In cooperation with the
NORTH CAROLINA
DEPARTMENT OF CONSERVATION AND DEVELOPMENT
DIVISION OF FORESTRY
F. H. Claridge - State Forester

FOREWORD

Through the McSweeney-McNary Act of 1928, Congress authorized the Secretary of Agriculture to conduct a comprehensive survey of the forest resources of the United States. The Forest Survey was organized by the Forest Service to carry out the provisions of the Act through the Regional Forest Experiment Stations. In the Southeastern states the Forest Survey is an activity of the Division of Forest Economics of the Southeastern Forest Experiment Station, Asheville, North Carolina.

The five-fold purpose of the Forest Survey is (1) to make a field inventory of the present supply of standing timber, (2) to ascertain the rate at which this supply is being increased through growth, (3) to determine the rate at which it is being reduced through industrial and domestic uses, fire, and other causes, (4) to determine the present consumption and the probable future trend in requirements for forest products, and (5) to interpret and correlate these findings to aid in the formulation of private and public policies regarding forest land management.

The forest resources of the State of North Carolina were originally inventoried by the Forest Survey during the period 1937-38, and these findings have been published. A resurvey of the Southern Coastal Plain was made in 1952 and the statistics were published in Forest Survey Release No. 41, September 1953. The survey has now been completed in the Northern Coastal Plain and is continuing in other areas of the State.

ACKNOWLEDGMENTS

The Southeastern Station gratefully acknowledges the cooperation of Fred H. Claridge, State Forester, for providing personnel and equipment for a portion of the field survey.

Forest survey work at the Southeastern Station is under the direction of James W. Cruikshank. Training and field supervision were provided by Robert W. Larson and L. C. Nix. Photo interpretation was done by R. C. Aldrich and mensurational work by Mackay B. Bryan. Office compilation was under the supervision of Agnes Nichols, assisted by Louise Sanford, Sammy Weeningham, Eunice Gamble, and Camilla Young.

FOREST STATISTICS FOR THE NORTHERN COASTAL PLAIN
OF NORTH CAROLINA, 1955

This is a progress report on the resurvey of forest resources in North Carolina which is now under way. It presents statistical data on forest area, timber volumes, growth, and the amount of timber cut for the 23-county area in the Northern Coastal Plain (fig. 1). The basic information was obtained between January 1954 and February 1955 from 1,920 one-fifth acre forest sample plots. In addition, 375 non-forest plots were checked on the ground to improve the accuracy of the forest area estimate. Procedures used in conducting the survey are described in more detail on page 44.

This area was first inventoried by the Forest Survey in 1937. Since then, vast quantities of timber have been cut, and new stands have grown up to replace the old. Changes in land use and ownership have been widespread. Improvement in forest protection and management practices have also had an effect on the timber stands which exist today. The trends and changes pointed out in the following pages all stem from a comparison of statistics for both surveys. Data for the 1937 survey were adjusted wherever necessary to remove differences due to definition or other standards used, so that valid comparisons could be made.

HIGHLIGHTS AND TRENDS FOUND BY THE 1955 SURVEY

Forest area
now 9 percent greater.--The 23 counties in the Northern Coastal Plain of North Carolina contain a total land area of 6.7 million acres. In 1955, forests were found to occupy 4.4 million acres, or about two-thirds of the area. Since 1937 the acreage of forest land has increased 357 thousand acres, a gain of 9 percent. Cropland, pasture, and other agricultural uses occupy

Figure 2.--Use of land in the Northern Coastal Plain of North Carolina.

1.9 million acres, and extensive areas of marsh and sand dunes exist in the coastal region. The proportions of land in forest and agricultural use are almost identical with those found in the Southern Coastal Plain in 1952.

Increases in forest area occurred in all but 4 of the 23 counties. Heaviest gains were recorded in the western portion of the unit and in the area north of Albemarle Sound, where abandonment of farmland in past years has been a contributing factor.

