FOREST SURVEY RELEASE NO. 40

JULY 1953

FOREST STATISTICS
FOR
CENTRAL GEORGIA, 1952

by

James F. McCormack, Forester
Division of Forest Economics

U.S. DEPARTMENT OF AGRICULTURE
FOREST SERVICE

SOUTHEASTERN FOREST EXPERIMENT STATION
ASHEVILLE, NORTH CAROLINA

E. L. Demmon, Director

FOREWORD

Through the McSweeney-McNary Act of 1928, Congress authorized the Secretary of Agriculture to conduct a comprehensive survey of the forest resources of the United States. The Forest Survey was organized by the Forest Service to carry out the provisions of the Act through the Regional Forest Experiment Stations. In the Southeastern states the Forest Survey is an activity of the Division of Forest Economics of the Southeastern Forest Experiment Station, Asheville, North Carolina.

The five-fold purpose of the Forest Survey is (1) to make a field inventory of the present supply of standing timber, (2) to ascertain the rate at which this supply is being increased through growth, (3) to determine the rate at which it is being reduced through industrial and domestic uses, fire, and other causes, (4) to determine the present consumption and the probable future trend in requirements for forest products, and (5) to interpret and correlate these finds to aid in the formulation of private and public policies regarding forest land management.

The forest resources of the State of Georgia were first inventoried by the Forest Survey during the period 1934-36, and these findings have been published. Since that time, the effects of timber cutting, forest growth, changes in land use, better management practices, and other factors have caused rapid changes in the growing stock which can only be measured accurately by on-the-ground surveys. A resurvey of the forest resources in Georgia was started in July 1950. This progress report presents area and timber volume statistics compiled from the resurvey for Central Georgia, designated as Survey Unit No. 3, and also includes growth and drain data.

ACKNOWLEDGMENTS

The Southeastern Station gratefully acknowledges the cooperation and assistance of State Forester Guyton DeLoach, the University of Georgia School of Forestry, the Union Bag and Paper Corporation, and the Macon Kraft Company in providing additional personnel to increase the rate of progress on the field survey.

The Division of Forest Economics is under the direction of James W. Cruikshank. Field inventory work was supervised by L. C. Nix, and photo interpretation was done by R. C. Aldrich. Office compilation of the data was under the direction of Agnes Nichols, assisted by Louise Shuford, Camille Young, Sammy Wainwright, and Eunice Gamble.

FOREST STATISTICS FOR CENTRAL GEORGIA, 1952

This progress report includes statistical data on forest area, timber volume, growth, and drain for 49 counties in Central Georgia designated as Survey Unit No. 3 (fig. 1). It is one of a series of reports being published as the survey work is completed in each section of the State. The field data were obtained from ground sample plots during the period April 1952 to December 1952. Procedures used in obtaining the estimates of land area and timber volumes are described briefly on page 44.

Central Georgia was covered by the original Forest Survey in 1936. The availability of these earlier statistics makes it possible to compare data for the two surveys and to evaluate changes and trends which have taken place during the past 16 years.

1952 HIGHLIGHTS AND SIGNIFICANT CHANGES

Forest land area increased more than one million acres.--Results of the 1952 survey in Central Georgia show the area of commercial forest land to be nearly 6.7 million acres as compared to 5.6 million in 1936. This amounts to a 20-percent increase in the acreage of forest land during the period between surveys. A corresponding reduction occurred in the acreage of crop and pasture land, indicating that the major shift in land use was from agriculture to forest.

The 49 counties in Central Georgia contain a gross land area of 10.5 million acres. Forests now occupy 6.7 million acres, or 64 percent of the total (fig. 2). Land in agricultural use accounts for 2.8 million acres, or about one-fourth of the gross area. Fields and pastures formerly used for agriculture but now classified as idle make up 700,000 acres, and cities, towns, rights-of-way, and other areas occupy the remaining 3 percent.

Figure 2.--Land use in Central Georgia, 1952 and 1936

The forest land is predominantly in private farm ownership. Publicly-owned forests account for only 5 percent of the total, with the bulk of this acreage in military reservations and the Clark Hill Dam project. About three-fourths of the forest land is on farms, and 19 percent is owned or operated by other private individuals and corporations.

