PREFACE

This report is published to provide coastal engineers insight into the important coastal process of longshore transport along sandy beaches by presenting the results of three-dimensional movable-bed laboratory tests. It is hoped that future studies will expand on the analyses of the data in this report. The report was prepared under the nearshore sediment transport research program of the U.S. Army Coastal Engineering Research Center (CERC).

The report was written by Philip Vitale, Hydraulic Engineer, under the general supervision of Dr. R.M. Sorensen, Chief, Coastal Processes and Structures Branch, Research Division.

The author acknowledges C. Galvin, R.P. Savage, and R.P. Stafford for their assistance and advice in the design and operation of the experiment, and M.S. Bartolomei, S.L. Douglas, B. Keely, M. Koenig, M.W. Leffler, J.G. Tingler, J. Sullivan, K.P. Zirkle, and, in particular, L.O. Tornese for their help in collecting and analyzing the data.

Comments on this publication are invited.

Approved for publication in accordance with Public Law 166, 79th Congress, approved 31 July 1945, as supplemented by Public Law 172, 88th Congress, approved 7 November 1963.

¹To obtain Celsius (C) temperature readings from Fahrenheit (F) readings, use formula: $C = (5/9) (F - 32)$.

To obtain Kelvin (K) readings, use formula: $K = (5/9) (F - 32) + 273.15$.

SYMBOLS AND DEFINITIONS

a'	ratio of sand volume to total volume of a sand deposit
b	subscript for breaker
C	wave phase velocity
C_g	wave group velocity
d	water depth
d_{50}	median sand size
$\overline{E}$	energy density
F_x	flux of wave energy per alongshore distance
g	acceleration of gravity
H	wave height
$\overline{H}$	average wave height
H_{rms}	root-mean-square wave height
H_s	significant wave height
I_l	longshore transport rate in immersed weight per unit time
i	subscript for any point seaward of breaker zone
K_p	empirical coefficient relating I_l to P_{lb}
K_s	empirical coefficient relation I_l to S_{xy}
k	wave number = $2\pi/L$
L	wavelength
n	ratio of C_g to C
o	subscript for deepwater condition
P_l	energy flux term
P_{lb}	longshore energy flux factor as used in this report
P_{ls}	longshore energy flux factor as used in the SPM
Q	longshore transport rate in volume per unit time
R	range of coordinate system defined in Figure 7

SYMBOLS AND DEFINITIONS--Continued

r	correlation coefficient
S	station of coordinate system defined in Figure 7
S_{xy}	radiation stress component (flux of y-momentum in x-direction)
T	wave period
t	time
u	onshore component of water particle velocity
v	alongshore component of water particle velocity
x	coordinate in onshore direction
y	coordinate in alongshore direction
z	coordinate in vertical direction
α	angle between wave crest and shoreline
α_g	angle between wave generator and shoreline
β	angle of beach slope with horizontal
η	water surface elevation
θ	wave phase
ξ	surf similarity parameter as used in this report
ξ_b	surf similarity parameter as used in Kamphuis and Readshaw (1978)
ρ	mass density of water
ρ_s	mass density of sand
ω	angular frequency of wave = $2\pi/T$

MOVABLE-BED LABORATORY EXPERIMENTS COMPARING
RADIATION STRESS AND ENERGY FLUX FACTOR AS PREDICTORS
OF LONGSHORE TRANSPORT RATE

by
Philip Vitale

I. INTRODUCTION

Three-dimensional movable-bed laboratory tests were conducted to compare radiation stress and energy flux factor as predictors of the longshore sediment transport rate. The tests were performed in the U.S. Army Coastal Engineering Research Center's (CERC) Shore Processes Test Basin (SPTB). This report presents derivations of the radiation stress and the energy flux factor, documents the experimental setup and procedure, tabulates most of the data, and performs the data analyses. Many photos were taken during the tests; however, only a few were used in the report. The complete set of test photos is available from CERC's Coastal Engineering Information and Analysis Center (CEIAC).

II. EMPIRICAL RELATIONS

The longshore transport data are related empirically to the two expressions representing wave conditions. One, radiation stress, is based on momentum flux, the other on energy flux. An important concept which is also used in the data analyses is the surf similarity parameter.

1. Momentum Flux.

The dependent variable studied here is the longshore transport rate caused by waves approaching the beach; therefore, the consequential momentum term is the onshore flux of alongshore momentum. The derivation of the term follows Longuet-Higgins (1970) which applies the concept of wave momentum flux to the generation of longshore currents.

The coordinate system used is shown in Figure 1. The y-axis is along the shoreline, the x-axis is normal to the shoreline and positive shoreward, and the z-axis originates at the stillwater level and is positive upward. Using this system, the onshore flux of alongshore momentum is the flux of y-momentum in the x-direction, S_{xy} . This term is one component of what is commonly called the radiation stress tensor.

Figure 1. Coordinate system for momentum flux derivation.

According to small-amplitude wave theory, the components of the water particle velocity in the x- and y-directions for a wave traveling at an angle, α , to the shoreline (Fig. 1) are, respectively,

$$u = \frac{H}{2} \frac{gT}{L} \frac{\cosh [k(z + d)]}{\cosh kd} \cos \theta \cos \alpha \quad (1)$$

$$v = \frac{H}{2} \frac{gT}{L} \frac{\cosh [k(z + d)]}{\cosh kd} \cos \theta \sin \alpha \quad (2)$$

where

- H = wave height
- g = acceleration of gravity
- T = wave period
- L = wavelength
- d = water depth
- k = wave number
- θ = wave phase.

