In cooperation with the

NORTH CAROLINA

DEPARTMENT OF CONSERVATION AND DEVELOPMENT

DIVISION OF FORESTRY

F. H. Claridge - State Forester

FOREWORD

Through the McSweeney-McNary Act of 1928, Congress authorized the Secretary of Agriculture to conduct a comprehensive survey of the forest resources of the United States. The Forest Survey was organized by the Forest Service to carry out the provisions of the Act through the Regional Forest Experiment Stations. In the Southeastern states the Forest Survey is an activity of the Division of Forest Economics of the Southeastern Forest Experiment Station, Asheville, North Carolina.

The five-fold purpose of the Forest Survey is (1) to make a field inventory of the present supply of standing timber, (2) to ascertain the rate at which this supply is being increased through growth, (3) to determine the rate at which it is being reduced through industrial and domestic uses, fire, and other causes, (4) to determine the present consumption and the probable future trend in requirements for forest products, and (5) to interpret and correlate these findings to aid in the formulation of private and public policies regarding forest land management.

The forest resources of North Carolina were first inventoried by the Forest Survey during the years 1937-38. In 1952 a resurvey was started to determine the changes which have taken place since the first inventory, and to obtain up-to-date figures on forest area, timber volumes, growth, and timber cut. So far, field work has been completed in 3 out of 4 survey units and is continuing in the Piedmont area. This report presents resurvey statistics for the Mountain Region of North Carolina, which is known as Survey Unit No. 4.

ACKNOWLEDGMENTS

The Southeastern Station gratefully acknowledges the financial assistance provided by The Champion Paper and Fibre Company, Canton, North Carolina, which resulted in employment of an additional field crew and materially increased the rate of survey progress in the Unit. The Station also wishes to acknowledge the cooperation of the Tennessee Valley Authority in conducting the field work for 3 counties.

Forest survey work at the Southeastern Station is under the direction of James W. Cruikshank. Aerial photo interpretation was done by William H. B. Haines and mensurational work by Mackay B. Bryan. Field data were collected by L. C. Nix, John Vossden, Robert C. Gilmore, Edwin H. Manchester, William B. Buckley, and Clifford J. Purdy, Jr. Office compilation was under the supervision of Agnes O. Nichols, assisted by Louise Shuford, Sammy Wenningham, Eunice Gamble, and Gentile Young.

FOREST STATISTICS FOR THE MOUNTAIN REGION
OF NORTH CAROLINA, 1955

The Mountain Region of North Carolina is located in a relatively narrow belt running along the western edge of the State. It is a 21-county area bounded on the east by the Piedmont and on the other sides by state lines of four adjoining southern states, as shown in figure 1. The steep, rugged terrain, together with marked differences in the type and composition of the forest cover, set this region apart from the rest of the State.

North Carolina's forest resources were originally inventoried by the Forest Survey during the years 1937-38. A new inventory of the State is now being made to obtain up-to-date information on forest area, timber volumes, growth, and the amount of timber cut. This progress report presents statistical data compiled from a resurvey of the Mountain Region started in March and completed in July 1955. Basic data were obtained from 1,450 one-fifth-acre forest sample plots distributed throughout all 21 counties. In addition, 300 nonforest plots were checked on the ground to increase the reliability of the forest area estimate. Procedures used in the Forest Survey are described briefly on page 46.

Timber stands which exist today are different in many respects from those which were found by the cruisers 17 years ago. The new inventory not only provides current facts on the forest resource, but it also presents an opportunity to determine the long-term trends which have had an effect in shaping the present-day stands. The changes discussed on the following pages all stem from a comparison of statistics for the two surveys. A careful adjustment of the 1938 survey data has been made to eliminate differences arising from definition or standards of measurement, so that valid comparisons could be made.

