ASHEVILLE, NORTH CAROLINA

E. L. Demmon, Director

FOREWORD

Through the McSweeney-McNary Act of 1928, Congress authorized the Secretary of Agriculture to conduct a comprehensive survey of the forest resources of the United States. The Forest Survey was organized by the Forest Service to carry out the provisions of the Act through the Regional Forest Experiment Stations. In the Southeastern states the Forest Survey is an activity of the Division of Forest Economics of the Southeastern Forest Experiment Station, Asheville, North Carolina.

The five-fold purpose of the Forest Survey is (1) to make a field inventory of the present supply of standing timber, (2) to ascertain the rate at which this supply is being increased through growth, (3) to determine the rate at which it is being reduced through industrial and domestic uses, fire, and other causes, (4) to determine the present consumption and the probable future trend in requirements for forest products, and (5) to interpret and correlate these finds to aid in the formulation of private and public policies regarding forest land management.

The first inventory of forest resources in the State of Georgia by the Forest Survey was made during the period 1934-36, and these findings have been published. Since then, the effects of forest growth, timber cutting, changes in land use, and other factors have caused rapid changes in the growing stock which can only be measured by on-the-ground surveys. A resurvey of the forest resources in Georgia was started in July 1950 and field work was completed in November 1953. This report presents statistics on forest area, timber volume, growth, and timber cut which were compiled from the resurvey.

ACKNOWLEDGMENTS

The Southeastern Station wishes to acknowledge the cooperation and assistance furnished by State Forester Guyton DeLoach, the University of Georgia School of Forestry, the Macon Kraft Company, the St. Regis Paper Company, the Union Bag and Paper Corporation, and the West Virginia Pulp and Paper Company in providing additional personnel to increase the rate of progress on the field survey.

The Division of Forest Economics is under the direction of James W. Cruikshank. Collection of the field data was supervised by Mackay B. Bryan and L. C. Nix. Photo interpretation was done by R. C. Aldrich. Office compilation of the data was under the direction of Agnes Nichols, assisted by Camilla Young, Louise Shuford, Sammy Wenningham, and Eunice Gamble.

Figure 1.--Location of Forest Survey Units in Georgia

FOREST STATISTICS FOR GEORGIA, 1951-53

This report presents a summary of statistical data on forest area, timber volumes, and naval stores for the State of Georgia which have already been published in separate survey unit releases. It also contains information on timber growth and the amount of timber cut annually. These statistics were compiled from a resurvey of forest resources in Georgia which was started in July 1950 and completed in November 1953.

Basic information on forest conditions was obtained through the examination of 9,300 forest sample plots, one-fifth acre in size, distributed throughout all counties in the State. An additional 2,700 plots in nonforest conditions were examined to improve the accuracy of preliminary forest land area estimates made from aerial photographs. The methods used in selecting and examining the sample plots are described briefly on page 77.

Eighteen years have elapsed since the first inventory of Georgia's forest resources was completed in 1936. During this period, timber cutting, growth, better fire protection, and shifts in the pattern of land use have caused considerable change in the extent and composition of the forests. Comparisons of the statistics for both surveys have been made to point out some of these changes.

SIGNIFICANT FACTS AND TRENDS FROM THE 1951-53 SURVEY

Two acres out of every three are forest land.--The importance of the forest resource in Georgia is shown by the fact that forests are growing on two-thirds of the land in the State. According to the recent survey, forests now occupy 24.1 million acres, or 65 percent of the total land area. Croplands and pasture occupy 11.4 million acres, and the remaining area is in urban or other uses.

Nearly all the forest land is producing timber for commercial use. Less than 18 thousand acres are in parks or other areas where the timber is reserved, and only 70 thousand acres are on unproductive sites where trees of commercial size will not grow.

Ninety-three percent of the commercial timber land is in private ownership. Nearly 16 million acres are in farm woodlands, and about six and one-half million are held by lumber companies, pulp companies, estates, or other private owners. Public ownership of forest land amounts to 1.7 million acres, or 7 percent of the total. For the most part, these lands are in military reservations, power developments, and National Forest holdings.

Commercial forest land increases 2.6 million acres.--Land clearing for agricultural use and the reversion of cleared land to forest are opposing processes constantly at work in the State. In the 18-year period between surveys, the acreage of commercial forest land increased 2.6 million acres. This gain of 12 percent indicates that abandoned farmland has been going back to forest at a much faster rate than new land has been cleared.

