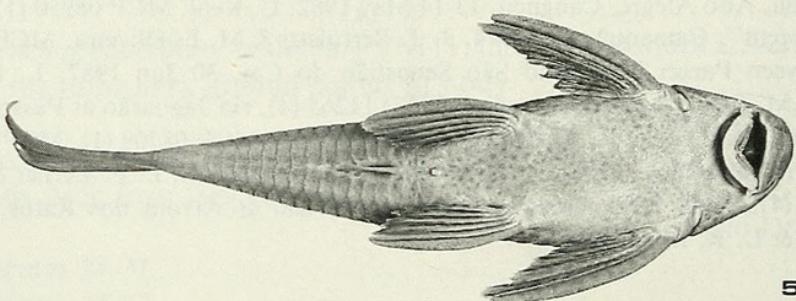

MCP 11088 (1), Río Taquarembó, Ansina, Taquarembó, 5 Oct 1985, C. A. S. Lucena & C. P. Silva.

Plates bordering supraoccipital	4	4	18	3	5	3.6			0.777

Diagnosis: *Hypostomus aspilogaster* is distinguished from all other *Hypostomus* species in Southern Brazil by the larger number of lateral scutes: 29-31 versus 25-27 in all other species except *H. commersonii* and *H. regani*. From *H. commersonii* it is distinguished by the number of scutes bordering the posterior margin of the supraoccipital

bone: 3-5 in *H. aspilogaster* and 1-2 in *H. commersonii*. *H. commersonii* also has a longer lower caudal fin spine (2.5-2.9 in SL; 3.0-3.5 in *H. aspilogaster*), and the lateral scutes are much rougher than those of *H. aspilogaster*. *Hypostomus regani* occasionally has 29 lateral scutes, but it is distinguished from *H. aspilogaster* by its larger eye, longer dorsal fin spine, longer adipose fin spine, larger number of teeth, possession of 1-2 plates bordering the supraoccipital bone (see tabs. 1 and 4), and inverse colour pattern, that is, light dots on darker ground.

Description: standard length of examined specimens 120.9 to 266.2 mm; other meristic and morphometric data summarized in table 1.

Head completely covered with dermal ossifications dorsally except for a comparatively large, roughly ovate naked area on snout tip. Dorsal margin of orbit slightly elevated, hardly continuing in an inconspicuous ridge on posttemporal plate and following scutes. Usually three, sometimes 4 or 5 scutes bordering posterior margin of supraoccipital bone. Body moderately low; dorsal profile gently descending from origin of dorsal fin to end of caudal peduncle. Caudal peduncle wide, roughly ovate in cross-section; widely flattened ventrally. Dorsal scutes between end of dorsal fin base and adipose fin flattened in their dorsal portion; those closer to dorsal fin usually not meeting in midline and with a central area lacking odontodes.

Outer face of upper lip covered with small scutelets; maxillary barbel comparatively short. Teeth very thin but not very numerous, with very small outer cusp.

Body completely covered with rows of smooth scutes dorsally, even in larger specimens. Abdomen and ventral surface of head ranging from completely naked in smaller specimens to completely covered with small scutelets in larger individuals.

Adipose fin spine short and curved. Caudal fin margin concave.

Colour in alcohol: ground colour of dorsal surface light- or yellowish-brown to dark grey-brown; lighter ventrally. Black or dark-brown small, roundish dots scattered all over dorsal surface, fins, and abdomen; smaller and closer together on head. This pattern usually inconspicuous on caudal fin.

Colour in life: living specimens of *H. aspilogaster* just alike alcohol preserved specimens.

***Hypostomus commersonii* Valenciennes (Fig. 1, 6-8; tab. 2)**

Hypostomus Commersonii Valenciennes, in Cuvier & Valenciennes, 1840: 495-497 (type-locality: Río de La Plata, Uruguay and rio São Francisco, Brazil; restricted to Río de La Plata, Montevideo, Uruguay, by WEBER, 1896).

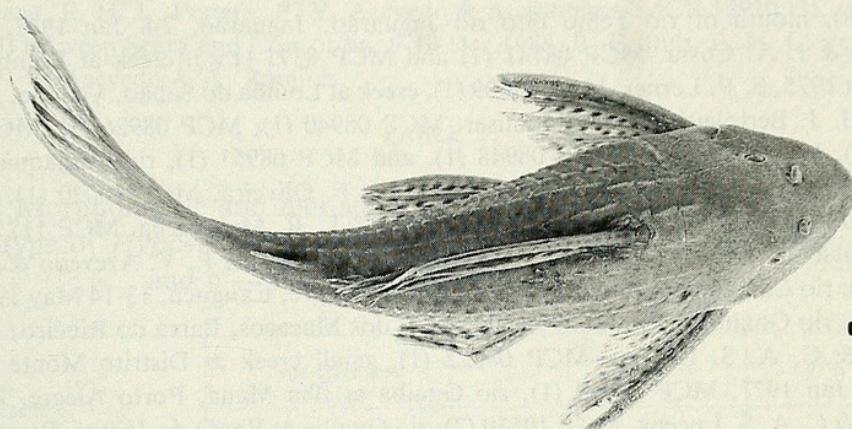

Plecostomus spiniger Hensel, 1870: 73-75 (type-locality: rio Cadeia, Rio Grande do Sul, Brazil).

Plecostomus limosus Eigenmann & Eigenmann, 1888: 167 (type-locality: Rio Grande do Sul; restricted to laguna dos Patos system by MALABARBA, 1989).

