PHLEBOTOMINE SAND FLIES OF NORTH AMERICA (DIPTERA: PSYCHODIDAE)¹

D. G. YOUNG² AND P. V. PERKINS²

ABSTRACT. Fourteen species of *Lutzomyia* sand flies are recorded from North America, north of Mexico. Two of them, *L. apache* n.sp. and *L. tanyopsis* n.sp. from Arizona, are described for the first time. *Lutzomyia diabolica* is treated as a valid species, distinct from *L. cruciata*. *Lutzomyia vexator*, having a widespread geographic distribution in North America, is considered as a monotypic taxon without subspecies. Identification keys, distributional data, references, biological and disease information are provided.

INTRODUCTION

During the past decade, interest in North American sand flies has increased due to confirmed reports of autochthonous human leishmaniasis in Texas (Shaw et al. 1976), canine leishmaniasis in Oklahoma (Anderson et al. 1980), and Rio Grande virus in *Neotoma* woodrats in Texas (Calisher et al. 1977). Phlebotomines are the suspected, but as yet unproven, vectors of these diseases in these foci.

This report summarizes the published and unpublished information on the taxonomy and geographic distribution of the known species of *Lutzomyia* França in North America (north of Mexico), including information on their bionomics and vector potential where known. References and identification keys are provided.

Coquillett (1907) first reported sand flies in the Western Hemisphere. He described Lutzomyia cruciata (as Flebotomus cruciatus) from Guatemala and L. vexator (as Flebotomus vexator) from Plummer's Island, Maryland. Shannon (1913) observed L. vexator females feeding on snakes at the type-locality and speculated that another female had bitten a person sleeping inside of a cabin.

A group of biologists from Cornell University were tormented at night by biting sand flies on Minnie's Island, Okefenokee Swamp, Georgia in 1912. Johannsen (1943) recalled that a "member of the party counted over 75

punctures on his body, another's hands and arms were swollen to abnormal size. . . ." Local residents, acutely aware of these insects, called them "merye wings," an Elizabethan English term reflecting the origin of most of the residents. Johannsen (1943) studied one defective sand fly (lot no. 1981), concluding that it differed from *L. vexator* in wing venation and palpal proportions but he did not further describe the specimen which has since been lost (Quentin Wheeler, in litt., 1982). The identity of these man-biting sand flies remains unknown, but they probably represented *L. shannoni* (Dyar) and/or *L. cruciata*.

Apart from this report and from man-biting observations of *L. shannoni* in the southeastern USA, the only other area in North America where sand flies commonly bite people is in southcentral Texas. Parman (1919) observed a species, later named *Phlebotomus diabolicus* Hall 1936, biting people at Uvalde, Texas. Lindquist (1936) added more information on the habits of this species and reported that females attacked man at night in dwellings from 2000 to 2400 hr. We now know that *L. diabolica* will attack man in the daytime as well.

Phlebotomine-borne diseases in the United States

Cutaneous leishmaniasis in humans

Simpson et al. (1968) documented the first parasitologically-confirmed human case of autochthonous leishmaniasis in the USA. Leishmaniae were observed in tissue smears and culture medium. The patient, who suffered from diffuse cutaneous leishmaniasis, had lived in San Benito, Cameron Co., Texas for her entire life except for occasional visits to the Mexican border states of Tamaulipas and Nuevo León. Subsequently, Shaw et al. (1976) discussed 2 additional human cases of cutaneous leishmaniasis in Texas (Gonzales and Dilworth counties). They believed that the disease had been locally acquired in both cases. Walton et al. (1977) identified one of the Texas strains (no. 1156) as belonging in the Leishmania mexi-

cana complex. Peters (1981), referring to the Texas Leishmania as Leish. mexicana pifanoi, suggested that the disease may have been introduced from Venezuela. Kreutzer et al. (1983) identified one Texas strain (WR 127) as Leishmania mexicana mexicana. Parasites were cultured from a boy with a facial lesion, who probably contracted the disease in the vicinity of Uvalde, Texas in 1981 (Larry Hendricks, personal communication). Three unrelated persons from or near San Antonio, Texas, contracted cutaneous leishmaniasis in 1982 and it is believed the infections were also locally acquired (Tracy Gustafson, personal communication). In view of these reports, there is a good possibility that Stewart and Pilchner (1945) earlier had correctly diagnosed cutaneous leishmaniasis in a boy who lived near Alice, Texas.

The epidemiology of leishmaniasis in Texas, though not yet studied, may be similar to that in nearby Coahuila State, Mexico where Ramos-Aguirre (1970) discussed 3 autochthonous human cases, 2 of which were of the diffuse form, similar to that reported by Simpson et al. (1968). Díaz Nájera (1971) collected specimens of L. diabolica at Muzquiz, Coahuila, a site where one of the patients lived. This sand fly, the only species known to bite people in Texas and northern Mexico, is the suspected vector. The nonforested, relatively dry habitat in these areas differs greatly from classical Leishmania mexicana foci in tropical forests of southern Mexico, Central and South America.

Visceral leishmaniasis in dogs

MacVean et al. (1979) and Anderson et al. (1980) reported visceral leishmaniasis in hunting dogs (fox hounds) from a kennel at Edmond near Oklahoma City, Oklahoma. The disease continues to be transmitted to dogs at this site, but its origin remains unknown. The causative agent is similar to Leishmania donovani infantum, a parasite causing canine and human visceral leishmaniasis in the Old World (Decker-Jackson and Tang 1982, Kocan et al. 1983), but Kreutzer et al. (1983) identified the parasite as Leishmania mexicana. MacVean et al. (1979) captured specimens of Lutzomyia near the kennel in the forest. We provisionally identified one of the males as L. vexator, on the basis of a drawing of the gonostylus kindly given to us by R. A. Ward, Walter Reed Army Institute of Research. The vector of leishmaniasis at this site remains unknown. Leishmania-infected dogs are occasionally imported into the United States and Canada from endemic areas (Maness 1981, Simpson et al. 1982) and there is recent serological evidence that coyotes from Texas

may be infected with the disease (Grogi et al. 1984).

Rio Grande Virus in vertebrates

Rio Grande virus, family Bunyaviridae, genus *Phlebovirus* (Bishop et al. 1980), was named by Calisher et al. (1977) who recovered the virus from *Neotoma* woodrats near Brownsville, Texas and found serological evidence of infection in other vertebrates but not in people. *Lutzomyia anthophora* (Addis) is the suspected vector based on the habits of the species, its close association with woodrats, and its proven ability to vertically* transmit the virus in the laboratory (Endris et al. 1983).

Parasites of amphibians and reptiles

Ayala (1973) gave references to his earlier, detailed studies on amphibian and reptile parasites associated with phlebotomines, especially L. vexator, in central California. He showed that sand flies were suitable hosts for Trypanosoma bufophlebotomi Ayala of toads and T. scelopori Avala and T. gerrhonti Ayala and McKay of lizards. A saurian malaria, Plasmodium mexicanum Thompson and Huff, developed to the sporozoite stage in sand flies and was infective when inoculated into Sceloporus fence lizards. Wild-caught sand flies also were found infected with hemogregarines (Hepatozoon sp. oocysts) that infected both lizards and snakes following experimental inoculations (Ayala 1970a).

METHODS AND MATERIALS

FIELD COLLECTIONS

The diversity of the sand fly fauna in a given area is best determined by using a combination of collection techniques. Such techniques were discussed by Lewis (1973, 1974) and Chaniotis (1978). In the present study, adult sand flies were routinely searched for in their diurnal resting sites, including tree trunks, under loose bark of dead standing trees, tree hollows, animal burrows and dens, rock crevices and other protected microhabitats. Specimens were captured with a simple tube aspirator, burrow traps and sticky paper traps. Endris et al. (1982) outlined procedures for handling such wild-caught sand flies for rearing purposes.

Flight traps and CDC light traps were used whenever possible (see Gressitt and Gressitt 1962, Sudia and Chamberlain 1962). They are effective devices for capturing most, but not all species. Limited attempts to recover immature

^{*} Direct transfer of the virus from parent to its offspring.

stages from soil samples using a Berlese funnel were unsuccessful. As far as is known, immatures have not been found in nature in North America.

Preservation and slide mounting

It is recommended that adult sand flies be stored dry between layers of tissue paper in a pill box before they are mounted on slides because specimens preserved in alcohol are much more difficult to macerate, particularly those that have been stored in the preservative for a year or more. Following maceration in 10% NaOH, however, the flies can be stored indefinitely in 70% EOH. Methods for preparing slide mounts and identifying sand flies are outlined below following Young (1979).

- 1. Place whole sand fly in 10–25% sodium hydroxide (NaOH) at room temperature in a small crucible for 30–60 minutes.
- 2. Heat the NaOH to the boiling point on a hot plate, then immediately remove crucible from heat and allow to cool for 30 minutes.
- 3. Put macerated fly directly into a drop of 90% liquid phenol in the depression in a depression microscope slide (temporary slide mount) and identify with the aid of a compound microscope. A coverslip can be placed over the specimen if necessary. The internal spermathecae of female sand flies should then be clearly visible.
- 4. Preserve in 70% alcohol in a vial, or proceed to step 5 if a permanent slide mount is needed.
- 5. Place one drop of Canada balsam in the depression of another microscope slide. Mix 2-5 drops of phenol with it and put specimen or specimens (up to 12) in the mixture.
- 6. Allow the phenol to slowly evaporate at room temperature until the balsam-phenol mixture becomes somewhat viscous. The mixture has now infiltrated the body of the sand fly and the spermathecae and other structures should be normal in appearance.
- 7. Dissect the specimen by removing the head and wings. Lift these parts and the remainder of the specimen with a small needle and position them on a coverslip in small drops of the balsam-phenol mixture in which the fly was dissected. Orient the head so that the cibarium can be viewed as in the illustrations in this paper.
- 8. Place a small piece of glass, from a previously ground coverslip, in each corner of the coverslip holding the dissected sand fly. Allow to dry until the drops of mixture are completely hard.
- Invert coverslip over a drop of Canada balsam placed in the middle of a clean microscope slide.
 Store the slide horizontally until dry.

MATERIAL EXAMINED

A number of colleagues generously supplied specimens, locality records (specimens not examined by the present authors), and other pertinent information. We gratefully acknowledge the help of F. S. Blanton, J. F. Butler, R. G.

