ABSTRACT

Red and white fir grade recovery percentages are presented by log and veneer block diameter classes. Less than 1 percent of veneer was recovered in A and B grades. About 55 percent of both the log volumes or block volumes was recovered as dry, untrimmed veneer. Relationships of recovery ratio and square feet or cubic feet of veneer to log volume are shown.

Keywords: Veneer mill studies, red fir, *Abies magnifica*, white fir, *Abies concolor*.

ACKNOWLEDGMENTS

The information presented in this paper was obtained through the cooperation and assistance of the American Forest Products Co., Inc.; Region 5, U.S. Forest Service; Bureau of Land Management, Department of the Interior; and the American Plywood Association.

INTRODUCTION

The true firs (*Abies* spp.) represent approximately 13 percent of the commercial sawtimber volume in the Western United States. This amounts to nearly 235 billion board feet. In California the true firs comprise about 25 percent of the softwood sawtimber volume. In the central Sierra of California, nearly 50 percent of the sawtimber volume is composed of California red fir (*A. magnifica* A. Murr.) and white fir (*A. concolor* (Gord. and Glend.) Lindl.).

Both these species have increased in importance as raw material for the wood using industry. However, only a small number of mills use true fir in plywood. In 1970, over 620 million board feet, log scale, of red and white fir were produced from National Forest lands in California; in contrast, these same Forest lands produced about 380 million feet in 1960.

With expanded utilization of the true firs, a need has developed for up-to-date information on grade and volume recovery of lumber and veneer from these species. To provide this information, the Pacific Northwest Forest and Range Experiment Station conducted this study in cooperation with other public agencies and the forest products industry.

Veneer yield information is presented according to current Forest Service Region 5 log grading and scaling practices for short logs.

Forest managers, timber buyers, and forest industry plant managers will find this report useful in estimating veneer grade and volume recovery.

The volume losses in red and white fir plywood production can be estimated from other reports (8,10).

STUDY PROCEDURE

Sampling

The timber sample was divided into two segments, one for processing in a veneer plant and one for processing at a sawmill. This report presents the peeling or veneer recovery phase. The lumber recovery phase will be discussed in a separate report.

Trees for the study were selected from 18 areas located on the Tahoe, Eldorado, and Stanislaus National Forests in the central Sierra Nevada of California. Area locations are shown in figure 1. The sample of 123 trees, including both California red fir and white fir, represented the full range of size and quality of true fir timber in the central Sierra Nevada. Individual trees were stratified on the basis of size, butt log grade,^{1/} and defect classes (5).

^{1/} Based on Forest Service Region 6 west-side Douglas-fir log grades without diameter limits.

Figure 1.--Approximate locations of timber sample areas (•) and study mill (*).

Each tree was examined before it was felled, and surface characteristics for the first 32 feet were diagrammed (1, 3). The felled trees were bucked into logs of multiple 8-foot block lengths. Small unpeelable logs from the upper part of the tree and segments less than 8 feet long were not considered study material and were not processed. Maximum bucked length was 34 feet.

Log Diagramming, Scaling, and Grading

Before the bucked logs were skidded, visible log surface characteristics were diagrammed, tree and log diameters and lengths were recorded, and logs were tagged for identification. Logs delivered to the mill were decked and kept under water spray until removed for debarking and bucking into blocks the day before they were peeled. These blocks were scaled (6) and retagged for identification. Individual blocks and short logs (composite of two blocks) were graded by applying the Forest Service grades for white fir to the log surface diagrams (7).

Peeling, Drying, and Grading

According to mill practice, all study blocks were steamed for approximately 18 hours at 180° F. The 977 blocks in the study ranged from 7 to 48 inches in small-end diameter. Block lengths and diameters were measured before they were peeled.

All blocks were peeled on a single 8-foot lathe with blocks positioned and chucked in the geometric center. Minimum core size possible was about 6 inches. The diameter of the peeler core, its condition (rotten, checked, or shattered due to spin-out), and its disposition (chipped, sawn into lumber, or burned) were recorded.

Veneer was peeled into 1/10-, 1/8-, and 3/16-inch thicknesses. A single block was peeled into only one thickness. Throughout the peeling phase of the study, a quality supervisor from the American Plywood Association made periodic checks on the quality and thickness of the peel.

Study blocks were peeled in groups of 20; block identity of individual pieces of veneer was maintained by color coding all veneer from a given block with a continuous stripe of water-soluble dye sprayed on the tight side of the veneer as it was peeled from the block (2). Green veneer from each of the 20-block groups was clipped, sorted, and stored separately from other 20-block groups of veneer. Loads of green veneer from a given group were color coded for group identity before storage.