The last two terms are defined as

$$k = \frac{2\pi}{L}$$

and

$$\theta = kx - \omega t$$

where t is time, and ω the wave angular frequency

$$\omega = \frac{2\pi}{T}$$

The y-momentum (alongshore momentum) per unit volume is ρv where ρ is the water mass density. The flux of this momentum in the x-direction (onshore) per unit alongshore distance and unit water depth is $\rho v u$. Integrating over the water column and averaging over time produce the mean along-shore momentum flux in the x-direction per unit alongshore distance

$$S_{xy} = \overline{\int_{-d}^{\eta} \rho v u \, dz} \quad (3)$$

where the overbar denotes the mean with respect to time and η the water surface elevation. Substituting equations (1) and (2) into (3) and dropping terms of higher than second order produce

$$S_{xy} = (\overline{EC}_g \cos \alpha) \frac{\sin \alpha}{C} \quad (4)$$

where C is the wave phase velocity, C_g the wave group velocity, and $\bar{E}$ the wave energy density

$$\bar{E} = \frac{\rho g H_{rms}^2}{8} \quad (5)$$

where H_{rms} is the root-mean-square (rms) wave height. The term in parentheses in equation (4) is the flux of wave energy per alongshore distance, F_x , assuming straight and parallel bathymetric contours. When zero wave energy dissipation is assumed,

$$F_x = \bar{E} C_g \cos \alpha = \text{constant} \quad (6)$$

In this report, dissipation is assumed to be zero up to the breaker zone; therefore, F_x is constant from deep water to the breaker zone. Since the ratio of $\sin \alpha$ to C is constant due to Snell's law, equation (4), which represents the alongshore wave momentum entering the surf zone, is constant seaward of the breaker zone.

Equation (4) can be revised for application of monochromatic waves, as in this report. For such wave conditions, the average wave height, $\bar{H}$, measured during the tests (and discussed later in Section IV) is equal to H_{rms} . By rewriting equation (4),

$$S_{xy} = \left(\frac{\rho g \bar{H}^2}{8} C_g \cos \alpha \right) \frac{\sin \alpha}{C} \quad (7)$$

S_{xy} is now defined for use with laboratory monochromatic wave data. Note that equation (4) is valid for any wave condition; equation (7) is valid only for conditions where $\bar{H}$ equals H_{rms} .

2. Energy Flux.

In literature, the longshore transport rate has been empirically related most frequently to a term found by multiplying both sides of equation (4) by the wave phase velocity, C , to yield

$$P_\ell = (\bar{E} C_g \cos \alpha) \sin \alpha \quad (8)$$

Unlike S_{xy} , P_ℓ is not constant seaward of the breaker line; therefore, specifying where P_ℓ is being calculated is necessary. This report, following convention, determines P_ℓ at the breaker line,

$$P_{\ell b} = (\bar{E} C_g \cos \alpha)_b \sin \alpha_b \quad (9)$$

representing the value of P_ℓ at the point closest to where the longshore transport is occurring. The subscript b denotes breaker values. The term

in parentheses in equation (9) has been shown to be constant (see eq. 6) seaward of the breaker line; therefore, subscript b may be replaced by i which represents any point seaward of the breaker line. Making this change, using equation (5), and letting H_{rms} equal $\bar{H}$ for monochromatic waves, equation (9) becomes

$$P_{lb} = \left(\frac{\rho g \bar{H}^2}{8} C_g \cos \alpha \right)_i \sin \alpha_b \quad (10)$$

The Shore Protection Manual (SPM) (U.S. Army, Corps of Engineers, Coastal Engineering Research Center, 1977) provides a term similar to P_{lb} except that the wave height used is the significant height, H_s . The term, called the longshore energy flux factor, is defined as

$$P_{ls} = \left(\frac{\rho g H_s^2}{8} C_g \cos \alpha \sin \alpha \right)_b \quad (11)$$

P_{ls} is derived in Galvin and Schweppe (1980). The relationship between H_{rms} and H_s has been shown in Longuet-Higgins (1952) to be

$$H_s^2 = 2 H_{rms}^2 \quad (12)$$

assuming a Rayleigh distribution of wave heights as well as a number of other conditions. Therefore,

$$P_{lb} = \frac{P_{ls}}{2} \quad (13)$$

Since P_{lb} and P_{ls} are essentially the same terms, this report uses the SPM terminology and refers to P_{lb} as the longshore energy flux factor.

3. Longshore Transport Rate.

The longshore transport rate, Q , given in the SPM in units of volume per unit time, is also commonly shown as I_l with units of immersed weight per unit time. The relationship between the two is

$$I_l = (\rho_s - \rho) g a' Q \quad (14)$$

where ρ_s is the mass density of sand and a' the ratio of sand volume to total volume of a sand deposit, which takes into account the sand porosity. For discussions of equation (14), see Komar and Inman (1970) and Galvin (1979). Since the laboratory tests described here measured I_l directly, this term is used in most of the data analysis.

4. Empirical Relations.

The expressions derived in the preceding paragraphs are used to set up the following empirical relations

$$I_{\ell} = K_p P_{\ell b} \quad (15)$$

and

$$I_{\ell} = K_s S_{xy} \quad (16)$$

where K_p and K_s are coefficients to be determined from the test data in this report.

Equation (15) is based on the concept that the work done in moving the sand alongshore is proportional to the energy which approaches the beach. The units are consistent and K_p is dimensionless.

Equation (16) is based on the concept that the sand transported alongshore depends on the alongshore force exerted by the wave motion on the bed inside the surf zone. By the equation of motion, this force is related to the change of momentum inside the surf zone. The alongshore momentum, S_{xy} , enters the surf zone through the breaker line but cannot exit through the shoreline boundary. Therefore, the change in alongshore momentum is S_{xy} and equation (16) results. K_s has dimensions of length over time.