Endris, G. B. Fairchild, R. C. Johnson, W. L. Kramer and R. C. Wilkerson, all associated with the University of Florida at the time of this study; J. F. Reinert, R. W. Intermill, P. G. Lawyer and J. I. Glick, US Army medical entomologists; R. H. Roberts, ARS, USDA, Gainesville; W. W. Wirth, US Department of Agriculture; R. J. Brenner and S. Frommer, University of California, Riverside: O. D. Wheeler, Cornell University; L. D. Hendricks and R. A. Ward, Walter Reed Army Institute of Research; Personnel of the US Army Health Services Command at various posts in the continental USA and C. G. Moore and D. B. Francy, Centers for Disease Control, Ft. Collins, Colorado.

Dr. V. F. Newhouse, Centers for Disease Control, deserves special recognition for allowing us to publish his records of North American sand flies identified earlier by G. B. Fairchild and W. J. Hanson but not confirmed by the present authors.

Holotypes of all new species will be deposited in the US National Museum of Natural History along with paratypes and other specimens. Paratypes also will be deposited in the collection at the University of Florida, and elsewhere as indicated in the text.

TAXONOMIC TREATMENT

Many of the species of *Lutzomyia* were originally described in the genus Phlebotomus Rondani and Berté (= Flebotomus)), a name now applied strictly to the medically-important group of Old World phlebotomines (Theodor 1965). The subgeneric and species group classification of Lutzomyia follows that of Lewis et al. (1977) and Martins et al. (1978). The morphological terminology agrees with that used by Quate and Vockeroth (1981). Thus, gonostylus and gonocoxite are substituted for style and coxite, respectively. The ejaculatory apodeme and sperm pump together refer to the familiar term, genital pump, that is used by many students of Phlebotominae. For quick reference, the structures shown in Fig. 2 are labelled. The immature stages are not treated in this review because of a lack of material, but references to them are given. Well known species are not redescribed because adequate descriptions are available in other papers cited here in each species account.

- 14. L. cubensis (Fairchild and Trapido 1950)

KEY TO THE NORTH AMERICAN SPECIES OF *LUTZOMYIA*

It is usually necessary to prepare slide mounts of sand flies in order to study the structures of taxonomic importance. Once the local fauna becomes known, however, it is often possible to identify specimens simply by using color characters, relative lengths of the legs, body, wings and other features which can be seen without the aid of a microscope. In general appearance, most sand flies resemble the one shown in Fig. 1. Sexual dimorphism is marked. The male has conspicuous external terminalia, its abdomen is relatively slender and it is usually smaller than the conspecific female.

Males*

1. Gonostylus of genitalia with 5 large spines; subterminal seta absent. Gonocoxite with a basal tuft or group of persistent setae

* The male of Lutzomyia tanyopsis n.sp. is not shown.

Gonostylus with 2-4 large spines; subterminal seta and gonocoxal tuft present or absent

2. Cibarium with a row of 8 or more short horizontal teeth. Gonocoxal tuft of 10-15 setae L. californica (Fig. 14) Cibarium without a row of horizontal teeth. Gonocoxal tuft of 4-7 setae ...

Paramere with dorsal setae restricted to apical third. Aedeagal filaments beyond apical inflated portion shorter than inflated portion ... L. oppidana (Fig. 11) Paramere with dorsal setae covering at least apical half. Aedeagal filaments beyond apical inflated portion longer than inflated portion

4. Lateral lobe barely extending beyond end of paramere. Gonostylus with paired basal spines inserted at same level; subterminal spine close to terminal pair. Antennal ascoids on flagellomere II shorter than one-third the length of flagellomereL. stewarti (Fig. 12) Lateral lobe extending well beyond end of paramere. Gonostylus with basal spines placed at different levels; subterminal spine more or less isolated from terminal pair. Antennal ascoids on flagellomere II longer than half the length of flagellomere

5. Antennal ascoids on flagellomere II extending beyond end of flagellomere Antennal ascoids on flagellomere II not reaching end of flagellomere L. vexator (Fig. 13)

6. Gonostylus with 2 or 3 strong spines; subterminal seta present. Paramere with an acute ventral projection Gonostylus with 4 strong spines; subterminal seta absent. Paramere with or without an acute ventral projection..

7. Paramere with a dorsal arm bearing recurved setae at enlarged end. Gonostylus with proximal spine much thinner than others. Gonocoxal tuft absent. Lateral lobe not inflated. Aedeagal filaments shorter than 3 times length of sperm pump and ejaculatory apodeme ...L. anthophora Paramere simple, without a dorsal arm. Gonostylus with proximal spine about the same size as others. Gonocoxite with basal tufts of setae. Lateral lobe inflated. Aedeagal filaments longer than 3 times length of sperm pump and ejaculatory apodeme . . L. aquilonia

8. Antennal ascoids with distinct proximal spurs. Palpomere 5 short (Figs. 8, 9) Antennal ascoids simple, without proximal spurs. Palpomere 5 longer (Figs. 4, 12)

9. Gonocoxite with numerous setae at middle and beyond. Lateral lobe longer than coxite. Antennal ascoids extending beyond ends of flagello-

Discussion: Both sexes of *L. cruciata* from North America have relatively small eyes (Fig. 2) when compared to those of *L. cruciata* from the neotropics and *L. diabolica* (Fig. 3). This character state and the slightly thicker setae of the coxite tuft of Florida males support the idea that the nearctic population of *L. cruciata* is an isolated one that may have been derived from neotropical stock that spread through the Gulf of Mexico coastal plain into Florida and Georgia. It is also possible that individuals entered Florida by crossing the Gulf of Mexico, possibly with the aid of hurricane winds, but this hypothesis seems less likely. *Lutzomyia cruciata* is not known to occur in the West Indies.

Existing populations of *L. cruciata* in Florida and Georgia are geographically isolated from those in southeastern Mexico and Central America and it does not appear that this species presently occurs in states west of Florida or in northern Mexico. *Lutzomyia cruciata* and *L. diabolica* have allopatric distributions in the USA (Fig. 18) but the extent of their geographic distributions in Mexico has not been determined. *Lutzomyia cruciata* occurs mainly in secondary and primary hardwood forests, but *L. diabolica* has been found in dry, sometimes treeless localities (e.g., area of Comstock, Texas).

All of the *L. cruciata* females from Florida and Georgia have a papillate lobe on each side of the 9th abdominal tergite (Fig. 2D). This modification is absent in females of *L. diabolica*, *L. gomezi* (Nitz.) and some *L. cruciata* females from Mexico, Guatemala, Honduras and Nicaragua.

In Belize, Lewis (1965) observed that 96% of L. cruciata females dissected were parous, thus indicating that the species is normally autogenous. Perkins (1982) established a laboratory colony of L. cruciata from a gravid female collected near Gainesville (Alachua Co.), Florida. All females from the F_1 through F_{26} generations were autogenous and deposited 35.8 \pm 13.5 eggs (range 1–60), 3–10 days following emergence. Other rearing data based on this colony are given by Perkins (1982).

Eighteen females of *L. cruciata* were collected in CDC light traps near Gainesville (Sugarfoot Hammock) in August and September, 1980 (8 trap nights). Five of them, held in a 120 ml feeding chamber (Endris et al. 1982), took

blood meals on the arm of a human volunteer during a 1–3 minute period. Their bites were quite painful when compared to those of L. shannoni. All 18 females died without depositing eggs and most lived 2.9 ± 2.4 days after capture. The specimens that took human blood meals survived from 6 to 8 days but none had mature eggs when dissected. Lab-reared females were given the opportunity to feed on man on numerous occasions but none, including those that had oviposited 1–7 days previously, did so.

There is little evidence indicating that *L. cruciata* is a natural vector of cutaneous leishmaniasis (*Leishmania mexicana*) in Belize (Williams 1970). Williams (1966), however, demonstrated that *Leishmania mexicana* multiplies and develops in *L. cruciata* females and that experimentally-infected flies transmitted the parasite by bite to a human volunteer.

light trap, V. Newhouse.

Discussion: Addis (1945b) redescribed L. diabolica from topotypic specimens, noting that the female had 6 horizontal teeth in the cibarium. Fairchild and Hertig (1948a, 1953b) distinguished the male of this species from that of L. cruciata by its more slender ejaculatory apodeme with its cup-shaped proximal end and by the presence of fewer and more slender setae of the gonocoxal tuft. Differences between the females of L. diabolica and L. cruciata were mainly those related to the size and number of vertical teeth in the cibaria, the former species having only 8-10 heavy blunt teeth; the latter with more numerous, smaller vertical teeth. Dorsolateral, papillate lobes of the ninth abdominal tergite were observed in females of both species but were less developed in L. diabolica. Only 4 females of L. diabolica were available to these authors for study.

Disney (1968) studied structural variation in numerous males and females of L. cruciata from Belize, concluding that it was not possible to separate this species from L. diabolica based on available criteria. He observed that the proximal end of the ejaculatory apodeme was of the "cruciata form" in 80% of the Belize males examined. The basal gonocoxal setae varied in

number from 8 to 23 ($\bar{x} = 16$), and the number of vertical teeth in the female cibarium ranged from 8 to 29 ($\bar{x} = 16$). Other features, including the spermathecae, chitinous arch of the cibarium and number of episternal setae, were studied. From his analysis, he concluded that variation among his material was infraspecific and that the name diabolica should be "suppressed, at least as a specific epithet,"

In the USA and Meixco. however, there are 2 distinct forms that can be identified as L. diabolica and L. cruciata and which are easily distinguished by the characters given in the keys. Disney (1968) was correct in assigning his Belize specimens to the latter species; L. diabolica is not known to occur there or in other countries south of Mexico but there is a good possibility that populations exist in western Guatemala.

Lutzomyia diabolica is very dark; the pleuron of each sex is as dark as the scutum, unlike L. cruciata which has a pale pleuron. There seems to be no single, consistent structural difference between the 2 species although the curious papillate lobes of the 9th tergite are present in all L. cruciata females from the USA and in 83% (n = 81) of L. cruciata females from Mexico and Central America. Females of L. diabolica lack such lobes

The ratio of the length of flagellomere 1 to the head height (flag. I/head height) of L. diabolica females ranges from 0.45 to 0.61 (n = 31, $\bar{x} = 0.53$, SD = 0.032); that for males ranges from 0.52 to 0.63 (n = 5, \bar{x} = 0.568, SD = 0.041). In females of L. cruciata females from Mexico and Central America (n = 73), this ratio varies from 0.61 to 0.88 ($\bar{x} = 0.732$, SD = 0.056); that for L. cruciata males ranges from 0.66 to 0.86 (n = 25, \bar{x} = 0.756, SD = 0.048). The number of horizontal teeth in the female cibarium of both species ranges from 4 to 7.