Green veneer items produced in this study included full sheets, half sheets, and random width strips in 4- and 8-foot lengths. The veneer was sorted onto carts by automatic pullers, except for 4-foot strips (fishtails) which were hand-pulled. Sapwood and heartwood veneer pieces were not separated at the green chain.

All veneer was dried by green item and thickness. The color code identity of veneer from each block in the group of 20, for a given item and thickness, was maintained during drying, grading, and tallying.

Dry veneer was graded by and under the supervision of the American Plywood Association quality supervisors. Grading was by U.S. commercial standards (4): A, A patch, B, B patch, C, C plug, D.

Each piece of veneer was tallied separately by grade, block, color code, and 20-block group number. Full sheets were dried separately and graded and tallied as they were pulled onto the dry sorting table. Half sheets and random width strips of veneer were dried together and graded as they came from the dryer. Half sheets were tallied as they were pulled onto the dry sorting table, but random width veneer was pulled onto carts then tallied by piece.

Dry veneer with isolated large defects which could be upgraded by reclipping was marked "reclip" and was pencil clipped and tallied as random width. Minimum reclipping width was 8 inches. Below grade veneer utilized by the mill was tallied but reported separately from graded veneer. Veneer needing redrying was pulled, graded, and tallied without going through the dryer again.

Compilation of data

Veneer recovery was summarized by grade, size, and peeler block number by use of computer programs (9) developed to handle veneer recovery data. Outputs from these programs include veneer grade yield in square-foot and cubic-foot volumes, recovery by block and log diameter classes, distribution of veneer by grade and piece size. The tally of dry, untrimmed veneer obtained from the peeled blocks was compiled into veneer grade yields on a square-foot, 3/8-inch basis.

The veneer grade yield for the short logs was obtained by combining the block veneer recovery of successive pairs of blocks from each sample tree. The cubic volumes of the blocks, veneer, core, below grade veneer, and residue were calculated.

The gross cubic block volume was computed by the following formula:

$$\text{Gross cubic-foot volume} = 0.001818L(D_S^2 + D_S D_L + D_L^2)$$

Where

0.001818 is a constant;

L is the actual block length in feet;

D_S is the average block diameter, small end, in inches; and

D_L is the average block diameter, large end, in inches.

Individual peeler blocks were summed to provide the cubic volume of short logs.

Residue veneer volume was obtained by subtracting the total veneer, core, and below grade veneer volumes from the gross block volume. The residue total, therefore, includes spur and roundup, green clipper, and dryer losses.

RESULTS

The graphs in figures 2 and 3 indicate the relative distribution of the short logs and peeler blocks by log grade. The 479 short logs produced 416,908 square feet of veneer, 3/8-inch basis. A summary of the total scale and cubic volumes of these logs for each log grade is presented in table 1. Detailed log volumes and distributions by log grade and diameter class are presented in Appendix A, tables 5 to 19. Blocks and logs were graded by the same log grade specifications.

The 977 veneer blocks produced 416,652 square feet of veneer. A summary of log scale and cubic volume is presented in table 2. Detailed volumes by log grade and diameter class are presented in appendix B, tables 20 to 34.

There is a difference between the total veneer volume shown for the short logs and that for blocks because any cull (less than one-third sound) veneer block that was bucked from a noncull short log but produced veneer was included with the adjacent block. However, these cull blocks, along with the small amount of veneer they produced, are not included in the tables of individual block data.

Figure 2.--Distribution of 479 red and white fir logs by percentage of total number of logs and net scale for each log grade.

Figure 3.--Distribution of 977 red and white fir veneer blocks by percentage of total number and net scale for each block grade.

Scaling Defects

All logs in this report are at least one-third sound as determined by the scaler. Figure 4 presents the relationship of defect percentage (Scribner scale) to log and block diameter for all grades combined. Average scaling defect percentage was 8.7 for short logs and 7.6 for peeler blocks.

Figure 4.--Relationship of percent defect to diameter for woods-length red and white fir logs and veneer blocks.

Veneer Recovery Ratio

The range in veneer recovery volume and recovery ratio can be compared by log grade and diameter class from appendix A, tables 5 to 9, and appendix B, tables 20 to 24. Veneer recovery ratio is square feet of dry, untrimmed veneer (3/8-inch basis) per board foot of net log or net block scale. Figure 5 shows the relationship of the recovery ratios to scaling diameter for all log grades combined. Although average recovery ratios shown in the tables differ between log grades, they are somewhat similar for logs of the same diameter classes.

Cubic Recovery Percentage

The veneer recovery percentages are similar among the four log and block grades (tables 1 and 2). With short logs, the cubic recovery decreased from 59.71 percent for grade 1, to 52.8 percent for grade 4, table 1. The relationship of cubic recovery ratio to block and log scaling diameter is shown in figure 6. Figure 7 shows for this sample the number of square feet of veneer (3/8-inch basis) that was produced per cubic foot of log or block volume. A mill manager having a cubic estimate of log or block input to the veneer mill could use figure 7 to estimate the total square-foot recovery volume that could be expected from the logs or blocks.

