FOREST RESOURCES OF NORTHEAST FLORIDA, 1949

by J. F. McCormack, Forester
Division of Forest Economics

SOUTHEASTERN FOREST EXPERIMENT STATION
ASHEVILLE, NORTH CAROLINA

I. T. HAIG, Director

In cooperation with
FLORIDA FOREST SERVICE
TALLAHASSEE, FLORIDA
C. H. COULTER, State Forester

FOREWORD

Through the McSweeney-McNary Act of 1928, Congress authorized the Secretary of Agriculture to conduct a comprehensive survey of the forest resources of the United States. The Forest Survey was organized by the Forest Service to carry out the provisions of the Act through the Regional Forest Experiment Stations. In the Southeastern States the Forest Survey is an activity of the Division of Forest Economics of the Southeastern Forest Experiment Station, Asheville, North Carolina.

The five-fold purpose of the Forest Survey is (1) to make a field inventory of the present supply of standing timber, (2) to ascertain the rate at which this supply is being increased through growth, (3) to determine the rate at which it is being reduced through industrial and domestic uses, fire, and other causes, (4) to determine the present consumption and the probable future trend in requirements for forest products, and (5) to interpret and correlate these finds to aid in the formulation of private and public policies regarding forest land management.

The State of Florida was inventoried by the Forest Survey in the period 1934-36 and reports presenting the findings have been published. Since then, better forest management, more intensive forest use, changes in land use, and other factors have caused changes in the forest growing stock that can only be measured accurately by on-the-ground surveys. A resurvey of the forest resources of Florida is now under way. This progress report presents area and volume statistics of the resurvey in Northeastern Florida (Survey Unit No. 1). Statistical reports covering other portions of the State will be published in the near future. When complete statistical data are available, an analytical report will be prepared which will interpret these statistics and focus attention upon the principal forest problems and possible solutions.

ACKNOWLEDGMENTS

The author gratefully acknowledges the assistance received from C. H. Coulter, State Forester, and his staff in facilitating the Survey work and in providing additional personnel to augment and intensify the collection of data in the field.

The timber inventory work in the field was under the supervision of Mackay B. Bryan. Photo interpretation work was done by N. F. Force, R. C. Aldrich, and R. W. Cooper. Sample plot work was under the direction of Fritz Lorentzen, E. W. Vetter, M. W. McClure, W. A. McCarty, H. W. Allen, E. A. Schluter, Ben Jusky, and F. S. Hill.

Office compilation of the data was under the direction of Miss Agnes Creasman, assisted by Mrs. Christine Paxton, Miss Priscilla Walker, and Miss Camilla Young.

Figure 1. - Counties in Northeast Florida included in Survey Unit No. 1

FOREST RESOURCES OF NORTHEAST FLORIDA

A resurvey of the forest resources of the entire state of Florida was started in June 1948 and is still in progress. This report presents up-to-date facts on forest area and timber volumes in Northeast Florida (Survey Unit No. 1) as determined in the resurvey. By comparison with the original inventory, which was completed in 1934, the trends in forest area and timber supply can be evaluated.

1949 FACTS AND SIGNIFICANT CHANGES

Forest area increases slightly: At the time of the resurvey there were 7.7 million acres of forest land, of which 99 percent was classified as commercial. This amounted to approximately a one-percent increase in both the total forest acreage and in the commercial forest acreage since the original survey. Forests cover nearly 81 percent of the total land area of the Unit.

More forest land in hardwood types: Hardwood types occupy 2.1 million acres, or 28 percent, of the commercial forest area. Softwood types occupy 5.5 million acres, or 72 percent. During the past 14 years there has been an increase of 10 percent in the total hardwood type area and a corresponding decrease in the area of pine types. It was found that the area of lowland hardwood types increased 66 percent and the area in upland hardwood types increased 43 percent. The area in turpentine pine types decreased 16 percent and in non-turpentine pine types, 6 percent.

Saw-timber stands occupy 24 percent of forest land: Stands of saw timber containing 1,500 board feet or more per acre occupied 24 percent of the commercial forest land in 1949. Most of these stands fell in the small saw timber class (see definition of terms, page 30). Twenty percent supported stands of pole timber, 10 percent was in the seedling and sapling class, and 46 percent was covered lightly by scattered trees of various sizes. No direct comparisons of the forest area by stand class with the original survey are possible, since different standards were used on the resurvey.

