FOREST STATISTICS FOR SOUTHWEST GEORGIA, 1951

This progress report presents statistical data on forest area and timber volumes for 22 counties in Southwest Georgia designated as Survey Unit No. 2 (fig. 1). The data were obtained from a resurvey of the forest resources in the State which was started in July 1950. Field work for the Southwest Georgia Unit was completed in April 1951. The land area and timber volume estimates are based on combined use of aerial photographs and ground sample plots.

The original Forest Survey of Southwest Georgia was made in 1934. Comparisons of the statistics from both surveys have been made to determine the changes and trends which have taken place during the past 16-year period.

1951 HIGHLIGHTS AND SIGNIFICANT CHANGES

Small increase in forest land area: The Southwest Georgia Survey Unit encloses a total land area of 5.6 million acres, of which 54 percent, or nearly 3.1 million acres, is occupied by forests (fig. 2). During the period between surveys the acreage of forest land increased 37 thousand acres, or about 1.2 percent. Most of the remaining land area is in agricultural use, with 37 percent classified as active and 6 percent as idle. Other land uses such as urban and industrial areas, rights-of-way, etc. occupy only 3 percent of the total land area.

Nearly 98 percent of the forest land in the Unit is in private ownership, the remainder being held by Federal, State, or county and municipal agencies. Farmers own 85 percent of the private forest acreage. Practically all of the forest land can be considered commercial in character, since less than 100 acres are included in parks or other areas where timber cutting is not permitted.

Figure 2.--Land use in Southwest Georgia, 1951

Pine forest types decrease in area: The extent of the forest area in pine types has decreased materially since 1936. Acreage comparisons

based on type definitions used in the original survey indicate that the area of longleaf, slash, and other pine types decreased more than 400 thousand acres, or 16 percent. This acreage has been taken over largely by hardwoods, with the greatest increase in the bottomland hardwood type (fig. 3).

Figure 3.--Change in area of forest types, 1934 to 1951

These shifts in the composition of the forests are primarily the result of cutting practices used in harvesting timber. Where stands of pine are mixed with hardwoods or cypress, the preferred pine timber is often cut, leaving the less desirable species to occupy the site.

Under resurvey standards which divide the forest into types on the basis of cubic volume or number of stems, the pine types still predominate, occupying more than 1.8 million acres, or 60 percent of the forest land. Hardwood types, including hardwood-pine mixtures, occur on 1.1 million acres, or 37 percent, and the cypress type occupies the remaining 3 percent.

Large increase in young timber: The number of sound trees in the sapling, pole, and small saw-timber size classes increased sharply during the period between surveys. This increase occurred in all species groups and amounted to 75 percent, or more than 300 million trees. The hardwood species groups exhibit the greatest gain, particularly the hard-textured hardwoods including the oaks and hickories. The changes by species group and diameter class are shown in table A.

Table A.--Percent change in the number of sound trees by species
group and diameter class

D.b.h. class (inches)	Pine	Cypress	Soft-textured hardwoods	Hard-textured hardwoods	All species
2	+22	+107	+194	+183	+105
4	+18	+ 61	+166	+230	+ 73
6	+17	+ 87	+ 51	+119	+ 36
8	+18	+ 56	+140	+130	+ 42
10	+28	+ 44	+171	+217	+ 59
12	+17	+ 94	+ 79	+ 61	+ 33
14	- 4	+ 59	+ 66	+ 72	+ 16
16	-10	- 10	+ 24	+ 72	+ 5
18	-20	- 29	+ 40	+ 43	+ 1
20+	-30	- 11	- 27	+ 58	- 14
All diameters	+19	+ 83	+160	+177	+ 75
All trees 6" and larger	+16	+ 68	+ 83	+118	+ 37

Considering only the trees 5.0 inches d.b.h. or larger, the number of pine trees increased 16 percent. This increase is due entirely to a greater number of trees in the 6-inch to 12-inch diameter classes. In contrast, the number of pine trees in the larger, more valuable sizes decreased heavily, showing the effects of more intensive utilization. Similar trends are exhibited by the cypress and soft-textured hardwood groups, although the decrease in the larger sizes was not as heavy. Trees in the hard-textured hardwood group show increases in number throughout all diameter classes, indicating that the impact of timber cutting was not as heavy on the oaks, hickories, and other hard hardwoods.