Hardwood forest types gain in area.--Since 1936, hardwood forest types in Central Georgia increased from 1.3 million to 2.3 million acres, a gain of 77 percent in area. During the same period the more important pine types show a relatively small increase of 64 thousand acres, indicating they have held their own but have not added any substantial acreage. Increases in the area of hardwood types can usually be traced to cutting practices which remove the preferred pine species from the stands, leaving the less desirable hardwoods to occupy the site and serve as a source of seed. Similar trends have been found in recent surveys of other southeastern areas, and they may be expected to continue until control or corrective measures can be applied on a large scale.

Figure 3.--Commercial forest land by forest type, 1952

Forest type classifications are currently based on cubic volume for all stands except seedlings and saplings, where numbers of stems are used. These classifications show that 67 percent of the forest land in Central Georgia is in pine or pine-hardwood types, and 33 percent is occupied by pure hardwood stands (fig. 3). Cypress stands are found on less than one percent of the area.

Greater number of small trees but fewer large ones.--One of the most revealing comparisons which can be made between two surveys is based on the number of trees found in each diameter class. Such a comparison by tree size and species group appears in table A. The number of saplings and smaller trees through the 10-inch diameter class increased heavily in all groups. These changes reflect over-all improvements in the stocking of young trees which can be attributed largely to better fire protection and natural restocking of abandoned agricultural land.

Table A also shows the effect of heavy demand for trees of larger size and better quality. Sharp decreases are evident in the number of trees in the 12-inch and larger diameter classes. The net effect of these changes has been a reduction in the number of pine and soft-textured hardwood trees of sawtimber size. It will require years of growth before smaller trees can replace the loss of volume in the larger, more valuable trees.

Table A.--Percent change in numbers of sound trees
by species group and diameter class, 1936 to 1952

D.b.h. class (inches)	Yellow pine	Other soft- woods	Soft- textured hardwoods	Hard- textured hardwoods	All species
2	+27	+184	+47	+45	+39
4	+29	+210	+42	+91	+45
6	+27	+ 53	+20	+33	+26
8	+32	+ 29	+13	+32	+28
10	+11	+153	+27	+34	+19
12	-13	+116	+ 7	+28	- 1
14	-32	+211	- 5	+24	-15
16	-58	+ 21	-32	- 4	-40
18	-66	- 58	-40	- 1	-45
20+	-80	- 74	-58	-27	-60
All diameters	+23	+142	+38	+49	+35
All trees 6" and larger	+14	+ 67	+11	+27	+15
All saw- timber trees	-14	+105	-13	+10	-10

Changes shown in the number of pine trees are more significant than for other species groups because pines make up 42 percent of the total. The other softwood group accounts for less than one percent of all trees, making the changes shown for this group relatively unimportant. Soft-textured and hard-textured hardwoods account for 27 and 30 percent of the total number of trees respectively.

The reduction in numbers of large trees has had a widespread effect on stand structure and timber volumes. Seventy percent of the forest area is now in either seedling and sapling or pole-size stands and only 25 percent of the area supports stands of sawtimber.

Sawtimber volume decreases sharply.--The volume of sawtimber in Central Georgia decreased from 13.3 billion board feet in 1936 to 9.2 billion in 1952, a loss of 31 percent. Table B shows the effect of heavy utilization on both pine and hardwood species. The actual increase in cypress sawtimber volume is very minor.

Table B.--Sawtimber volume compared, 1936 and 1952

Species group	1936 ^{1/}	1952	Change
	<u>Million</u> <u>bd. ft.</u>	<u>Million</u> <u>bd. ft.</u>	<u>Percent</u>
Pines	7,756	4,845	-38
Hardwoods	5,443	4,231	-22
Cypress	100	140	+40
All species	13,299	9,216	-31

^{1/} Original survey volumes have been recomputed to allow for differences in standards between the two surveys and to provide a uniform basis for comparison. Thus, they will not agree with volumes previously published.

These changes may seem surprising in view of the large increase in forest area. However, much of the land which has recently reverted to forest supports only stands of seedlings and saplings which, as yet, contain no sawtimber volume. The more widely used pine sawtimber trees have been reduced by 2.9 billion board feet, or 38 percent. Hardwood volume exhibits a similar trend, being down 22 percent. The heavier use of pine usually has the effect of increasing the proportion of hardwoods in remaining stands of timber.

Pine species make up slightly more than half the present sawtimber volume. Loblolly is the most prevalent single species, accounting for two-thirds of the softwood volume. The remainder is mostly shortleaf pine, followed by small amounts of slash, longleaf, and pond pine. Hardwood trees contain 46 percent of the board-foot volume, the most important species being blackgum and sweetgum.