5. Surf Similarity Parameter.

Kamphuis and Readshaw (1978) showed that K_p and K_s are dependent upon the surf similarity parameter,

$$\xi_b = \frac{\tan \beta}{(H_b/L_o)^{1/2}} \quad (17)$$

in which $\tan \beta$ is the beach slope, H_b the breaker height, and L_o the deepwater ($d/L > 1/2$) wavelength. ξ_b reflects variations in beach shape, breaker type, and rate of energy dissipation. Using the results of laboratory tests, the following relationships were found by Kamphuis and Readshaw

$$K_p \approx 0.7 \xi_b \quad \text{for} \quad 0.4 < \xi_b < 1.4 \quad (18)$$

$$K_s \approx 0.08 \xi_b \quad \text{for} \quad 0.4 < \xi_b < 1.25 \quad (19)$$

For values of ξ_b higher than the upper limits, K_p and K_s become independent of ξ_b .

The surf similarity parameter is evaluated in this report to determine its effect on the longshore transport rate.

III. EXPERIMENTAL SETUP

This section discusses the setup in the SPTB (Figs. 2 and 3) and describes the wave generators, wave gages, and cameras and their positions. Also discussed are the sand-moving system, the method for measuring the longshore current velocity, and the size distribution of the sand used in the experiment. The design of the setup was based in large part on Fairchild (1970).

Figure 2. Diagram of test basin setup.

Figure 3. Photo of test basin setup.

1. Basin Layout.

A diagram of the basin setup is shown in Figure 2. The basin is 45.72 meters long, 30.48 meters wide, and 1.22 meters deep. The alongshore and the shore-normal directions of the sand beach were 7.62 and 11.45 meters, respectively. The backbeach was 3.05 meters in the shore-normal direction, but it was not part of the test beach.

Immediately downdrift of the beach was the sand trap, 0.91 meter wide and 12.7 centimeters deep (Fig. 4), used to catch the longshore transport.

Concrete aprons, 4.57 meters in the alongshore direction, were located on the downdrift side of the sand trap and on the updrift side of the beach. The updrift apron provided enough distance for the longshore current to develop between the updrift training wall and the beach. This phenomenon is discussed in Galvin and Eagleson (1965). The downdrift apron served two purposes—one as a platform for depositing the longshore transport that escaped the trap, the other as a surface on which the waves traveled to diminish diffraction effects since no downdrift training walls were used.

The major limitation in the experimental planning was the size of the SPTB, which permitted three wave generators, each 6.10 meters long, to be linked together and leave enough room to be rotated through various angles to the beach. The other limitation was the decision not to use downdrift training walls due to the wave reflection problem. When downdrift training walls are used, the wave energy, which is reflected off the beach at an angle in the downdrift direction, strikes the downdrift wall and is reflected back toward the updrift direction. The energy is then reflected by the updrift wall and the process repeats. The reflected wave energy is being trapped within the

Figure 4. Photo of sand trap.

two walls; this produces some complicated wave variability problems (e.g., see Fairchild, 1970). With no downdrift training walls, the reflected wave energy moves away from the beach area into the outer parts of the test basin where most of it is eventually dissipated by the rubble slope along the edge of the basin (Fig. 2). This, however, creates a problem with wave diffraction. The energy of the wave leaving the generator spreads laterally into still water and gradually decreases the wave height toward the updrift end of the wave crest.

To minimize the decrease in wave height over the test beach, it was designed using the diffraction diagram for a wave traveling past a semi-infinite breakwater from Figure 2-33 of the SPM. The period and angle used in the diffraction analysis were 3 seconds and 10° , respectively, since these values produced the maximum diffraction closest to the beach. The spreading of wave energy into the shadow of a breakwater is analogous to the spreading of wave energy into the area of the test basin downdrift of the generators. The diagram (Fig. 5) indicated that the alongshore length of the beach should be 7.62 meters. Most of the diffraction-caused decrease in wave height occurs over the downdrift concrete apron.

Rubble, ranging in size from 7.62 to 15.24 centimeters, was placed at several locations in the basin to absorb wave energy and provide gradual slopes between the concrete aprons and the basin floor. The beach, sand traps, concrete aprons, and adjacent rubble were all built to the same shore-normal profile (Fig. 6). This profile was based on Chesnutt's (1978) long-term two-dimensional tests in which waves were run onto a sand beach to determine profile response. After superposing several of Chesnutt's (1978)

Figure 5. Diagram of diffraction analysis used to determine the alongshore length of the test beach.

Figure 6. Shore-normal profile of the test beach, sand trap, concrete aprons, and adjacent rubble.

profiles run for 80 hours or more with wave periods similar to those used in this experiment, the shore-normal profile in Figure 6 was drawn as a compromise or average through the superposed profiles. This profile was used to lessen the onshore-offshore adjustment of the beach.

Figure 7 shows the coordinate system used for the test beach. The origin is at the updrift, shoreward corner of the beach. Ranges (in meters) are along the alongshore axis, and stations (in meters) along the shore-normal axis. Any point on the beach, or in the basin, can be described by a range-station pair.

Figure 7. Coordinate system used for test beach with locations of wave gages (R = range, S = station).

2. Generators.

The three piston-type 6.10 meter-long generators used in this experiment produced only monochromatic waves and are discussed in Stafford and Chesnutt (1977). The generators were set at four different angles--0°, 10°, 20°, and 30°--to the beach during the experiment. For each setting, an updrift training wall was built from the generator to the 1-foot depth. This allowed circulation past the wall to feed the longshore current. Figure 2 shows the setup of the four generators and training wall.