Females of L. diabolica are agressive manbiters, attacking mostly at night but occasionally in the daytime as well. The natural resting and breeding sites of this species are unknown. At Garner State Park, Uvalde Co., Texas, about 1500 specimens were collected from late May to early June 1983 on the inside walls of latrines. The new record of this species from Plainview. Texas, represents the northernmost limit of its known geographic range but few attempts have been made to collect this species in northern Texas, New Mexico or Oklahoma.

Lindquist (1936) and Endris et al. (1982) reared L. diabolica in the laboratory; the former author providing information on its life cycle and describing the immature stages. Females are anautogenous. Additional field studies of this species are recommended in view of its man-biting habits and possible role as a vector

of cutaneous leishmaniasis in Texas and northern Mexico.

Species Group MIGONEI THEODOR

3. Lutzomyia xerophila Young, Brenner and Wargo, Fig. 4.

Lutzomyia xerophila Young, Brenner and Wargo 1983:313 (3, \$\varphi\$, Cahuilla Hills, Palm Desert, Riverside Co., California).

KNOWN DISTRIBUTION: USA. California

(Riverside Co.), Fig. 19.

MATERIAL EXAMINED: USA. California—5 δ, 150 \$\times\$ (holotype, allotype and paratypes) type-locality, 12-IX-1980; 21-V-1981 to 4-X-1981, CO₂ traps, M. Wargo. 2 δ, 24 \$\times\$ (Riverside Co.), Rancho Mirage, Magnesia Springs Canyon, 16-VI-1981, CO₂ trap, R. Brenner.

Discussion: Lutzomyia xerophila is provisionally placed in the migonei Group of Lutzomyia (Theodor 1965) on the basis of male and female structures, but the male lacks a subterminal seta on the gonostylus unlike other males in the group. This pale species is easily recognized by the characteristic spermathecae of the female and by the male terminalia. Intraspecific variation of the cibarial armature of females is shown in Fig. 4.

Specimens have been taken only in CO₂ traps in the Colorado Desert of Riverside Co., California from May to November. Nothing is known about the feeding habits, diurnal resting sites or biology of this recently described species.

SUBGENUS COROMYIA BARRETTO

4. Lutzomyia (Coromyia) aquilonia (Fairchild and Harwood), Fig. 5.

Phlebotomus aquitonius Fairchild and Harwood 1961:244 (&, &, Columbia Wildlife Refuge, Othello, Adams Co., Washington). Eads et al. 1965:25 (listed). Harwood 1965:1 (locality records, Whitman Co., Washington and Southern Alberta, British Columbia, Canada). Quate 1965:91 (listed). Shemanchuk et al. 1978:1355 (seasonal dist., in marmot burrows, Police Coulee, Alberta, Canada).

Lutzomyia aquilonia: Theodor 1965:184 (listed). Rosabal and Miller 1970:180 (♂, ♀ keyed). Forattini 1971:99 (listed). Martins and Morales-Farias 1972:365 (listed). Forattini 1973:212 (keyed, brief tax. discussion). Chaniotis 1978:19 (listed). Martins et al. 1978:92 (dist.). Eads 1978:539 (dist., refs.). Young, 1979:91 (listed).

KNOWN DISTRIBUTION: Canada. Alberta and British Columbia. USA. Colorado (Larimer Co.); Washington (Adams and Whitman counties), Fig. 19.

MATERIAL EXAMINED: USA. Colorado—11 &, 5 \(\) (Larimer Co.), approx. 400 m east of Horsetooth Reservoir, light and oil traps, 18-VIII and 8-IX-1983, C. Moore and B. Francy. Washington—3 &, 3 \(\) (holotype, allotype and paratypes) (Adams Co.), Columbia Wildlife Refuge, Othello, VII-VIII-1959, 1960, R. Harwood.

Discussion: The small median seta shown on the male gonostylus (Fig. 5A) is absent in the other males of this species examined. The female sperm ducts are illustrated for the first time following immersion of the slide-mounted specimen in 90% liquid phenol for one week.

Shemanchuk et al. (1978) collected 106 specimens of *L. aquilonia* in the burrows of the marmot, *Marmota flaviventris nosophora* Howell, during a 3-year study in Southern Alberta. Flies were collected from August to October at one site, and in July and August at the Columbia Wildlife Refuge, Washington State (Fairchild and Harwood 1961). The specimens from Colorado were collected near nests of *Neotoma* woodrats located in rock crevices.

The feeding habits of this species remain unknown.

SUBGENUS DAMPFOMYIA ADDIS

5. Lutzomyia (Dampfomyia) anthophora (Addis), Fig. 6.

Phlebotomus anthophorus Addis 1945b:119 (&; 9, Uvalde, Uvalde Co., Texas); 1945c:319 (rearing data, descript, immature stages); 1945:328 (keyed). Packchanian 1946:37 (refs.). Barretto 1947:185 (refs.). Thurman et al. 1949:199 (listed). Vargas and Díaz Nájera 1953a:46 (Michoacan State, Mexico, compared to L. dodgei); 1953b:309 (Morelos State, Mexico). Quate 1955:242 (keyed, refs.). Fairchild and Hertig 1956:307 (dist., keyed, refs.); 1959:123 (Nuevo León State, Mexico). Forattini 1959:195 (rearing data from Addis 1945c). Chaniotis and Anderson 1964:27 (mention). Quate 1965:91 (listed). Eads et al. 1965:251 (listed). Easton et al. 1968:466 (Presidio and Kinney Co., Texas records).

Lutzomyia anthophora: Barretto 1962:95 (listed). Theodor 1965:193 (listed). Rosabal and Miller 1970:180 (♂, ♀ keyed). Williams 1970:332 (mention). Forattini 1971:100 (listed). Young 1972:61 (in woodrat nests, Texas). Martins and Morales-Farias 1972:365 (listed). Forattini 1973:122 (tax.). Calisher et al. 1977:1000 (Cameron Co., Texas, possible vector of Rio Grande Virus). Martins et al. 1978:57 (dist.). Eads 1978:539 (dist., refs.). Chaniotis 1978:19 (mention). Young et al. 1981:446 (larval food). Endris et al. 1982:401 (rearing data,

lab. hosts). Endris et al. 1983:862 (transovarial transmission of Rio Grande Virus).

KNOWN DISTRIBUTION: Mexico to USA. Texas (Bexar, Cameron, Kinney, Medina, Presidio, San Patricio, Uvalde and Val Verde counties), Fig. 19.

MATERIAL EXAMINED: USA. Texas-1 3, 3 9 (Bexar Co.), San Antonio, Lackland AFB, 20-XI-1965, D. Young and C. Parrish. 3 9 (Cameron Co.). Laguna Atascosa Wildlife Refuge. 26-IV-1965, light trap, R. Eads (USNM). 1 3, 1 9 (Cameron Co.), 12 km E of Brownsville, i-I-1966, Neotoma nest, D. Young. 39 &, 8 9, same data but V-1975. 2 9 (Medina Co.), D'Hanis. 29-IX-1983, Neotoma nest, P. Lawyer. 2 9 (San Patricio Co.), 12 km E of Sinton, 10-VI-1966, Neotoma nest, D. Young, 4 9 (Uvalde Co.), Uvalde, 28-IX-1944, on rabbits, H. Brundrett (USNM). 1 9 (Val Verde Co.), Del Rio, IX-1963, light trap, R. Eads. Mexico. Morelos -11 & Miacatlán, 27-IV to 5-V-1980, flight trap. M. Camino. Nuevo León-1 3, 32 km NW of Monterrey, 9-IX-1955, rock crevice, P. Galindo and H. Trapido.

Discussion. In addition to the material noted above hundreds of *L. anthophora* collected in *Neotoma* woodrat dens near Brownsville, Texas in 1966, 1975 and 1980 were examined.

The spermathecae with the unusual bubble-like evaginations (Fig. 6I) and the distinctive male terminalia (Fig. 6A) readily distinguish *L. anthophora* from other species in North America. It is currently impossible to separate females of this species from those of *L. dodgei* (Vargas and Díaz Nájera) from SW Mexico where they are sympatric. Vargas and Díaz Nájera (1953a) distinguished these females by differences in the cibarial armatures and spermathecae, characters that were found in this study to be unreliable for species identification.

Fairchild and Hertig (1956) believed that the female of *L. dodgei* described by Vargas and Díaz Nájera (1953a) actually was a female of *L. anthophora*. This conclusion was erroneously based on their study of specimens that were later named *L. atalupai* by De León (1971), not *L. dodgei* (Porter and Young, unpublished observations). Thus, *L. anthophora* and *L. dodgei* will key out together in couplet 2 of Fairchild and Hertig's 1956 key to the species of *Dampfomyia*.

Addis (1945b) reported L. anthophora females feeding on domestic rabbits at Uvalde, Texas. No specimens were taken on other hosts or from suspected resting sites. Young (1972) found both sexes of this species in the dens of woodrats, Neotoma micropygus Baird, and concluded that adults were present throughout the year in South Texas. Subsequently, one of us

(D.G.Y.) collected more than 600 specimens of L. anthophora from a single woodrat den, east of Brownsville, Texas, on 31 May 1975. It was estimated that an equal number escaped capture. At that time, and in 1980, other specimens were also discovered resting in or near small rodent nests located underneath discarded lumber and cardboard. From these field associations and on laboratory observations, it is suspected that L. anthophora females feed primarily on small mammals: suitable laboratory hosts include hamster (Addis 1945c), white mouse, squirrel (Sciurus), calf, rabbit, opossum (Didelphis) and domestic pig (Endris et al. 1982), Females feed to repletion and are gonotrophically concordant; 33 females (14%) out of 228 females that survived first oviposition in the laboratory took a second blood meal. Seven of these fed a third time and one took a partial fourth bloodmeal before dying (Endris and Young, unpublished observations).

