Virginia

Department of Conservation and Development
Division of Forestry

George W. Dean, State Forester

FOREWORD

Through the McSweeney-McNary Act of 1928, Congress authorized the Secretary of Agriculture to conduct a comprehensive survey of the forest resources of the United States. The Forest Survey was organized by the Forest Service to carry out the provisions of the Act through the Regional Forest Experiment Stations. In the southeastern states the Forest Survey is an activity of the Division of Forest Economics, Southeastern Forest Experiment Station, Asheville, North Carolina.

The five-fold purpose of the Forest Survey is (1) to make a field inventory of the present supply of standing timber, (2) to ascertain the rate at which this supply is being increased through growth, (3) to determine the rate at which it is being reduced through industrial and domestic uses, fire, and other causes, (4) to determine the present consumption and the probable future trend in requirements for forest products, and (5) to interpret and correlate these findings to aid in the formulation of private and public policies regarding forest land management.

ACKNOWLEDGMENTS

The Southeastern Station received material assistance on the field phase of the Survey and wishes to acknowledge this cooperation. The Virginia Division of Forestry furnished personnel and equipment for one field crew, and the pulp and paper companies listed below contributed funds through Virginia Forests, Inc., to finance a second crew.

Camp Manufacturing Company	Johns-Manville Products Corp.
Chesapeake Corp. of Virginia	Mead Corporation
Continental Can Company	National Container Corp. of Va.
P. H. Glatfelter Company	West Virginia Pulp and Paper Co.

The Division of Forest Economics at the Southeastern Station is under the direction of J. F. McCormack. Collection of field data was supervised by Ronald C. Froelich and aerial photo interpretation was done by W. H. B. Haines. Other staff assistance was as follows:

<u>Field inventory</u>	<u>Office compilation</u>
Hubert H. Broyles	Woodfin Black
M. H. Goforth	Eunice Gamble
Frank H. Hawley	Agnes Nichols
Philip L. Howard	Louise Shuford
Davie L. Hunt	Sammy Wenningham
Herbert A. Knight	Camilla Young

FOREST STATISTICS FOR THE COASTAL PLAIN

OF VIRGINIA, 1956

The Coastal Plain of Virginia lies in the eastern quarter of the State extending from the Potomac River to the North Carolina line (fig. 1). It includes 30 counties on the Virginia mainland west of Chesapeake Bay and the 2 counties on the Eastern Shore. The topography is rather flat along the coast and Chesapeake Bay, becoming gently rolling near the boundary with the Piedmont. The Potomac, Rappahannock, York, and James Rivers break the central and northern portion of the Coastal Plain into three long peninsulas extending in a southeasterly direction to Chesapeake Bay.

The first Forest Survey of Virginia was made in 1940. In the spring of 1956 a resurvey of the State was begun to obtain up-to-date statistics on forest area, timber volume, growth, and amount of timber cut. This is the first of three progress reports to be issued before publication of a statistical report for the entire State; and it covers the Virginia Coastal Plain, which is designated as Survey Unit Number 1.

Comparison of the results of the two surveys is made in the following pages to point out changes and trends that have taken place in the 16-year interval. In order to permit true comparisons, the 1940 data were examined carefully and adjustments were made to eliminate differences resulting from changes in standards and definitions.

Area estimates of forest and other land use classes were based on examination of 46,000 points systematically spaced on aerial photographs. Subsamples of 1,386 photo points classified as forest and 383 classified as nonforest were visited on the ground. Data from these field sample plots were used to adjust for changes in land use since date of photography, as well as to provide detailed information on forest conditions.

PRESENT CONDITION AND RECENT TRENDS

Small increase in forest land area.--The 1956 Survey shows that 4.1 million acres or 65 percent of the land in the Coastal Plain is forested (table 1). This is an increase of 4.4 percent or 172,000 acres since 1940. All but 49,000 acres or 99 percent of the total forest area is suitable and available for timber production. The 49,000 acres of unproductive forest land and productive public forest land withdrawn from timber production is about double the area reported in 1940. This increase results mainly from use of forest land in defense installations for target impact areas and other uses that render the timber unsuitable or the areas unsafe for timber harvest operations.