For the 10° and 20° tests, the training wall was curved to allow for wave refraction. However, since the wall stopped at the 1-foot depth, the curves

were small and considered not worth the construction effort. Therefore, the curve for the 30° tests was deleted and a straight training wall was used.

3. Sand-Moving System.

As the waves approached the beach at an angle, the sand moved in the downdrift direction. Most of it deposited in the sand trap. The sand which escaped the trap deposited either on the downdrift concrete apron or beyond the apron and rubble (covered to keep sand from being lost within it) onto the basin floor. This area is shown in Figure 2 as the supplementary deposition area. Although separate measurements of the sand deposited in each area were not taken, it is estimated that 80 to 95 percent of the longshore transport fell into the trap. The greater the transport rate and the suspended sediment, the greater was the amount of sand escaping the sand trap.

The trap was cleaned continually during a test using an eductor attached to a small centrifugal pump. Water was pumped through the eductor at high speed, creating a suction to pick up the sand (Fig. 8). The sand was pumped to the weighing station (Fig. 9), deposited in one of two bins, and weighed submerged. When divided by the appropriate time period, the value became the immersed weight longshore transport rate.

After the weighing, the sand was pumped, using another eductor, into a sand feeder. The sand feeder is a vertical cylinder open at both ends in which sand is introduced through the top and removed by waves through the bottom. A diagram and a photo of the feeder are given in Figures 10 and 11. The primary advantage of the feeder is that it permits waves to control the amount of sand introduced onto the beach. Savage (1961) discusses the feeder and its development.

In summary, the complete sand-moving system (Fig. 12) included the following:

- (a) A sand trap, a downdrift concrete apron, and a downdrift deposition area which trapped the sand;

- (b) a downdrift eductor-pump combination which moved the trapped sand to the weighing station;

- (c) a weighing station which weighed the amount of sand moved;

- (d) an updrift eductor-pump combination which moved the sand from the weighing station to the sand feeder; and

- (e) a sand feeder which redeposited the sand onto the beach.

4. Instruments.

Wave heights were measured using parallel-wire wave gages (see Fig. 7). Gages 1 and 2, located seaward of the toe of the beach, were used for all 15 tests. Gage 3, located over the beach, was used for tests 5 to 15. Gage 4A, located close to the breaker line, was used for tests 5 to 11. Beginning with test 12 for the remainder of the tests, gage 4A was adjusted to measure the breaker height and then renamed gage 4B.

Figure 8. Diagram of eductor.

Figure 9. Photo of weighing station.

Figure 11. Photo of sand feeder.

Figure 10. Diagram of sand feeder.

Figure 12. Diagram of complete sand-moving system.

Two cameras were mounted over the beach on the catwalk of the SPTB. One was a view camera with an adapter for taking 4- by 5-inch Polaroid black-and-white photos, and the other a standard 35-millimeter camera. The locations of the cameras are given in Table 1.

Other instruments used in the tests include standard hydraulic scales for weighing the sand, and a standard level and rod for surveying the beach after each test.

Table 1. Locations of overhead cameras mounted on the catwalk.

Location ¹	Camera	
	View (m)	35-mm (m)
Range	3.9	3.9
Station	4.9	4.7
Elevation above SWL	8.5	8.5

¹Accurate only to ± 0.1 meter.

5. Dye Injection.

Longshore current velocities for tests 5 to 15 were measured by injecting dye into the surf zone through a hose which ran from the sand feeder to a small stake in the surf zone. Dye was poured by hand into the top of the hose. Table 2 gives the locations of the dye injection by test numbers. The change in location of the stake in tests 7 to 10 was a procedural error and not planned for a special purpose. The dye injection procedure is discussed in detail in the next section.

Table 2. Locations of dye injection by test number.

Test Nos.	Dye injected at range (m)	Dye timed from range (m)	Dye timed to range (m)	Timed distance traveled (m)
5 and 6	3.00	3.60	7.60	4.00
7 to 10	3.82	3.82	7.73	3.78
11 to 15	3.00	3.73	7.73	4.00

6. Sand Size.

Figure 13 shows the size distribution of the sand used for all 15 tests. The median diameter was 0.22 millimeter. The geometric standard deviation is defined as

$$\sigma_g = \frac{d_{16}^{1/2}}{d_{84}} \quad (20)$$

where d_{16} and d_{84} are the sand sizes at which 16 and 84 percent, respectively, of the sample is coarser. The value of σ_g for the sand used was 1.22. Figure 13 indicates that the sand was well sorted.

Figure 13. Size distribution of sand used for all tests.

IV. EXPERIMENTAL PROCEDURE

Each test was composed of three major data collection cycles: an hourly cycle, a daily cycle, and a test cycle. For example, wave heights were measured every hour (hourly cycle), water temperature was measured twice a day (daily cycle), and beach surveys were taken at the end of each test (test cycle). The typical test schedule was 4 hourly cycles daily for 6 days for a total of 24 run-hours per test. Tests 1 and 2, as discussed later, were exceptions to this schedule. Figure 14 is a schematic diagram of the interrelationship of the three cycles. Since waves were run every other day, a complete test took about 3 weeks.

Figure 14. Schematic diagram of the interrelationship of the three experimental cycles.