Some of the increase in the number of smaller trees is undoubtedly due to a shift from old-growth to second-growth conditions. However, most of the change may be attributed to more intensive fire protection. Other measures, including better cutting practices, reforestation, and more conservative turpentining programs, have also had their effect.

The number of cull trees in the stand has also shown an appreciable increase since 1934 with most of the added volume being in rotten cull hardwoods. Trees with any marked degree of defect, either sound or rotten, are seldom removed in cutting operations. Thus, cull trees tend to accumulate in the stand unless silvicultural measures are taken to remove them.

Saw-timber volume increases 13 percent: Saw-timber trees in Southwest Georgia contain a total volume of 5.5 billion board feet. The predominating pine species make up 3.8 billion, or 69 percent, of this total. The volume of hardwood saw timber amounts to 1.4 billion board feet, or 26 percent, and cypress accounts for the remaining 5 percent. A comparison of the 1951 board-foot inventory volume with the volume found in 1934 shows an over-all increase of 13 percent. The pine volume increased only slightly, but the volumes of hardwood and cypress species were up 42 percent, as shown in table B.

Table B.--Change in volume of saw timber, 1934 to 1951

Species group	1934 ^{1/}	1951	Change
	<u>Million</u> <u>bd. ft.</u>	<u>Million</u> <u>bd. ft.</u>	<u>Percent</u>
Pines	3,716	3,835	+ 3
Hardwoods	1,005	1,429	+42
Cypress	187	266	+42
All species	4,908	5,530	+13

^{1/} Original survey volumes have been recomputed to allow for changes in standards between surveys and to provide a uniform basis for comparison. Thus, they will not agree with volumes previously published.

Slash pine is the most abundant species, with longleaf pine next in importance. Together, these two species make up nearly three-fourths of the pine saw-timber volume and more than half of the total volume including all species. Most of the pine board-foot volume is in small trees. The 10- to 12-inch diameter class contains 52 percent, the 14- to 18-inch contains 38 percent, and only 10 percent is found in trees 20 inches d.b.h. or larger. The size of the average pine saw-timber tree is 11.9 inches in diameter at breast height.

Hardwood sawlog quality poor: The board-foot volume of hardwood saw-timber trees is largely of poor quality. Using hardwood log-grade rules developed by the Forest Products Laboratory, based on specifications of the National Hardwood Lumber Association, only 16 percent of the net hardwood volume qualified as select or grade 1, and 24 percent as grade 2. The remaining 60 percent is almost equally divided between grade 3A logs, which contain a large proportion of low-grade factory lumber, and grade 3B logs, which are primarily suitable for cross ties and timbers.

In contrast, 20 percent of the softwood sawlog volume was grade 1, nearly half was grade 2, and only one-third was classified as grade 3. The softwood trees were graded using rules adapted from the Crossett Log Grades.

Sound growing stock volume increases 21 percent: The total growing stock volume is computed in terms of cubic feet and standard cords. It includes trees of pole-timber size (5.0 to 8.9 inches d.b.h. for softwoods and 5.0 to 10.9 inches d.b.h. for hardwoods) as well as the larger saw-timber trees. Trees below 5.0 inches in size are considered saplings or seedlings and are not assigned volumes for inventory purposes.

During the past 16-year period the volume of primary (sound tree) growing stock increased 288 million cubic feet, a gain of 21 percent. As shown in table C, there was a small but encouraging increase in pine volume, and the volumes of both hardwood and cypress timber were up sharply.