Figure 2.--Change in land use, 1940 to 1956.

Forest land predominately in farm ownership.--Sixty-nine percent of the commercial forest land in the Virginia Coastal Plain was on farms (fig. 3). Nineteen percent was owned by pulp and paper companies, sawmills, and other wood-using industries, and nine percent was in other private ownerships. Federal, state, county, and municipal

Figure 3.--Ownership of commercial forest land, 1956.

Agricultural land, including land in cultivation, pasture, and idle or resting cropland, has been reduced 17 percent in the past 16 years. About half of this reduction in agricultural land reverted to forest, 7 percent was covered by small bodies of water, and 40 percent was utilized in expanded urban areas, suburban developments, roads, airports, and other nonforest and nonagricultural uses (fig. 2).

ownerships accounted for the other three percent. Forest land ownership estimates were based primarily upon classification of each of the 1,370 ground sample plots established on forest land. The only exception was that of public ownership, which received a 100-percent canvass to determine acreages and policy on timber production.

Area of forest owned by wood-using industries has increased 51 percent since 1940. Farm and other private ownership figures for the 1940 and 1956 Forest Surveys cannot be compared because of differences in sources of data and in definitions used. An analysis of Census of Agriculture figures shows a 6.5-percent reduction in farm woodland area between 1939 and 1954.

Area of pine types decreased 8 percent.--Comparisons made using the 1940 forest type definitions show a drop of 185,000 acres or 8 percent in pine and mixed pine-hardwood types during the period between surveys. This trend to hardwood types resulted partly from the

preferred use of the pines, and also from the steady buildup of hardwood stocking in all tree-size classes. The increased proportion of hardwoods in forest stands would cause some shifts from pine to hardwood forest types even in stands where the pine component remained unchanged. Pine type area decreases were 124,000 acres for loblolly pine, 34,000 acres for Virginia pine, and 27,000 acres for shortleaf pine (fig. 4). Since 1940 the proportion of pine types has dropped from 62 percent to 55 percent of the commercial forest area in the Coastal Plain.

Figure 4.--Comparison of the 1940 and 1956 commercial forest area by forest type. Pine-hardwood types are included with the pine types.

Pine sawtimber volume holding steady.--The board-foot volume of pine timber dropped only 2 percent in the past 16 years (table A), but there is now a larger proportion of the volume in the smaller trees. The volume in pines 15.0 inches d.b.h. or larger dropped 17 percent, as compared to an increase of 7 percent in the smaller sawtimber trees.

Table A.--Comparison of sawtimber volumes, 1940 and 1956

Species group	1940 ^{1/}	1956	Change	
	Million bd.-ft.	Million bd.-ft.	Million bd.-ft.	Percent
Yellow pines	7,536	7,398	-138	-2
Other softwoods	337	255	-82	-24
Soft hardwoods	2,936	3,182	+246	+8
Hard hardwoods	2,671	4,265	+1,594	+60
All species	13,480	15,100	+1,620	+12

^{1/} Original survey volumes have been recomputed to eliminate differences resulting from changes in standards between the two surveys. Thus, the 1940 estimate shown here will not agree with volumes previously published.

During the period between Forest Surveys, hardwood sawtimber volumes increased in all sizes for an overall rise of 33 percent. A closer examination reveals that the volume of the more preferred soft hardwood group dropped more than one-third in the diameters above 20 inches, while hard hardwoods of similar size increased sharply.

Total growing stock increased 14 percent.--Cubic-foot volume of sound trees 5.0 inches d.b.h. or larger increased 14 percent since 1940 (table B). Pines remained constant, while the small component of cedar and cypress dropped 28 percent, netting a one-percent decrease for all softwoods. Hardwood cubic volume jumped 33 percent during the 16 years.