Table A.--Change in commercial forest area

Survey unit	1934-36	1951-53	Change	
	<u>Thousand acres</u>	<u>Thousand acres</u>	<u>Thousand acres</u>	<u>Percent</u>
Southeast ^{1/}	7,355.3	7,626.8	271.5	+ 4
Southwest	3,014.0	3,057.5	43.5	+ 1
Central	5,581.0	6,687.5	1,106.5	+20
North Central	2,549.0	3,521.9	972.9	+38
North	2,835.3	3,075.4	240.1	+ 8
State	21,334.6	23,969.1	2,634.5	+12

^{1/} Includes Okefenokee Swamp and coastal islands which were not surveyed in 1934.

This trend has been particularly strong in the Central and North Central units as shown in table A. These areas combined show an increase of more than 2 million acres.

Stands of pine timber predominate.--Fifty-eight percent of the forest land supports pine types. The loblolly pine type is the most extensive, occupying 4.8 million acres, or 20 percent of the

wooded area in the State. Stands of slash and longleaf pine, located principally in the South Georgia Coastal Plain, cover a combined total of 6.2 million acres, or 26 percent. Hardwood forest types occupy a total of 10.1 million acres, being more prevalent in the Piedmont and Mountain areas.

Figure 2.--Area of commercial forest land by forest type

One very consistent trend throughout the State is an increase in the proportion of hardwood stands and a decrease in pine. A comparison of type acreages for both surveys shows that 34 percent of the forested area is now in hardwood types, as compared to 22 percent during the first survey. In making this comparison, the 1936 system of classification was used in both surveys to eliminate differences due to type definitions. The trend has been quite similar in all survey units. Type conversion is brought about by cutting practices which leave hardwoods as the residual stand. About 15 percent of the pine type area that is cut over each year is changed to hardwood type by cutting.

Figure 3.--Proportion of forest land by broad type

One-fourth of forest land is poorly stocked.--The rate of timber production is low on nearly one-fourth of the commercial forest land in Georgia because of poor stocking conditions. Approximately

24 percent of the stands are less than 40 percent stocked with trees of commercial species including the small seedling and sapling sizes. About three-fourths of this area is expected to restock naturally, and 1.4 million acres will require planting to bring about full production of timber within a reasonable length of time. A portion of the area needing planting will have to be treated to remove a dense brush cover before planting will be practical.

Present stands contain many more small trees.--The structure of the present timber stands in Georgia shows the effects of two opposite trends at work during recent years. Heavy and extensive timber cutting operations have reduced the number of trees in the larger diameter classes. On the other hand, such measures as more intensive fire protection, planting, and conservative use of turpentine trees have permitted the establishment and growth of many million more small trees.

Stand tables listing the number of sound trees by species group and diameter for the two surveys show there are fewer pine trees 14 inches or larger in diameter and more pine trees 12 inches or smaller. The same trend is evident in the hardwood trees, but the point of change is slightly higher, falling between the 14- and 16-inch diameter classes.

Table B.--Comparison of numbers of sound trees

D.b.h. class (inches)	Yellow pines			Hardwoods		
	1934-36	1951-53	Change	1934-36	1951-53	Change
	<u>Million trees</u>	<u>Million trees</u>	<u>Percent</u>	<u>Million trees</u>	<u>Million trees</u>	<u>Percent</u>
2	1,098	1,615	+47	1,644	2,696	+64
4	536	830	+55	438	661	+51
6	311	441	+42	204	241	+18
8	217	277	+28	114	142	+25
10	131	162	+24	73	98	+34
12	82	86	+ 5	49	57	+16
14	44	36	-18	30	34	+13
16	21	14	-33	19	17	-11
18	10	5	-50	11	10	- 9
20+	10	3	-70	15	10	-33
Total	2,460	3,469	+41	2,597	3,966	+53

Although poor stocking conditions are present on a considerable area of forest land, the changes shown in table B indicate a general improvement in the stocking picture for the State as a whole. The

large increase in small trees resulted in net gains of 41 percent for pines and 53 percent for hardwoods. This rising inventory of young timber will add materially to the growing stock and improve the rate of timber growth as the trees are recruited into merchantable size classes. There is still plenty of space in the woods for more trees to grow, and the general level of timber stocking should continue to improve providing conditions remain favorable. For the immediate future, however, losses in the larger tree sizes point toward a lack of sufficient pine sawtimber in some areas.

Sawtimber volume down 13 percent.--The demand for saw logs, pulpwood, and other forest products from Georgia's timber lands reached record-breaking levels during the interval between surveys. The pressure on the timber supply created by such heavy utilization reduced the volume of sawtimber by 5.7 billion board feet, or 13 percent, since 1934. The decline is present in all species groups, with the heaviest loss in pine (table C).