The Tidewater country in the eastern portion of the unit is a low, flat, poorly drained area containing broad expanses of swamp and pocosin. The word "pocosin" is believed to be of Indian origin meaning "swamp on a hill," and it describes a forest type peculiar to the coastal plain. An elevated rim around the circumference prevents adequate drainage. In the central portion of these pocosins a deep muck soil and a high water table permit only scrubby timber growth. Over 260 thousand acres of pocosin were classed as unproductive forest land because of inability to produce timber suitable for commercial use.

The bulk of the commercial forest acreage is in farm woodlands which contain 2.4 million acres, or 58 percent of the total. Industrial and other private owners hold 1.6 million acres, making the total area in private ownership slightly more than 4.0 million acres. Public ownership of commercial forest land amounts to 94 thousand acres, or only about 2 percent. Most of it is in the Croatan National Forest and the Cherry Point Marine Air Station in Carteret and Craven Counties, and along the right-of-way of the Intracoastal Waterway.

Figure 3.--Change in area of forest types, 1937 to 1955.

Acreage of pine types reduced.--A comparison of forest areas for the two surveys reveals a decrease of 412 thousand acres in pine forest types (fig. 3). The proportion of pine types existing in 1937 was 69 percent, but only 58 percent of the plots were classified as pine in 1955. In making this comparison, the 1937 type specifications were used for both surveys to provide a valid estimate of change.

Conversion of pine types to hardwoods has shown up as a persistent trend in the Coastal Plain area of North Carolina and in other areas of the Southeast as well. It usually occurs when the more valuable pine

species are cut out of mixed stands, leaving hardwoods to occupy the available growing space. To make matters worse, the residual hardwood stands often contain a high proportion of poor-quality material.

Small trees rise sharply in number.--The number of trees in all classes up to 16 inches in diameter shows a marked increase in both softwood and hardwood species groups, while the larger trees show decreases (fig. 4). These changes result from a number of factors which have influenced the development and structure of the forest stands in recent years.

Increases in the number of small trees are largely the result of better forest protection and a rapid rate of growth. A very promising feature of the change is the 64-percent increase in number of 2- and 4-inch pine trees. This means there are 150 million more young pine saplings in the present stands which will form an important part of the oncoming crop of timber. Pines in the pole and small sawtimber sizes have also made gains.

It is also apparent from figure 4 that increases in small hardwood trees of volume size have been considerably greater than in pine. This change has been brought about by continued heavy cutting of the preferred pine species. The larger, more valuable trees in both species groups have also declined in number because of heavy use. Changes in timber volume which are discussed on the following pages can be traced directly to these changes in stand structure.

Figure 4.--Change in number of sound trees since 1937.

Pine sawtimber volume holds its own.--One important highlight of the 1955 survey is the fact that yellow pine sawtimber volume has held up very well in spite of heavy demand in recent years. There is now less longleaf, loblolly, and shortleaf pine but more pond pine available. Pond pine is usually found on wet or swampy sites and is less accessible. Losses in large trees have been offset by increases in small trees. The net result is a slight increase in total pine volume as indicated in table A.

Table A.--Comparison of sawtimber volume, 1937 and 1955

Species group	1937 ^{1/}	1955	Change	
	<u>Million bd. ft.</u>	<u>Million bd. ft.</u>	<u>Million bd. ft.</u>	<u>Percent</u>
Yellow pines	9,064	9,142	+ 78	+ 1
Cypress and cedar	1,228	934	-294	-24
Hardwoods	5,777	6,218	+441	+ 8
All species	16,069	16,294	+225	+ 1

^{1/} Original survey volumes have been recomputed to allow for differences in standards between the two surveys and to provide a uniform basis for comparison. Thus, the 1937 estimates shown here will not agree with the volumes previously published.

Throughout the range of yellow pine in this unit many stands are found growing on excellent sites. The sawtimber stands have better than average stocking, and the average volume per acre is probably the highest to be found anywhere in the State. Under these conditions, growth has been able to replace the amount of pine cut and used for all the various industrial and domestic purposes. However, a larger proportion of the board-foot volume is now found in small sawtimber trees.