Uruguay:

MCP 09856 (1), MCP 09857 (1), MCP 09858 (1), MCP 09859 (1), MCP 09860 (1), MCP 09861 (1), MCP 09862 (1), MCP 09863 (1), MCP 09864 (1), MCP 09865 (1), MCP 09866 (1), MCP 09867 (1), MCP 09868 (1), MCP 09869 (1) and MCP 09870 (1), Río Negro, Arreria Farm, Depto. Cerro Largo, 19-21 May 1984, C. A. S. Lucena & others.

Diagnosis: *Hypostomus commersonii* is distinguished from other *Hypostomus* species inhabiting Southern Brazil by the presence of four very rough lateral ridges on flanks. *H. commersonii* has 28-30 lateral scutes (25-27 in remaining species except *H. aspilogaster* and *H. regani*). From *H. regani*, it is easily distinguished by its smaller eye, smaller snout, smaller mandibular ramus, smaller number of teeth (see tabs 2 and 4) and by presenting the inverse colour pattern, that is, dark dots on lighter ground. From *H. aspilogaster*, it is distinguished by the longer lower caudal ray and by having 1-2 scutes bordering the posterior margin of the supraoccipital bone (3-5 in *H. aspilogaster*).

Description: standard length of examined specimens 111.1 to 423.0 mm; other meristic and morphometric data summarized in table 2.

Head completely covered with dermal ossifications dorsally, except for a small, roughly ovate naked area on snout tip, which usually disappears in larger specimens. Dorsal margin of orbit slightly elevated, continuing in a low ridge on posttemporal plate. Another low ridge on supraoccipital, diverging in two separate ridges on predorsal plates always present. Usually one, sometimes two scutes bordering posterior margin of the supraoccipital bone. Body deep; dorsal profile gently descending from origin of dorsal fin to end of caudal peduncle. Caudal peduncle roughly ovate in cross-section; slightly flattened ventrally. Dorsal scutes between end of dorsal fin base and adipose fin spine somewhat flattened in their dorsal portions; those closer to dorsal fin sometimes with a central area devoided of odontodes.

Outer face of upper lip covered with small scutelets; maxillary barbel comparatively short. Teeth small and not much numerous; with a well developed outer cusp of about half length of inner.

Body completely covered with rows of scutes with a rough keel, forming four rough ridges along flanks. These ridges sometimes very strong. Abdomen and lower surface of head usually covered with minute scutelets, even in smaller specimens.

Distal half of pectoral fin spine of larger specimens usually covered dorsally with proeminent odontodes anteriorly curved. Adipose fin spine very strong but short and curved. Caudal fin margin concave to strongly concave; medium-sized outer rays.

Colour in alcohol: ground colour of dorsal surface light- to dark-brown; slightly lighter to whitish ventrally. All body and fins covered with very small, roundish, black or dark-brown dots; smaller and closer together on head. This pattern sometimes inconspicuous on caudal fin and ventral portion of caudal peduncle.

Colour in life: living specimens of *H. commersonii* usually darker than alcohol preserved specimens.

Remarks: *H. commersonii* is by far the largest species in Southern Brazil, attaining more than half a meter. *H. commersonii* was the only species found inhabiting lentic, open environments such as large lagoons and freshwater swamps.

Hypostomus luteus (Godoy)
(fig. 2, 9-14; tab. 3)

Plecostomus luteus Godoy, 1980: 29-32, figs 15, 16 (type-locality: rio Pelotas at Volta Grande Dois, Marcelino Ramos, Rio Grande do Sul, Brazil).

Ramires. MCP 12492 (1), rio Uruguay at Itá, 1 Oct 1988, P. V. Azevedo, E. H. L. Pereira, L. A. C. Bergmann & A. Ramires.

Diagnosis: large *Hypostomus luteus* specimens are distinguished from all other *Hypostomus* species by the impressive bright yellowish-orange colour (pale yellowish in alcohol-preserved specimens). Smaller specimens usually have at least the entire caudal fin and usually also the dorsal fin yellow, and small yellow dots scattered on the dorsal surface. Besides *H. luteus*, the following two South Brazilian species have light dots on darker ground: *H. roseopunctatus* and *H. regani*. The three species are characterized by the number of jaw teeth 6-16 in *H. roseopunctatus*, 22-40 in *H. luteus*, and 57-111 in *H. regani*.

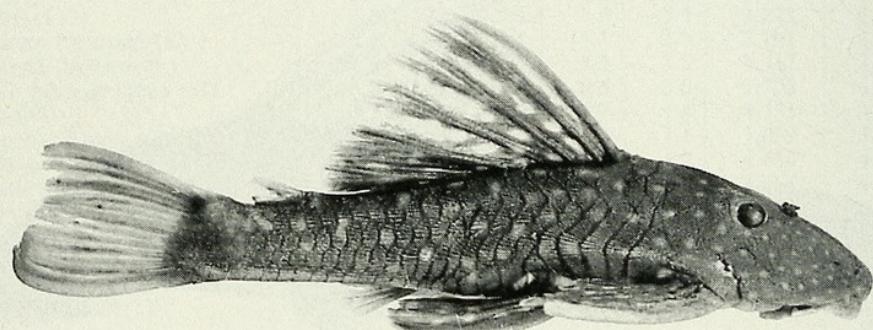

FIGS 9-11.