Table C.--Comparison of sawtimber volumes

Species group	1934-36 ^{1/}	1951-53	Change	
	<u>Million bd. ft.</u>	<u>Million bd. ft.</u>	<u>Million bd. ft.</u>	<u>Percent</u>
Yellow pines	25,202	21,351	3,851	-15
Other softwoods	1,906	1,761	145	- 8
Hardwoods	15,493	13,808	1,685	-11
All species	42,601	36,920	5,681	-13

^{1/} Original survey volumes have been recomputed to allow for differences in standards between surveys and to provide a uniform basis for comparison. Adjustment has been made for the Okefenokee Swamp and coastal islands which were not surveyed in 1934.

The use of pine sawtimber has been particularly heavy in the Piedmont and Mountain sections of the State. In the Central unit, pine volume decreased 38 percent, and in the Northern units, 47 percent. These reductions were partially offset by a 21-percent increase in Southeast Georgia, and a 3-percent increase in the Southwestern section. Hardwood sawtimber volume decreased in the Central and Southeastern sections and increased elsewhere in the State.

Two-thirds of sawtimber volume in softwood trees.--Southern yellow pine trees contain 58 percent of the present sawtimber volume in Georgia. Other softwood species, principally cypress, contain an additional 5 percent for a combined total which equals nearly two-thirds of the board-foot volume available. Slash pine is the most important individual species, making up nearly one-fifth of the entire volume. Loblolly pine is a close second, followed by longleaf pine, red oaks, blackgum, and other species.

Figure 4.--Sawtimber volume by species

Sixty percent of the yellow pine sawtimber volume is in relatively small 10- and 12-inch diameter trees, and 94 percent is in trees less than 19 inches in size. This is in contrast with hardwood species, where one-fourth of the board-foot volume is in trees with diameters of 20 inches or more. The size of the average pine sawtimber tree is only 11.5 inches in diameter at 4.5 feet above ground.

Figure 5.--Distribution of sawtimber volume by diameter class groups

Most hardwood sawtimber is of low quality.--Saw logs in hardwood trees were graded in the survey using Hardwood Log Grades for Standard Lumber developed by the Forest Products Laboratory. These rules take into account the size and soundness of the log, the number and location of knots, holes, scars, or other defects, and the extent of sweep or crook, if any. Only 8 percent of the volume in hardwood logs was graded as select or grade No. 1, and 16 percent was in grade No. 2. The remaining 76 percent fell into grade No. 3, which is composed of low-grade factory lumber logs, or logs suitable for the manufacture of crossties and timbers.

Saw logs in softwood species were graded under modified Crossett Log Grades, which depend primarily on log size, and the number and size of knots. Nearly three-fourths of the pine volume was found to be in grade No. 2 or better logs. Cypress and the other softwood species were of still better quality, with about 85 percent of the volume in grade No. 2 or better.

Volume of growing stock shows little change.--Growing stock volumes are computed in terms of cubic feet of solid wood. These estimates include all sound pole-size trees (starting at 5.0 inches in diameter) as well as the volume in the larger sawtimber trees. Trees smaller than 5 inches in diameter are considered seedlings or saplings and are not assigned volume in the timber inventory.

The volume of growing stock present at the time of each survey was found to be practically the same for the State as a whole. Pine volume was down a little and hardwood volume up slightly for a net loss of one percent. There was no change at all in the volume of other

softwoods. However, as with sawtimber volume, there has been considerable change in pine growing stock volume in the individual survey units. In the Central and North Central units, pine volume was down 20 and 22 percent respectively. In the North unit, pine growing stock dropped 29 percent. The decline in these areas was nearly offset by increases in the southern sections of the State.

Table D.--Comparison of volume in all trees 5.0 inches
d.b.h. and larger

GROWING STOCK				
Species group	1934-36 ^{1/}	1951-53	Change	
	<u>Million cu. ft.</u>	<u>Million cu. ft.</u>	<u>Million cu. ft.</u>	<u>Percent</u>
Yellow pines	7,403	7,254	149	-2
Other softwoods	519	519	0	0
Hardwoods	4,859	4,919	60	+1
All species	12,781	12,692	89	-1

CULL TREES				
Yellow pines	169	818	649	+384
Other softwoods	103	98	5	- 5
Hardwoods ^{2/}	1,563	2,780	1,217	+ 78
All species	1,835	3,696	1,861	+101

^{1/} See footnote 1, table C.