Addis (1945c) and Endris (1982) studied the life cycle of L. anthophora in the laboratory. The former author used a rabbit blood-garden soil mixture for larval food; the latter used a composted rabbit feces-laboratory chow mixture (Young et al. 1981). At 28°C, the mean time from egg deposition to adult emergence was 49 days (n = 72, Addis 1945c) but was only 39 days in the later study (n = 41) (Endris 1982). These conflicting results apparently were due to differences in the larval diets. Addis (1945c) described the immature stages from reared material.

Endris et al. (1983) experimentally infected L. anthophora females with Rio Grande virus that was subsequently recovered from 54.8% of their F_1 progeny. This was the first virologically confirmed demonstration of vertical transmission of a Phlebovirus by sand flies. Leishmania mexicana (WRAIR strain 411 from Texas) was successfully transmitted to non-infected Syrian hamsters by the bites of experimentally infected, laboratory-reared L. anthophora (Endris and Young, unpublished observations).

SUBGENUS PSATHYROMYIA BARRETTO (= Species Group shannoni)

Lutzomyia (Psathryomyia) shannoni (Dyar), Fig. 7.

Phlebotomus shannoni Dyar 1929:121 (3, Cano Saddle, Gatun Lake, Panama Canal Zone). Barretto 1947:222 (full refs., synonyms). Thurman et al. 1949:199 (biting man, Florida). DISCUSSION: Only selected references to L. shannoni are given here. Forattini (1973), Martins et al. (1978) and Young (1979) provide additional references and synonyms.

There are no records of this species in Texas or in northern Mexico, north of Puebla State (Martins et al. 1978). The magnitude of this distributional gap may be partly due to the lack of collecting but, more likely, it reflects the absence of extensive hardwood forests, the pre-

ferred macrohabitat of this species. Future collections in east Texas may reveal its presence there. The new records from Maryland and Delaware represent the known northern distributional limits of *L. shannoni*.

Both sexes of *L. shannoni* from the USA and the neotropics (from southern Mexico to northern Argentina) are remarkably similar in structure. There is little or no morphological variation (Rozeboom 1944). In terms of anthropophilic behavior, however, Fairchild (1955) and others have noted that females bite humans more commonly in the USA and Mexico than elsewhere.

Rosabal and Miller (1970) collected 530 males and 233 females from tree hollows in Louisiana. No parasites were observed in 29 females dissected. Perkins (1982) dissected 414 male and 166 female L. shannoni from 2 localities in Florida (Gulf and San Felasco Hammocks) and found acephaline gregarines in 3 males (0.7%) and 15 females (9.1%). Three mites, provisionally identified as Eustigmaeus sp., were found attached to the abdomens of 2 female flies. The ovary of one female was parasitized by a small unidentified nematode. One female L. shannoni collected on 17-VII-1981, Gulf Hammock, had thousands of relatively large unidentified flagellates in the midgut and foregut but not in the mouthparts. The fly was dissected 9 days after it had fed on man, but no signs of human disease were subsequently observed. The midgut of a dissected male L. shannoni from the same locality contained relatively small flagellates that were probably monoxenous. Further studies are being made to characterize these flagellate infections.

Perkins (1982) established a laboratory colony of *L. shannoni* from field-collected females in Florida (Endris et al. 1982) and provided information on its life cycle and biology.

Females normally deposit as many as 40 viable eggs without having had a previous bloodmeal. Only 12 (3.4%) of 349 reared, nonbloodfed females failed to develop fully formed eggs by the fourth day following emergence. Autogenous females with developing eggs also took multiple bloodmeals between ovipositions. beginning 24 hours post-emergence. Laboratory hosts included man, pig, hamster, squirrel (Sciurus), calf, horse, opossum (Didelphis) and dog (Endris et al. 1982). Christensen and de-Vasquez (1982), using the precipitin test for bloodmeal determination in Panama, demonstrated that L. shannoni feeds on a variety of mammals, some birds but no reptiles. Females fed on sloths more than any other mammal species, and the authors suggested that L. shannoni may play a role in the transmission of

Leishmania braziliensis among these reservoir hosts in Panama.

Lutzomyia shannoni has not been found in the endemic focus of Leishmania mexicana in Texas, but experimentally-infected L. shannoni females (WRAIR strain 411 from Texas) transmitted the parasite to non-infected hamsters by bite (Lawyer and Young, unpublished data). Perkins (1982) reported that 26/27 lab-reared females became infected with this strain after feeding on infected hamsters. Zeledón and Alfaro (1973) found unidentified promastigotes in 4/117 (3.4%) wild-caught L. shannoni females in Costa Rica, and later Zeledón et al. (1979) identified other flagellates recovered from this sand fly as Endotrypanum sp. and Leishmania herreri, both sloth parasites.

7. Lutzomyia (Psathyromyia) tanyopsis Young and Perkins, n.sp., Fig. 8.

Holotype ? (measurements in mm). Wing length 2.28; width 0.66. Most of insect lightly pigmented, pleuron slightly paler than scutum. Head from vertex to distal end of clypeus 0.50 high; 0.38 wide. Eyes small, separated by 0.15 or by a distance = to about 6.8 facet diameters. Flagellomere I 0.27 long, combined length of II + III = 0.23; ascoids present on all flagellomeres except last (flag, XIV), each ascoid with a long proximal spur. Labrum 0.34 long. Lengths of palpomeres: 1, 0.05; 2, 0.17; 3, 0.19; 4, 0.13; 5, 0.31; with about 12 sensilla at middle of palpomere 3. Cibarium with 4 short equidistantlyspaced horizontal teeth, middle pair inwardly directed and outer pair slanted outwardly; an irregular row of about 10 small vertical teeth present; cibarial arch complete but more diffuse in middle; pigment patch subtriangular, wider posteriorly. Pharynx 0.20 long, without spines. Pleuron with 6 upper and 4 lower episternal setae. Lengths of wing vein sections: alpha* 0.36; beta 0.34; delta 0.04; gamma 0.47. Lengths of femora, tibiae and basitarsi as follows: foreleg, 0.85, 0.83, 0.50; midleg, 0.88, 1.02, 0.54; hindleg, 0.98, 1.32, 0.63. Spermathecae spherical with basal annulations; individual ducts smooth walled, about 8X length of common duct.

KNOWN DISTRIBUTION: USA. Arizona (Pima Co.), Fig. 20.

MATERIAL EXAMINED: USA. Arizona—Holo-

^{*} alpha = Length of R_2 from its junction with R_3 to costa (see Fig. 2B).

beta = Length of R from junction of R_2 and R_3 to junction with R_4 .

delta = Length of R_1 extending beyond junction of R_2 and R_3 .

gamma = Length of R from origin of R_5 to origin of R_{2+3} and R_4 .

type Q (Pima Co), Sabino Canyon, Coronado National Forest, 9-VIII-1953, light trap, G. Butler (USNM). Paratypes, 2 Q, same data.

Discussion: We tentatively place *L. tanyopsis* in the subgenus *Psathyromyia* because of the long proximal spurs of the antennal ascoids and the cibarial armature. The spermathecae, however, differ in structure from those of other *Psathyromyia* females and from those of the neotropical species *L. aclydifera* (Fairchild and Hertig), *L. dreisbachi* (Causey and Damasceno) and *L. hermanlenti* (Martins, daSilva and Falcão), that also have long proximal spurs on the ascoids. The undiscovered male of *L. tanyopsis* also probably will have ascoidal spurs and other features that should readily associate it with the female and determine its definite placement in the genus.

The specific name, "tanyopsis," is a Greek word meaning long face or long in appearance

(see Fig. 8A).

DISCUSSION. Lutzomyia texana is one of the largest species in North America. The wing length of females ranges from 2.55 to 2.93 mm (n = 9) and of the males from 2.30 to 2.57 mm

(n = 9) (all from Texas).

The poorly preserved specimens from Honduras were tentatively identified as L. texana. They might actually represent L. barrettoi majuscula Young, a closely related species occurring in Colombia and Central America. It has not been established where, or if populations of these 2 species meet in Central America. Structural differences between these taxa are slight and may reflect intraspecific variation of a single widespread species.

Lutzomyia texana was first collected in a nest of the leaf-cutting ant, Atta texana, near San Antonio, Texas (Dampf 1938). Eads et al. (1965) excavated a number of Atta nests near Brownsville, Texas, but failed to recover larvae or resting adults of L. texana. Light trap catches by these authors, however, showed that adults were present throughout the year near Brownsville, but not in the Del Rio, Texas area.

Young (1972) reported that armadillo burrows serve as the usual resting sites for this species in Texas. In June 1980, one of us found 9 recently bloodfed females in a burrow inhabited by armadillos near Sinton, Texas, but there is no direct evidence that the flies had fed on these mammals. The flies died before their eggs were laid.

SUBGENUS HELCOCYRTOMYIA BARRETTO

9. Lutzomyia (Helcocyrtomyia) apache (Young and Perkins n.sp., Figs. 10, 16 and 17.

Holotype & (measurements in mm). Wing length 2.47; width 0.66. Head, scutum, abdominal sclerites and external genitalia infuscated; rest of body pale or nearly pale. Head from vertex to tip of clypeus, 0.41 high; 0.39 wide. Eyes separated by 0.15 or by a distance to about 8 facet diameters. Flagellomere I, 0.27

long, combined length of II + III, 0.25; ascoids simple, present on all flagellomeres except last (XIV); ascoids on II reaching to or beyond end of flagellomere. Labrum 0.19 long. Lengths of palpomeres: 1, 0.04; 2, 0.12; 3, 0.18; 4, 0.15; 5. 0.34; about 8 palpal sensilla scattered on middle half of palpomere 3. Cibarium without visible teeth; pigment patch narrow and faint; cibarial arch diffuse, more conspicuous at sides. Pharynx 0.16 long, with posterior ridges but no spines. Pleuron with 5-6 upper and 4-5 lower episternal setae. Lengths of wing vein sections: alpha 0.46; beta 0.35; delta 0.13; gamma 0.50. Lengths of femora, tibiae and basitarsi as follows: foreleg, 0.89, 0.86, 0.51; midleg, 0.87. 1.00, 0.58; hindleg, 0.95, 1.34, basitarsus missing; hind femur without spines. Terminalia. Gonostyle 0.24 long with 5 spines, basal pair inserted at different levels, isolated median spine closer to basal pair than to terminal pair, no subterminal seta. Gonocoxite 0.31 long, with basal tuft of 5 slender setae and about 12 scattered distal setae. Paramere simple, with dorsal setae on at least half its length. Aedeagus slender, well-pigmented with acute tip. Ejaculatory apodeme and sperm pump 0.25 long, each aedeagal filament 1.20 long or about 4.8X length of ejaculatory apodeme and sperm pump, the distal end inflated subterminally as shown in Fig. 10B. Lateral lobe 0.47 long.