HIGHLIGHTS AND TRENDS FOUND BY THE 1955 SURVEY

Four out of every five acres are forested.--The Mountain Region in Western North Carolina is the most heavily forested area in the State. Nearly 4.4 million acres were found to be under forest cover during the 1955 survey. This is 77 percent of the total land area in the Unit, making the ratio of forest to nonforest land nearly 4 acres to 1 (fig. 2). The proportion of forest land by county ranges from a low of 44 percent in Allegheny to a high of 94 percent in Swain County. It is highest in the western portion of the Unit, where 7 counties each have more than 80 percent of their land area in forest. Cropland, pasture, and other agricultural uses occupy most of the remaining acreage.

Figure 2.--Land use in the Mountain Region of North Carolina.

The present trend in land use is toward more forest and less agricultural land. Since 1938, the area supporting forests has been spreading as more and more abandoned fields and pastures were taken over by timber stands. The 1955 survey shows a 14-percent gain in forest area, which amounts to more than a half million acres. The trend is unit-wide, with each of the 21 counties showing a higher proportion of forest land now than they had 17 years ago.

Public agencies own 30 percent of the forest land.--Various Federal, State, and local government agencies own and administer 1.3 million acres of forest land in the mountain area (table A). The Pisgah and Nantahala National Forests contain over 900,000 acres of Federally-owned land, with boundaries extending into all but 2 of the 21 counties. The eastern portion of the Great Smoky Mountains National Park, located in Haywood and Swain Counties, contains 270,000 acres of rugged and isolated forest country. The National Park Service also owns about 28,000 acres of forest along the right-of-way of the Blue Ridge Parkway, a modern scenic highway built high up along the ridge of the mountain chain. The Qualla Reservation of the Cherokee Indians lies mostly in Swain and Jackson Counties and contains 53,000 acres of forest land. Much of the remaining public forest land is found in 20 municipal watersheds owned by cities and towns, the largest of which is the Asheville watershed, containing about 20,000 acres.

All the public forest land is not available for commercial timber production. There are 320,000 acres within the boundaries of parks, recreation areas, memorial forests, and municipal watersheds where

commercial cutting operations are not permitted. An additional 31,000 acres of rock outcrops, cliffs, and mountain balds were classed as noncommercial forest land because of poor site conditions.

Table A.--Land ownership, 1955

Ownership	Forest land area			
	Commercial	Noncommercial	Total	
	<u>Acres</u>	<u>Acres</u>	<u>Acres</u>	<u>Percent</u>
Public:				
National forests	890,600	19,800	910,400	20.9
Great Smoky Mts. N. P.	--	270,500	270,500	6.2
Blue Ridge Parkway	--	28,000	28,000	0.6
Indian	52,100	400	52,500	1.2
Other Federal	6,300	--	6,300	0.2
State	5,800	1,400	7,200	0.2
County & municipal	16,900	30,700	47,600	1.1
Total public	971,700	350,800	1,322,500	30.4
Private:				
Farm woodlands	2,288,600	6,900	2,295,500	52.7
Industrial & other	730,700	3,500	734,200	16.9
Total private	3,019,300	10,400	3,029,700	69.6
Total forest land	3,991,000	361,200	4,352,200	100.0

Approximately half of all the forest land in the Unit is in private farm woodlands, where the number of owners is large and the size of the average tract is small. An additional 17 percent is held by industrial or other private interests.

Forest types are principally hardwood.--Western North Carolina is a region of hardwood forests. Timber stands composed mainly of hardwood species are found on 3.2 million acres, or about 80 percent of the commercial forest area. The oak-hickory type is by far the most extensive. In this broad type classification, the most prevalent species are white oaks, red oaks, and hickory in association with yellow-poplar, basswood, and soft maple. Limited areas of the northern hardwood type including sugar maple, beech, and yellow birch, are found along the upper elevations. Stands of yellow pine, usually found on the lower slopes, make up about three-fourths of the softwood type area. Mixtures of white pine and hemlock are also important, and a small acreage of spruce and balsam fir is found on the tops of the higher mountains.

Figure 3.--Change in area of forest types, 1938 to 1955.