During the period between surveys hardwood sawtimber increased by 441 million board feet, or 8 percent, while the volume of cypress and whitecedar went down nearly 25 percent. Cypress and cedar are durable species much in demand for boat and water tank construction. The drain on whitecedar has been particularly heavy, reducing the volume of this species by nearly 65 percent. There were slight decreases in the volume of blackgum, sweetgum, and yellow-poplar, and heavy increases in other hardwoods, particularly oaks.

Loblolly pine is principal species.--The most important timber tree in the Northern Coastal Plain is loblolly pine. This species alone, with a volume in excess of 7 billion board feet, makes up 75 percent of the softwood and 45 percent of the total sawtimber volume (fig. 5). Pond pine and cypress are the only other softwood species of any consequence. In the hardwoods, tupelo, black, and sweetgum are the predominating species and together they make up 60 percent of the volume in hardwood sawtimber trees.

Figure 5.--Volume of sawtimber by species.

Nearly half of the available sawtimber is in trees which measure 12 and 14 inches in diameter at breast height, a point four and one-half feet above ground (fig. 6). More than 80 percent is in trees less than 19 inches in size. The proportion of hardwood volume in each diameter class increases with tree size. Starting at 35 percent in the 12-inch class, it runs to more than 60 percent in trees 22 inches and larger.

Figure 6.--Distribution of sawtimber volume by diameter class.

Growing stock up 8 percent.--Since 1937, the volume of growing stock has increased 8 percent. However, as table B indicates, the trends for the various species groups have differed widely. Pine volume is up slightly, hardwoods show a very substantial increase, and cypress and cedar suffered a heavy loss. The opposite trends in softwood species leave the total softwood volume practically unchanged since the original survey. The major increase is in hardwood species.

Growing stock is a term which includes all sound pole-size trees (starting at 5.0 inches in diameter) as well as the larger sawtimber trees. Volumes of solid wood, excluding bark, are computed in terms of cubic feet. Trees smaller than 5 inches in diameter are called seedlings or saplings, and they are not assigned volume for inventory purposes.

Table B.--Comparison of volume in all trees 5.0 inches d.b.h. and larger, 1937 to 1955

GROWING STOCK				
Species group	1937 ^{1/}	1955	Change	
	<u>Million cu. ft.</u>	<u>Million cu. ft.</u>	<u>Million cu. ft.</u>	<u>Percent</u>
Yellow pines	2,247	2,324	+ 77	+ 3
Cypress and cedar	287	224	- 63	- 22
Hardwoods	1,741	2,079	+338	+ 19
All species	4,275	4,627	+352	+ 8

CULL TREES				
Yellow pines	97	85	- 12	- 12
Cypress and cedar	13	27	+ 14	+108
Hardwoods ^{2/}	456	702	+246	+ 54
All species	566	814	+248	+ 44

^{1/} See footnote 1, table A.

^{2/} Excludes limb volume of hardwood sawtimber trees.

The amount of material in cull trees, particularly hardwoods, also increased sharply. In both surveys tree quality was judged on the ability to produce merchantable saw logs either at the time of inventory or in the future. The cull tree volumes shown in table A are contained in trees too crooked, limby, or rotten to be cut into logs. However, they are not entirely worthless. Many of them can be used to produce fence posts, pulpwood, fuelwood, and other products where clear length, straightness, and soundness are not limiting factors. The increase in cull hardwood volume poses a difficult problem in forest management. These trees occupy valuable growing space which could be used for the production of higher grade material, yet, since they cannot pay their way, they are seldom removed from the stand in commercial saw-log operations.