Table C.--Change in volume of all trees 5.0 inches d.b.h. and larger, 1934 to 1951

Species group	Primary growing stock			Secondary growing stock		
	1934 ^{1/}	1951	Change	1934 ^{1/}	1951	Change
	<u>Million</u> <u>cu. ft.</u>	<u>Million</u> <u>cu. ft.</u>	<u>Percent</u>	<u>Million</u> <u>cu. ft.</u>	<u>Million</u> <u>cu. ft.</u>	<u>Percent</u>
Pines	1,037	1,087	+ 5	11	34	+209
Hardwoods	298	508	+70	159	342	+115
Cypress	56	84	+50	6	9	+ 50
All species	1,391	1,679	+21	176	385	+119

^{1/} See footnote 1, table B.

^{2/} Limb volume of saw-timber-size hardwood trees excluded.

The increase in sound growing stock volume in terms of cubic feet or cords is, of course, due primarily to the large increase in the number of small trees. Pine timber makes up about two-thirds of the total cubic volume and hardwoods account for most of the remainder.

The cubic volume of secondary growing stock (cull trees) has more than doubled during the period. The increase in cull pine timber amounts to more than 200 percent, but the actual increase in volume is small. However, the increase in cull hardwood volume is significant in terms of volume. It means that two out of every five hardwood trees 5.0 inches d.b.h. and larger were culls from the standpoint of sawlog merchantability, either now or prospectively. The tremendous increase in hardwood volume, much of it cull or of low quality, is one of the most serious problems facing forest managers today.

Considerable acreage will require planting: About 280 thousand acres of forest land in the seedling and sapling and poorly-stocked stand-size classes are less than 40 percent stocked with sound trees and lack the necessary seed trees to restock the areas naturally. These idle acres will require planting if they are to be made reasonably productive in the near future. About half of the acreage is suitable for the operation of tractor-drawn planting machines, and the rest would require hand planting, since the areas needing planting are less than 10 acres in size, or because ground conditions would prohibit the use of planting machinery. This classification was limited to the pine, hardwood-pine, and upland hardwood forest types where the planting of pine seedlings could be commercially profitable.

Gum naval stores activity diminishes: The number of slash and longleaf pines being worked has decreased by nearly four and one-half million trees, or 32 percent, since 1934. The number of resting trees is down 54 percent, and four-fifths of the worked-out trees have disappeared. The acreage of slash and longleaf stands in working timber crops is also down sharply, having dropped from 850 thousand acres to about 340 thousand. On the other hand, the number of round trees 9.0 inches or larger in diameter which are suitable for gum-farming has more than doubled during the period.

Timber stocking pattern varied: Considering all sound trees of seedling, sapling, and larger sizes, about one-third of the forest land was found to be in a poorly-stocked or nonstocked condition, having less than 40 percent of the required number of trees per acre. The productivity of these lands will be low until they are restocked either naturally or through planting programs.

At the other extreme, 38 percent of the forest land was found to be in an overstocked condition, having more than the required number of trees for full stocking. In time, the stocking in many of these stands will be reduced through natural mortality or other agencies, but there are undoubtedly many areas which will require silvicultural treatment to prevent stagnation and provide for a reasonable rate of growth.

^{1/} Sound wood and bark. Limbs of sound sawlog-size hardwoods are included in secondary growing stock volumes.

DEFINITION OF TERMS

Land-Use Classes

Forest land. Includes (a) lands which are at least 10 percent stocked with trees of any size and capable of producing saw timber or other wood products, and (b) lands from which the trees described in (a) have been removed to less than 10-percent stocking but which have not been developed for other use; subdivided into the following classes:

Commercial: Forest land which is (a) producing, or physically capable of producing, usable crops of wood (usually saw timber), (b) economically available now or in the future, and (c) not withdrawn from timber use.

Noncommercial: Forest land which is (a) incapable of yielding wood products (usually saw timber) because of adverse site conditions, or (b) so inaccessible as to be permanently unavailable economically, and (c) not withdrawn for specific purposes.

Reserved: Public forest land that has been withdrawn from timber utilization through statute, ordinance, or administrative order.