The area of hardwood forest types is increasing. Since 1938 they have gained a half million acres, indicating that a large proportion of the land which reverted to forest during the period became stocked with hardwood species (fig. 3). During the 17-year period, the areas in shortleaf and Virginia pine types have exhibited opposite trends with shortleaf decreasing and Virginia pine increasing. The net result has been a decrease of 60,000 acres in yellow-pine types, a loss of 7 percent. Mixtures of white pine and hemlock show only a slight increase in area.

Number of sound trees shows a substantial increase.--Comparisons of stand table data obtained from the 1938 and 1955 surveys show a rise of nearly 150 million in the number of sound trees one inch and larger in diameter, an increase of 13 percent. The number of trees of volume size, which range in diameter from 5.0 inches up, shows a gain of 118 million. Part of this increase is undoubtedly the result of increases in forest land area discussed earlier. However, it is obvious that timber cutting, fire protection, and other activities have influenced the development of present stands.

The upward trend is found in all species groups except yellow pines. Shortleaf, pitch, and Virginia pines comprise only one-eighth of the total stand, but they are much sought after for the production of lumber, pulpwood, and other forest products. A heavy rate of cutting has decreased the number of yellow pines in the larger, more valuable sizes, as shown in figure 4. The number of 10-inch trees is slightly higher, but the only important increase has been in the 6- and 8-inch pole trees. The smaller sapling-size trees also show a decrease, which may be an indication that hardwoods are hindering the reestablishment of young pines that will be vitally needed for the production of future timber crops.

White pine is the most important other softwood tree in the Mountain Region. It is also eagerly cut by loggers, but many of the trees are scattered throughout the hardwood stands, making the harvesting of this individual species more difficult. White pine grows rapidly and has been widely planted throughout the area in recent years. It also tends to reproduce itself and spread out under an effective program of forest fire control. The number of white pines has increased in all diameters up through 22 inches in size.

The largest gains are, of course, in the number of sound hardwoods. These species show a total increase of 125 million trees including a gain of 100 million trees in volume sizes. Most individual hardwood species have followed the same trend and now exist in greater numbers up to 22 or 24 inches in size. One of the reasons behind this change is the poor quality of much of the timber. Such species as scarlet and chestnut oaks are in good supply, but they produce lumber that is excessively knotty or brash. The heavy, dense wood found in hickory and black locust makes general use of these species for lumber or timbers impractical. The use of hardwoods for pulpwood is on the increase but is still of relatively minor importance. At the present time, there is obviously an oversupply of low-grade hardwoods which are creating problems in silviculture and utilization for this segment of the forest resource.

Figure 4.--Change in number of sound trees since 1938.

Sawtimber volume is 22 percent greater.--The volume of sawtimber material in the Unit now stands at 8.7 billion board feet. It has increased by 1.6 billion feet, or 22 percent, in 17 years (table B). As would be expected from the change in numbers of trees, the yellow pines are down 14 percent with a loss of 163 million feet. The other species groups show increases which are about equal in terms of percent, but the hardwood species account for nine-tenths of the over-all rise.

Table B.--Comparison of sawtimber volume, 1938 and 1955

Species group	1938 ^{1/}	1955	Change	
	<u>Million</u> <u>bd. ft.</u>	<u>Million</u> <u>bd. ft.</u>	<u>Million</u> <u>bd. ft.</u>	<u>Percent</u>
Yellow pines	1,154	991	-163	-14
Other softwoods	1,116	1,449	+333	+30
Hardwoods	4,835	6,236	+1,401	+29
All species	7,105	8,676	+1,571	+22

^{1/} Original survey volumes have been recomputed to allow for differences in standards between the two surveys and to provide a uniform basis for comparison. Thus, the 1937 estimates shown here will not agree with the volumes previously published.

Along with the change by species group there has also been a shift in volume by tree-size class. Many of the larger trees have either been harvested and used, or lost through mortality from natural causes. The volume of soft-textured hardwoods (including the preferred yellow-poplar, basswood, and buckeye species) in trees 26 inches and larger has been cut in half. However, these losses have been more than compensated for by volume increases in the smaller hardwood sawtimber trees.