^{2/} Excludes limb volume of hardwood sawtimber trees.

The heavy rate of timber cutting and the surge of young ingrowth coming on have also created a shift in growing stock volume by tree-size class. For the State, the proportion of pine volume in pole-size trees has jumped from 25 to 34 percent during the 18-year period. Hardwood growing stock volume is following the same trend but at a slower rate than pine. This change is most pronounced in the North Central unit where half the pine growing stock now available is in trees 6 and 8 inches in diameter.

The amount of wood in low-quality cull trees has doubled during the past 18-year period. These trees are too crooked, limby, or rotten, to be cut into saw logs for lumber, but many of them can be used for the production of pulpwood, fence posts, or other forest products. The volume of cull trees in the stands tends to build up because they are seldom harvested during saw-log cutting operations. It now amounts to 23 percent of the total cubic volume in the State as compared to 13 percent in 1934. The influence of these changes in tree quality and tree size as they affect timber volumes is shown in figure 6.

Figure 6.--Change in timber volumes by class of material

Gum naval stores important in South Georgia.--The practice of facing longleaf and slash pine trees for the production of gum naval stores is a widespread activity throughout the Southern Coastal Plain area of the State. Crops of working, resting, or worked-out timber were found on 35 percent of the acreage in the turpentine types. In the 1951-52 season a total of 904 thousand barrels of crude gum were collected and manufactured into 190 thousand barrels of turpentine and 552 thousand drums of rosin.

About 27 percent of the longleaf and slash pine trees 9.0 inches or larger in diameter were being worked for naval stores. An additional 14 percent were in the resting stage and 7 percent were worked out. The remainder, 52 percent, had not been faced. Only 4 percent of all the trees being worked were smaller than 9.0 inches in diameter.

Since 1934 there has been a marked decline in naval stores activity in South Georgia. The area occupied by turpentine timber crops is now only one-third of the area being worked at the time of the original survey. Also, the number of working trees in the stands has been reduced from about 65 million to 47 million.

Annual growth of sawtimber is 3.2 billion board feet, of growing stock 12.6 million cords.--The yearly increase of sawtimber volume in Georgia resulting from growth of all species amounted to 3.2 billion board feet. Pine sawtimber is being produced at the rate of 2.3 billion feet per year, or 73 percent of the annual increase. The reason pine growth exceeds that of other species groups is twofold. Pine makes up a higher proportion of the timber volume in the State, and it also grows at a much faster rate.

The annual increase of growing stock volume, including all sound trees 5.0 inches d.b.h. and larger, amounted to 12.6 million rough cords, or 867 million cubic feet, of solid wood. Southern yellow pine was again the leading species, but the volume produced represented only 66 percent of the total increase.

Table E.--Net annual growth by species group

Species group	Sawtimber	Growing stock	
	<u>Million bd. ft.</u>	<u>Million cu. ft.</u>	<u>Thousand cords</u>
Yellow pines	2,288	573	8,365
Other softwoods	58	15	197
Soft hardwoods	478	166	2,366
Hard hardwoods	327	113	1,638
All species	3,151	867	12,566

Estimates of growth are based on the examination of thousands of increment cores taken from sample trees in all sections of the State. These cores indicate the rate of tree diameter growth, and also the number of young trees expected to reach volume size during the course of a year, thus creating ingrowth. The volume of timber mortality, or death of trees from natural causes, is deducted from total growth to arrive at net growth estimates.

On a per-acre basis, stands of slash pine were the highest producers, with an average of 216 board feet, or seven-tenths of a cord per year. The average growth of all stands was 136 board feet, or six-tenths of a cord per acre per year.

The rates of timber growth, particularly pines, are excellent for all areas of the State. Annual growth percentages for pine sawtimber range from 10 to 13 percent, and for pine growing stock, from 7 to 10 percent. However, it is important to note that the actual volume increase in any forest type or condition depends on the degree of stocking as well as on the rate of growth. The growth percentages are higher in Central and North Georgia, but the forests in South Georgia are producing more timber per acre because the stands are better stocked.

A large volume of timber is cut annually.--For the entire State, the volume of sawtimber cut for all purposes amounted to 3.0 billion board feet. The cut of growing stock material, including both pole-timber and sawtimber trees, totaled 10 million cords, or 779 million cubic feet of wood. Fuelwood and fence posts cut for domestic or farm use are included in these estimates as well as saw logs and other commercial products. The pressure of this cutting was heaviest on the pine timber supply, with approximately four-fifths of the production coming from this species.