Figure 5.--Relationship of veneer recovery ratio to log and block diameters of red and white fir. Recovery ratio is square feet of dry, untrimmed veneer, 3/8-inch basis, per board foot of net scale.

Figure 6.--The relationship of cubic feet of veneer volume per cubic foot of log and block volume for red and white fir by diameter.

LOGS:

$$Y = -12.62417 + 3.04709(D) - 0.098121(D^2) + 0.001018(D^3)$$

BLOCKS:

$$Y = -14.813508 + 3.294422(D) - 0.109927(D^2) + 0.001201(D^3)$$

Y is square feet per cubic-foot ratio, D is block or log diameter.

Figure 7.--The relationship of square feet of veneer (3/8-inch basis) per cubic foot of log or block volume for red and white fir by diameter.

The following example uses both the recovery ratio data in figure 5 and square feet per cubic foot curves in figure 7.

A mix of log lengths and diameters could be used. However, assume for these examples an average scaling diameter of 18 inches and a 17-foot scaling length for 250 logs.

Example using square feet to cubic-foot ratio:

Gross scale = 57,500 board feet, Scribner

Net scale = 52,325 board feet, Scribner

Average cubic feet per log = 34.5 (calculated from number of logs and cubic log volume for 18-inch logs, appendix A, table 9)

Total cubic feet in example = 8,625.

The yield from 18-inch logs was 16.4 square feet of veneer, 3/8-inch basis, per cubic foot of log (read from short log curve, 18-inch diameter, fig. 7).

250 logs = 141,450 square feet, 3/8-inch basis.

Example using recovery ratio:

Recovery ratio for 18-inch logs = 2.65 (read from short log curve for fig. 5).

Recovery ratio of square feet of 3/8-inch veneer per board foot net scale = $2.65 \times 52,325 = 138,661$ square feet, 3/8-inch basis.

Calculations by the two methods result in a difference of about 2 percent or 2,789 square feet of veneer, 3/8-inch basis.

The calculations in each example could be made using the overall study ratios of 16.64 square feet per cubic foot and 2.58 square feet per board foot net scale.

Veneer Grade Recovery

The veneer recovery volume for each veneer grade produced from logs of various diameter classes is requested often by forest product industry representatives. This report provides this information for red and white fir. Tables 3 and 4 show the average veneer recovery percentages by each log grade for logs and blocks. A more detailed description of veneer grade recovery by log grade and diameter classes for short logs is shown in appendix A, tables 10 to 14, and for veneer blocks, in appendix B, tables 25 to 29.

The actual or uncurved distributions of veneer grade percentages by diameter classes in appendix A and appendix B are presented as regressions in figures 8 and 9. A detailed discussion of all appendix tables is not justified. However, the regression curves point up obvious grade recovery information. For short logs, the volume of B patch and better veneer recovered was only slightly over 1 percent, regardless of the grade. The percentage of C veneer was nearly as high for grade 3 as for grade 2 (56.4 and 59.2 percent, respectively). Of all veneer from grade 4 logs, 83 percent was grade D; 21 percent of the veneer from grade 1 logs was grade D; for all short logs in the study, 51.3 percent of the veneer product was grade D.

The individual veneer blocks present a similar pattern of veneer grade recovery. The percentage of C veneer decreases in rather uniform increments from grade 1 to 3 (table 4). However, it then drops sharply from 46.1 to 10.5 percent for grade 4. Both short logs and blocks had a similar C plug veneer grade recovery. Short log grades 1 and 2 recovered 18.1 and 16.0 percent of C plug, and grades 3 and 4 recovered 5.5 and 5.1 percent. Individual veneer blocks recovered 20.9 and 20.2 percent of C plug for grades 1 and 2 but recovered only 8.3 percent for grade 3 and 4.7 percent for grade 4. These percentages are summarized in tables 3 and 4.

Veneer Item Recovery

Distribution of the veneer volume by grade and item is shown for short logs in appendix A, tables 15 to 19, and for blocks in appendix B, tables 30 to 34. Veneer thickness is shown for each item size--full sheets, half sheets, and random width veneer. Approximately 33 percent of the volume from woods-length logs was peeled as 1/10-inch veneer, 49 percent as 1/8-inch veneer, and 18 percent as 3/16-inch veneer.

Table 3.—Average veneer grade recovery of short logs of red and white fir by log grade

Log grade	Number of logs	Veneer volume, 3/8-inch basis	Veneer grade						
			A	A patch	B	B patch	C	C plug	D
Square feet									
Percent									
1	46	65,273	0	0	0.3	1.0	59.2	18.1	21.4

All grades	479	416,908	(1/)	0	.1	.2	38.4	10.0	51.3

1/ Less than 0.05 percent.