1. Hourly Cycle.

The various types of data collected in a typical hourly cycle are shown in Figure 14, along with an indication of time of collection. Before a new hour of run-time was started, photos of the beach were taken from overhead with both the 35-millimeter camera (Fig. 15) and the view camera. A reference rope in the alongshore direction at station 5 and painted arrows on the concrete at each station bordering the beach can be seen in Figure 15. Photos, such as shown in Figure 15, provide a record of the change in waterline and breaker bar throughout the tests. The waves were then turned on and usually, within 5 minutes of the start, an overhead photo of the breaking wave was taken with the view camera. The angle between the breaking wave and the reference rope was later measured from the photo to determine the breaking angle of the wave (see Fig. 16). Note that this procedure assumes the alongshore direction remained constant throughout the test. In actuality, however, the alongshore contours are changing, as evidenced in Figure 15.

After a run-time of 30 minutes, wave data were collected for 2 minutes. A sample strip-chart record is shown in Figure 17. The wave height was determined from this record. For a given length of wave record, a horizontal line was drawn along what appeared to be the average wave-crest elevation. A horizontal line was also drawn for the wave troughs. The distance between the two lines was measured to determine the average wave height, $\bar{H}$. This procedure assumes that a nearly uniform distribution of wave heights is produced by the monochromatic wave generators.

Figure 15. Example of overhead photo.

Figure 16. Example of photo of breaking wave.

Figure 17. Example of strip-chart wave record.

Immediately after the wave data were collected, dye was injected into the surf zone, as discussed in Section III, and the leading edge of the dye was timed over a distance of approximately 4 meters (see Table 2) to determine the longshore current velocity. Also recorded were the station at which the dye left the downdrift edge of the beach and the station at which the waves were breaking. Therefore, the determination of whether the dye moved offshore, along the breaker line, or onshore could be made. Most of the dye injections traveled along the breaker line.

During the hourly cycle, sand was continually picked up from the trap area and weighed when a bin was full. A complete record of the amount of sand moved in a given time period existed only at the end of the day after the waves had been stopped and all the remaining sand had been picked up and weighed. Therefore, the longshore transport rate can be given for a daily cycle or a test cycle only.

2. Daily Cycle.

At the start of every test day (see Fig. 14), the water temperature was recorded, the water level was corrected to 0.710 meter, the wave gages were calibrated, and a check of all equipment was made. The hourly cycles were then started. Four hourly cycles were usually completed each day.

Shortly before the waves were turned off at the end of the day, photos of the surf zone were taken from the side (see Fig. 18 for examples). After the waves were stopped, all the sand in the sand trap, on the downdrift concrete apron, and in the downdrift deposition area was moved to the weighing station and weighed. The day's longshore transport movement was then determined after the final weighing. This quantity, divided by the total number of run-hours, provided the immersed weight longshore transport rate for the day.

3. Test Cycle.

At the beginning of each test, new test values for the wave period, T , the generator angle, α_g , and the generator eccentricity, Ecc , were selected and set (Fig. 14). Ecc is half the distance the generator bulkhead moves. The combination of period and eccentricity produced a predicted wave height, using the calibration curve of the generators (see Fig. 2 in Fairchild, 1970). This guided the selection of T and Ecc but was not used for wave height determination.

The beach was regraded to the shore-normal profile (see Fig. 6) before each new test. This included raking the beach to remove all traces of ripples from the prior test. The basin was usually flooded to cover the entire beach and left over a weekend to allow the new beach to stabilize before the new test cycle began.

After the test was completed, the basin was drained in 10-centimeter increments, producing depth contours of 0, 10, 20, 30, 40, 50, and 60 centimeters. An overhead photo of the waterline was taken at each increment. An example series is shown in Figure 19. Surveys of the beach were then taken, using a standard level and rod, along ranges 1.5, 2, 3, 4, 5, 6, 7, and 7.6 meters. The elevation on each range was read at all major breaks in slope.

Figure 18. Example of surf zone photos.

Figure 19. Example series of drainage photos.

Figure 19. Example series of drainage photos.--Continued

Finally, photos of the beach were taken at close range to document important bed forms, such as ripples and bars (Fig. 20).

Figure 20. Example of bed-form photo.

4. Range of Variables.

Table 3 gives the test variables for all 15 tests. Note that the 0.710-meter water depth and the sand were the same for all tests. The wave heights listed are the average of all the hourly measurements of gages 1 and 2 for each test.

Table 3. Test cycle variables and data.

Test No.	Total run-time (hr)	Period (s)	Generator angle (degrees)	Water temperature ($^{\circ}\text{C}.$)	Wave height (cm)	Breaker angle (degrees)	Longshore current (cm/s)	$I_L \cdot 10^4$ (N/s)
1	25	2.35	10	22.8	8.2	8	-- ¹	6,117

V. DATA

The data collected during the experiments are provided in Appendixes A to D. Appendix A contains the hourly and daily data for each test. Appendix B lists the beach survey data, which are plotted in Appendix C, taken after each test. Appendix D provides 35-millimeter photos of the beach taken during a test with the waves stopped.

1. Hourly and Daily Data in Appendix A.

Table 4 is an example of how the daily and hourly data are tabulated in Appendix A. Column 1 lists the run-time over which the data were collected. Run-time is defined as the cumulative time of wave operation from the beginning of the test. A run-time of 05 10 means that up to that point, waves had been run at the beach for a cumulative total of 5 hours and 10 minutes. This would be the case even if the first wave had been run 2 days before.

Column 2 lists the length of time (in minutes) waves were stopped to take overhead photos of the beach. The letters CFD or TC indicate that the testing was completed for the day or the test was completed. Between any two entries in column 2, the waves were run continuously. For example, from the beginning of the test at run-time 00 00 to run-time 01 00 (see Table 4), the waves were continuously run. At that point the waves were stopped for 5 minutes to take overhead photos of the beach. The waves were then restarted and run continuously until run-time 02 00.