Figure 7.--Distribution of 1952 timber cut by product

The leading product, as shown in figure 7, is saw logs for the manufacture of lumber. Pulpwood is second in importance, and the combined cut of saw logs and pulpwood equals 83 percent of the volume cut for all products. In 1952 the production of lumber hit an all-time

high and the volume of pulpwood produced has been increasing steadily in recent years. The amount of fuelwood, cooperage, and hewn ties produced in the State has been on the decline.

Volume of pine sawtimber cut exceeds growth.--Because of continuing heavy demand, yellow pine sawtimber volume in Georgia is still dropping at nearly the same average rate which took place during the period between surveys. The annual volume loss during the resurvey was 0.7 percent, while the average decline since 1934 has been 0.8 percent per year. This statewide figure is a balance resulting from opposite trends in the individual survey units. The decrease in pine volume is concentrated in the Central and Northern sections of the State as shown in figure 8. The most severe reduction occurred in the North Central unit, where the rate of decline was 7 percent annually. The excess of pine sawtimber growth over volume cut in the Southern units has had a counterbalancing effect. The board-foot volume of other species groups in the State is increasing.

Figure 8.--Annual yellow pine sawtimber growth and amount cut by survey units

Inaccessible area	443.6	8,358	1,400
All classes	7,717.3	138,798	23,023

^{1/} Includes 540 thousand tons of stumps on agricultural land.

^{2/} Stump-land areas less than 25 acres in extent and partially worked areas.

^{3/} Areas unworkable at present due to density of timber stands.

Table 19.--Number of trees^{1/} by species group, quality class, and tree size

(In thousands of trees)

Species group and quality class	Sapling-size trees	Pole-size trees	Small sawtimber trees	Large sawtimber trees	All trees
Yellow pines:					
Sound trees	2,445,173	717,275	284,531	22,226	3,469,205
Sound culls	400,166	92,524	45,883	3,467	542,040
Rotten culls	6,591	2,808	879	237	10,515
Total	2,851,930	812,607	331,293	25,930	4,021,760
Other softwoods:					
Sound trees	204,849	41,421	19,041	2,559	267,870
Sound culls	8,318	3,579	1,827	120	13,844
Rotten culls	2,777	1,443	1,332	847	6,399
Total	215,944	46,443	22,200	3,526	288,113
Soft hardwoods:					
Sound trees	1,711,358	263,772	51,931	17,933	2,044,994
Sound culls	667,158	123,624	18,837	6,143	815,762
Rotten culls	76,073	50,683	9,530	6,684	142,970
Total	2,454,589	438,079	80,298	30,760	3,003,726
Hard hardwoods:					
Sound trees	1,645,709	216,891	39,331	19,206	1,921,137
Sound culls ^{2/}	1,878,922	223,186	24,903	10,373	2,137,384
Rotten culls	46,006	16,918	5,239	5,388	73,551
Total	3,570,637	456,995	69,473	34,967	4,132,072
All species	9,093,100	1,754,124	503,264	95,183	11,445,671

^{1/} All trees 1.0 inch d.b.h. and larger.

^{2/} Includes scrub oak and noncommercial species.

Table 20.--Area^{1/} of seedling and sapling stands and unstocked areas
by plantability class
(In thousand acres)

Forest type	No planting required ^{2/}	Suitable for machine planting	Hand planting required	All classes
Longleaf pine	822.1	137.8	82.0	1,041.9
Slash pine	992.7	78.8	83.5	1,155.0
Loblolly pine	1,555.0	72.5	204.8	1,832.3
Shortleaf pine	628.7	16.3	43.1	688.1
Pond pine	145.7	11.0	5.1	161.8
Virginia pine	122.9	--	1.0	123.9
Oak-pine	811.7	35.2	79.1	926.0

STANDARD FOREST SURVEY TABLES

The tables which appear on the following pages have been standardized as to format and contents so that forest statistics for Georgia can be compared or combined with similar statistics for other states. This practice is being followed to provide readers with comparable data on forest area, timber volumes, growth, and timber cut for each state as the initial surveys or resurveys are completed.

Table 40.--Land area by major classes of land,
Georgia, 1953

Class of land	Area
	<u>Thousand acres</u>
Forest:	
Commercial	23,969
Noncommercial	
Productive-reserved	18
Unproductive	70
Total forest land	24,057
Nonforest land ^{1/}	13,372
Total, all classes	37,429

^{1/} Includes 51,600 acres of Census water created since 1950 and 178,200 acres of water in small lakes and streams defined by the Bureau of the Census as land area.