Table B.--Comparison of volumes in all trees 5.0 inches d.b.h. or larger, 1940 and 1956

Class of material and species group	1940 ^{1/}	1956	Change	
	<u>Million cu. ft.</u>	<u>Million cu. ft.</u>	<u>Million cu. ft.</u>	<u>Percent</u>

All species	423	394	-29	-7
All live trees	4,555	5,123	+568	+12

^{1/} See footnote 1, table A.

^{2/} Less than 0.5 percent change.

As shown in figure 5, hardwood growing stock volume made a spectacular increase in the smaller diameters, but changed little

in the large diameters. A slight gain in the volume of smaller softwood trees was about balanced by a drop in the volume of larger trees.

Figure 5.--Comparison of 1940 and 1956 growing stock volume by tree diameter.

A start has been made in reducing cull-tree volume.--Cubic volume of cull trees has dropped 7 percent since 1940, as indicated in table B. The decrease is in the hardwoods and is greatest in the smaller diameters. It seems probable that the recent widespread cultural operations on larger private holdings have already created a measurable effect. Pulp and paper companies and a few other large forest owners have cut, bulldozed, girdled, or poisoned large areas of inferior hardwoods in an effort to reestablish pine stands either through planting or natural reseeding.

In spite of the small decrease in cull volume, about 8 percent of the total cubic volume is still in cull trees. About nine-tenths of this volume is in trees classified as sound culls. These trees are considered unsuitable for saw logs, mainly because of roughness, but much of their volume could be used for pulpwood or other products not requiring straight or clear sections.

Net growth of pine sawtimber is over one-half billion board-feet.--The net annual growth of sawtimber in the Virginia Coastal Plain was estimated at 836 million board-feet for 1956 (table 18). Pine accounted for 514 million board-feet, or a little over 60 percent of the total. The rate of net growth on sawtimber was about 7 percent for pines, 2 percent for other softwoods, 4.5 percent for soft hardwoods, and 4 percent for hard hardwoods (table 19).

Hard hardwood increase held in check.--Sawtimber volume increased during 1956 in each species group except the hard hardwoods (table 21). In that category, timber cut almost equaled growth, and volume dropped in the amount of natural mortality. Total growing stock in each species group also increased but, here again, hard hardwoods were at the bottom of the list. This seems odd in view of the large increases in hard hardwood volume and area of upland hardwood type since 1940. The explanation is found in recent cultural operations aimed at reestablishing pine stands in areas occupied partially or entirely by low-value hardwoods. These cutting, poisoning, girdling, and bulldozing operations were started only recently but have already covered a considerable area in the Virginia Coastal Plain.

Table 1.--Gross area^{1/} by broad use class, 1956

^{1/} Estimates of timber cut by county are less accurate than inventory volumes, and use of individual county statistics should be avoided. For general use, data for a minimum of 10 counties should be combined.

DEFINITION OF TERMS

Land-Use Classes

Forest land: Includes (a) lands which are at least 10 percent stocked with trees of any size and capable of producing sawtimber or other wood products, and (b) lands from which the trees described in (a) have been removed to less than 10-percent stocking but which have not been developed for other use; subdivided into the following classes:

Commercial: Forest land which is (a) producing, or physically capable of producing, usable crops of wood (usually sawtimber), (b) economically available now or in the future, and (c) not withdrawn from timber use.

Noncommercial: Forest land (a) withdrawn from timber utilization through statute, ordinance, or administrative order but which otherwise qualifies as commercial forest land, or (b) incapable of yielding usable wood products (usually sawtimber) because of adverse site conditions, or so physically inaccessible as to be unavailable economically in the foreseeable future.

Nonforest land: Includes land under cultivation or in pasture where the timber has been cleared to less than 10 percent stocking, idle or abandoned agricultural land, marsh land, and land in urban, residential, or industrial areas, school yards, cemeteries, roads, railroads, and other rights-of-way.