Columns 3 and 4 list the water temperature and the water depth, respectively. These measurements were taken in the morning before the testing started and in the afternoon after the testing stopped.

Column 5 lists the immersed weight of sand moved during testing from the previous entry in the column. A value is always listed with a CFD or TC entry since it was only at the end of the day that the balance of sand not weighed during the time the waves were running could be picked up and weighed. In Table 4, the value of 4,227 immersed pounds of sand is the quantity of sand transported from run-hour 04 00 to 08 00. This column is not a cumulative listing of sand transported.

Columns 6, 7, 8, and 9 list the wave heights measured by gages 1, 2, 3, and 4A or 4B, respectively. Section III discusses the locations of these gages, which are shown in Figure 7. Column 10 lists the breaker angles measured from the Polaroid 4- by 5-inch photos of the breaking waves (see Fig. 16). Column 11 lists the longshore current velocity measured by dye injections, as discussed in Section III. Column 12 lists the breaker type, using the following code: sg, surging; p, plunging; c, collapsing; and sp, spilling. A double entry indicates both types of breakers were evident with the first type predominant.

2. Summary Data Table.

For a comparison of test conditions, Table 3 provides the average values of water temperature, wave height, wave breaker angle, longshore current velocity, and average longshore transport rate in immersed pounds per second for each test. Also included are the wave period and generator angle.

Table 4. Example of hourly and daily data tables in Appendix A.

3. Survey Data.

After each test, the SPTB was drained and the beach was surveyed. The distance and elevation pairs are listed in Appendix B and plotted in Appendix C. The elevation datum is the stillwater level (SWL), which corresponded to a 0.710-meter water depth.

4. Overhead Photos.

Every hour during testing, the waves were stopped to take an overhead 35-millimeter photo of the beach (see Fig. 15). The photos show the waterline, the longshore bar, and the swash zone. They are useful for a qualitative description of how the beach responded to the waves. Appendix D contains a series of photos for run-times 01 00, 08 00, 16 00, and 24 00.

VI. DATA ANALYSIS

This section includes the data analysis to determine the relations between I_ℓ and S_{xy} and I_ℓ and $P_{\ell b}$. The empirical coefficients found from these relations are then, in turn, related to the surf similarity parameter, ξ , which is adapted to the data collected. Also included is an explanation of the calculations of S_{xy} , $P_{\ell b}$, ξ , and I_ℓ , along with plots of the various relationships. The wave height used in the calculations is that measured at the toe of the beach (average of gages 1 and 2 wave heights). The breaker wave height, which would have been a better value, was not used for the following reasons. The wave height at the toe of the beach was measured for all 15 tests; the breaker height was not. Also, only one gage was used to measure breaker height, while two were used at the beach toe. The significant difference in height between waves measured at the two beach toe gages (see App. A) indicates that some wave height variability existed along the wave crest. Therefore, the average of the measurements at the two beach toe gages is probably a more reliable estimate of the entire wave passing the toe than the one gage measurement at the breaker is of the entire breaker wave. A comparison of the data in this report with past studies is shown in a Q versus $P_{\ell b}$ graph.

1. Calculation of S_{xy} .

Equation (7)

$$S_{xy} = \left(\frac{\rho g \bar{H}^2}{8} C_g \cos \alpha \right) \frac{\sin \alpha}{C}$$

was used to calculate S_{xy} . Rearranging the equation,

$$S_{xy} = \frac{\rho g}{16} \bar{H}^2 n \sin 2\alpha \quad (21)$$

where n is the ratio C_g/C and a function of the water depth and wave period or length. S_{xy} was calculated at the toe of the beach by using the average of the wave heights measured at that location (see Fig. 7), and by using the generator angle for α . This was calculated for each set of wave data. Thus, for the standard 24-hour test, 24 values of S_{xy} were calculated (see App. E). The average of S_{xy} for each test is listed in Table 5.

Table 5. Test cycle calculations.

Test	Total run time (hr)	S_{xy} (N/m)	P_{lb} (J/m/s)	I_l (N/s)	K_s (m/s)	K_p	ξ
1	25	1.179	2.201	0.6116	0.5190	0.2779	0.6604
2	30	1.137	2.043	0.6889	0.6058	0.3373	0.6686
3	24	2.280	3.232	0.8396	0.3682	0.2598	0.3374
4	24	2.158	3.615	0.6188	0.2868	0.1712	0.4508
5	24	0.987	0.789	0.7544	0.7640	0.9557	0.8997
6	24	1.977	2.144	0.9966	0.5042	0.4648	0.6815
7	24	3.161	4.158	0.7281	0.2303	0.1751	0.4787
8	24	3.018	3.918	0.3446	0.1142	0.0880	0.4835
9	24	2.808	4.286	0.5227	0.1862	0.1220	0.3761
10	24	8.250	14.761	1.0605	0.1285	0.0718	0.3764
12	24	2.942	4.839	1.6328	0.5550	0.3374	0.6644
13	24	2.241	2.948	1.1941	0.5328	0.4051	0.9190
14	24	11.578	28.802	3.2938	0.2845	0.1144	0.6112
15	24	9.253	13.536	2.5502	0.2756	0.1884	0.3934

2. Calculation of P_{lb} .

Equation (10)

$$P_{lb} = \left(\frac{\rho g \bar{H}^2}{8} C_g \cos \alpha \right)_i \sin \alpha_b$$

was used to calculate P_{lb} . The term in the parentheses, like S_{xy} , was calculated at the toe of the beach. However, the sine term used the breaker angle as measured from the photos of the breaking waves. The breaker angle used in the calculation was the average of the breaker angles collected 30 minutes before and after the wave data were collected (see Fig. 14). P_{lb} was calculated for each set of wave data, 24 values of P_{lb} were calculated for the standard 24-hour test (see App. E). The average of P_{lb} for each test is listed in Table 5.