Saw-timber volume decreases: The total volume of saw timber in 1949 was estimated to be 10.1 billion board feet, including 460 million board feet in 12-inch hardwoods, which were not considered saw timber in the original survey. Disregarding the 12-inch hardwoods, the 1949 volume was 9.6 billion board feet, a decrease of 14 percent from 1934.

Table A.--Change in volume of saw timber, 1934 to 1949

Species group	1934	1949	Change
	Thousand bd. ft.	Thousand bd. ft.	Percent
Pines ^{1/}	6,495,700	6,639,100	+ 2
Hardwoods ^{1/}	2,645,300	1,309,700	- 50
Cypress ^{2/}	2,017,800	1,655,200	- 18
All species	11,158,800	9,604,000	- 14

^{1/} Excludes volume of hardwoods 12 inches d.b.h.

^{2/} Includes volume of white cedar.

Total sound-tree volume decreases: The net cubic-foot volume of all sound trees 5.0 inches d.b.h. and larger dropped from 3.8 billion cubic feet in 1934 to 3.4 billion in 1949, a decrease of 11 percent.

The volume of sound wood in cull trees of all species groups increased. In 1949, approximately one-fourth of the total volume of wood was in cull trees as compared to 12 percent in 1934. Including scrub oak and noncommercial species, 57 percent of the total hardwood volume was classed as cull material.

Table B.--Change in volume of all trees 5.0 inches d.b.h. and larger,
1934 to 1949

Species group	Sound tree volume			Cull tree volume		
	1934	1949	Change	1934	1949	Change
	Million cu. ft.	Million cu. ft.	Percent	Million cu. ft.	Million cu. ft.	Percent
Pines ^{1/}	2,106	2,060	- 2	16	50	+ 212
Hardwoods ^{2/}	1,063	799	- 25	452	1,051	+ 133
Cypress	680	579	- 15	38	63	+ 66
All species	3,849	3,438	- 11	506	1,164	+ 130

^{1/} Excluding turpentine butts.

^{2/} Excluding volume in limbs.

Area in working turpentine crops decreases: In 1949 there were 484,900 acres in working turpentine timber crops, a decrease of 65 percent since 1934. The number of turpentine trees being worked decreased from 21 million in 1934 to 10 million in 1949. There were 50 million round turpentine pines 9.0 inches d.b.h. and larger available for gum production in 1949. This is nearly double the number available at the time of the original survey.

Nearly two-thirds of the forest land is understocked: Resurvey data indicate that 2.6 million acres of the commercial forest land were less than 10 percent stocked with sound trees of commercial species. There are also 2.2 million acres which were from 10 to 39 percent stocked with an adequate number of sound trees. This area of 4.8 million acres, which is less than 40 percent stocked, amounts to 64 percent of the total commercial forest acreage. In the pine types, stands of longleaf pine and pond pine have over 80 percent of their area in a poorly stocked condition. The cypress and lowland hardwood types are in better condition from a stocking standpoint, since only about 30 percent of the area is less than 40 percent stocked with sound trees.

Table 1.--Gross area^{1/} by broad use class, 1949

Class of use	Area	
	<u>Acres</u>	<u>Percent</u>
Forest land:		
Commercial	7,601,700	75.9

Worked-out timber	436	4,344	426	5,206
All classes	137,466	71,944	2,856	212,266

^{1/} Includes sound and rough cull trees.

^{2/} In 1934 there were 25,100,000 round trees 9.0 inches d.b.h. and larger compared to 49,824,000 in 1947.

^{3/} In 1934 there were 21,404,000 working trees 9.0 inches d.b.h. and larger compared to 9,919,000 in 1947.