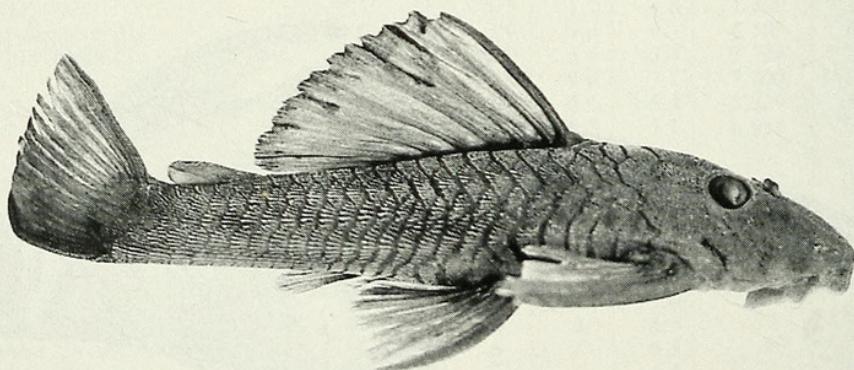

Hypostomus luteus, MCP 12807 (279.0 mm SL); 9) dorsal, 10) lateral, and 11) ventral views.

12

13

14

FIGS 12-14.

Hypostomus luteus, progressive development of the yellow color: 12) MCP 12816 (226.0 mm SL), 13) MCP 12493 (134.7 mm SL), and 14) MCP 12492 (77.2 mm SL).

Description: standard length of examined specimens 134.7 to 312.5 mm; other meristic and morphometric data summarized in table 3.

Head covered with dermal ossifications dorsally, except for a roundish of ovate naked area on snout tip. Dorsal margin of orbit only slightly elevated, continuing in an inconspicuous ridge on posttemporal plate and on a series of scutes beginning just behind posttemporal plate (at least in larger specimens). Low ridges also present on predorsal and dorsal scutes. Usually three scutes bordering posterior margin of supraoccipital bone. Body moderately low; dorsal profile gently descending from origin of dorsal fin to end of caudal peduncle. Caudal peduncle roughly ovate in cross-section; slightly flattened ventrally. Ventral scutes of caudal peduncle somewhat expanded laterally, forming conspicuous lateral ridges in its lower margins, at least in larger specimens. Dorsal scutes between end of dorsal fin base and adipose fin spine flat in their dorsal portion; those closer to dorsal fin usually with a central area devoided of odontodes.

Outer face of upper lip covered with small scutelets, specially on lateral portions; maxillary barbel variable in size, moderately short. Teeth strong and not very numerous, with a well developed outer cusp of about half length of inner cusp.

Body completely covered with rows of comparatively smooth scutes dorsally; moderately rough in larger specimens. Abdomen variably covered with minute scutelets; with naked areas even in larger specimens. Ventral surface of head usually completely covered with scutelets, even in smaller specimens.

Distal half of pectoral fin spine of larger specimens usually covered dorsally with somewhat hypertrophied odontodes, slightly curved anteriorly. Adipose fin spine moderately long and straight. Caudal fin margin slightly concave, with comparatively short outer rays.

Colour in alcohol: except for the teeth, all yellow or yellowish orange areas described below become faint yellowish in alcohol preserved specimens.

Colour in life: small individuals up to about 80 mm SL are homogeneously grey-brown pigmented dorsally, without any light marks. During growth, scattered light-yellow dots appear all over the dorsal surface and fins. As growing proceeds further to about 130 mm SL the entire caudal fin and sometimes portions of the dorsal fin become strongly yellow or yellowish orange. In medium-sized individuals unpaired fins and portions of pectoral and ventral fins become yellow. The body scutes become yellow from the caudal peduncle to the head; larger specimens have either the posterior half or the entire body completely yellow. Tooth crowns strongly colored with orange.

Hypostomus regani (Ihering)

(figs 2, 15-17; tab. 4)

Plecostomus regani Ihering, 1905: 558-559 (type-locality: rio Piracicaba, São Paulo, Brazil).

Plecostomus luteomaculatus Devincenzi & Teague, 1942: 20-22, pl. 3, figs 2-3 (type-locality: rio Uruguay at Paysandu, Uruguay; new synonymy).

Specimens examined:

Type-specimens:

Lectotype of *P. regani* (by present designation): BMNH 1905.6.7: 3 (170.8 mm SL); rio Piracicaba, São Paulo, Brazil.

Paralectotypes of *P. regani*: BMNH 1905.6.7: 2 (ca. 233 mm SL), same data as holotype.

Holotype of *P. luteomaculatus*: MHNM CI359 (249.7 mm SL), Río Uruguay at Paysandu, Uruguay, 1941, G. W. Teague.

São Paulo:

MZUSP 23005 (1), rio Pardo at "Usina de Limoeiro", 13 Apr 1965, H. A. Britski. MZUSP 22636 (5, 2 measured), rio Paraná at Jupiá, 11 Dec 1960, P. E. Vanzolini & pty.

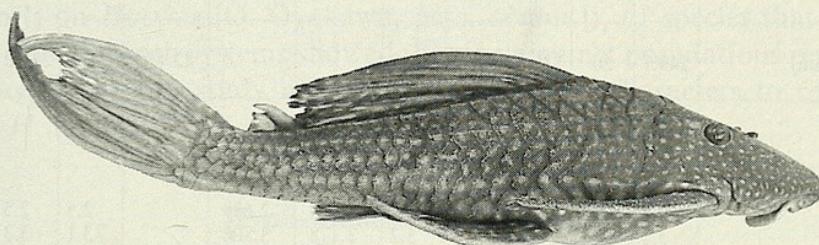

Diagnosis: *Hypostomus regani* is distinguished from other *Hypostomus* species inhabiting the rio Uruguay system by its characteristic violet-brown ground colour with light dots all over the dorsal surface. Two other species in that area share the light dots on darker ground: *H. roseopunctatus* and *H. luteus*, from which it differs in the larger number of teeth (57-111).

Description: standard length of examined specimens 136.6 to 281.2 mm; other meristic and morphometric data summarized in table 4.