3. Calculation of ξ .

The surf similarity parameter of Kamphuis and Readshaw (1978) was presented in equation (17) as

$$\xi_b = \frac{\tan \beta}{(H_b/L_o)^{1/2}}$$

For the data in this report, a different surf similarity parameter is needed since $\bar{H}$ will be substituted for H_b , as discussed at the beginning of this section. Therefore, the surf similarity parameter in the following analysis is

$$\xi = \frac{\tan \beta}{(\bar{H}/L_o)^{1/2}} \quad (22)$$

The same beach slope was used for all 15 tests and was determined as shown in Figure 21. A value of ξ was calculated for each test using the average $\bar{H}$ for the entire test. These values are listed in Table 5.

Figure 21. Determination of beach slope used to calculate the surf similarity parameter.

4. Special Tests.

Three tests were performed under special circumstances. Test 2 was a repeat of test 1; test 8 was a repeat of test 7, except the sand feeder was moved shoreward; and test 11 was done with a generator angle of zero.

Tests 1 and 2 were both run with a period of 2.35 seconds, a generator angle of 10° , and a generator eccentricity of 5.97 centimeters. Test 1 ran for 25 hours, test 2 for 50 hours. A twofold comparison of the two tests was originally planned. The first 25 hours of test 2 data was to be compared to the test 1 data, and then, both sets of data were to be compared to the last 25 hours of test 2. Unfortunately, due to an experimental error, only the first 30 hours of the test 2 longshore transport data was collected accurately. Therefore, the only comparison made was test 1 to the first 30 hours of test 2. Reference to test 2 in the remainder of the report refers to the first 30 hours only. Appendix A contains all 50 hours of test 2 data.

Table 6 compares the results of the two tests. The differences listed give an indication of the repeatability of the data collection. The longshore transport rate changed by 12.6 percent, which is a significant variation. This is an inherent problem of longshore transport tests, indicating that some important unknown factors are at work.

Table 6. Comparison of tests 1 and 2.

Test	Total run-time (hr)	Avg $\bar{H}$ (cm)	Avg α_b (degrees)	I_L (N/s)	S_{xy} (N/m)	P_{lb} (J/m/s)
1	25	8.17	8	0.612	1.18	2.20
2	30	8.03	7	0.689	1.14	2.04
Pct difference ¹		-1.7	-12.5	+12.6	-3.4	-7.3

$$^1 \text{Pct difference} = \frac{(\text{Test 1} - \text{Test 2}) 100}{\text{Test 1}}$$

Tests 7 and 8 were both run with a period of 1.90 seconds, a generator angle of 20° , and a generator eccentricity of 5.97 centimeters. The only difference was that the sand feeder, which was located at the SWL for all other tests, was moved shoreward 1.4 meters for test 8. The feeder was moved because the shoreline at the end of test 7 significantly angled shoreward toward the downdrift side of the beach. This can be seen in the test 7 photos in Appendix D. The feeder was moved shoreward to see if a straight shoreline resulted. It did, as the photos in Appendix D for test 8 show. Another major effect was the change in I_L from 0.728 newton per second for test 7 to 0.345 newton per second for test 8, a decrease of 53 percent. Test 8 is excluded from the remaining data analyses.

Test 11 was run with a period of 2.35 seconds, a generator angle of 0° , and a generator eccentricity of 5.97 centimeters. The test was meant as a control to determine the amount of sand moved by the diffusion caused by breaking waves. This value of I_L for test 11 was 0.089 newton per second. A comparable quantity of sand, 0.059 newton per second, also moved updrift. Test 11 is also excluded from the remaining data analyses.

5. Daily Cycle Graphs.

As discussed previously, longshore transport could be measured only on a daily cycle or test cycle basis. For the typical 24-hour test, six values of longshore transport rate were calculated. Each rate covered a period of 4 run-hours. During this time period, four values of S_{xy} and P_{lb} were calculated, averaged, and related to the corresponding value of I_L . These values are listed in Appendix F and plotted in Figures 22 and 23. Table 7 lists the important statistical parameters.

Table 7. Daily cycle statistics.

Relation	Figure No.	r^2	Least squares lines		
			Standard slope	Y-intercept	Through origin slope
I_L versus S_{xy}	22	0.74	0.21	0.38	0.28
I_L versus P_{lb}	23	0.73	0.09	0.58	0.13

The square of the correlation coefficients, r^2 , represents the fraction of the variation of I_L about its mean which is explained by the abscissa term. r^2 for S_{xy} and P_{lb} are 0.74 and 0.73, respectively. These numbers show that I_L correlates well with both terms to approximately equal degrees. The least squares lines listed in Table 7 are in Figures 22 and 23, which also include the least squares lines calculated with the limitation that the lines pass through the origin. The slopes of these lines are 0.28 for the I_L versus S_{xy} graph and 0.13 for the I_L versus P_{lb} graph.

Figure 22. Relation between longshore transport rate, I_ℓ , and radiation stress, S_{xy} , using daily cycle data (tests 8 and 11 excluded).

Figure 23. Relation between longshore transport rate, I_l , and longshore energy flux factor, P_{lb} , using daily cycle data (tests 8 and 11 excluded).

6. Test Cycle Graphs.

The average longshore transport rate for each test was calculated and compared with the test average of S_{xy} and P_{lb} . These values are listed in Table 5 and plotted in Figures 24 and 25. Statistical values are in Table 8. r^2 for I_l versus S_{xy} and I_l versus P_{lb} are 0.72 and 0.74, respectively. As with the daily cycle calculations, I_l is shown to correlate well with both terms to approximately equal degrees. Figures 24 and 25 include both the standard least squares line and the least squares line forced through the origin. The slopes of the latter lines are 0.26 for the I_l versus S_{xy} graph and 0.13 for the I_l versus P_{lb} graph.