The gradual disappearance of blight-killed chestnut has also had an effect on the sawtimber supply. In 1938, about 800 million board feet were judged to be sufficiently sound for use as lumber, timbers, paneling, or extract wood. A great deal of this material has been salvaged and the remainder has deteriorated to a point where it is no longer considered as a source of raw material. A few of the remaining chestnut snags may still be cut for commercial use, but none of the chestnut was assigned board-foot volume in the 1955 survey.

The two national forests in the Region contain an estimated 2.8 billion board feet of sawtimber on 891 million acres of commercial forest land. These timber stands are heavier and more mature than the general run. They contain an average of 3,128 board feet per acre, as compared to 1,864 feet per acre found on private lands.

Species of oak predominate.--Nearly 3.5 billion board feet, or two-fifths of the sawtimber volume in the Unit, is made up of various species of oak. The red oaks constitute the largest group, with scarlet, northern red, and black oak as principal species (fig. 5). In the white oak group, chestnut oak trees contain two-thirds of the volume. Yellow-poplar and hickory are also important. The remaining hardwood sawtimber is made up of a large number of minor species including ash, beech, basswood, maple, birch, and locust. In the softwoods, both shortleaf pine and white pine each contain about three-fourths of a billion board feet. These species are followed in order by hemlock, Virginia pine, spruce, and balsam fir.

Figure 5.--Sawtimber volume by species.

Approximately 80 percent of the sawtimber volume is found in trees ranging from a minimum 9-inch diameter through 20 inches in size. Volumes are heaviest in the smaller diameter classes as indicated in figure 6. Hardwood species contain nearly three-fourths of the sawlog material and make up the bulk of the volume in all tree sizes. The yellow pines do not usually run much larger than 20 inches in diameter, but some of the white pines, hemlocks, and hardwood species range up to 40 inches and more in size.

Figure 6.--Distribution of sawtimber volume by diameter class.

Growing stock volume is up 40 percent.--The level of growing stock volume shows a surprising rate of increase since 1938. The present estimate of 2.9 billion cubic feet is 40 percent greater than at the time of the original survey. Here again, hardwood species account for most of the gain, being up three-quarters of a billion feet. There was also a considerable increase in the amount of other softwood growing stock, but the yellow pines show no change in volume (table C). To make the difference between growing stock and sawtimber volume clear, the following description is given: Growing stock is a term which includes the volume of all sound pole trees, starting at 5.0 inches in diameter at breast height, as well as the larger sawtimber trees which start at 9 inches for softwoods and 11 inches for hardwoods. Volumes are customarily computed in terms of cubic feet of wood, excluding bark, or in terms of standard cords including wood plus bark. Growing stock does not include the volume of cull trees, or of trees smaller than 5.0 inches in size which, for inventory purposes, are assumed to have no volume.

Table C.--Comparison of volume in all trees 5.0 inches
d.b.h. and larger, 1938 and 1955

Species group and class of material	1938 ^{1/}	1955	Change	
	<u>Million cu. ft.</u>	<u>Million cu. ft.</u>	<u>Million cu. ft.</u>	<u>Percent</u>
Growing stock:				
Yellow pines	384	384	0	0
Other softwoods	229	307	+78	+34
Hardwoods	1,477	2,228	+751	+51
All species	2,090	2,919	+829	+40
Cull trees:				
Yellow pines	49	104	+55	+112
Other softwoods	15	45	+30	+200
Hardwoods ^{2/}	555	864	+309	+56
All species	619	1,013	+394	+64
All live trees	2,709	3,932	+1,223	+45

^{1/} See footnote 1, table B.

^{2/} Excludes limb volume of hardwood sawtimber trees.

Table C shows that the amount of material in cull trees is also up sharply. A cull quality classification is assigned to a tree when it contains sufficient sound or rotten defect to make it

unmerchantable for saw logs either at the time of inventory, or at some future date when it will reach sawtimber size. Many of the cull trees can actually be used for such products as pulpwood, fence posts, and other items where clear length and straightness are not limiting factors.

The increase in both growing stock and cull trees has left the proportion of cull volume in the stands about the same. At the time of the first survey, 23 percent of the total volume in all live trees was classed as cull, while cull volume at present accounts for 26 percent.