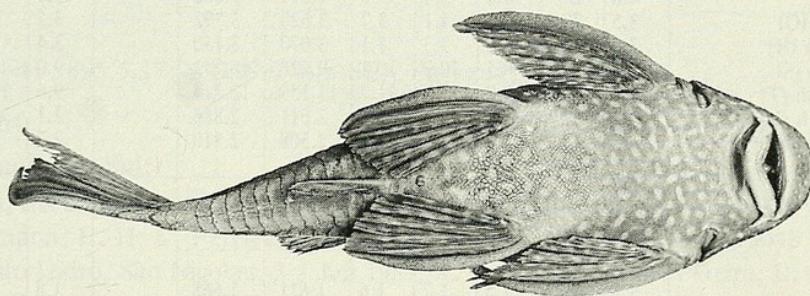

Head covered with dermal ossifications dorsally, except for a small, roughly ovate naked area on snout tip. Dorsal margin of orbit very slightly elevated, hardly continuing in an inconspicuous ridge on posttemporal plate. A very low ridge on supraoccipital, diverging in two separate ridges on predorsal plates often present. Usually one, sometimes two scutes bordering posterior margin of supraoccipital bone. Body deep; dorsal profile gently descending from origin of dorsal fin to end of caudal peduncle. Caudal peduncle roughly ovate in cross-section; flattened ventrally. Dorsal scutes between end of dorsal-fin base and adipose-fin spine flattened in their dorsal portion; those closer to dorsal fin usually with a central area unprovided of odontodes.

Colour in alcohol: ground colour of dorsal surface brown, grey-brown or violet-brown; slightly lighter to whitish ventrally. Except for ventral surface of caudal peduncle, body and fins covered with roundish or elongate, light-brown to yellowish dots. Dots smaller and closer together on head; usually aligned (sometimes forming actual lines) on posterior portion of flanks. Unpaired fin membranes sometimes darker than scutes.

Colour in life: living *H. regani* specimens usually strongly violet-brown with yellowish dots.

Remarks: Despite the fact that *Plecostomus luteomaculatus* was originally described from rio Uruguay we consider *P. luteomaculatus* as a junior synonym of *H. regani*. No diagnostic differences between specimens from upper rio Paraná and rio Uruguay were found. It is rare to find conspecific populations occurring in both the upper Paraná system and the rio Uruguay basin. Many recent studies (on *Cheirodon* and *Odontostilbe* [MALABARBA, 1988]; on *Acestrorhynchus*, *Oligosarcus*, and *Cynopotamus* [N. Menezes, pers. comm.]; on *Hoplias* [O. Oyakawa, pers. comm.]), of species that were previously believed to occur in both systems showed that the disjunct populations represent different species. Maybe a future study will produce diagnostic characters to revise the present concept of *H. regani*.

Hypostomus ternetzi (Boulenger) (figs 1, 18-20; tab. 5)

Plecostomus ternetzi Boulenger, 1895: 525-526 (type-locality: Paraguay; figures in Boulenger, 1896).

Specimens examined:

Type-specimen:

Holotype: BMNH 1895.5.17: 6 (199.0 mm SL), Paraguay, C. Ternetz.

Other specimens:

Brazil, Rio Grande do Sul:

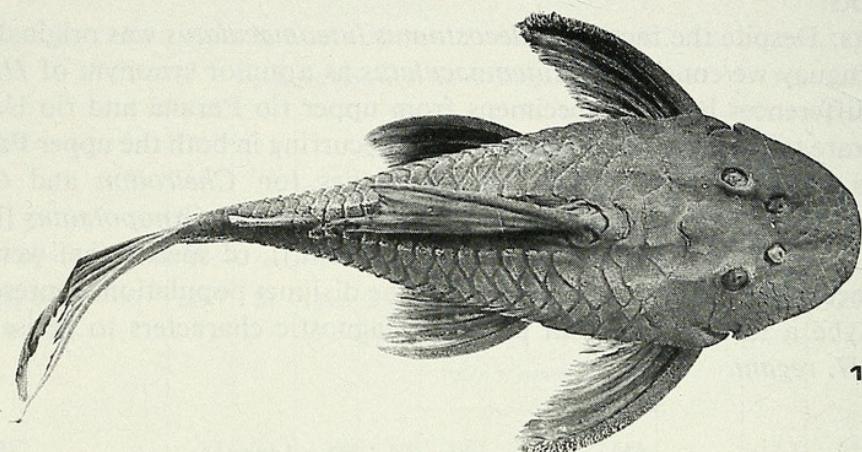

MCP 12523 (1), rio Uruguay at Porto de Santo Izidro, São Nicolau, 4-5 Nov 1988, C. A. S. Lucena, L. A. C. Bergmann, E. H. L. Pereira, P. V. Azevedo & A. Ramires. MCP 13048 (1), rio Uruguay at Porto de Santo Izidro, São Nicolau, 3-4 Jan 1989, R. E. Reis, E. H. L. Pereira, L. A. C. Bergmann, P. V. Azevedo & A. Ramires. MCP 12524 (1), MHNG 2448.38 (1), rio Uruguay at "Rancho da Amizade", São Borja, 31 Oct-1 Nov 1988, C. A. S. Lucena, L. A. C. Bergmann, E. H. L. Pereira, P. V. Azevedo & A. Ramires.

Diagnosis: *Hypostomus ternetzi* is distinguished from other *Hypostomus* species inhabiting the rio Uruguay system by its homogeneous brown dorsal colour pattern, lack of any conspicuous dots, very wide body (2.8-2.9 in SL, versus 3.0-4.1 in remaining species), long lower caudal ray (1.8-2.0 in SL, versus 2.2-4.0 in remaining species), and by the deep caudal peduncle (7.7-8.1 in SL, versus 8.4-12.2 in remaining species) except *H. roseopunctatus* (7.8-9.0 in SL).