Annual growth of growing stock totals 3.3 million cords; saw-timber growth 824 million board feet.--Forests in the Northern Coastal Plain are producing an annual volume of timber equal to 3.3 million cords of wood, including bark, or 227 million cubic feet of solid wood. This amount includes ingrowth and the growth which takes place on all sound trees 5.0 inches d.b.h. and larger. Yellow pines are producing at the rate of 1.8 million cords per year, or about 55 percent of the total growth of all species. Growth on sawtimber-size trees amounted to 824 million board feet, of which 68 percent was pine.

Estimates of volume growth are based on increment cores taken from thousands of sample trees throughout all counties in the unit. These cores are used to determine the rate of tree diameter growth. They also indicate the number of young trees which may be expected to grow into volume size during the course of a year, thus establishing the volume of ingrowth. Net growth is arrived at by subtracting timber mortality losses by insects, disease, fire, and other natural causes from the total growth estimate. Ingrowth from sapling trees makes up approximately 10 percent of the net growth in growing stock, and trees growing from pole to sawtimber size make up about one-fourth of the increase in board-foot volume.

In terms of growth per acre, stands of loblolly pine show the highest rate of production, with an average of 325 board feet, or 1.1 cords, per year. Stands in all forest types and conditions averaged 226 board feet, or 0.9 cord, per acre per year. These rates for Unit 2 are about one-third higher than those found in the Southern Coastal Plain, reflecting better stocking and site conditions. The average production of 423 board feet per acre per year in stands of loblolly pine sawtimber will probably be the highest rate found anywhere in North Carolina.

Timber supply is building up.--A comparison of growth with the amount of timber cut shows that timber volumes are gradually increasing (table C). Sawtimber cut for all purposes exceeded 500 million board feet, but the excess of growth over the amount cut left a gain of 268 million feet. A parallel trend was found in growing stock, where nearly half of the total amount of wood produced was left to build up the supply.

Table C.--Comparison of net annual growth and timber cut

Species group	Sawtimber			Growing stock		
	Growth	Cut	Change	Growth	Cut	Change
	Million board feet			Million cubic feet		
Yellow pines	563.4	398.4	+165.0	125.8	85.4	+ 40.4
Cypress and cedar	22.5	21.7	+ .8	5.1	5.2	- .1
Hardwoods	238.0	135.6	+102.4	96.2	34.1	+ 62.1
All species	823.9	555.7	+268.2	227.1	124.7	+102.4

This favorable trend was found in all species groups except cypress and whitecedar, which are relatively slow-growing species and which are still being cut heavily. The annual rate of increase on growing stock ranges from 1.7 percent for pine to 3.0 percent for the soft hardwood species.

In the previous discussion of stand structure it was pointed out that small hardwood trees are increasing in number more rapidly than pine. This trend also shows up in the volume change resulting from the interaction of growth, timber cutting, and mortality. The annual increase in hardwood sawtimber makes up only 38 percent of the gain in board-foot volume, but the increase in hardwood growing stock is 61 percent of the total. The tendency for hardwoods to increase can be expected to continue in the future unless the utilization of these species can be stimulated.

^{1/} Estimates of timber drain by county are less accurate than inventory volumes, and use of individual county statistics should be avoided. For general use, data for a minimum of 10 counties should be combined.

DEFINITION OF TERMS

Land-Use Classes

Forest land: Includes (a) lands which are at least 10 percent stocked with trees of any size and capable of producing sawtimber or other wood products, and (b) lands from which the trees described in (a) have been removed to less than 10-percent stocking but which have not been developed for other use; subdivided into the following classes:

Commercial: Forest land which is (a) producing, or physically capable of producing, usable crops of wood (usually sawtimber), (b) economically available now or in the future, and (c) not withdrawn from timber use.

Noncommercial: Forest land (a) withdrawn from timber utilization through statute, ordinance, or administrative order but which otherwise qualifies as commercial forest land, or (b) incapable of yielding usable wood products (usually sawtimber) because of adverse site conditions, or so physically inaccessible as to be unavailable economically in the foreseeable future.