Sixty-nine percent of the sawtimber volume is in stands having an operable volume of 1,500 or more board feet per acre. The balance is scattered throughout stands of poletimber and young trees, making it difficult to harvest this portion. Only 14 percent of the volume is in trees 20 inches or larger in diameter.

Three-fourths of hardwood sawtimber volume poor quality.--All sawlogs in hardwood trees 12 inches or larger in diameter were graded in the 1952 survey, using the Hardwood Log Grades for Standard Lumber developed by the Forest Products Laboratory. Seventy-five percent of the board-foot volume in hardwood sawlogs was classified as grade 3, which will produce mostly low-quality factory lumber or crossties and timbers. Only 9 percent of the volume was classified as select or grade 1, and 16 percent was grade 2. This means that only one-fourth of the lumber produced from the average hardwood sawlog could be expected to make No. 1 common or better.

Softwood sawlogs, if sawn on grade, would yield somewhat better lumber. Modified Crossett Log Grades used in the survey indicate that 70 percent of the board-foot volume is in grade 1 or grade 2 logs and only 30 percent is in grade 3.

Growing stock decreases 14 percent in volume.--The total volume of growing stock is computed in terms of cubic feet of solid wood. It includes the volume of all sound pole-size trees (5.0 to 8.9 inches in diameter for softwoods and 5.0 to 10.9 inches for hardwoods), as well as the volume in sawtimber trees. Trees less than 5.0 inches in diameter at breast height are considered seedlings or saplings and are not assigned volumes for inventory purposes.

The heavy drain on trees of sawtimber size is responsible for an over-all decline of 14 percent in the growing stock. The trends by species group are similar to those for board-foot volume, with pine down 20 percent and hardwoods down 7 percent since 1936.

Table C.--Volume comparison, all live trees 5.0 inches d.b.h. and larger, 1936 and 1952

Species group	Growing stock			Cull trees		
	1936 ^{1/}	1952	Change	1936 ^{1/}	1952	Change
	<u>Million</u> <u>cu. ft.</u>	<u>Million</u> <u>cu. ft.</u>	<u>Percent</u>	<u>Million</u> <u>cu. ft.</u>	<u>Million</u> <u>cu. ft.</u>	<u>Percent</u>
Pines	2,143	1,722	-20	38	293	+671
Hardwoods ^{2/}	1,655	1,535	- 7	404	704	+ 74
Cypress	28	40	+43	2	3	+ 50
All species	3,826	3,297	-14	444	1,000	+125

^{1/} See footnote 1, table B.

^{2/} Excludes limb volume of hardwood sawtimber trees.

Table C also includes the volumes of cull timber and shows changes which have occurred between surveys. The amount of material in cull trees is up sharply for both pine and hardwood species groups. Nearly one-fourth of the total available wood volume is in low-quality trees which are seldom harvested and remain to occupy valuable growing space.

Productive capacity of forest land hampered by poor stocking.--Only one-fifth of the forest land in Central Georgia can be classed as medium or well stocked with sound trees of usable size (5.0 inches and larger in diameter). The remaining area is deficient from a growing-stock standpoint, and this condition will seriously affect the timber-growing capacity of this area during the immediate future. When the smaller seedling- and sapling-size trees are included, the degree of stocking is considerably better, but it will require a number of years before these smaller trees can produce wood suitable for commercial use.

Supply of pine timber continues to diminish.--The amount of drain on pine timber continues to exceed the growth, causing a continuation of

the downward trend which is evident from the survey volume comparisons. In 1952 the net board-foot growth of pine was estimated to be 644 million board feet as compared to 787 million board feet of drain. Drain on the volume of pine growing stock, which includes pole-size trees, also exceeded the growth (fig. 4).

The hardwood species are currently increasing in volume because of a relatively low rate of drain. Growth of hardwood sawtimber amounted to 293 million board feet in 1952 and the volume of drain was 226 million, or about three-fourths of the growth. The excess of growth over drain for hardwood growing stock amounted to 900 thousand cords.