Table 18.—Area of turpentine timber crops by working status,
1949

Crop working status	Area	
	Acres	Percent
Round timber	882,100	50.3
Working timber		
Front-faced	291,000	16.6
Back-faced	193,900	11.0
Resting timber	241,100	13.7
Abandoned timber	64,800	3.7
Worked-out timber	81,900	4.7
All classes	1,754,800	100.0

Table 19.--Area of stump land and tonnage of wood naval stores stumps
by availability class, 1949

Availability class	Area	Tonnage ^{1/}
	<u>Acres</u>	<u>Thousand tons</u>
Merchantable area	3,226,000	^{4/} 10,418
Marginal area ^{2/}	252,700	763
Potential area ^{3/}	148,900	483
Inaccessible area	156,800	468
All classes	3,784,400	12,132

^{1/} Includes stumps on agricultural land.

^{2/} Stump-land areas less than 25 acres in extent and partially worked areas.

^{3/} Unworkable at present due to density of timber stands.

^{4/} A check on the tons of stumps harvested from 90,000 acres indicates the recoverable tonnage under existing practices is approximately two-thirds of the merchantable volume shown.

^{1/} Sound wood and bark, excluding volume of palms (limbs of sawlog-size hardwoods are included in cull volumes).

^{2/} Includes bay, magnolia, and yellow-poplar.

DEFINITION OF TERMS

Land-Use Classes

Forest. Land bearing forest growth, land from which the forest has been removed and which shows no evidence of any other recent land use, or former agricultural land which now has a five-percent stocking of trees. Subdivided into the following classes:

Commercial: Land bearing, or capable of bearing, timber of commercial character and available now or prospectively for commercial use.

Reserved: Forest land in public ownership upon which commercial timber cutting is prohibited.

Non-productive: Forest land of such low productivity or so inaccessible that commercial timber will not be produced.

Non-forest. Land less than five percent stocked with trees and showing evidence of non-forest use.

Agriculture: Under cultivation or in pasture, including farm yards on active farms.

Idle: Land previously cultivated or pastured but now idle or abandoned. If reverting to forest there must be less than five percent stocking of trees.

Marsh: Low, boggy, non-forested land usually supporting a heavy growth of grass.

Dunes and beaches: Non-forested sand dunes or coastal beaches.

Urban and other: Includes towns, suburban areas being developed for residential or other urban purposes, school yards, cemeteries, industrial sites, roads, railroads, power lines, and other rights-of-way. Scattered areas of timber within exterior boundaries of cities or villages are also included.

Water: Includes both the small ponds and lakes less than 40 acres in size and streams, sloughs, and canals less than ten chains in width classed as "land area" by the Bureau of the Census. Also includes the "inland water" listed by the Census. On coastal areas the water-line is the mean high-tide mark; tidal flats are classed as water.

Forest Types

Longleaf pine. Stands in which coniferous species comprise at least 25 percent of the dominant and codominant trees, with longleaf pine predominating.

Slash pine. Stands in which coniferous species comprise at least 25 percent of the dominant and codominant trees, with slash pine predominating.

Loblolly pine. Stands in which coniferous species comprise at least 25 percent of the dominant trees, with loblolly pine predominating. Spruce pine is included in this type.

Pond pine. Stands in which coniferous species comprise at least 25 percent of the dominant and codominant trees with pond pine predominating.

Sand pine. Stands in which coniferous species comprise at least 25 percent of the dominant and codominant trees with sand pine predominating.

Cypress. Stands in which coniferous species comprise at least 25 percent of the dominant and codominant trees, with cypress predominating. White cedar is also included with this type.

Lowland hardwoods. Stands in which mixed hardwoods such as tupelo gum, black-gum, sweetgum, white oak, water oak, red maple, and ash comprise at least 75 percent of the dominant and codominant trees. Found along rivers, small streams, and in swamps and bays.

Upland hardwoods. Stands in which mixed hardwoods such as red oak, white oak, post oak, hickory, ash, sweetgum, elm, and yellow-poplar comprise at least 75 percent of the dominant and codominant trees. Found on the drier upland sites and on low rolling hills bordering the flatwood zone.

Scrub oak. Stands in which scrub species such as blackjack, bluejack, turkey and laurel oaks predominate and in which sound commercial species comprise less than five percent of satisfactory stocking.

Palms. Stands in which there is at least a five-percent stocking of merchantable palm trees and less than five-percent stocking of other sound commercial species.