Nonforest land: Includes land under cultivation or in pasture where the timber has been cleared to less than 10 percent stocking, idle or abandoned agricultural land, marsh land, and land in urban, residential, or industrial areas, school yards, cemeteries, roads, railroads, and other rights-of-way.

Water: Includes lakes, bays, and estuaries over 40 acres in size, and streams, canals, and sloughs at least one-eighth of a mile in width which are classed as "inland water" by the Bureau of the Census. Smaller lakes and ponds between one acre and 40 acres in size, and waterways between 120 feet and 660 feet in width, which are classed as land area by the Bureau of the Census, are also included as water areas.

Forest Types

Forest type is determined on the basis of cubic volume for all stand sizes except seedlings and saplings (stand size 4), in which case the number of stems are the criteria.

Pine types: Forests in which 50 percent or more of the stand is in pine species. Plurality of volume or number of trees is used to determine the specific type.

Oak-pine type: Forests in which 50 percent or more of the stand is hardwoods, usually upland oaks, but in which southern yellow pines make up 25-49 percent of the stand.

Oak-hickory type:

Upland hardwood: Forests in which 50 percent or more of the stand is composed of upland oak, hickory, yellow-poplar, maple, gum, and other hardwoods, except where pines comprise 25-49 percent of the stand.

Scrub oak: Upland forests in which 50 percent or more of the stand is composed of scrub oak species, except where pines comprise 25-49 percent of the stand.

Oak-gum-cypress type: Bottomland forests in which 50 percent or more of the stand is tupelo, blackgum, sweetgum, ash, oak, elm, maple, in mixture with cypress and other associated species, except where pines comprise 25-49 percent of the stand.

Stand-Size Classes

Sawtimber: Stands containing at least 1,500 board feet net volume per acre, International 1/4-inch log rule, in sound, live, softwood trees 9.0 inches d.b.h. or larger, or hardwood trees 11.0 inches d.b.h. or larger. Two classes of sawtimber stands are recognized:

Large sawtimber: Stands of sawtimber having more than 50 percent of the net board-foot volume in trees 15.0 inches d.b.h. or larger.

Small sawtimber: Stands of sawtimber having 50 percent or less of the net board-foot volume in trees 15.0 inches d.b.h. or larger.

Poletimber: Stands failing to meet the minimum sawtimber specifications, but at least 10-percent stocked with trees 5.0 inches d.b.h. or larger and with at least half the minimum stocking in pole-size trees.

Seedling and saplings: Stands not qualifying as sawtimber or poletimber stands, but having at least a 10-percent stocking of trees of commercial species and with half the minimum stocking in seedlings and saplings.

Nonstocked and other areas: Forest areas not qualifying as sawtimber, poletimber, or seedling and sapling stands.

Diameters

D.b.h. (diameter at breast height): Stem diameter in inches, outside bark, measured at 4-1/2 feet above the ground.

Diameter class: All trees were tallied by 2-inch diameter classes, each class including diameters 1.0 inch below and 0.9 inch above the stated midpoint, e.g., trees 7.0 to and including 8.9 inches are included in the 8-inch class. Corresponding limits apply to other diameter classes.

Timber Quality Classification

Growing Stock

Sawtimber trees: Live softwood trees at least 9.0 inches d.b.h. and hardwood trees at least 11.0 inches d.b.h., with not less than one merchantable log 12 feet long, or with less than 50 percent of the gross volume of the tree in sound sawtimber. To be merchantable all saw logs must be at least 8 feet long and at least 50 percent sound. They must also meet the following requirements:

Softwood logs^{1/} must have a scaling diameter of 6 inches or larger, and sweep or crook must not exceed two-thirds of the scaling diameter.

Hardwood logs must have a scaling diameter of 8 inches or larger and must pass specifications^{2/} for standard lumber logs, or tie and timber logs.

Poletimber trees: Straight-boled trees between 5.0 inches d.b.h. and sawtimber size.

Sapling-size trees: Trees 1.0 inch to 4.9 inches d.b.h. which will grow into poletimber or sawtimber-size trees of sound quality.