Figure 4.--Timber growth and drain relationship in Central Georgia, 1952

The net growth estimate is composed of the growth on all sound trees of volume size plus the ingrowth created by trees reaching volume size during the year. Mortality, or the loss of volume in trees which die from natural causes, is excluded. The timber drain estimate is based on the measurement and tally of stumps found on ground sample plots. Stumps of all trees cut during the past three-year period were recorded by species groups, and the measurements were converted into tree volume. The average volume of drain for the three-year period was taken as the annual estimate.

The rates of timber growth in Central Georgia are excellent as indicated by the net annual growth percents (tables 22 and 23). Pine sawtimber volume is increasing at the rate of 13 percent per annum, and all pine growing stock at 10 percent. However, in most stands the actual increase in volume per acre is relatively low because of poor stocking conditions. The average volume growth of sawtimber and growing stock per acre is 147 board feet and 0.6 cords respectively. Growth percentages, even though they are high, must be related to current volume before their effect can be evaluated. The forest lands in Central Georgia have the capacity to grow much more timber than they are producing at the present time. The remedy is to build up the growing stock.

Table 1.--Gross area^{1/} by broad use class, 1952

^{1/} Estimates of timber drain by county are less accurate than inventory volumes, and use of individual county statistics should be avoided. For general use, data for a minimum of 10 counties should be combined.

DEFINITION OF TERMS

Land-Use Classes

Forest land: Includes (a) lands which are at least 10 percent stocked with trees of any size and capable of producing sawtimber or other wood products, and (b) lands from which the trees described in (a) have been removed to less than 10-percent stocking but which have not been developed for other use; subdivided into the following classes:

Commercial: Forest land which is (a) producing, or physically capable of producing, usable crops of wood (usually sawtimber), (b) economically available now or in the future, and (c) not withdrawn from timber use.

Noncommercial: Forest land (a) withdrawn from timber utilization through statute, ordinance, or administrative order but which otherwise qualifies as commercial forest land, and (b) incapable of yielding usable wood products (usually sawtimber) because of adverse site conditions, or so physically inaccessible as to be unavailable economically in the foreseeable future.

Nonforest land: Includes land in any of the following classes:

Active agriculture: Land under cultivation or in pasture including farm yards and work lots.

Pasture: Land under fence used primarily for grazing purposes where the timber has been cleared to less than 10-percent stocking and a real attempt to produce a sod has been made.

Idle agriculture: Land previously cultivated or pastured but now idle or abandoned and having less than a 10-percent stocking of forest trees.

Marsh: Low, wet areas characterized by a heavy growth of grass and reeds and an absence of timber.

Urban and other areas: Includes towns, residential and industrial suburban areas, school yards, cemeteries, roads, railroads, power lines, and other rights-of-way.

Water: Includes lakes, bays, and estuaries over 40 acres in size, and streams, canals, and sloughs at least one-eighth of a mile in width which are classed as "inland water" by the Bureau of the Census. Smaller lakes and ponds between one acre and 40 acres in size, and waterways between 120 feet and 660 feet in width, which are classed as land area by the Bureau of the Census, are also included as water areas.

Forest Types

Forest type is determined on the basis of cubic volume for all stand sizes except seedlings and saplings (stand size 4), in which case the number of stems are the criteria.

Pine types: Forests in which 50 percent or more of the stand is in pine species. Plurality of volume or number of trees is used to determine the specific type.

Oak-pine type: Forests in which 50 percent or more of the stand is hardwood, usually upland oaks, but in which southern yellow pines make up 25-49 percent of the stand.

Oak-hickory type

Upland hardwood: Forests in which 50 percent or more of the stand is composed of upland oak, hickory, yellow-poplar, maple, gum, and other hardwoods, except where pines comprise 25-49 percent of the stand.

Scrub oak: Upland forests in which 50 percent or more of the stand is composed of scrub oak species, except where pines comprise 25-49 percent of the stand.

Oak-gum-cypress type

Lowland hardwood: Bottomland forests in which 50 percent or more of the stand is tupelo, blackgum, sweetgum, ash, oak, elm, maple, and associated species, except where pines comprise 25-49 percent of the stand.

Cypress: Bottomland forests in which 50 percent or more of the stand is cypress, except where pines comprise 25-49 percent of the stand.

Stand-Size Classes

Sawtimber: Stands containing at least 1,500 board feet net volume per acre, 1/4-inch log rule, in sound, live, softwood trees 9.0 inches d.b.h. or larger, or hardwood trees 11.0 inches d.b.h. or larger. Two classes of sawtimber stands are recognized:

Large sawtimber: Stands of sawtimber having more than 50 percent of the net board-foot volume in trees 15.0 inches d.b.h. or larger.