Water: Includes lakes, bays, and estuaries over 40 acres in size, and streams, canals, and sloughs at least one-eighth of a mile in width which are classed as "inland water" by the Bureau of the Census. Smaller lakes and ponds between one acre and 40 acres in size, and waterways between 120 feet and 660 feet in width, which are classed as land area by the Bureau of the Census, are also included as water areas.

Forest Types

Forest type is determined on the basis of cubic volume for all stand sizes except seedlings and saplings (stand size 4), in which case the number of stems is the criterion.

Yellow pine types: Forests in which 50 percent or more of the cubic volume or number of stems in the stand is loblolly, pond, shortleaf, or Virginia pine. In mixtures the predominating species determines the type.

Hardwood-pine type: Forests in which 50 percent or more of the stand is in hardwoods, but in which southern yellow pine species make up 25 to 49 percent of the stand.

Oak-hickory type: Upland hardwood forests in which 50 percent or more of the stand is composed of upland oak, hickory, yellow-poplar, soft maple, and other hardwood species, except in cases where yellow pines make up 25 to 49 percent and the stand would be classified as oak-pine.

Oak-gum-cypress type: Bottomland forests in which 50 percent or more of the stand is tupelo, blackgum, sweetgum, ash, lowland oak, elm, soft maple, cypress, and other associated species, except where pines comprise 25 to 49 percent of the stand.

Stand-Size Classes

Sawtimber: Stands containing at least 1,500 board-feet net volume per acre, International 1/4-inch log rule, in sound, live, softwood trees 9.0 inches d.b.h. or larger, or hardwood trees 11.0 inches d.b.h. or larger. Two classes of sawtimber stands are recognized:

Large sawtimber: Stands of sawtimber having more than 50 percent of the net board-foot volume in trees 15.0 inches d.b.h. or larger.

Small sawtimber: Stands of sawtimber having 50 percent or more of the net board-foot volume in trees smaller than 15.0 inches d.b.h.

Poletimber: Stands failing to meet the minimum sawtimber specifications, but at least 10 percent stocked with trees 5.0 inches d.b.h. or larger and with at least half the minimum stocking in pole-size trees.

Seedling and saplings: Stands not qualifying as sawtimber or poletimber stands, but having at least a 10-percent stocking of trees of commercial species and with half the minimum stocking in seedlings and saplings.

Nonstocked and other areas: Forest areas not qualifying as sawtimber, poletimber, or seedling and sapling stands.

Diameters

D.b.h. (diameter at breast height): Stem diameter in inches, outside bark, measured at 4-1/2 feet above the ground.

Diameter class: All trees were tallied by 2-inch diameter classes, each class including diameters 1.0 inch below and 0.9 inch above the stated midpoint, e.g., trees 7.0 to and including 8.9 inches are included in the 8-inch class. Corresponding limits apply to other diameter classes.

Timber Quality Classification

Growing Stock

Sawtimber trees: Live softwood trees 9.0 inches d.b.h. or larger and hardwood trees 11.0 inches d.b.h. or larger, with a sound volume of at least 50 percent of the gross board-foot volume up to the point of minimum saw-log merchantability. To be considered sound, a saw log must be at least 8 feet long, must be at least 50 percent sound, and must meet the following additional requirements:

Softwood logs^{1/} must have a scaling diameter of 6 inches or more, and sweep or crook must not exceed one-third of the scaling diameter per 8 feet of log length.

Hardwood logs must have a scaling diameter of 8 inches or more and must pass specifications^{2/} for standard lumber logs or tie and timber logs.

Sound poletimber trees: Straight-boled trees between 5.0 inches d.b.h. and sawtimber size that can be expected to become sawtimber.

Sound saplings: Trees 1.0 inch to 4.9 inches d.b.h. which show promise of growing into sawtimber.