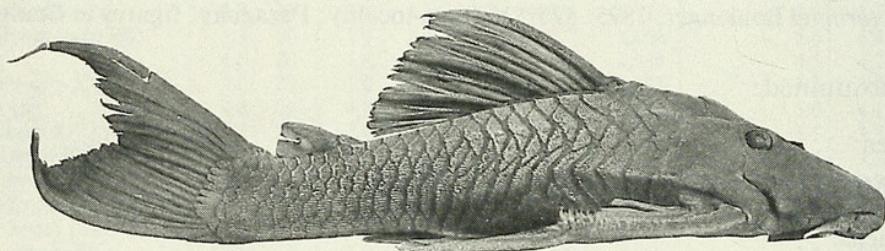

Description: standard length of examined specimens 119.6 to 177.1 mm; other meristic and morphometric data summarized in table 5.

Head covered with dermal ossifications dorsally except for a small, roughly squarish or ovate naked area on snout tip. Dorsal margin of orbit slightly elevated, continuing in a low ridge on posttemporal plate. Usually a single (in one specimen two) scutes bordering posterior margin of supraoccipital bone. Body comparatively more raised; dorsal profile gently descending from origin of dorsal fin to end of caudal peduncle.

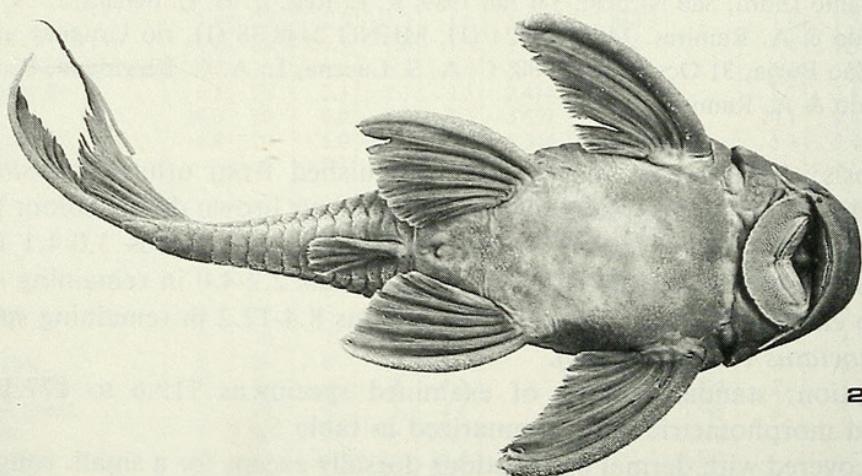

Caudal peduncle strongly compressed; not much flattened ventrally. Ventral scutes of caudal peduncle somewhat expanded laterally, forming conspicuous lateral ridges in its lower margin. Dorsal scutes between end of dorsal fin base and adipose fin spine somewhat flattened in their dorsal portions, those closer to dorsal fin sometimes with a central area devoided of odontodes.

Plates bordering supraoccipital	1	4	1	2	1.3

Outer face of upper lip usually with small odontodes areas, restricted to lateral portions; maxillary barbel moderately long. Teeth small and numerous, with a small outer cusp.

Body completely covered with rows of comparatively smooth scutes dorsally; low ridges on predorsal scutes and first scutes behind posttemporal plate. Abdomen margins

covered with minute scutelets, leaving central area unprovided of scutelets (at least in three medium-sized specimens examined). Ventral surface of head covered with scutelets, except for a small area just behind lower lip.

Distal half of pectoral fin spines in one specimen covered dorsally with well developed, anteriorly curved proeminent odontodes (male?); less developed in others (females?). Adipose fin spine very long and robust; slightly curved. Caudal fin margin strongly concave with very long outer rays.

Colour in alcohol: dorsal surface of head and body with an homogeneous dark pattern; slightly lighter ventrally. Roundish dots slightly darker than dorsum sometimes hardly discernible (in one specimens) or completely absent. Fin membranes usually slightly darker than body.

Remarks: life colour pattern unknown. We have seen only the holotype, two specimens from Paraguay and four specimens from rio Uruguay. The two populations show minor differences. The few available specimens do not allow a conclusive analysis of the taxonomic status of the two populations.

Hypostomus isbrueckeri sp. n.

(figs 1, 21-24; tab. 6)

Etymology: *Hypostomus isbrueckeri* is named in honour of Dr. Isaäc J. H. Isbrücker (ZMA) who has extensively contributed to the knowledge of loricariid diversity.

Bergmann & A. Ramires.

Diagnosis: *Hypostomus isbrueckeri* sp. n. is distinguished from all other *Hypostomus* species by the presence in mature males of a yellow vertical band (whitish in alcohol-preserved specimens) in the distal margin of caudal fin.

Description: standard length of examined specimens 129.2 to 246.4 mm; other meristic and morphometric data summarized in table 6.

Head covered with dermal ossifications dorsally, except for a naked area on snout tip, oval in shape. Dorsal margin of orbit not or very slightly elevated, continuing in a very inconspicuous ridge on posttemporal plate. Usually three scutes bordering posterior margin of supraoccipital; these scutes sometimes fragmented in four or five small scutelets. Body very low; dorsal profile gently descending from origin of dorsal fin to end of caudal peduncle. Caudal peduncle roughly ovate in cross-section; slightly flattened ventrally. Dorsal scutes between end of dorsal fin base and adipose fin spine flat in their dorsal portions; those closer to dorsal fin sometimes with a central area unprovided of odontodes.