Annual growth of sawtimber is 438 million board feet; of growing stock 2.4 million cords.--Western North Carolina forests are currently producing sawtimber at the rate of 438 million board feet per year. About half of this annual volume increase takes place on the oaks, hickories, and other hard-textured hardwood species which dominate the stands. Altogether, the hardwoods account for 320 million board feet, or approximately three-fourths of the total sawtimber growth.

The yearly increase in growing stock volume, including all sound trees 5.0 inches d.b.h. and larger, amounts to 155 million cubic feet of solid wood, or 2.4 million cords of wood and bark. Here again, the proportion of volume growth is about three-fourths hardwood and one-fourth softwood.

These timber growth estimates for the Mountain survey unit are based on the examination of increment cores taken from 2,400 sample trees scattered throughout all 21 counties. The cores were used to measure the rate of increase in tree diameter. They were also used to determine the number of young trees which are expected to reach volume size during the year, thus creating ingrowth. Sapling trees growing into pole size make up about 18 percent of the net growth on growing stock, and pole trees growing into sawtimber sizes account for 38 percent of the increase in board-foot volume.

Stands of white pine show the highest rate of production, with an average of 229 board feet, or 0.8 cord per acre per year. The average growth of timber stands, including all forest types and conditions in the unit, is 120 board feet, or 0.6 cord, per acre annually. This average is rather low, but it is heavily weighted by the slower-growing oaks and other hard hardwood species. In terms of total volume growth, the average annual rate of increase for all species is about 5 percent for sawtimber volume in board feet, and 6 percent for growing stock volume in standard cords.

Supply of hardwoods continues to increase.--In the 17-year period between 1938 and 1955, the volume of hardwood sawtimber increased 29 percent, while the supply of hardwood growing stock shows a gain of 51 percent. Comparisons of the current rate of growth with the amount

of timber cut indicate that this strong upward trend is still continuing (fig. 7). Logging operations, together with all other uses, are removing an average of 172 million board feet of hardwood sawtimber annually.

Figure 7.--Comparison of timber growth and timber cut in the Mountain Region of North Carolina.

This is only a little more than half the annual growth, leaving 147 million feet in the stands to increase the available supply. The annual gain in growing stock volume is even greater, with the volume cut amounting to 42 million cubic feet, or only 37 percent of the yearly growth.

The recent trend in the volume of softwood sawtimber is in the opposite direction. Harvesting activities for the removal of yellow pine, white pine, and hemlock have reached a level of 137 million board feet per year, which is 16 percent greater than the volume of growth for these species. The demand for white pine has been particularly heavy, with a good share of the output going into furniture manufacture. Yellow pine species are always preferred for the production of construction lumber and pulpwood bolts, and the requirements for these items have been increasing in recent years.

Cutting pressure on the softwood supply has been heaviest on the larger sawtimber-size trees. The volume of softwood growing stock, which includes the smaller pole trees, continues to follow the long-term trend by showing a surplus of growth over cut. This situation, where sawtimber is declining and growing stock is increasing, reflects the change in stand structure created by the effects of timber cutting and growth. Today's softwood timber stands are considerably younger, and they contain many more small trees and fewer large ones.

Table 1.--Gross area^{1/} by broad use class, 1955

^{1/} Estimates of timber drain by county are less accurate than inventory volumes, and use of individual county statistics should be avoided. For general use, data for a minimum of 10 counties should be combined.

DEFINITION OF TERMS

Land-Use Classes

Forest land: Includes (a) lands which are at least 10 percent stocked with trees of any size and capable of producing sawtimber or other wood products, and (b) lands from which the trees described in (a) have been removed to less than 10-percent stocking but which have not been developed for other use; subdivided into the following classes:

Commercial: Forest land which is (a) producing, or physically capable of producing, usable crops of wood (usually sawtimber), (b) economically available now or in the future, and (c) not withdrawn from timber use.