Small sawtimber: Stands of sawtimber having 50 percent or less of the net board-foot volume in trees 15.0 inches d.b.h. or larger.

Poletimber: Stands failing to meet the minimum sawtimber specifications, but at least 10-percent stocked with trees 5.0 inches d.b.h. or larger and with at least half the minimum stocking in pole-size trees.

Seedling and saplings: Stands not qualifying as sawtimber or poletimber stands, but having at least a 10-percent stocking of trees of commercial species and with half the minimum stocking in seedlings and saplings.

Nonstocked and other areas: Forest areas not qualifying as sawtimber, poletimber, or seedling and sapling stands.

Diameters

D.b.h. (diameter at breast height): Stem diameter in inches, outside bark, measured at 4-1/2 feet above the ground.

Diameter class: All trees were tallied by 2-inch diameter classes, each class including diameters 1.0 inch below and 0.9 inch above the stated midpoint, e.g., trees 7.0 to and including 8.9 inches are included in the 8-inch class. Corresponding limits apply to other diameter classes.

Timber Quality Classification

Growing Stock

Sawtimber trees: Live softwood trees at least 9.0 inches d.b.h. and hardwood trees at least 11.0 inches d.b.h., with not less than one merchantable log 12 feet long, or with less than 50 percent of the gross volume of the tree in sound sawtimber.

Poletimber trees: Straight-boled trees between 5.0 inches d.b.h. and sawtimber size.

Sapling-size trees: Trees 1.0 inch to 4.9 inches d.b.h. which will grow into poletimber or sawtimber size trees of sound quality.

Other Material

Sound cull trees: Live trees of all sizes that are unmerchantable for sawlogs now or prospectively because of species, poor form, excessive limbiness, or other sound defect.

Rotten cull trees: Live trees of all sizes that are unmerchantable for sawlogs now or prospectively because of rotten defect.

Hardwood limbs: The limb volume of all hardwood sawtimber and cull trees to a minimum diameter of 4.0 inches inside bark.

Species Groups

Yellow pines: Includes longleaf, slash, loblolly, pond, and shortleaf pine.

Other softwoods: Pondcypress, baldcypress, eastern redcedar, and Atlantic whitecedar.

Soft-textured hardwoods: Black and tupelo gum, yellow-poplar, sweetgum, cottonwood, soft maple, basswood, magnolia, sweetbay, and willow.

Hard-textured hardwoods: All of the oaks, hickories, ash, beech, elm, river birch, hackberry, sycamore, black locust, mulberry, black walnut, holly, dogwood, and persimmon.

Volume Estimates

Board-foot volume: The volume in board feet, measured by the International 1/4-inch rule, exclusive of defect, of that portion of sound sawtimber trees between the stump and the upper limit of merchantability for sawlogs.

Volume in cords: For sound trees the volume in standard cords (including bark) of the sound portion of trees 5.0 inches d.b.h. and larger, between stump and a minimum top-stem diameter of 4.0 inches inside bark. Similar volumes are given for cull trees. The volume in limbs, in sections four feet long and at least 4.0 inches in diameter inside bark, of all sawtimber size hardwoods is shown separately.

Volume in cubic feet: Same as volume shown in cords except bark is not included.

International 1/4-inch log rule: A rule for estimating the board-foot volume of 4-foot log sections, according to the formula $V = .905 (0.22D^2 - 0.71D)$. The taper allowance for computing the volume in log lengths greater than four feet is 0.5 inch per 4-foot section. Allowance for saw kerf is 1/4 inch.

Standard cord: A stacked pile, 4 x 4 x 8 feet, of round or split bolts, estimated to contain, on the average, about 73 cubic feet of solid wood.

Stocking

Stocking is the extent to which growing space is effectively utilized by trees. The number of stems present by d.b.h. classes was used as a basis for stocking classification. Areas having the minimum numbers of trees listed below, either in a single diameter class or proportionately in any combinations of diameter classes, were considered fully stocked.

<u>D.b.h.</u>	<u>Minimum number trees per acre</u>
Seedlings	1,000
2 inches	800
4 inches	590
6 inches	400
8 inches	240
10 inches	155
12 inches	115
14 inches	90

Growth and Drain

Net growth.--The estimated volume of net growth includes the growth on the present growing stock plus the ingrowth accrual resulting from smaller trees reaching volume size. It excludes mortality, or loss of volume in trees dying from natural causes. Net growth estimates are based on the volume or number of sound trees. Other material is not included.