Stand-Size Classes

Saw timber. Stands containing at least 1,500 board feet net, International 1/4-inch log rule, per acre in sound, live, softwood trees 9.0 inches d.b.h. or larger or hardwood trees 11.0 inches d.b.h. or larger. Two classes of saw-timber stands are recognized:

Large saw timber: Stands of saw timber having more than 50 percent of the net board-foot volume in softwood trees 15.0 inches d.b.h. or larger, or hardwood trees 17.0 inches d.b.h. or larger.

Small saw timber: Stands of saw timber having 50 percent or less of the net board-foot volume in softwood trees 15.0 inches d.b.h. or larger, or hardwood trees 17.0 inches d.b.h. or larger.

Pole timber. Stands at least 10 percent stocked with pole-size or larger timber, with at least one-half the minimum stocking in pole sizes, and which have less than 1,500 board feet net per acre of saw timber.

Seedling and sapling. Stands less than 10 percent stocked by pole-size or larger trees and with less than 1,500 board feet net per acre, but at least 40 percent stocked with commercial species. Eight hundred seedlings or saplings per acre are considered full stocking.

Poorly stocked and unstocked. Stands of pole-size or larger trees that are less than 10 percent stocked, seedling or sapling stands less than 40 percent stocked, or nonstocked forest land.

Diameters

D.b.h. (diameter at breast height). Stem diameter in inches, outside bark, measured at $4\frac{1}{2}$ feet above the ground.

Diameter class. All trees were tallied by 2-inch diameter classes, each class including diameters 1.0 inch below and 0.9 inch above the stated midpoint; e.g., trees 7.0 to and including 8.9 inches are in the 8-inch class.

Tree Classification

Sound saw-timber trees. Softwood trees at least 9.0 inches d.b.h. and hardwood trees at least 11.0 inches d.b.h., with not less than one merchantable log 12 feet long, or with less than 50 percent of the gross volume of the tree in sound saw timber.

Sound pole timber trees. Straight-boled trees between 5.0 inches d.b.h. and saw-timber size.

Sound sapling-size trees. Trees 1.0 inches to 4.9 inches d.b.h. which will grow into pole or saw-timber size trees of sound quality.

Rough cull trees. Trees that fail to qualify as sound timber because of poor form, excessive limbiness, or other sound defect. Volumes shown for rough cull trees also include the limbs, in sections four feet long and at least 4.0 inches in diameter inside bark, of sound saw-timber-size hardwoods. Scrub oak and noncommercial species are included in this group.

Rotten cull trees. Trees that fail to qualify as sound timber because of rotten defect.

Palms. All species of Sabal 5.0 inches d.b.h. and larger with at least 12 feet of clear stem. All palm trees were considered to be free of rotten defect.

Species Groups

Softwoods. All of the pines, eastern redcedar, Atlantic white-cedar, pond cypress, and baldcypress.

Soft hardwoods. Black and water tupelos, sweetgum, and soft maple. The other soft-textured hardwoods include sweetbay, cottonwood, willow, basswood, southern magnolia, and yellow-poplar.

Hard hardwoods. All of the oaks, hickories, and ash. The other hard-textured hardwoods include river birch, elm, hackberry, and sycamore.

Volume Estimates

Board-foot volume. The volume in board feet, measured by the International 1/4-inch rule, exclusive of defect, of that portion of saw-timber trees between the stump and the upper limit of merchantability for sawlogs.

Volume in cords. For sound trees the volume in standard cords (including bark) of the sound portion of trees 5.0 inches d.b.h. and larger, between stump and a minimum top-stem diameter of 4.0 inches inside bark. For cull trees similar volumes are included plus the volume in limbs, in sections four feet long and at least 4.0 inches in diameter inside bark, of saw-timber size hardwoods.

Volume in cubic feet. Same as volume shown in cords except bark is not included.

International 1/4-inch log rule. A rule for estimating the board-foot volume of 4-foot log sections, according to the formula $V = .905 (0.22D^2 - 0.71D)$. The taper allowance for computing the volume in log lengths greater than four feet is 0.5 inch per 4-foot section. Allowance for saw kerf is 1/4 inch.

Standard cord. A stacked pile, 4 x 4 x 8 feet, of round or split bolts, estimated to contain, on the average, 90 cubic feet of softwoods (wood and bark) or 80 cubic feet of hardwoods (wood and bark).