DEFINITION OF TERMS

Land-Use Classes

Forest land: Includes (a) lands which are at least 10 percent stocked with trees of any size and capable of producing sawtimber or other wood products, and (b) lands from which the trees described in (a) have been removed to less than 10-percent stocking but which have not been developed for other use; subdivided into the following classes:

Commercial: Forest land which is (a) producing, or physically capable of producing, usable crops of wood (usually sawtimber), (b) economically available now or in the future, and (c) not withdrawn from timber use.

Noncommercial: Forest land (a) withdrawn from timber utilization through statute, ordinance, or administrative order but which otherwise qualifies as commercial forest land, or (b) incapable of yielding usable wood products (usually sawtimber) because of adverse site conditions, or so physically inaccessible as to be unavailable economically in the foreseeable future.

Nonforest land: Includes land under cultivation or in pasture where the timber has been cleared to less than 10 percent stocking, idle or abandoned agricultural land, marsh land, and land in urban, residential, or industrial areas, school yards, cemeteries, roads, railroads, and other rights-of-way.

Water: Includes lakes, bays, and estuaries over 40 acres in size, and streams, canals, and sloughs at least one-eighth of a mile in width which are classed as "inland water" by the Bureau of the Census. Smaller lakes and ponds between one acre and 40 acres in size, and waterways between 120 feet and 660 feet in width, which are classed as land area by the Bureau of the Census, are also included as water areas.

Forest Types

Forest type is determined on the basis of cubic volume for all stand sizes except seedlings and saplings (stand size 4), in which case the number of stems are the criteria.

Pine types: Forests in which 50 percent or more of the stand is in pine species. Plurality of volume or number of trees is used to determine the specific type.

Oak-pine type: Forests in which 50 percent or more of the stand is hardwoods, usually upland oaks, but in which southern yellow pines make up 25-49 percent of the stand.

Oak-hickory type

Upland hardwood: Forests in which 50 percent or more of the stand is composed of upland oak, hickory, yellow-poplar, maple, gum, and other hardwoods, except where pines comprise 25-49 percent of the stand.

Scrub oak: Upland forests in which 50 percent or more of the stand is composed of scrub oak species, except where pines comprise 25-49 percent of the stand.

Oak-gum-cypress type

Lowland hardwood: Bottomland forests in which 50 percent or more of the stand is tupelo, blackgum, sweetgum, ash, oak, elm, maple, and associated species, except where pines comprise 25-49 percent of the stand.

Cypress: Bottomland forests in which 50 percent or more of the stand is cypress, except where pines comprise 25-49 percent of the stand.

Stand-Size Classes

Sawtimber: Stands containing at least 1,500 board feet net volume per acre, International 1/4-inch log rule, in sound, live, softwood trees 9.0 inches d.b.h. or larger, or hardwood trees 11.0 inches d.b.h. or larger. Two classes of sawtimber stands are recognized:

Large sawtimber: Stands of sawtimber having more than 50 percent of the net board-foot volume in trees 15.0 inches d.b.h. or larger.

Small sawtimber: Stands of sawtimber having 50 percent or less of the net board-foot volume in trees 15.0 inches d.b.h. or larger.

Poletimber: Stands failing to meet the minimum sawtimber specifications, but at least 10-percent stocked with trees 5.0 inches d.b.h. or larger and with at least half the minimum stocking in pole-size trees.

Seedling and saplings: Stands not qualifying as sawtimber or poletimber stands, but having at least a 10-percent stocking of trees of commercial species and with half the minimum stocking in seedlings and saplings.

Nonstocked and other areas: Forest areas not qualifying as sawtimber, poletimber, or seedling and sapling stands.

Diameters

D.b.h. (diameter at breast height): Stem diameter in inches, outside bark, measured at 4-1/2 feet above the ground.

Diameter class: All trees were tallied by 2-inch diameter classes, each class including diameters 1.0 inch below and 0.9 inch above the stated midpoint, e.g., trees 7.0 to and including 8.9 inches are included in the 8-inch class. Corresponding limits apply to other diameter classes.

Timber Quality Classification

Growing Stock

Sawtimber trees: Live softwood trees at least 9.0 inches d.b.h. and hardwood trees at least 11.0 inches d.b.h., with not less than one merchantable log 12 feet long, or with less than 50 percent of the gross volume of the tree in sound sawtimber. To be merchantable all saw logs must be at least 8 feet long and at least 50 percent sound. They must also meet the following requirements:

Softwood logs must have a scaling diameter of 6 inches or larger, and sweep or crook must not exceed two-thirds of the scaling diameter.