Table 8. Text cycle statistics.

Relation	Figure No.	r^2	Least squares lines		
			Standard slope	Y-intercept	Through origin slope
I_l versus S_{xy}	24	0.72	0.21	0.40	0.26
I_l versus P_{lb}	25	0.74	0.09	0.58	0.13
K_s versus ξ	26	0.70	0.82	-0.07	
K_p versus ξ	27	0.56	0.89	-0.22	

Figure 24. Relation between longshore transport rate, I_l , and radiation stress, S_{xy} , using test cycle data (tests 8 and 11 excluded).

Figure 25. Relation between longshore transport rate, I_l , and longshore energy flux factor, P_{lb} , using test cycle data (tests 8 and 11 excluded).

7. Surf Similarity Relation.

Figures 26 and 27 were drawn to test the dependence of K_s and K_p on ξ . Test numbers are indicated in the figures. Table 8 lists the statistics. The K terms were calculated using equations (15) and (16). These graphs show that K is far from being constant, as is commonly assumed, and that it is strongly related to ξ .

8. Comparison to Past Data.

The units of I_l and P_{lb} were converted to those used in the SPM and plotted in Figure 28, which is taken from Figure 4-36 of the SPM. The SPM figure was modified by shifting the x-axis to convert from P_{ls} to P_{lb} . Equation (13) shows the relation between P_{lb} and P_{ls} . Test numbers for the data points of this report are noted in Figure 28.

Two major observations are immediately apparent. The first is that the laboratory data in this report, as in laboratory data from past reports, have considerable scatter. Since the surf similarity parameter, ξ , in this report varies by a significant amount for the different tests, as shown in Figures 26 and 27, some scatter is expected. The surf similarity parameter, of course, does not explain all of the scatter in the laboratory data. There are still some laboratory and scale effects which are not yet understood.

Figure 26. Relation between K_S and the surf similarity parameter, ξ , using test cycle data (tests 8 and 11 excluded).

43

Figure 27. Relation between K_P and the surf similarity parameter, ξ , using test cycle data (tests 8 and 11 excluded).

Figure 28. Comparison of data in this report to past reports, using SPM Figure 4-36 (tests 8 and 11 excluded).

The second observation is that most of the data fall beneath the SPM curve connoting low values of K_p . Since the SPM curve is based on field data, mostly from Komar and Inman (1970), a possible explanation is that the field data were collected under conditions of higher values of ξ than those for the laboratory data. Kamphuis and Readshaw (1978) suggest that Komar and Inman's data were indeed collected under conditions of high ξ_b . It seems reasonable to assume that the ξ values were also high.

VII. SUMMARY AND CONCLUSIONS

An analysis of the radiation stress, S_{xy} , and the energy flux factor, $P_{\ell b}$, shows that both predict longshore transport rate, I_ℓ , to comparable degrees. Approximately 70 percent of the variance of I_ℓ about its mean is explained by each term. There appears to be no major advantage in choosing one over the other to predict the longshore transport rate. However, S_{xy} has the advantage of being constant seaward of the breaker zone while $P_{\ell b}$ is not. This makes the calculation of S_{xy} more convenient than $P_{\ell b}$, which must be determined at the breaker line. On the other hand, $P_{\ell b}$ has the advantage of having the same units as I_ℓ , which means that K_p is dimensionless.

The empirical coefficients, K_s and K_p , are far from constant although K_p is commonly assumed to be so in practice. Part of the variation of the coefficients can be related to the variation of the surf similarity parameter, ξ , as shown in Figures 26 and 27. These figures show that K_s and K_p will increase with ξ . The considerable scatter evident in Figure 28 can be partly explained by the relation between the empirical coefficients and ξ . The data in this report and past laboratory and field data are compared in Figure 28. The laboratory data generally predict lower values of I_ℓ for a given $P_{\ell b}$ compared to the field data. Part of this trend can be explained by the differences in the surf similarity parameters, assuming the field data were collected under conditions of high ξ . Also, laboratory and scale effects probably contribute to the lower laboratory transport rates. The relative importance of these factors is suggested as a subject of future research.

Vitale, Philip Movable-bed laboratory experiments comparing radiation stress and energy flux factor as predictors of longshore transport rate / by Philip Vitale.--Fort Belvoir, Va. : U.S. Army Coastal Engineering Research Center ; Springfield, Va. : available from NTIS, 1981. [94] p. : ill. ; 27 cm.--(Miscellaneous report / U.S. Army Coastal Engineering Research Center ; no. 81-4) Cover title. "April 1981." Bibliography: P. 46. Three-dimensional movable-bed laboratory test results are used to empirically relate the longshore sediment transport rate to the radiation stress and the longshore energy flux factor. Both correlate equally well with the longshore transport rate; the surf similarity parameter also shows a strong influence on the rate. 1. Hydraulic models. 2. Movable beds. 3. Sediment transport. 4. Wave energy. I. Title. II. Series: Miscellaneous report (Coastal Engineering Research Center (U.S.)) ; no. 81-4. TC203 .U581mr no. 81-4 627	Vitale, Philip Movable-bed laboratory experiments comparing radiation stress and energy flux factor as predictors of longshore transport rate / by Philip Vitale.--Fort Belvoir, Va. : U.S. Army Coastal Engineering Research Center ; Springfield, Va. : available from NTIS, 1981.