Noncommercial: Forest land (a) withdrawn from timber utilization through statute, ordinance, or administrative order but which otherwise qualifies as commercial forest land, or (b) incapable of yielding usable wood products (usually sawtimber) because of adverse site conditions, or so physically inaccessible as to be unavailable economically in the foreseeable future.

Nonforest land: Includes land under cultivation or in pasture where the timber has been cleared to less than 10 percent stocking, idle or abandoned agricultural land, marsh land, and land in urban, residential, or industrial areas, school yards, cemeteries, roads, railroads, and other rights-of-way.

Water: Includes lakes, bays, and estuaries over 40 acres in size, and streams, canals, and sloughs at least one-eighth of a mile in width which are classed as "inland water" by the Bureau of the Census. Smaller lakes and ponds between one acre and 40 acres in size, and waterways between 120 feet and 660 feet in width, which are classed as land area by the Bureau of the Census, are also included as water areas.

Forest Types

Forest type is determined on the basis of cubic volume for all stand sizes except seedlings and saplings (stand size 4), in which case the number of stems are the criteria.

Yellow pine types: Forests in which 50 percent or more of the cubic volume or number of stems in the stand is shortleaf, pitch, or Virginia pine species. In mixtures the predominating species determines the type.

White pine and spruce-fir types: Forests in which 50 percent or more of the stand is eastern white pine and hemlock, either singly or in combination, or in which 50 percent or more is in spruce and balsam fir species.

Oak-pine type: Forests in which 50 percent or more of the stand is hardwoods, usually upland oaks, but in which southern yellow pine species make up 25 to 49 percent of the stand.

Maple-beech-birch type: Forests in which 50 percent or more of the stand is made up of hard maple, beech, or yellow birch, singly or in combination. Commonly associated species include white pine, hemlock, basswood, buckeye, and northern red oak.

Oak-hickory type: Upland hardwood forests in which 50 percent or more of the stand is composed of oak, hickory, yellow-poplar, soft maple, basswood, sweet birch, ash, and other hardwood species, except in cases where yellow pines made up 25 to 49 percent and the stand was classified as oak-pine type.

Stand-Size Classes

Sawtimber: Stands containing at least 1,500 board feet net volume per acre, International 1/4-inch log rule, in sound, live, softwood trees 9.0 inches d.b.h. or larger, or hardwood trees 11.0 inches d.b.h. or larger. Two classes of sawtimber stands are recognized:

Large sawtimber: Stands of sawtimber having more than 50 percent of the net board-foot volume in trees 15.0 inches d.b.h. or larger.

Small sawtimber: Stands of sawtimber having 50 percent or more of the net board-foot volume in trees smaller than 15.0 inches d.b.h.

Poletimber: Stands failing to meet the minimum sawtimber specifications, but at least 10-percent stocked with trees 5.0 inches d.b.h. or larger and with at least half the minimum stocking in pole-size trees.

Seedling and saplings: Stands not qualifying as sawtimber or poletimber stands, but having at least a 10-percent stocking of trees of commercial species and with half the minimum stocking in seedlings and saplings.

Nonstocked and other areas: Forest areas not qualifying as sawtimber, poletimber, or seedling and sapling stands.

Diameters

D.b.h. (diameter at breast height): Stem diameter in inches, outside bark, measured at 4-1/2 feet above the ground.

Diameter class: All trees were tallied by 2-inch diameter classes, each class including diameters 1.0 inch below and 0.9 inch above the stated midpoint, e.g., trees 7.0 to and including 8.9 inches are included in the 8-inch class. Corresponding limits apply to other diameter classes.

Timber Quality Classification

Growing Stock

Sawtimber trees: Live softwood trees at least 9.0 inches d.b.h. and hardwood trees at least 11.0 inches d.b.h., with not less than one merchantable log 12 feet long, or with less than 50 percent of the gross volume of the tree in sound sawtimber. To be merchantable all saw logs must be at least 8 feet long and at least 50 percent sound. They must also meet the following requirements:

Softwood logs^{1/} must have a scaling diameter of 6 inches or larger, and sweep or crook must not exceed two-thirds of the scaling diameter.