Hardwood logs must have a scaling diameter of 8 inches or larger and must pass specifications^{1/} for standard lumber logs, or tie and timber logs.

Poletimber trees: Straight-boled trees between 5.0 inches d.b.h. and sawtimber size.

Sapling-size trees: Trees 1.0 inch to 4.9 inches d.b.h. which will grow into poletimber or sawtimber-size trees of sound quality.

Other Material

Sound cull trees: Live trees of all sizes that are unmerchantable for saw logs now or prospectively because of species, poor form, excessive limbiness, or other sound defect.

Rotten cull trees: Live trees of all sizes that are unmerchantable for saw logs now or prospectively because of rotten defect.

Hardwood limbs: The limb volume of all hardwood sawtimber and cull trees to a minimum diameter of 4.0 inches inside bark.

Species Groups

Yellow pines: Includes longleaf, slash, loblolly, pond, Virginia, and shortleaf pine.

Other softwoods: Cypress, white pine, hemlock, eastern redcedar, and Atlantic whitecedar.

Soft-textured hardwoods: Blackgum, tupelo, yellow-poplar, sweetgum, cottonwood, soft maple, basswood, cucumber, willow, and sweetbay.

Hard-textured hardwoods: All of the oaks, hickories, ash, beech, elm, river birch, hackberry, sycamore, black locust, mulberry, black walnut, holly, dogwood, and persimmon.

^{1/} For detailed hardwood log grade specifications, see "Hardwood log grades for standard lumber: proposals and results." U. S. Forest Products Laboratory, D1737, 1949.

Volume Estimates

Board-foot volume: The volume in board feet, measured by the International 1/4-inch rule, exclusive of defect, of that portion of sound sawtimber trees between the stump and the upper limit of merchantability for saw logs.

Volume in cords: For sound trees the volume in standard cords (including bark) of the sound portion of trees 5.0 inches d.b.h. and larger, between stump and a minimum top-stem diameter of 4.0 inches inside bark. Similar volumes are given for cull trees. The volume in limbs, in sections four feet long and at least 4.0 inches in diameter inside bark, of all sawtimber-size hardwoods is shown separately.

Volume in cubic feet: Same as volume shown in cords except bark is not included.

International 1/4-inch log rule: A rule for estimating the board-foot volume of 4-foot log sections, according to the formula $V = .905 (0.22D^2 - 0.71D)$. The taper allowance for computing the volume in log lengths greater than four feet is 0.5 inch per 4-foot section. Allowance for saw kerf is 1/4 inch.

Standard cord: A stacked pile, 4 x 4 x 8 feet, of round or split bolts, estimated to contain, on the average, about 73 cubic feet of solid wood.

Growth and Timber Cut

Net growth.--The estimated volume of net growth includes the growth on the present growing stock, the growth on trees which died or were cut during the year, and the ingrowth resulting from smaller trees reaching volume size. It excludes mortality, or loss of volume in trees dying from natural causes. Net growth estimates are based on growth of sound trees. Growth of "other material" is not included.

In board feet: The change during the calendar year in sawtimber volume resulting from growth, ingrowth, and mortality losses.

In cubic feet or cords: The change during the calendar year in the volume of all sound trees 5.0 inches and larger resulting from growth, ingrowth, and mortality losses.

Timber cut.--The volume of timber cut is based on the measurement and tally of stumps found on regular ground sample plots. Stumps of all trees cut during the past 3-year period are recorded and the measurements are converted into equivalent tree volume. The average yearly volume of timber cut for the 3-year period is then taken as the annual estimate. Board-foot volumes include the saw-log portion of all sawtimber-size trees which were cut. Estimates in cubic feet or cords include the entire stem from stump to 4.0-inch top of all sound trees 5.0 inches in diameter and larger.

Gum Naval Stores Conditions

Round timber.--A minimum of 15 longleaf and slash pine trees 9.0 inches d.b.h. or larger per acre that have not been worked for naval stores.

Working.--Longleaf and slash pine trees that are now being worked for naval stores.

Front-faced: Turpentine tree species on which the front or first face is now being worked.

Back-faced: Turpentine tree species on which the front face has been worked out and on which a back (second or third, etc.) face is being worked.

Resting.--Longleaf and slash pine trees with a worked-out or abandoned front face and on which back-facing has not been started.

Worked-out.--Longleaf and slash pine trees on which two or more faces have been worked out and with no possibility of supporting another face.