Other Material

Sound cull trees: Live trees of all sizes that are unmerchantable for saw logs now or prospectively because of species, poor form, excessive liminess, or other sound defect.

Rotten cull trees: Live trees of all sizes that are unmerchantable for saw logs now or prospectively because of rotten defect.

Hardwood limbs: The limb volume of all hardwood sawtimber and cull trees to a minimum diameter of 4.0 inches inside bark.

Species Groups

Yellow pines: Includes longleaf, slash, loblolly, pond, Virginia, and shortleaf pine.

Other softwoods: Cypress, eastern redcedar, and Atlantic whitecedar.

Soft hardwoods: Blackgum, tupelo, yellow-poplar, sweetgum, cottonwood, soft maple, basswood, willow, sweetbay, sycamore, and hackberry.

Hard hardwoods: All of the oaks, hickories, ash, beech, river birch, black locust, mulberry, black walnut, holly, dogwood, and persimmon.

^{1/} For detailed specifications of log grades, see "Interim log grades for southern pine". Southern Forest Experiment Station, 18 pp. 1953.

^{2/} For detailed hardwood log grade specifications, see "Hardwood log grades for standard lumber: proposals and results". U. S. Forest Products Laboratory, D1737, 1949.

Volume Estimates

Board-foot volume: The volume in board feet, measured by the International 1/4-inch rule, exclusive of defect, of that portion of sound sawtimber trees between the stump and the upper limit of merchantability for saw logs.

Volume in cords: For sound trees the volume in standard cords (including bark) of the sound portion of trees 5.0 inches d.b.h. and larger, between stump and a minimum top-stem diameter of 4.0 inches inside bark. Similar volumes are given for cull trees. The volume in limbs, which are at least 4.0 inches in diameter inside bark, is shown separately for all sawtimber-size hardwoods.

Volume in cubic feet: Same as volume shown in cords except bark is not included.

International 1/4-inch log rule: A rule for estimating the board-foot volume of 4-foot log sections, according to the formula $V = .905 (0.22D^2 - 0.71D)$. The taper allowance for computing the volume in log lengths greater than four feet is 0.5 inch per 4-foot section. Allowance for saw kerf is 1/4 inch.

Standard cord: A stacked pile, 4 x 4 x 8 feet, of round or split bolts, estimated to contain, on the average, about 74 cubic feet of solid wood.

Growth and Timber Cut

Net growth.--The estimated volume of net growth includes the growth on the present growing stock, the growth on trees which died or were cut during the year, and the ingrowth resulting from smaller trees reaching volume size. It excludes mortality, or loss of volume in trees dying from natural causes. Net growth estimates are based on growth of sound trees. Growth of "other material" is not included.

In board feet: The change during the calendar year in sawtimber volume resulting from growth, ingrowth, and mortality losses.

In cubic feet or cords: The change during the calendar year in the volume of all sound trees 5.0 inches and larger resulting from growth, ingrowth, and mortality losses.

Timber cut.--The volume of timber cut is based on the measurement and tally of stumps found on regular ground sample plots. Stumps of all trees cut during the past 3-year period are recorded and the measurements are converted into equivalent tree volume. The average yearly volume of timber cut for the 3-year period is then taken as the annual estimate. Board-foot volumes include the saw-log portion of all sawtimber-size trees which were cut. Estimates in cubic feet or cords include the entire stem from stump to 4.0-inch top of all sound trees 5.0 inches in diameter and larger. Timber cut from cull or dead trees is not included.

Stocking

Stocking is the extent to which growing space is effectively utilized by trees. The number of stems present by d.b.h. classes was used as a basis for stocking classification. Areas having the minimum numbers of trees listed below, either in a single diameter class or proportionately in any combinations of diameter classes, were considered fully stocked.