Allotype 9 (measurements in mm). Wing length 2.18; width 0.56. Coloration as in 9. Head 0.39 high; 0.33 wide. Eyes separated by 0.15 or by a distance = to about 8.5 facet diameters. Flagellomere I, 0.23 long, combined length of II + III, 0.22; ascoids simple, on all flagellomeres except last (XIV), tips of those on flag. II extending beyond end of flagellomere. Labrum 0.19 long. Lengths of palpomeres: 1. 0.04; 2, 0.11; 3, 0.15; 4, 0.13; 5, 0.31; palpal sensilla as in m. Cibarium with 4 sharp, equidistantly-spaced horizontal teeth and a row of 10-14 small vertical teeth; cibarial arch conspicuous at sides, nearly invisible in middle; pigment patch subtriangular, faint, Pharvnx 0.16 long, without spines. Pleuron with 4 upper and 2-3 lower episternal setae. Lengths of wing vein sections: alpha 0.39; beta 0.34; delta 0.05; gamma 0.37. Lengths of femora, tibiae and basitarsi: foreleg, 0.73, 0.71, 0.44; midleg, 0.76, 0.93, 0.51; hindleg, 0.86, 1.13, 0.69; femora without spines. Spermathecae button-like as shown in Fig. 10F with long, slender individual ducts, each about 25X length of common duct or greater than 5X length of stem of genital fork.

KNOWN DISTRIBUTION: USA. Arizona (Apache, Cochise and Gila counties), Fig. 20.

MATERIAL EXAMINED: USA. Arizona—holotype ♂ (Apache Co.), Springerville, 3-VII-1953,

light trap, W. Wirth. \mathcal{P} allotype (Cochise Co.), 3.1 km SW of Portal, V-VI-1967, blacklight trap, C. Sabrosky. Other paratypes, 12 \mathcal{E} ; 11 \mathcal{P} , same data as holotype. 2 \mathcal{P} , same data as allotype. 2 \mathcal{P} (Gila Co.), 27 km NE of Payson, Tonto Creek, 10-VIII-1978, light trap, C. Ray (UCR).

DISCUSSION: Structural similarities indicate that *L. apache* is closely related to *L. vexator* and *L. oppidana*, both of which may occur with it in the USA and northern Mexico. Both sexes of *L. apache* can be separated from those of the other species by the characters given in the keys. *Lutzomyia vindicator* (Dampf), known from Mexico, differs from *L. apache* by its broader, differently shaped paramere, shorter aedeagal filaments (less than 4X the length of the ejaculatory apodeme and sperm pump) and by the wider shorter individual sperm ducts of the female. The cibarial armatures of these females are remarkably similar.

The wing length of 8 female paratypes of *L. apache* ranges from 2.42 to 2.88 mm; that of 5 male paratypes ranges from 2.37 to 2.55 mm.

The specific name, "apache," refers to the tribe of American indians living in the southwestern USA and northern Mexico.

10. Lutzomyia (Helcocyrtomyia) oppidana (Dampf), Figs. 11, 16 and 17.

Phlebotomus oppidanus Dampf 1944:247 (\$\circ\), San Jacinto, Federal District, Mexico). Barretto 1947:215 (listed). Vargas and Díaz Nájera 1953b:312 (listed). Fairchild and Hertig 1957:325 (\$\circ\), Nuevo León State, Mexico, keyed); 1959:124 (listed). Fairchild and Harwood 1961:240 (coll. data, Adams Co., Washington, keyed). Fairchild and Hertig 1961:26 (compared to L. vargasi \$\delta\$). Ortiz and Alvarez 1963:312 (listed). Harwood 1965:1 (coll. records, Washington State and British Columbia, rearing). Eads et al. 1965:251 (listed). Ortiz 1965b:25 (listed). Quate 1965:92 (listed). Easton et al. 1967:429 (Presidio Co., Texas). Easton et al. 1968:467 (Presidio Co., Texas).

Lutzomyia oppidana: Barretto 1962:96 (listed). Theodor 1965:183 (listed). Rosabal and Miller 1970:780 (keyed). Forattini 1971:99 (listed). Young 1972:61 (listed). Downes 1972:1135 (listed). Martins and Morales-Farias 1972:365 (Listed). Forattini 1973:209 (redescript., keyed). Chaniotis 1974:334 (Ravalli Co., Montana); 1978:19 (mention). Eads 1978:541 (Larimer Co., Colorado). Martins et al. 1978:77 (dist.).

KNOWN DISTRIBUTION: Mexico. USA. Colorado (Fort Collins and Larimer counties), Montana (Ravalli Co.), Texas (Presidio Co.) and Washington (Adams and Whitman counties). Canada. Alberta and British Columbia, Fig. 21.

MATERIAL EXAMINED: USA, Colorado—16 ♂, 18 ♀ (Fort Collins Co.), approx. 400 m east of Horsetooth Reservoir, 18-VIII- and 8-IX-1983, oil and light traps, C. Moore and B. Francy. Montana—1 ♀ (Ravalli Co.), 8 km E of Hamilton, Rock pile, 22-VIII-1973, B. Chaniotis. Washington—6 &, 15 ♀ (Adams Co.), Othello, Columbia Wildlife Refuge, 25-V to 9-VIII-1960, R. Harwood, Mexico. 30 ♂, 9 ♀ (Nuevo León), 32 km NW of Monterrey, 9-IX-1955, rock crevices, P. Galindo and H. Trapido.

DISCUSSION: The habits of L. oppidana are poorly known. Harwood (1965) reported that females in the laboratory fed on snakes and lizards, but not on frogs, white mice or humans. Diurnal resting sites include animal burrows,

small caves and rock crevices.

This species apparently has a widespread geographic distribution in the western USA and Mexico.

11. Lutzomyia (Helcocyrtomyia) stewarti (Man-

gabeira and Galindo), Figs. 12, 16 and 17. Phlebotomus stewarti Mangabeira and Galindo 1944:185 (♂, ♀, Livermore, Alameda Co., California). Rozeboom 1944:274 (listed). Addis 1945a:328 (keyed). KNOWN DISTRIBUTION: Mexico. USA. California (Alameda, Contra Costa, Kern, Mendocino, Monterey, Riverside, San Diego, San Mateo and

Yolo counties), Fig. 21.

MATERIAL EXAMINED: USA. California—1 さ paratype (Contra Costa Co.), Marsh Creek, 21-IX-1943, P. Galindo and O. Mangabeira. 1 9 (Mendocino Co.) Ukiah, 29-VII-1948, light trap, W. Wirth. 2 ♂ (Monterey Co.), Ft. Hunter Liggett, 26-V-1981 and 24-VII-1981, light trap. 2 δ , 5 \circ (Riverside Co.), 5.6 km S of Palm Desert, 11-13-VIII-1969 and 31-I to 23-II-1970, Malaise trap, S. Frommer. 1 &; 3 ♀ (Riverside Co.), Deep Canyon, Coyote Creek, 10-17-V-1975, Malaise trap, S. Frommer and R. Worlev. 1 & (Riverside Co.), Rancho Mirage, Magnesia Springs Canyon, 16-VI-1981, CO₂ trap, R. Brenner.

Discussion: A female of L. stewarti was identified from Ukiah, Mendocino Co., California. This specimen was provisionally, but incorrectly, determined earlier as L. californica by Fairchild and Hertig (1957) and was cited as that species by Chaniotis and Anderson (1968).

Lauret (1965) collected 154 adults of L. stewarti in light traps from 1 June to 10 October 1956 at Woodside, San Mateo Co., California. Chaniotis (1967) stated that in California adults of L. stewarti are active for about 6 months of the year and that the fourth instar larvae diapause during the winter months.

Adults rest, and perhaps breed, in the burrows of ground squirrels, Citellus spp., where they feed on lizards and snakes (Chaniotis and

Anderson 1968).

Chaniotis (1967) reared L. stewarti in the laboratory and provided data on its life cycle, feeding and mating behavior, and other habits. Ayala and Lee (1970) observed sporozoites of Plasmodium mexicanum, a saurian malaria, in wild-caught L. stewarti after they were experimentally infected in the laboratory.

Discussion: Fairchild and Hertig (1957) studied males and females of L. vexator from California and concluded that they differed

subspecifically from specimens collected on Plummer's Island, Maryland, the type-locality. They stated that the California specimens, which they named *L. vexator occidentis*, had the following distinguishing characteristics: "Male with genital filaments shorter, less than 4 times length of pump; style shorter and stouter, the two subapical spines farther apart and the most basal one of this pair closer to the basal spine than in *vexator*. Basal tuft of coxite of 4 setae. Female with spermathecae shorter, more slender, less than twice as long as stem of genital fork. Cibarium narrower, with but 4 horizontal teeth, lacking the sublateral shorter teeth found in *vexator*."

Chaniotis and Anderson (1964, 1967) redescribed L. v. occidentis from California specimens, noting that the aedeagal filaments of 10 males were 4 times the length of the ejaculatory apodeme and sperm pump and that the basal gonocoxal tuft consisted of 4 or 5 long hair-like setae. The length of the aedeagal filaments of Florida males that were examined in this study varied from 3.6 times to 4.6 times the length of the ejaculatory apodeme and sperm pump and the gonocoxal tuft consisted of 4 or 5 setae. This range of measurements encompasses that observed for all other males examined (including California and Washington State specimens) except that one male from Plummer's Island had aedeagal filaments 4.9 times the length of the ejaculatory apodeme and sperm pump. The length of the gonostylus and presence or absence of sublateral teeth in the female cibarium are not diagnostic. Of 7 females examined from the same population in Texas, 2 had sublateral teeth while the other 5 lacked them. The length of the gonostylus of 16 males from Washington State ranged from 0.21 to 0.24 mm and from 0.24 to 0.26 for 3 males from Maryland. In view of this variation and of our inability to detect clear-cut, consistent differences among specimens from various localities, L. vexator is treated as a monotypic species that has a widespread geographic distribution in North America.