Outer face of upper lip either with or without minute dermal ossifications; maxillary barbel variable in size, usually moderately long. Teeth small and numerous, with a small outer cusp.

Body completely covered with rows of comparatively smooth scutes dorsally; dorsal ridges of odontodes usually hardly discernible even in larger individuals. Anterior half of ventral surface usually naked; sometimes with a few minute scutelets scattered on

abdomen of larger specimens. Ventral surface of head ranging from almost naked, except for a few scutelets in front of gill openings, to almost completely covered with minute ossifications.

Distal half of pectoral fin spines usually covered dorsally with anteriorly curved proeminent odontodes in larger specimens. Adipose fin spine moderately long; straight to slightly curved. Caudal fin margin slightly concave, ventral lobe longer than dorsal.

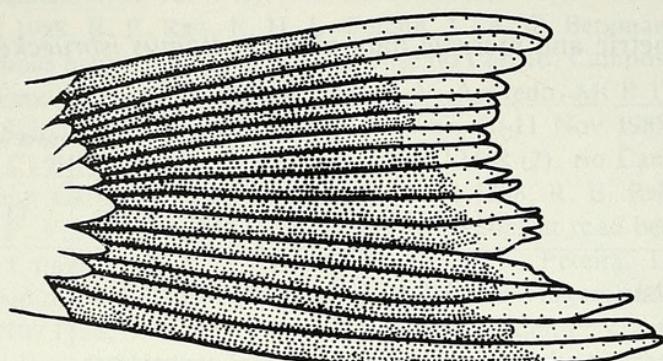

FIG. 24.

Hypostomus isbrueckeri sp. n., yellow band on caudal-fin margin of holotype, MCP 10488.

Colour in alcohol: ground colour of dorsal surface grey-brown; whitish to pale yellowish or even light grey-brown ventrally. Dorsal surface of head and body covered with roundish darker dots, smaller and closer together on head. Paired fins with same colour pattern. Dorsal fin dots may be confluent sometimes, forming small bars. Caudal fin usually darker than body and without dots. Mature males (four specimens dissected) with a whitish vertical band in caudal fin distal margin, varying in width.

Colour in life: living specimens present same basic colour but light band in caudal fin is yellowish-orange.

***Hypostomus roseopunctatus* sp. n.**
(figs 2, 25-28; tab. 7)

Hypostomus sp. — WEBER, 1987: 280-283, figs 6, 7c (one specimen from rio Uruguay at Uruguaiana, Rio Grande do Sul, Brazil).

Etymology: *roseopunctatus*, from the latin *roseus*, pink and *punctatus*, meaning dotted, spotted, in allusion to the colour pattern.

Type-specimens:

Holotype: MCP 12239 (232.7 mm SL), rio Pelotas at road from Esmeralda to Anita Garibaldi, Rio Grande do Sul, Brazil, 5-9 Sep 1988, Mr. Pedro.

Diagnosis: *Hypostomus roseopunctatus* sp. n. is distinguished from other *Hypostomus* species inhabiting Southern Brazil by the lower number of teeth in each premaxillary or dentary (6-16 versus more than 21 in the remaining species). The new species is similar to *H. microstomus* Weber (1987) in the small number of teeth in each premaxillary and dentary (6-16) differing in the size of the mandibular ramus; in the proportion of its length in the interorbital width 2.1-3.6 in the former versus 3.8-5.5 in *H. microstomus*; and in the possession of 3 scutes bordering the posterior margin of the supraoccipital, versus only one in *H. microstomus* (but one *H. microstomus* paratype with 3). Furthermore, *H. roseopunctatus* presents 9-10 scutes accompanying the dorsal fin base, and *H. microstomus* presents 6-7, usually 7. Another species from the upper rio Paraná system, *H. margaritifer* (Regan, 1908), has a small number of teeth. That species, however, shows 18-31 teeth in both upper and lower jaws, versus a maximum of 16 in *H. roseopunctatus*.

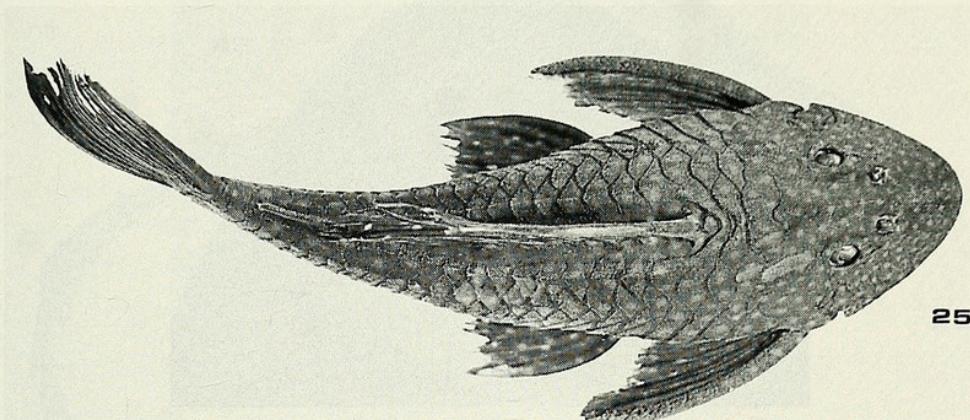

Description: standard length of examined specimens 105.8 to 232.7 mm. Other meristic and morphometric data summarized in table 7.

Head covered with dermal ossifications dorsally, except for a roundish naked area on snout tip. Dorsal margin of orbit elevated, continuing in a gently elevated ridge on post-temporal plate. Usually three (one specimen with 4 and another with 5) scutes bordering posterior margin of supraoccipital. Body not very deep; dorsal profile gently descending from origin of dorsal fin to caudal peduncle. Caudal peduncle roughly ovate in cross-section. Dorsal scutes between end of dorsal fin base and adipose fin spine flat in their dorsal portions; those closer to dorsal fin with a central area devoided of odontodes.