<u>D.b.h.</u>	<u>Minimum number trees per acre</u>
Seedlings	1,000
2 inches	800
4 inches	590
6 inches	400
8 inches	240
10 inches	155
12 inches	115
14 inches	90

RELIABILITY OF FOREST SURVEY DATA

In general, the errors which affect the accuracy of Forest Survey area and timber volume estimates arise from two sources. These may be described as (1) sampling errors which result from using sampling procedures rather than making a complete inventory or canvass, and (2) non-sampling errors which arise from human mistakes in judgment, measurement, recording, or arithmetic.

In Forest Survey work a diligent effort is made to maintain a high degree of accuracy in the collection and compilation of data. The sampling errors are held to a specified minimum through survey design and sampling technique. These errors are the only measurable errors involved in computing the reliability of the data. The non-sampling errors are minimized or eliminated through training, supervision, field check cruises, and complete editing and machine verification in compiling the data.

Forest area.--The sampling intensity of the 1955 survey provided an estimate of the total forest area in the State with a standard error of ± 0.7 percent. The probabilities are two out of three that the actual forest area is within ± 0.7 percent of the estimated acreage. The standard error per million acres was ± 1.5 percent.

Cubic volume.--The standard error of the net cubic-foot volume estimate was ± 2.1 percent, or ± 4.5 percent per billion cubic feet. Here again, the probabilities are two out of three that the actual volume does not vary from the estimated volume by more than this percentage. The error of the volume in standard cords was not computed but it should be approximately the same.

Board-foot volume.--The standard error of the total board-foot volume estimate was ± 2.4 percent.

Growth.--Estimates of timber growth are based on measurements of radial growth in sample trees, and on mortality data taken on sample plots. Because of technical problems involved, no attempt was made to compute the sampling error of growth estimates.

Timber cut.--Estimates of the amount of timber cut were based on the number and size of stumps tallied on cutover plots. Stumps of all trees cut during the 3-year period preceding date of inventory were recorded, and the measurements were converted into tree volume. The average volume of timber cut for the 3-year period was taken as the annual estimate. The standard error for the total volume of growing stock cut was ± 9.5 percent, or ± 3.4 percent per billion cubic feet.

Use of county data.--The tables showing forest area, timber volumes, and timber cut by county are included to permit grouping of the data in any desired area combinations. In designing the survey, provision was made for controlling the range of sampling error on a county basis. However, comparison or use of individual county statistics should be avoided because of the possibility that they may be subject to considerable error. It is recommended that area or volume data for a minimum of five counties be combined, and that at least 10 counties be used when working with data on timber cut.

The actual range of errors on county data are shown below:

<u>Item</u>	<u>Percent of error</u>	
	<u>Low</u>	<u>High</u>
Forest area	± 1.6	± 7.7
Growing stock volume	± 6.6	± 16.9
Board-foot volume	± 7.1	± 19.1

HOW THE FOREST INVENTORY IS MADE

The present system of inventory is a two-step method which includes land-use classification of points on aerial photographs followed by the cruising of ground sample plots. The county is the basic work unit. The detailed procedure is as follows:

1. Preliminary estimates of the acreage of land in forests and other land-use classes are obtained by classifying points printed on every third aerial photograph in alternate flight lines within a county. The proportion of points falling in each class is used to estimate the acreage. This estimate is later checked and revised through the use of ground plots.

2. Ground sample plots are selected in a systematic manner from the forest land classifications made in Step 1, using an interval which will provide sufficient plots to meet established limits of error per billion cubic feet of timber. This results in a proportional sample of all existing timber stands. Timber cruisers make a detailed description and tally of the ground plots to obtain data on timber volume, quality, stocking, and mortality. Samples of agricultural and other photo classifications are also checked on the ground to verify or adjust the area estimates based on these classifications.

3. Growth estimates are based on increment borings taken proportionally from sample trees of various diameters and species in each forest type and stand class. The volume of timber cut is computed from a tally of the stumps of trees cut on the plots during a specified period.

4. All field data are sent to Asheville for editing and are placed on punch cards for machine sorting and tabulation. Final estimates are based on statistical summaries of the data.