Lutzomyia vexator is easily reared in the laboratory. Marshall Hertig maintained a closed colony from 1932 to 1936 at Harvard University from specimens collected at Plummer's Island, Maryland. Chaniotis and Anderson (1964) and Chaniotis (1968) successfully reared L. vexator and provided information on its biology under laboratory conditions and in the field (Chaniotis and Anderson 1968). A laboratory colony is presently being maintained at the University of Florida (Endris et al. 1982).

Ayala and colleagues (1968-73) published several articles on sand flies (mostly *L. vexator*)

and associated parasites in California. There, the sand flies rest in ground squirrel burrows that are also occupied by lizards, snakes and other cold-blooded vertebrates which serve as hosts for these insects.

Sporozoites of *Plasmodium mexicanum* a saurian malaria, were observed in experimentally-infected sand flies (mostly *L. vexator*) from California. These sporozoites were infective to *Scleoporus* lizards when injected intraperitoneally. Transmission was not demonstrated by sand fly bite and no natural infections were found in the presumed vector.

During the past 3 years in Florida, over 600 laboratory-reared females of *L. vexator* that had previously fed on *Plasmodium floridense*-infected anoles (*Anolis carolinensis*) were dissected. Oocysts were seen in over 50% of the flies that were dissected 4–20 days after the infecting bloodmeals, but no sporozoites were detected.

In addition to these preliminary observations, it is noted that naturally infected *Anolis* have been found in several Florida localities where phlebotomine sand flies do not occur. Although hardly conclusive, these observations suggest that *P. floridense* is not transmitted to *Anolis* and fence lizards (*Sceloporus*) in Florida by phlebotomines.

SUBGENUS MICROPYGOMYIA BARRETTO

13. Lutzomyia (Micropygomyia) californica (Fairchild and Hertig), Fig. 14.

Phlebotomus californicus Fairchild and Hertig 1957:328 (3, \$, \$ft. Yuma, Imperial Co., California). Fairchild and Harwood 1961:242 (Othello, Adams Co., Washington). KNOWN DISTRIBUTION: USA. Arizona—(Pinal Co.). California (Imperial, Inyo, Kern, Lassen, Monterey, Riverside, San Diego and Yolo counties). Texas (Presidio and Val Verde counties). Washington (Adams Co.), Fig. 23.

MATERIAL EXAMINED: USA. Arizona—5 ♀ (Pinal Co.), Superstitition Mountains, 11-111 and 11-X-1942, in cave, R. Flock (USNM). California—1 δ holotype, $1 \circ allotype$ (Imperial Co.), Ft. Yuma, 28-IX-1948, light trap, R. Coleman, 1 & (Riverside Co.), P. L. Boyd Desert Research Center, 15-16-X-1969, Malaise trap, S. Frommer and R. Worley, 1.9 (Riverside Co.), Deep Canyon, Covote Creek, 10-17-V-1975, Malaise trap. S. Frommer. 2 ♀ (Riverside) Co.), Cahuilla Hills, Palm Desert, 22-VII-1981. CO₂ trap, R. Brenner, 1 & 1 ♀ same data but 16-IX-1981 and 4-XI-1981. Texas—1 ♀ (Val. Verde Co.), Del Rio, IX-1963, light trap, R. Eads. Washington—7 &, 13 \(\text{(Adams Co.)}, Othello. Columbia Wildlife Refuge, VI-VIII-1960, marmot burrows, R. Harwood,

Discussion: Fairchild and Hertig (1957) pointed out that *L. californica and L. chiapaensis* (Dampf) are very similar in structure, differing only in the relative lengths of the female sperm ducts and in details of the male terminalia. Now that additional material is available, there is a strong possibility that these differences reflect geographic variation of a single widespread species that occurs from Panama to northwest USA. We have not examined specimens from Mexico, however, and will therefore continue to recognize these species as distinct.

Apart from the longer common sperm duct of the L. chiapaensis female there are no other structural differences between it and L. californica. There is considerable variation in the number of horizontal teeth in the female cibarium. Chaniotis and Anderson (1968) counted 16-34 such teeth in 10 or more females from California. The Texas female, examined by us, has 20 teeth; 13 females from Othello, Washington have 16-25 teeth. Females referable to L. chiapanensis show similar variation. The female holotype of L. chiapanensis from Chiapas State, Mexico, has 25 horizontal teeth (Dampf 1947). Specimens from Panama (n = 5), Costa Rica (n = 1) and El Salvador (n =1) have 20-24, 20 and 28 teeth respectively.

The males of *L. californica* and *L. chiapanensis* are distinguished by the shape and setation of the gonocoxites. Unlike *L. californica, Lutzomyia chiapanensis* has a gonocoxite that is noticeably widened basally and has numerous setae distal to the basal tuft.

In California, females of *L. californica* feed on lizards and snakes, probably within mammal burrows which also serve as resting sites for the flies (Chaniotis and Anderson 1968). These authors collected *L. californica* in Yolo Co., California, in low numbers from June 24 to October 12, 1965, and suggested that there are 3 generations per year in that area.

14. Lutzomyia (Micropygomyia) cubensis (Fairchild and Trapido). Fig. 15.

Phlebotomus cubensis Fairchild and Trapido 1950:414 (3; \$\partial \text{, near Camaguey, Cuba}\). Fairchild 1955:194 (listed). Ortiz 1965a:290 (\$\partial \text{keyed}\). Avila et al. 1969:3 (mention).

Luzomyia cubensis: Barretto 1962:95 (listed). Theodor 1965:187 (listed). Young 1972:63 (Big Pine Key, Monroe Co., Florida). Martins and Morales-Farias 1972:369 (listed). Forattini 1973:335 (listed, keyed). Lewis 1975:502 (mouthpart morphol.). Eads 1978:540 (listed). Chaniotis 1978:19 (mention). Martins et al. 1978:62 (dist.).

KNOWN DISTRIBUTION: Cuba. USA. Florida (Monroe Co.), Fig. 23.

MATERIAL EXAMINED: USA. Florida—1 \$\,^2\$ (Monroe Co.), Big Pine Key, 16-I-1969, flight trap, A. Gurney (USNM). 2 δ, 2 \$\,^2\$ (Monroe Co.), Middle Torch Key, 13-II-1978, flight trap, W. Wirth. Cuba. 9 δ, 8 \$\,^2\$ (holotype, allotype and paratypes), Camaguey and Chapaste, V-VI-1949, tree buttresses, G. Fairchild and H. Trapido.

Discussion: Lutzomyia cubensis is a small sand fly that successfully colonized some of the Florida Keys presumably from West Indian stock. Its close relatives, L. cayennensis (Floch and Abonnenc) and allies, feed mostly on lizards.

CONCLUDING REMARKS

Much more information on sand flies in North America is needed to understand the extent of their geographic ranges, bionomics and disease relationships. With few exceptions, most observations and collections of these flies were made incidental to other insect studies. The phlebotomine fauna of the western USA is richer than that of the eastern states and it is there that additional species are likely to be discovered and where studies on the known species are especially needed.

ACKNOWLEDGMENTS

We wish to thank Dr. G. B. Fairchild and Dr. Ronald A. Ward for the critical reviews of this manuscript. We also wish to thank Olimpia Arezaga for her excellent work in typing the original and revised manuscripts.

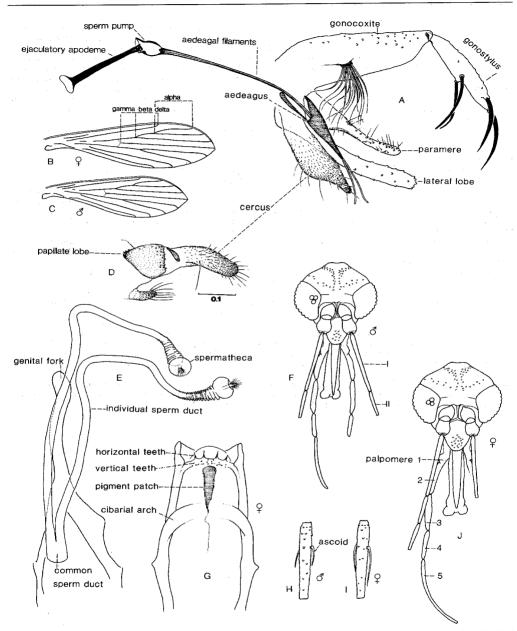

Fig. 2. Lutzomyia cruciata (Coquillett). A. Male terminalia, lateral view; B. Female wing; C. Male wing; D. End of female abdomen showing papillate lobe of tergite 8, scale in mm; E. Spermathecae and genital fork; F. Male head; G. Female cibarium; H. Male flagellomere II; I. Female flagellomere II; J. Female head. Drawn from Florida specimens at same scale as comparable structures in Fig. 4.

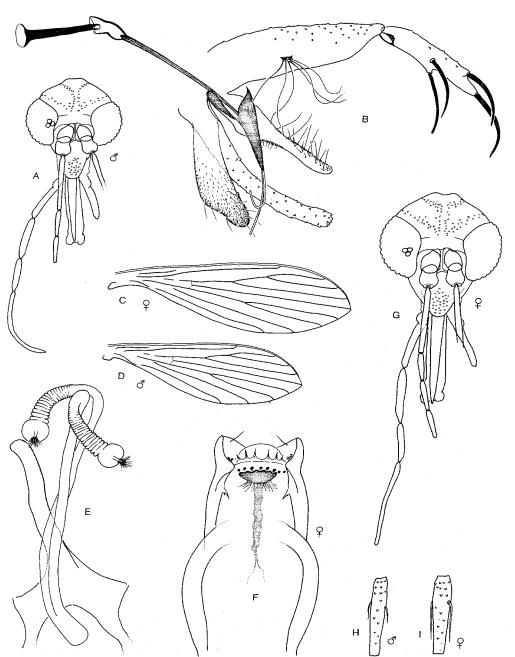

Fig. 3. Lutzomyia diabolica (Hall). A. Male head; B. Male terminalia; C. Female wing; D. Male wing; E. Spermathecae and genital fork; F. Female cibarium; G. Female head; H. Male flagellomere II; I. Female flagellomere II. Drawn from Texas specimens at same scale as comparable structures in Fig. 4.