In board feet: The change during the calendar year in sawtimber volume resulting from growth, ingrowth, and mortality losses.

In cubic feet or cords: The change during the calendar year in the volume of all sound trees 5.0 inches and larger resulting from growth, ingrowth, and mortality losses.

Timber drain.--The volume of timber drain is based on the measurement and tally of stumps found on regular ground sample plots. Stumps of all trees cut during the past three-year period are recorded and the measurements are converted into equivalent tree volume. The average volume of drain for the three-year period is then taken as the annual estimate. Board-foot drain volumes include the sawlog portion of all sawtimber size trees which were cut. Drain in cubic feet or cords includes the entire stem from stump to 4.0-inch top of all sound trees 5.0 inches in diameter and larger.

RELIABILITY OF FOREST SURVEY DATA

In general, the errors which affect the accuracy of Forest Survey area and timber volume estimates arise from two sources. These may be described as (1) sampling errors which result from using sampling procedures rather than making a complete inventory or canvass, and (2) non-sampling errors which arise from human mistakes in judgment, measurement, recording, or arithmetic.

In Forest Survey work a diligent effort is made to maintain a high degree of accuracy in the collection and compilation of data. The sampling errors are held to a specified minimum through survey design and sampling technique. These errors are the only measurable errors involved in computing the reliability of the data. The nonsampling errors are minimized or eliminated through training, supervision, field check cruises, and complete editing and machine verification in compiling the data.

Forest area.--The sampling intensity of the 1952 survey was sufficient to provide an estimate of the total forest acreage in the Unit with a standard error of ± 0.4 percent. The probabilities are two out of three that the estimated forest acreage is within ± 0.4 percent of the actual acreage.

Cubic volume.--The standard error of the 1952 net cubic-foot volume in the Unit was ± 2.0 percent. Here again, the probabilities are two out of three that the estimated volume does not vary from the actual volume by more than this percentage. The standard error of the volume in cords was not computed but it should be approximately the same.

Board-foot volume.--The standard error of the 1952 estimate of board-foot volume in the Unit was ± 2.3 percent.

Use of county data.--The tables showing area and timber volumes by county are included to permit grouping of the data in any desired combinations. The survey was designed so that the number of sample plots taken in each county would provide an estimate of the timber volume in cubic feet which would not exceed ± 15 percent. The actual range of error of the cubic volume estimates by county is from ± 11.2 percent to ± 14.9 percent. The errors of board-foot volume estimates by county range from ± 11.5 percent to ± 18.0 percent, and of forest area from ± 5.6 percent to ± 12.0 percent.

In spite of the accuracy limit set on volume estimates by county, comparison of individual county statistics may be subject to considerable error and should be avoided. Grouping the data for a number of counties will increase the reliability and make the combined estimates sufficiently accurate for general use. For example, grouping the growing stock volume data for four counties with errors ranging from 11 to 15 percent resulted in a total volume estimate with only 7 percent error.

HOW THE FOREST INVENTORY IS MADE

The present system of inventory is a two-step method which includes land-use classification of points on aerial photographs followed by the cruising of ground sample plots. The county is the basic work unit. The detailed procedure is as follows:

1. Preliminary estimates of the acreage of land in forests and other land-use classes are obtained by classifying points printed on every third aerial photograph in alternate flight lines within a county. The proportion of points falling in each class is used to estimate the acreage. This estimate is later checked and revised through the use of ground plots.

2. Ground sample plots are selected in a systematic manner from the forest land classifications made in Step 1, using an interval which will provide sufficient plots to meet established limits of error per billion cubic feet of timber. This results in a proportional sample of all existing timber stands. Timber cruisers make a detailed description and tally of the ground plots to obtain data on timber volume, quality, stocking, and mortality. Samples of agricultural and other photo classifications are also checked on the ground to verify or adjust the area estimates based on these classifications.

3. Growth estimates are based on increment borings taken proportionally from sample trees of various diameters and species in each forest type and stand class. The volume of timber drain is computed from a tally of the stumps of trees cut on the plots during a specified period.

4. All field data are sent to Asheville for editing and are placed on punch cards for machine sorting and tabulation. Final estimates are based on statistical summaries of the data.