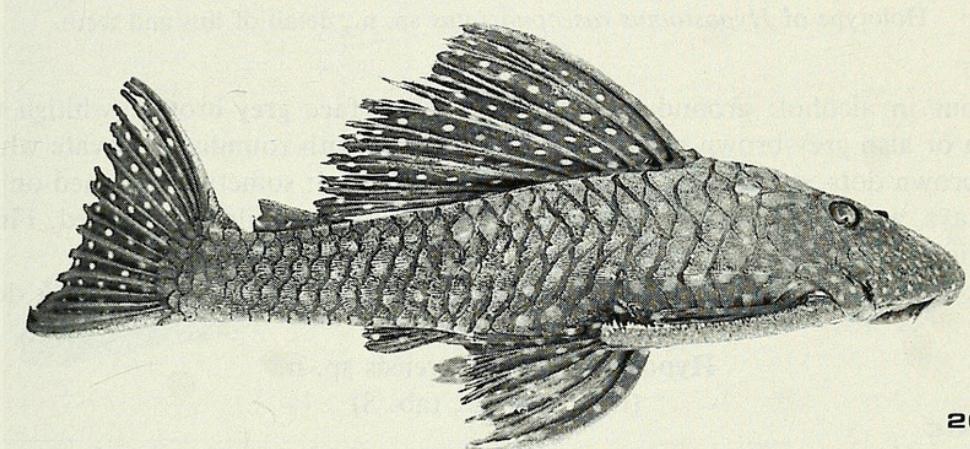

Outer face of upper lip with or without a few dermal ossifications; maxillary barbel long. Teeth big and strong, with a flat, wide outer and small inner cusp (fig. 28).

Body completely covered with rows of somewhat smooth scutes dorsally; first with very slightly prominent odontodes forming three low longitudinal ridges (hardly discernible in smaller individuals). A fourth ridge is present in lateral margin of ventral scutes of caudal peduncle, behind anal fin. Anterior half of ventral surface almost naked (in smaller individuals) to almost completely covered by scutelets. Head ranging from almost naked ventrally, except for a few scutelets in front of gill openings, to almost completely covered with scutelets. Abdomen almost naked, with just a few odontodes scattered between pectoral and pelvic fin insertions, to almost completely covered with small, squarish dermal ossifications.

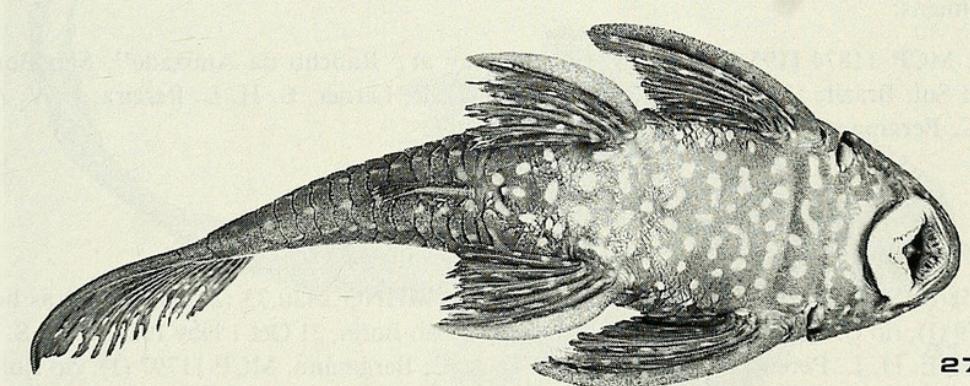

Distal half of pectoral fin spines covered with slightly prominent odontodes, not modified into hooks, on dorsal surface. Caudal fin margin concave; ventral lobe longer than dorsal. Adipose fin spine moderately long and straight. Ventral spine of caudal fin as long as or slightly longer than the pectoral fin spine.

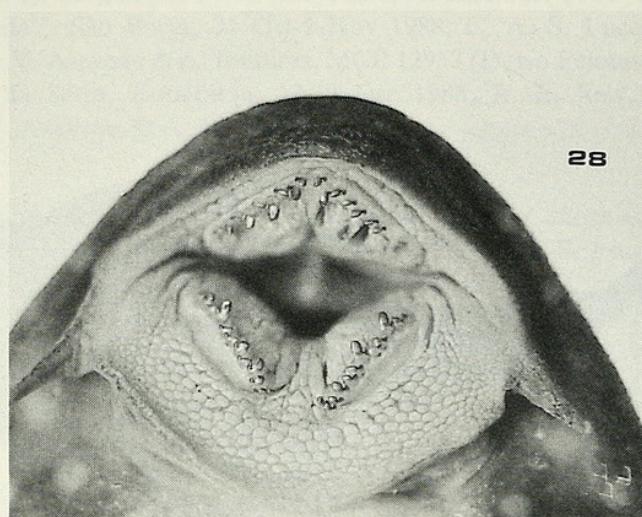

FIG. 28.

Holotype of *Hypostomus roseopunctatus* sp. n., detail of lips and teeth.

Colour in alcohol: ground colour of dorsal surface grey-brown; whitish to pale yellowish or also grey-brown ventrally. Body covered with roundish or ovate whitish to reddish-brown dots, smaller and more numerous on head; sometimes aligned on flanks. Spines, rays, and membranes of all fins with same dots irregularly arranged. Fin membranes slightly darker than scutes.

Colour in life: living specimens darker and slightly bluish with light pink dots.