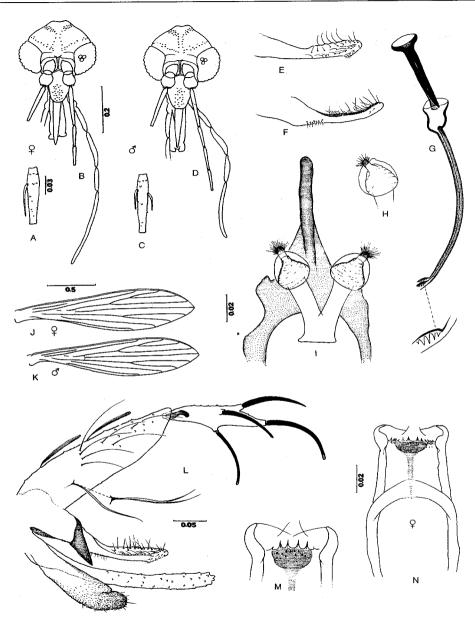

Fig. 4. Lutzomyia zerophila Young, Brenner and Wargo. A. Female flagellomere II; B. Female head; C. Male flagellomere II; D. Male head; E. and F. Different views of male parameres; G. Male aedeagal filaments, ejaculatory apodeme and sperm pump drawn at same scale as Fig. 4L; H. Spermatheca drawn in Canada balsam; I. Spermathecae and genital fork drawn in phenol; J. Female wing; K. Male wing; L. Male terminalia; M. Female cibarium; same scale as Fig. 4N; N. Female cibarium. All figures after Young et al. (1983), except Fig. 4M, from California specimens. Scale in mm.

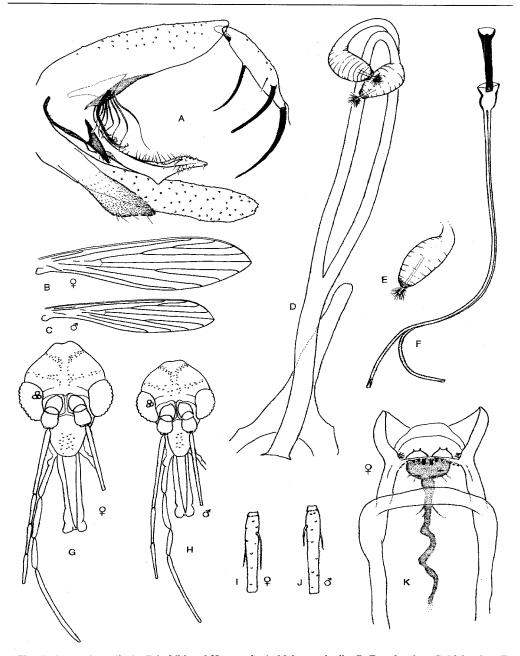

Fig. 5. Lutzomyia aquilonia (Fairchild and Harwood). A. Male terminalia; B. Female wing; C. Male wing; D. Spermathecae and genital fork; E. Spermatheca of allotype; F. Male aedeagal filaments, ejaculatory apodeme and sperm pump; G. Female head; H. Male head; I. Female flagellomere II; J. Male flagellomere II; K. Female cibarium. Drawn from Washington State specimens at same scale as comparable structures in Fig. 4.

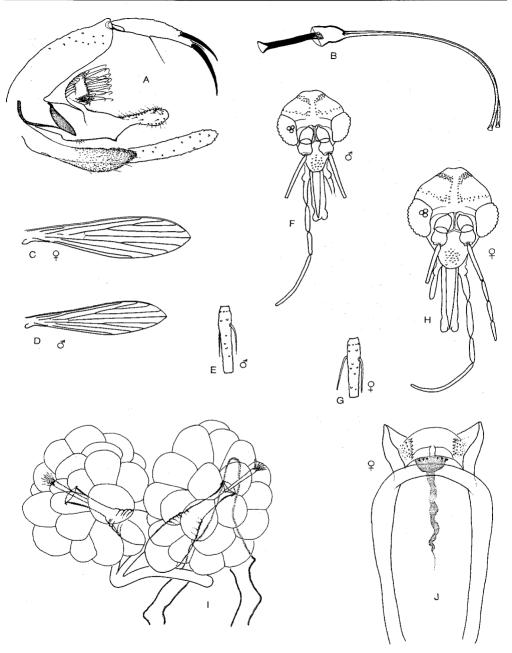

Fig. 6. Lutzomyia anthophora (Addis). A. Male terminalia; B. Male aedeagal filaments, ejaculatory apodeme and sperm pump; C. Female wing; D. Male wing; E. Male flagellomere II; F. Male head; G. Female flagellomere II; H. Female head; I. Spermathecae showing bubble-like evaginations and genital fork; J. Female cibarium. Drawn from Texas specimens at same scale as comparable structures in Fig. 4.

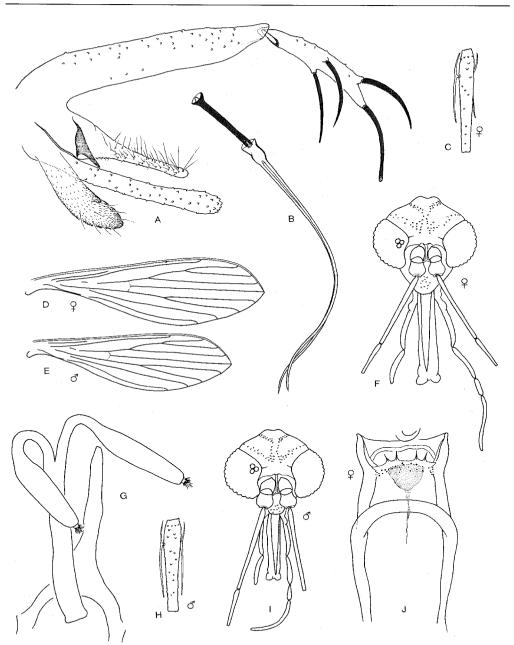

Fig. 7. Lutzomyia shannoni (Dyar). A. Male terminalia; B. Male aedeagal filaments, ejaculatory apodeme and sperm pump; C. Female flagellomere II; D. Female wing; E. Male wing; F. Female head; G. Spermathecae (thin outer envelope surrounding each spermatheca not shown) and genital fork; H. Male flagellomere II; I. Male head; J. Female cibarium. Drawn from Florida specimens at same scale as comparable structures in Fig. 4.

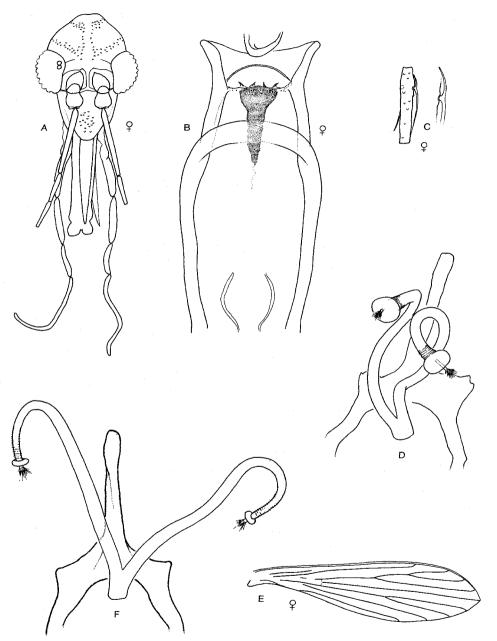

Fig. 8. Lutzomyia tanyopsis Young and Perkins n.sp. (8A-E holotype) and Lutzomyia vexator (Coquillett) from Ft. Ord, California (8F). A. Female head; B. Female cibarium; C. Female flagellomere II; D. Spermathecae and genital fork; E. Female wing; F. Spermathecae and genital fork. All structures drawn at same scale as those in Fig. 4.

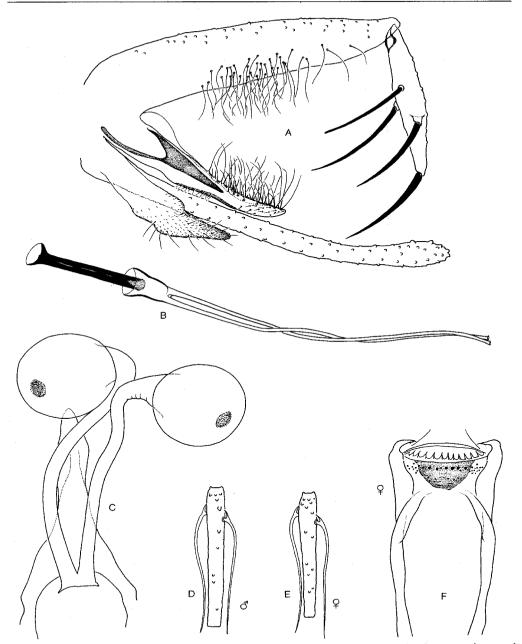

Fig. 9. Lutzomyia texana (Dampf). A. Male terminalia; B. Male aedeagal filaments, ejaculatory apodeme and sperm pump; C. Spermathecae and genital fork; D. Male flagellomere II; E. Female flagellomere II; F. Female cibarium. Drawn from Texas specimens at same scale as comparable structures in Fig. 4. Also see Figs. 16G, H, and 17G, H.

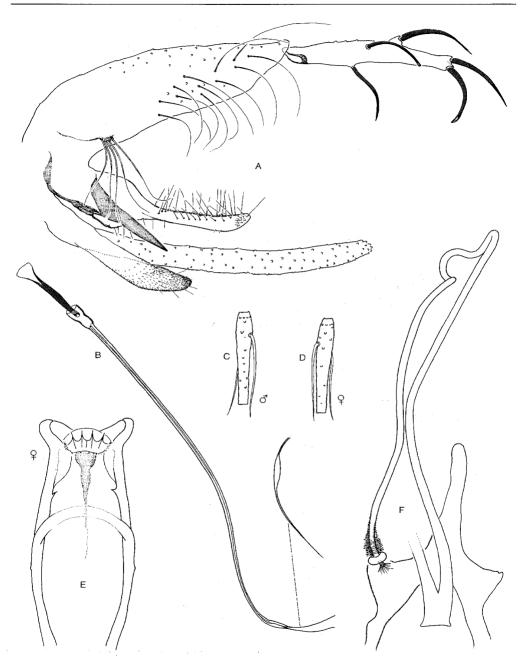

Fig. 10. Lutzomyia apache Young and Perkins n.sp. A. Male terminalia; B. Male aedeagal filaments, ejaculatory apodeme and sperm pump; C. Male flagellomere II; D. Female flagellomere II; E. Female cibarium; F. Spermatheca (only one is shown) and genital fork. Drawn from Springerville, Arizona, specimens at same scale as comparable structures in Fig. 4. Also see Figs. 16E, F and 17E, F.