Stocking

Stocking is the extent to which growing space is effectively utilized by trees. The number of stems present by d.b.h. classes was used as a basis for stocking classification. Areas having the minimum numbers of trees listed below, either in a single diameter class or proportionately in any combinations of diameter classes, were considered fully stocked.

<u>D.b.h.</u>	<u>Minimum number trees per acre</u>
Seedlings	1,000
2 inches	800
4 inches	590
6 inches	400
8 inches	240
10 inches	155
12 inches	115
14 inches	90

RELIABILITY OF FOREST SURVEY DATA

In general, the errors which affect the accuracy of Forest Survey area and timber volume estimates arise from two sources. These may be described as (1) sampling errors which result from using sampling procedures rather than making a complete inventory or canvass, and (2) non-sampling errors which arise from human mistakes in judgment, measurement, recording, or arithmetic.

. In Forest Survey work a diligent effort is made to maintain a high degree of accuracy in the collection and compilation of data. The sampling errors are held to a specified minimum through survey design and sampling technique. These errors are the only measurable errors involved in computing the reliability of the data. The non-sampling errors are minimized or eliminated through training, supervision, field check cruises, and complete editing and machine verification in compiling the data.

Forest area.--The sampling intensity of the 1951-53 survey provided an estimate of the total forest area in the State with a standard error of ± 0.3 percent. The probabilities are two out of three that the actual forest area is within ± 0.3 percent of the estimated acreage. The standard error per million acres was ± 1.5 percent.

Cubic volume.--The standard error of the net cubic-foot volume estimate was ± 1.2 percent, or ± 4.3 percent per billion cubic feet. Here again, the probabilities are two out of three that the actual volume does not vary from the estimated volume by more than this percentage. The error of the volume in standard cords was not computed but it should be approximately the same.

Board-foot volume.--The standard error of the total board-foot volume estimate was ± 1.4 percent.

Growth.--Estimates of timber growth are based on measurements of radial growth in sample trees, and on mortality data taken on sample plots. Because of technical problems involved, no attempt was made to compute the sampling error of growth estimates.

Timber cut.--Estimates of the amount of timber cut were based on the number and size of stumps tallied on cutover plots. Stumps of all trees cut during the 3-year period preceding date of inventory were recorded, and the measurements were converted into tree volume. The average volume of timber cut for the 3-year period was taken as the annual estimate. The standard error for the total volume of growing stock cut was ± 4.3 percent, or ± 3.8 percent per billion cubic feet. Estimates of the volume cut by product were made using the best available statistics on production.

Use of county data.--The tables showing forest area, timber volumes, and timber cut by county are included to permit grouping of the data in any desired area combinations. In designing the survey, provision was made for controlling the range of sampling error on a county basis. However, comparison or use of individual county statistics should be avoided because of the possibility that they may be subject to considerable error. It is recommended that area or volume data for a minimum of five counties be combined, and that at least 10 counties be used when working with data on timber cut.

The actual range of errors on county data are shown below:

<u>Item</u>	<u>Percent of Error</u>	
	<u>Low</u>	<u>High</u>
Forest area	± 0.9	± 12.3
Growing stock volume	± 7.0	± 15.7
Board-foot volume	± 6.9	± 23.4

HOW THE FOREST INVENTORY IS MADE

The present system of inventory is a two-step method which includes land-use classification of points on aerial photographs followed by the cruising of ground sample plots. The county is the basic work unit. The detailed procedure is as follows:

1. Preliminary estimates of the acreage of land in forests and other land-use classes are obtained by classifying points printed on every third aerial photograph in alternate flight lines within a county. The proportion of points falling in each class is used to estimate the acreage. This estimate is later checked and revised through the use of ground plots.

2. Ground sample plots are selected in a systematic manner from the forest land classifications made in Step 1, using an interval which will provide sufficient plots to meet established limits of error per billion cubic feet of timber. This results in a proportional sample of all existing timber stands. Timber cruisers make a detailed description and tally of the ground plots to obtain data on timber volume, quality, stocking, and mortality. Samples of agricultural and other photo classifications are also checked on the ground to verify or adjust the area estimates based on these classifications.

3. Growth estimates are based on increment borings taken proportionally from sample trees of various diameters and species in each forest type and stand class. The volume of timber cut is computed from a tally of the stumps of trees cut on the plots during a specified period.

4. All field data are sent to Asheville for editing and are placed on punch cards for machine sorting and tabulation. Final estimates are based on statistical summaries of the data.