Table 4.—Average veneer grade recovery of red and white fir by block grade

Block grade	Number of blocks	Veneer volume, 3/8-inch basis	Veneer grade						
			A	A patch	B	B patch	C	C plug	D
Square feet			Percent						
1	48	32,310	0	0	0.5	1.0	65.1	20.9	12.5
2	94	63,655	0	0	.2	.6	53.9	20.2	25.1
3	599	199,829	(1/)	0	(1/)	0	46.1	8.3	45.6
4	236	120,858	0	0	(1/)	0	10.5	4.7	84.8
All grades	977	416,652	(1/)	0	.1	.2	38.4	10.0	51.3

1/ Less than 0.05 percent.

Figure 8.--Recovery of veneer grades by log scaling diameter for each log grade and all logs combined; AP is A patch, BP is B patch. For grades 3 and 4 and all grades combined, A, AP, B, and BP are less than 1 percent of total.

Figure 9.--Recovery of veneer grades by block scaling diameter for each block grade and all blocks combined; AP is A patch, BP is B patch. For grades 3 and 4, A, A patch, B, and B patch have insufficient data for plotting.

A separate column is included in these tables for below grade veneer. This represents veneer clipped and dried for use in mill-certified plywood panels. Grade D specifications admit some rot in the veneer sheet. Some of the below grade veneer was produced from veneer with amounts of rot that exceeded the grade D specification.

The green veneer full sheets were peeled and clipped to approximately 52½ by 101 inches. The resulting dry veneer sheet averaged slightly over 51 by 101 inches.

Veneer production from individual blocks was almost equally divided among the three veneer items: full sheets, 34.1 percent of the volume; half sheets, 34.2 percent; and random width strips, 31.7 percent.

CONCLUSIONS

The veneer grade recovery from the mix of red and white fir logs in this study was less than 1 percent A and B grade veneer. There was no significant difference in veneer grade recovery between No. 1 and No. 2 grade logs. However, grade C veneer recovery ranged from 59 percent for No. 1 logs to 12 percent for No. 4 logs.

Approximately 55 percent of the cubic volume of the short log or block was recovered as dry, untrimmed veneer.

The overall average veneer recovery ratio was 2.58 based on total net scale and total dry, untrimmed veneer. This would be reduced by about 16 percent by losses in plywood production from the dryer through panel trimming.

A veneer mill can use this information to estimate total square-foot, 3/8-inch basis, production from known scale or cubic volume of logs or blocks. Veneer grade production can be estimated from curves of grade recovery.

The overlapping and similarity of veneer grade recovery between log grades indicates the need for a revised red and white fir log grade or quality estimating system.

Woodfin, R. O., Jr. and W. Y. Pong

1974. Veneer recovery of red and white fir--California.
USDA For. Serv. Res. Pap. PNW-171, 48 p., illus.

Red and white fir grade recovery percentages are presented by short log and veneer block diameter classes. Less than 1 percent of veneer was recovered in A and B grades. Relationships of recovery ratio and square feet or cubic feet of veneer to log volumes are shown.

Keywords: Veneer mill studies, red fir, *Abies magnifica*, white fir, *Abies concolor*.

The mission of the PACIFIC NORTHWEST FOREST AND RANGE EXPERIMENT STATION is to provide the knowledge, technology, and alternatives for present and future protection, management, and use of forest, range, and related environments.

Within this overall mission, the Station conducts and stimulates research to facilitate and to accelerate progress toward the following goals:

1. Providing safe and efficient technology for inventory, protection, and use of resources.
2. Development and evaluation of alternative methods and levels of resource management.
3. Achievement of optimum sustained resource productivity consistent with maintaining a high quality forest environment.

The area of research encompasses Oregon, Washington, Alaska, and, in some cases, California, Hawaii, the Western States, and the Nation. Results of the research will be made available promptly. Project headquarters are at:

Fairbanks, Alaska	Portland, Oregon
Juneau, Alaska	Olympia, Washington
Bend, Oregon	Seattle, Washington
Corvallis, Oregon	Wenatchee, Washington
La Grande, Oregon	

Mailing address: Pacific Northwest Forest and Range
Experiment Station
P.O. Box 3141
Portland, Oregon 97208

The FOREST SERVICE of the U. S. Department of Agriculture is dedicated to the principle of multiple use management of the Nation's forest resources for sustained yields of wood, water, forage, wildlife, and recreation. Through forestry research, cooperation with the States and private forest owners, and management of the National Forests and National Grasslands, it strives — as directed by Congress — to provide increasingly greater service to a growing Nation.