Hardwood logs must have a scaling diameter of 8 inches or larger and must pass specifications^{2/} for standard lumber logs, or tie and timber logs.

Poletimber trees: Straight-boled trees between 5.0 inches d.b.h. and sawtimber size.

Sapling-size trees: Trees 1.0 inch to 4.9 inches d.b.h. which will grow into poletimber or sawtimber-size trees of sound quality.

Other Material

Sound cull trees: Live trees of all sizes that are unmerchantable for saw logs now or prospectively because of species, poor form, excessive limbiness, or other sound defect.

Rotten cull trees: Live trees of all sizes that are unmerchantable for saw logs now or prospectively because of rotten defect.

Hardwood limbs: The limb volume of all hardwood sawtimber and cull trees to a minimum diameter of 4.0 inches inside bark.

Species Groups

Yellow pines: Includes shortleaf, pitch, Virginia, and Table-Mountain pine.

Other softwoods: White pine, hemlock, spruce, balsam fir, and eastern redcedar.

Soft hardwoods: Blackgum, yellow-poplar, soft maple, basswood, sycamore, cucumber, and buckeye.

Hard hardwoods: All of the oaks, hickories, ash, beech, birch, hard maple, black locust, black walnut, holly, dogwood, persimmon, and sourwood.

^{1/} For detailed specifications of log grades, see "Interim log grades for southern pine." Southern Forest Experiment Station, 18 pp. 1953.

^{2/} For detailed hardwood log grade specifications, see "Hardwood log grades for standard lumber: proposals and results." U. S. Forest Products Laboratory, D1737. 1949.

Volume Estimates

Board-foot volume: The volume in board feet, measured by the International 1/4-inch rule, exclusive of defect, of that portion of sound sawtimber trees between the stump and the upper limit of merchantability for saw logs.

Volume in cords: For sound trees the volume in standard cords (including bark) of the sound portion of trees 5.0 inches d.b.h. and larger, between stump and a minimum top-stem diameter of 4.0 inches inside bark. Similar volumes are given for cull trees. The volume in limbs, which are at least 4.0 inches in diameter inside bark, is shown separately for all sawtimber-size hardwoods.

Volume in cubic feet: Same as volume shown in cords except bark is not included.

International 1/4-inch log rule: A rule for estimating the board-foot volume of 4-foot log sections, according to the formula $V = .905 (0.22D^2 - 0.71D)$. The taper allowance for computing the volume in log lengths greater than four feet is 0.5 inch per 4-foot section. Allowance for saw kerf is 1/4 inch.

Standard cord: A stacked pile, 4 x 4 x 8 feet, of round or split bolts, estimated to contain, on the average, about 74 cubic feet of solid wood.

Growth and Timber Cut

Net growth.--The estimated volume of net growth includes the growth on the present growing stock, the growth on trees which died or were cut during the year, and the ingrowth resulting from smaller trees reaching volume size. It excludes mortality, or loss of volume in trees dying from natural causes. Net growth estimates are based on growth of sound trees. Growth of "other material" is not included.

In board feet: The change during the calendar year in sawtimber volume resulting from growth, ingrowth, and mortality losses.

In cubic feet or cords: The change during the calendar year in the volume of all sound trees 5.0 inches and larger resulting from growth, ingrowth, and mortality losses.

Timber cut.--The volume of timber cut is based on the measurement and tally of stumps found on regular ground sample plots. Stumps of all trees cut during the past 3-year period are recorded and the measurements are converted into equivalent tree volume. The average yearly volume of timber cut for the 3-year period is then taken as the annual estimate. Board-foot volumes include the saw-log portion of all sawtimber-size trees which were cut. Estimates in cubic feet or cords include the entire stem from stump to 4.0-inch top of all sound trees 5.0 inches in diameter and larger. Timber cut from cull or dead trees is not included.

Stocking

Stocking is the extent to which growing space is effectively utilized by trees. The number of stems present by d.b.h. classes was used as a basis for stocking classification. Areas having the minimum numbers of trees listed below, either in a single diameter class or proportionately in any combinations of diameter classes, were considered fully stocked.