Other Material

Sound cull trees: Live trees of all sizes that are unmerchantable for saw logs now or prospectively because of species, poor form, excessive limbiness, or other sound defect.

Rotten cull trees: Live trees of all sizes that are unmerchantable for saw logs now or prospectively because of rotten defect.

Species Groups

Yellow pines: Includes loblolly, pond, shortleaf, and Virginia pine.

Other softwoods: Cypress, eastern redcedar, and Atlantic whitecedar.

Soft hardwoods: Blackgum, tupelo, yellow-poplar, sweetgum, cottonwood, soft maple, basswood, magnolia, sweetbay, willow, elm, hackberry, sycamore, and black cherry.

Hard hardwoods: All the oaks, hickories, ash, beech, hard maple, river birch, black walnut, black locust, honey locust, mulberry, sourwood, dogwood, holly, and persimmon.

^{1/} For detailed specifications of log grades, see "Interim log grades for southern pine." Southern Forest Expt. Station, 18 pp. 1953.

^{2/} For detailed hardwood log grade specifications, see "Hardwood log grades for standard lumber: proposals and results." U. S. Forest Products Laboratory, D1737. 1949.

Volume Estimates

Board-foot volume: The volume in board-feet, measured by the International 1/4-inch rule, exclusive of defect, of that portion of sound sawtimber trees between the stump and the upper limit of merchantability for saw logs.

Volume in cords: For sound trees the volume in standard cords (including bark) of the sound portion of trees 5.0 inches d.b.h. or larger, between stump and a minimum top stem diameter of 4.0 inches inside bark. Similar volumes are given for cull trees.

Volume in cubic feet: Cubic-foot volume of the same material shown in cords except that bark is not included.

International 1/4-inch log rule: A rule for estimating the board-foot volume of 4-foot log sections, according to the formula $V = .905 (0.22D^2 - 0.71D)$. The taper allowance for computing the volume in log lengths greater than four feet is 0.5 inch per 4-foot section. Allowance for saw kerf is 1/4 inch.

Standard cord: A stacked pile, 4 x 4 x 8 feet, of round or split bolts, estimated to contain, on the average, about 74 cubic feet of solid wood.

Growth and Timber Cut

Net growth.--The growth on trees that were of volume size at the beginning of the year and the ingrowth resulting from smaller trees growing into volume size during the year, minus the partial loss of growth on trees that died or were cut during the year and the loss of volume in trees dying from natural causes during the year. Net growth is based on growth of sound trees. Growth on "Other material" is not included.

In board-feet: The change during the calendar year in sawtimber volume resulting from growth, ingrowth, and mortality losses.

In cubic feet or cords: The change during the calendar year in the volume of all sound trees 5.0 inches and larger resulting from growth, ingrowth, and mortality losses.

Timber cut.--The volume of timber cut is based on the measurement and tally of stumps found on regular ground sample plots. Stumps of all trees cut during the past 3-year period are recorded and the measurements are converted into equivalent tree volume. The average yearly volume of timber cut for the 3-year period is then taken as the annual estimate. Board-foot volumes include the saw-log portion of all sawtimber-size trees which were cut. Estimates in cubic feet or cords include the entire stem from stump to 4.0-inch top of all sound trees 5.0 inches in diameter and larger. Timber cut from cull or dead trees is not included.

Stocking

Stocking is the extent to which growing space is effectively utilized by trees. The number of stems present by d.b.h. classes was used as a basis for stocking classification. Areas having the minimum numbers of trees listed below, either in a single diameter class or proportionately in any combinations of diameter classes, were considered fully stocked.