Gum Naval Stores Conditions

Round timber. A minimum of 15 longleaf and slash pine trees 9.0 inches d.b.h. or larger per acre that have never been worked for naval stores.

Working. Longleaf and slash pine trees that are now being worked for naval stores.

Front-faced. Turpentine tree species on which the front or first face is now being worked.

Back-faced. Turpentine tree species on which the front face has been worked out and on which a back (second or third, etc.) face is being worked.

Resting. Longleaf and slash pine trees with a worked-out front face at least 5 feet high and on which back-facing has not been started.

Abandoned. Longleaf and slash pine trees on which faces less than 5 feet high were discontinued.

Worked-out. Longleaf and slash pine trees on which two or more faces at least 5 feet high have been worked out and with no possibility of supporting another face.

Stocking

Stocking classifications were based on the number of stems present by d.b.h. classes. Areas **having** the minimum numbers of trees listed below, either in a single diameter class or in combinations, were considered adequately stocked.

<u>DBH</u>	<u>Minimum number trees per acre</u>
2 inches	800
4 inches	600
6 inches	450
8 inches	300
10 inches	200
12 inches	150
14 inches	110

RELIABILITY OF THE DATA

In general there are two possible sources of error in estimating timber volumes and land areas in various categories under procedures used by the Forest Survey. These are (1) common mistakes resulting from errors of judgment in classifying or recording data, mistakes made in compiling the information or bias in the application of techniques, and (2) sampling errors.

In Forest Survey work a diligent effort is made to maintain a high degree of accuracy in the collection and compilation of the data. Common errors are eliminated or minimized through training and frequent check cruises in the field and through complete editing and machine verification of office procedures in compiling the data.

Sampling errors (standard errors of estimate) carry no connotation of faulty work, but are theoretical measures of the reliability of the estimates based on the variability exhibited by the sample data. Sampling errors were the only measurable errors involved in computing the reliability of the data.

Forest area. The sampling intensity was sufficient to provide an estimate of the forest acreage of the Unit with a standard error of ± 0.6 percent. This indicates the probabilities are two out of three that the actual forest area is within ± 0.6 percent of the given estimate.

Timber volumes. The standard error of estimate of the board-foot volume of saw timber in the Unit is ± 2.4 percent. Here again, the probabilities are two out of three that the actual volume is ± 2.4 percent of the given estimate. Corresponding errors for the total volume in cords or cubic feet were not computed, but they should be smaller.

Use of county data. The tables showing area and timber volumes by county are included to facilitate the grouping of county data in any combination desired. Statistics for individual counties have a standard error of estimate for forest area ranging from ± 2.7 to ± 7.0 percent, and for board-foot volume from ± 7.0 to ± 18.0 percent. Obviously detailed comparison between counties are subject to considerable error and should be avoided. Grouping a number of counties together will increase the reliability of the area and volume estimates and make these data sufficiently accurate for most purposes.

HOW THE FOREST INVENTORY IS MADE

The present system of inventory is based upon interpretation of aerial photographs supplemented by cruising of randomly selected ground plots. The county is the basic work unit. Steps in the procedure are as follows:

1. Acreages of forest land are estimated with the use of a dot grid placed on every 3rd contact print along flight lines in each county. The proportion of dots falling on forest areas when applied to the gross area of the county yields a preliminary estimate of the acreage of forest land. This is later revised after certain field checks.

2. Every 3rd plot listed as forest in step one is classified into forest type, stand class, and density class by careful stereoscopic analysis of the photographs. The proportion of plots falling in each classification when applied to the forest area of the county gives the area in each classification. These areas are revised following ground checking.

3. Timber cruisers make a detailed on-the-ground tally of every 3rd large saw-timber photo plot, every 4th small saw-timber, every 6th pole timber, every 13th seedling and sapling plot, and every 26th poorly stocked plot, to obtain volume, growth, cull, and mortality data, and to check accuracy of photo classification. They also check a sample of the idle and agricultural plots to determine the area reverting to forest.

4. Growth estimates are based on increment borings taken from trees of the various diameters and species in each forest type and stand class.

5. All field data are sent to the Asheville office for editing and are placed on punch cards for machine tabulation. Statistical techniques are used to correct for changes in photo classification, and to determine final figures on areas, volumes, and growth.