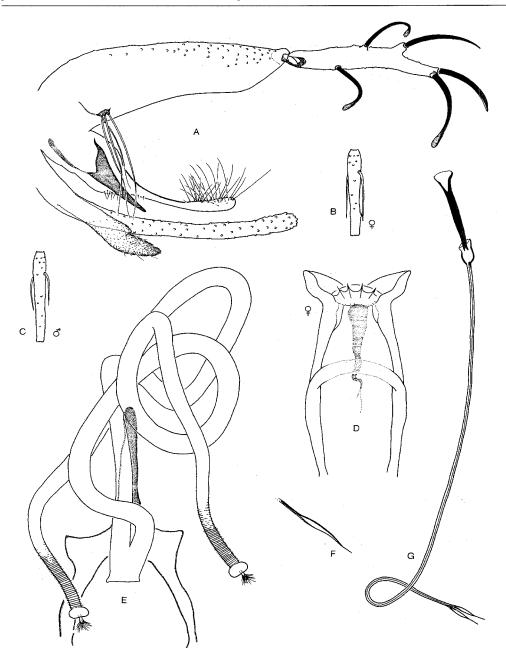

Fig. 11. Lutzomyia oppidana (Dampf). A. Male terminalia; B. Male flagellomere II; C. Female flagellomere II; D. Female cibarium; E. Spermathecae and genital fork; F. Tip of aedeagal filament; G. Aedeagal filaments, ejaculatory apodeme and sperm pump. Drawn from Mexico specimens at same scale as comparable structures in Fig. 4. Also see Figs. 16A, B and 17A, B.

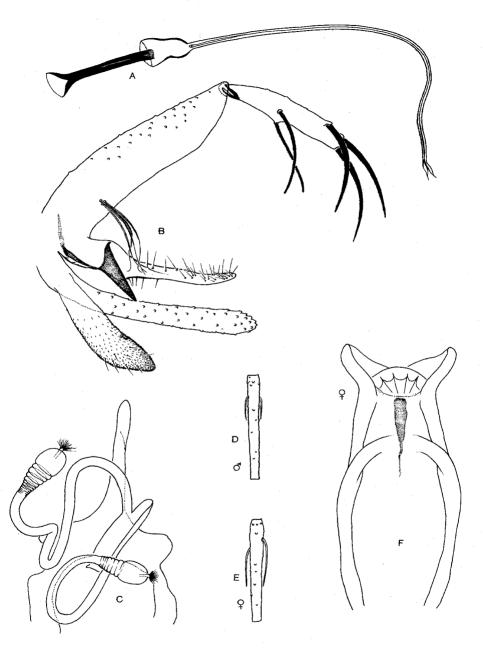

Fig. 12. Lutzomyia stewarti (Mangabeira and Galindo). A. Male aedeagal filaments, ejaculatory apodeme and sperm pump; B. Male terminalia; C. Spermathecae and genital fork; D. Male flagellomere II; E. Female flagellomere II; F. Female cibarium. Drawn from California specimens at same scale as comparable structures in Fig. 4. Also see Figs. 16C, D and 17C, D.

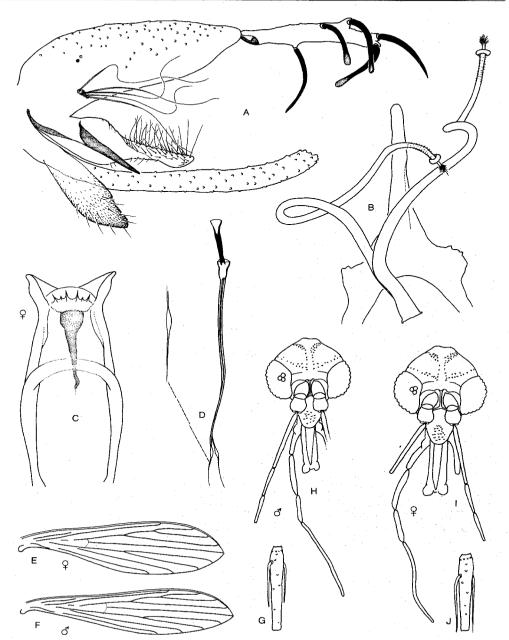

Fig. 13. Lutzomyia vexator (Coquillett). A. Male terminalia; B. Spermathecae and genital fork; C. Female cibarium; D. Male aedeagal filaments, ejaculatory apodeme and sperm pump with one filament tip enlarged; E. Female wing; F. Male wing; G. Male flagellomere II; H. Male head; I. Male flagellomere II; J. Female flagellomere II. Drawn from Florida specimens at same scale as comparable structures in Fig. 4. Also see Fig. 8F.

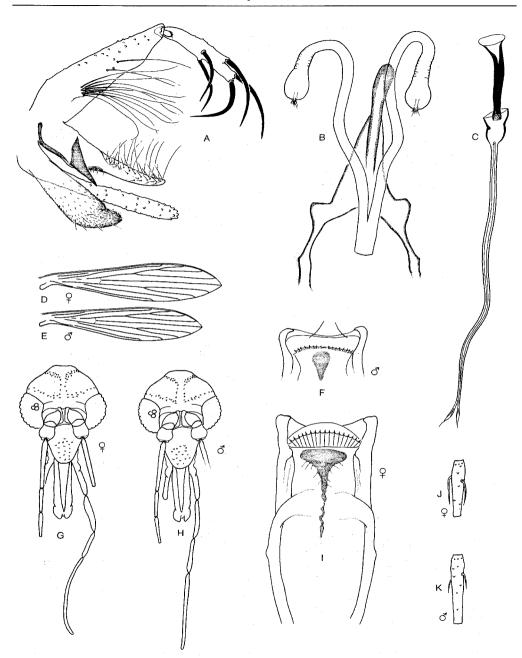

Fig. 14. Lutzomyia californica (Fairchild and Hertig). A. Male terminalia; B. Spermathecae and genital fork; C. Male aedeagal filaments, ejaculatory apodeme and sperm pump; D. Female wing; E. Male wing; F. Male cibarium; G. Female head; H. Male head; I. Female cibarium; J. Female flagellomere II; K. Male flagellomere II. Drawn from California specimens at same scale as comparable structures in Fig. 4.

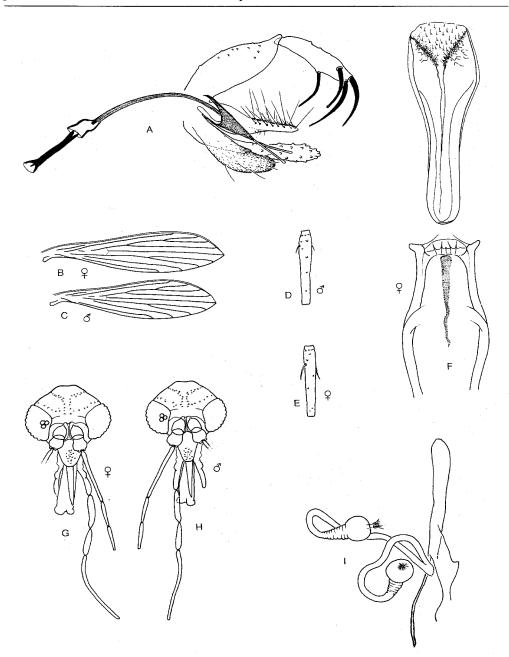

Fig. 15. Lutzomyia cubensis (Fairchild and Trapido). A. Male terminalia; B. Female wing; C. Male wing; D. Male flagellomere II; E. Female flagellomere II; F. Female cibarium and pharynx; G. Female head; H. Male head; I. Spermathecae and genital fork. Drawn from Florida specimens at same scale as comparable structures in Fig. 4.

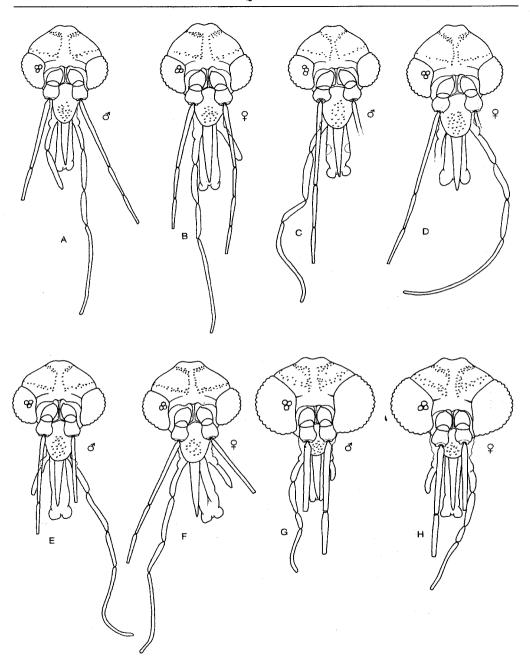

Fig. 16. Male and female heads of Lutzomyia oppidana (A and B); L. stewarti (C and D); L. apache (E and F), and L. texana (G and H). All drawn at same scale as heads in Fig. 4.

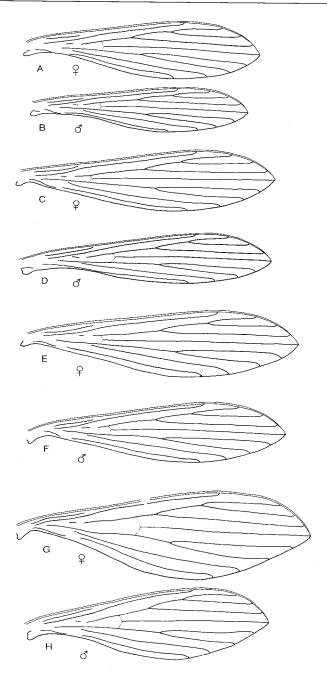

Fig. 17. Male and female wings of Lutzomyia oppidana (A and B); L. stewarti (C and D); L. apache (E and F), and L. texana (G and H). All drawn at same scale as wings in Fig. 4.