<u>D.b.h.</u>	<u>Minimum number trees per acre</u>
Seedlings	1,000
2 inches	800
4 inches	590
6 inches	400
8 inches	240
10 inches	155
12 inches	115
14 inches	90

RELIABILITY OF FOREST SURVEY DATA

In general, the errors which affect the accuracy of Forest Survey area and timber volume estimates arise from two sources. These may be described as (1) sampling errors which result from using sampling procedures rather than making a complete inventory or canvass, and (2) non-sampling errors which arise from human mistakes in judgment, measurement, recording, or arithmetic.

In Forest Survey work a diligent effort is made to maintain a high degree of accuracy in the collection and compilation of data. The sampling errors are held to a specified minimum through survey design and sampling technique. These errors are the only measurable errors involved in computing the reliability of the data. The non-sampling errors are minimized or eliminated through training, supervision, field check cruises, and complete editing and machine verification in compiling the data.

Forest area.--The sampling intensity of the 1956 survey provided an estimate of the total forest area with a standard error of ± 0.7 percent. The probabilities were two out of three that the actual forest area was within ± 0.7 percent of the estimated acreage. The standard error per million acres was ± 1.4 percent.

Cubic volume.--The standard error of the net cubic-foot volume estimate was ± 2.4 percent, or ± 5.2 percent per billion cubic feet. Here again, the probabilities were two out of three that the actual volume did not vary from the estimated volume by more than these percentages. The error of the volume in cords was not computed, but it should have been approximately the same as for cubic volume.

Board-foot volume.--The standard error of the total board-foot volume estimate was ± 2.9 percent.

Growth.--Estimates of timber growth were based on measurements of radial growth on 3,696 sample trees, and on mortality data taken on sample plots. Because of technical problems involved, no attempt was made to compute the sampling error of growth estimates.

Timber cut.--Estimates of the amount of timber cut were based on the number, size, and species of stumps tallied on cutover plots. Stumps of all trees cut during the 3-year period preceding the date of inventory were included, and the measurements were converted into tree volume. The average volume of timber cut for the 3-year period was taken as the annual estimate. The standard error for the total volume of growing stock cut was ± 8.8 percent, or ± 3.7 percent per billion cubic feet.

Use of county data.--The tables showing forest area, timber volumes, and timber cut by county are included to permit grouping of the data in any desired area combinations. In designing the survey, provision was made for controlling the range of sampling error on a county basis. However, comparison or use of individual county statistics should be avoided because of the possibility that they may be subject to considerable error. It is recommended that area or volume data for a minimum of five counties be combined, and that at least 10 counties be used when working with data on timber cut.

The actual range of errors in county data are as follows:

<u>Item</u>	<u>Percent of error</u>	
	<u>Low</u>	<u>High</u>
Forest area	± 1.1	± 6.2
Growing stock volume	± 8.0	± 13.1
Board-foot volume	± 8.9	± 14.6

HOW THE FOREST INVENTORY IS MADE

The present system of inventory is a two-step method which includes land-use classification of points on aerial photographs followed by the cruising of ground sample plots. The county is the basic work unit. The detailed procedure is as follows:

1. Preliminary estimates of the acreage of land in forests and other land-use classes are obtained by classifying points printed on every third aerial photograph in alternate flight lines within a county. The proportion of points falling in each class is used to estimate the acreage. This estimate is later checked and revised through the use of ground plots.

2. Ground sample plots are selected in a systematic manner from the forest land classifications made in Step 1, using an interval which will provide sufficient plots to meet established limits of error per billion cubic feet of timber. This results in a proportional sample of all existing timber stands. Timber cruisers make a detailed description and tally of the ground plots to obtain data on timber volume, quality, stocking, mortality, and timber cut. Samples of agricultural and other photo classifications are also checked on the ground to verify or adjust the area estimates based on these classifications.

3. Growth estimates are based on increment borings taken proportionally from sample trees of various diameters and species in each forest type and stand class. The volume of timber cut is computed from a tally of the stumps of trees cut on the plots during a specified period.

4. All field data are sent to Asheville for editing and are placed on punch cards for machine sorting and tabulation. Final estimates are based on statistical summaries of the data.