***Hypostomus uruguayensis* sp. n.**
(figs 1, 29-31; tab. 8)

Etymology: *Hypostomus uruguayensis* sp. n. is named after its type-locality.

Uruguay:

FHCM ZVCP68 (3), rio Cuareim (=Quarai) barra de Yucutujá, "El Ombu", Depto. Artigas, Feb 1982, Exp. Zool. Lab.

Diagnosis: *Hypostomus uruguayensis* sp. n. is distinguished from other *Hypostomus* species inhabiting the rio Uruguay system by its very light ground colour with darker dots, lower number of lateral scutes (26-27) and strongly concave caudal fin margin. *Hypostomus ternetzi* has a similar strongly concave caudal fin margin and a low number of lateral scutes (26), but is homogeneously dark dorsally. *Hypostomus uruguayensis* can be distinguished from that species by the body width (3.1-3.5 in SL) and depth of caudal peduncle (9.4-10.5 in SL) versus 2.9 and 7.7-8.1 in SL in *H. ternetzi*, respectively.

Description: standard length of examined specimens 148.3 to 259.9 mm; other meristic and morphometric data summarized in table 8.

Head covered with dermal ossifications dorsally, except for a small, roughly squarish or ovate naked area on snout tip. Dorsal margin of orbit very slightly elevated, continuing in a very inconspicuous ridge on posttemporal plate. Usually three scutes bordering posterior margin of supraoccipital bone; these scutes often fragmented in up to seven small scutelets. Body moderately low; dorsal profile gently descending from origin of dorsal fin to end of caudal peduncle. Caudal peduncle roughly ovate in cross-section; slightly flattened ventrally. Dorsal scutes between end of dorsal fin base and adipose fin spine flat in their dorsal portion; those closer to dorsal fin sometimes with a central area devoided of odontodes.

Outer face of upper lip usually with very small odontodes areas, restricted to lateral portions; maxillary barbel much variable in size, usually moderately long. Teeth very thin, small and numerous, with a large, well developed outer cusp, always longer than half inner cusp.

Body completely covered with rows of comparatively smooth scutes dorsally. Abdomen covered with minute dermal ossifications, even in smaller individuals; some naked areas often present near base of pelvic fins. Ventral surface of head ranging from almost naked, except for a few scutelets in front of gill openings, to almost completely covered with minute dermal ossifications.

Distal half of pectoral fin spines usually covered dorsally with well developed, anteriorly curved proeminent odontodes in larger specimens. Adipose fin spine moderately long and slightly curved. Caudal fin margin strongly concave with long outer rays.

Colour in alcohol: ground colour of dorsal surface pale-yellowish or very light yellowish-brown; whitish or light-yellowish ventrally. Dorsal surface of head and body covered with roundish grey-brown dots; smaller and closer together on head. All fins with same colour pattern; usually very conspicuous in dorsal fin membrane and somewhat arranged in stripes on caudal fin.

Colour in life: living individuals just like alcohol preserved specimens.

DISCUSSION

The large number of *Hypostomus* species names from the laguna dos Patos system in literature deserves some comments. Besides a museum collections survey, recent extensive and niche-explorative sampling throughout the laguna dos Patos system revealed

two *Hypostomus* species: *H. commersonii* and *H. aspilogaster*, although nine species names have been cited in literature. Two of these, *H. spiniger* and *H. limosus*, are junior synonyms of *H. commersonii*. Five other species names are probably misidentifications, repeated in subsequent works: *Plecostomus bicirrosus* (synonym of *H. plecostomus*) cited by HENSEL (1870); *Plecostomus lima* (type-locality: rio das Velhas, Minas Gerais) cited by EIGENMANN & EIGENMANN (1890); *Plecostomus guacari* (synonym of *H. plecostomus*) cited by NICHOLS (1919); *Hypostomus wuchereri* (type-locality: Bahia) cited by BOSSEMEYER *et al.* (1981); and *Plecostomus plecostomus* (type-locality: Surinam) cited by BERTOLETTI (1986).

Plecostomus garmani Regan, 1904 was described from a single specimen from rio das Velhas, previously identified by EIGENMANN & EIGENMANN (1890) as *Plecostomus lima*. Erroneously, EIGENMANN (1910) cited all specimens previously identified as *P. lima* by EIGENMANN & EIGENMANN (1890) as *P. garmani*, including the material from Rio Grande do Sul. This citation was repeated in subsequent works.

Finally, FOWLER (1954) erroneously mentioned *Plecostomus robinii* (Valenciennes) from "Villa de Barro, Rio Grande do Sul, Brazil", following the citation "Villa de Barro, Rio Grande, Brazil" by Stigchel (1947).

Small hirudines are common external parasites of all *Hypostomus* species included in this study.

ACKNOWLEDGMENTS

We are indebted to the following persons and institutions for the loan and exchange of specimens, information, and other assistance: Eugenia B. Böhlke and William G. Saul (ANSP), Gordon Howes (BMNH), Carlos Rios (FHCM), Karsten E. Hartel and Horácio Higuchi (MCZ), Frederico Achaval (MHNM), Marie Louise Bauchot (MNHN), Heraldo A. Britski and José L. Figueiredo (MZUSP), Stanley H. Weitzman (USNM), Hans-J. Paepke (ZMB) and Manoel P. de Godoy.

The comments and criticism of Carlos A. S. Lucena, Zilda M. S. Lucena (both MCP), Paulo A. Buckup (UMMZ), and Volker Mahnert (MHNG) contributed greatly to improve the paper.

Luiz A. C. Bergmann, Edson H. L. Pereira, and Paulo V. Azevedo provided valuable field and technical assistance in MCP.

This study was partially supported by a personal grant from CNPq to RER proc. no. 305344-87.0.