<u>D.b.h.</u>	<u>Minimum number trees per acre</u>
Seedlings	1,000
2 inches	800
4 inches	590

RELIABILITY OF FOREST SURVEY DATA

In general, the errors which affect the accuracy of Forest Survey area and timber volume estimates arise from two sources. These may be described as (1) sampling errors which result from using sampling procedures rather than making a complete inventory or canvass, and (2) non-sampling errors which arise from human mistakes in judgment, measurement, recording, or arithmetic.

In Forest Survey work a diligent effort is made to maintain a high degree of accuracy in the collection and compilation of data. The sampling errors are held to a specified minimum through survey design and sampling technique. These errors are the only measurable errors involved in computing the reliability of the data. The non-sampling errors are minimized or eliminated through training, supervision, field check cruises, and complete editing and machine verification in compiling the data.

Forest area.--The sampling intensity of the 1955 survey provided an estimate of the total forest area with a standard error of ± 0.6 percent. The probabilities are two out of three that the actual forest area is within ± 0.6 percent of the estimated acreage. The standard error per million acres was ± 1.3 percent.

Cubic volume.--The standard error of the net cubic-foot volume estimate was ± 2.6 percent, or ± 4.4 percent per billion cubic feet. Here again, the probabilities are two out of three that the actual volume does not vary from the estimated volume by more than this percentage. The error of the volume in standard cords was not computed, but it should be approximately the same as for cubic volume.

Board-foot volume.--The standard error of the total board-foot volume estimate was ± 3.6 percent.

Growth.--Estimates of timber growth are based on measurements of radial growth in sample trees, and on mortality data taken on sample plots. Because of technical problems involved, no attempt was made to compute the sampling error of growth estimates.

Timber cut.--Estimates of the amount of timber cut were based on the number and size of stumps tallied on cutover plots. Stumps of all trees cut during the 3-year period preceding date of inventory were recorded, and the measurements were converted into tree volume. The average volume of timber cut for the 3-year period was taken as the annual estimate. The standard error for the total volume of growing stock cut was ± 11.2 percent, or ± 3.0 percent per billion cubic feet.

Use of county data.--The tables showing forest area, timber volumes, and timber cut by county are included to permit grouping of the data in any desired area combinations. In designing the survey, provision was made for controlling the range of sampling error on a county basis. However, comparison or use of individual county statistics should be avoided because of the possibility that they may be subject to considerable error. It is recommended that area or volume data for a minimum of five counties be combined, and that at least 10 counties be used when working with data on timber cut.

The actual range of errors on county data are shown below:

<u>Item</u>	<u>Percent of error</u>	
	<u>Low</u>	<u>High</u>
Forest area	± 1.5	± 7.1
Growing stock volume	± 6.2	± 15.6
Board-foot volume	± 8.0	± 20.8

HOW THE FOREST INVENTORY IS MADE

The present system of inventory is a two-step method which includes land-use classification of points on aerial photographs followed by the cruising of ground sample plots. The county is the basic work unit. The detailed procedure is as follows:

1. Preliminary estimates of the acreage of land in forests and other land-use classes are obtained by classifying points printed on every third aerial photograph in alternate flight lines within a county. The proportion of points falling in each class is used to estimate the acreage. This estimate is later checked and revised through the use of ground plots.

2. Ground sample plots are selected in a systematic manner from the forest land classifications made in Step 1, using an interval which will provide sufficient plots to meet established limits of error per billion cubic feet of timber. This results in a proportional sample of all existing timber stands. Timber cruisers make a detailed description and tally of the ground plots to obtain data on timber volume, quality, stocking, and mortality. Samples of agricultural and other photo classifications are also checked on the ground to verify or adjust the area estimates based on these classifications.

3. Growth estimates are based on increment borings taken proportionally from sample trees of various diameters and species in each forest type and stand class. The volume of timber cut is computed from a tally of the stumps of trees cut on the plots during a specified period.

4. All field data are sent to Asheville for editing and are placed on punch cards for machine sorting and tabulation. Final estimates are based on statistical summaries of the data.