Reserved commercial: Reserved forest land that otherwise qualifies as commercial forest land.

Reserved noncommercial: Reserved forest land that otherwise qualifies as noncommercial forest land.

Non-forest land. Includes land in any of the following classes:

Active agriculture: Land under cultivation or in pasture including farm yards and work lots.

Pasture: Land under fence used primarily for grazing purposes where the timber has been cleared to less than 10-percent stocking and a real attempt to produce a sod has been made.

Idle agriculture: Land previously cultivated or pastured but now idle or abandoned and having less than a ten-percent stocking of forest trees.

Marsh: Low, wet areas characterized by a heavy growth of grass and reeds and an absence of timber.

Urban and other areas: Includes towns, residential and industrial suburban areas, school yards, cemeteries, roads, railroads, power lines, and other rights-of-way.

Water. Includes lakes, bays, and estuaries over 40 acres in size, and streams, canals, and sloughs at least one-eighth of a mile in width which are classed as "inland water" by the Bureau of the Census. Smaller lakes and ponds between one acre and 40 acres in size, and waterways between 120 feet and 660 feet in width, which are classed as land area by the Bureau of the Census, are also included as water areas.

Forest Types

Forest type is determined on the basis of cubic volume for all stand sizes except seedlings and saplings (stand size 4), in which case the number of stems are the criteria.

Pine types: Forests in which 50 percent or more of the stand is in pine species. The predominating pine species is used to determine the specific pine type.

Hardwood-pine types: Forests in which 50 percent or more of the stand is composed of hardwood species, but which contain 25 to 50 percent pine.

Lowland hardwood type: Forests on low, moist, or wet sites in which 50 percent or more of the stand is mixed hardwoods including tupelo, black gum, sweetgum, ash, oak, elm, soft maple, and cottonwood, except where pine comprises 25 to 50 percent of the stand.

Cypress type: Bottomland forests in which 50 percent or more of the stand is cypress, except where pines comprise 25 to 50 percent of the stand.

Oak-hickory type: Forests in which 50 percent or more of the stand is upland oaks, hickory, yellow-poplar, gums, and other hardwoods, except where pines comprise 25 to 50 percent of the stand.

Scrub oak type: Forests in which 50 percent or more of the stand is composed of scrub oak species, except where pines comprise 25 to 50 percent of the stand.

Stand-Size Classes

Saw timber. Stands containing at least 1,500 board feet net volume per acre, 1/4-inch log rule, in sound, live, softwood trees 9.0 inches d.b.h. or larger, or hardwood trees 11.0 inches d.b.h. or larger. Two classes of saw-timber stands are recognized:

Large saw timber: Stands of saw timber having more than 50 percent of the net board-foot volume in trees 15.0 inches d.b.h. or larger.

Small saw timber: Stands of saw timber having 50 percent or less of the net board-foot volume in trees 15.0 inches d.b.h. or larger.

Pole timber. Stands failing to meet the minimum saw-timber specifications, but at least 10-percent stocked with trees 5.0 inches d.b.h. or larger and with at least half the minimum stocking in pole-size trees.

Seedling and saplings. Stands not qualifying as saw-timber or pole-timber stands, but having at least a 10-percent stocking with half the minimum stocking in seedlings and saplings.

Nonstocked and other areas. Forest areas not qualifying as saw-timber, pole-timber, or seedling and sapling stands.

Diameters

D.b.h. (diameter at breast height). Stem diameter in inches, outside bark, measured at 4-1/2 feet above the ground.

Diameter class. All trees were tallied by 2-inch diameter classes, each class including diameters 1.0 inch below and 0.9 inch above the stated midpoint, e.g., trees 7.0 to and including 8.9 inches are included in the 8-inch class. Corresponding limits apply to other diameter classes.

Growing Stock Classification

Primary Growing Stock.

Sound saw-timber trees: Live softwood trees at least 9.0 inches d.b.h. and hardwood trees at least 11.0 inches d.b.h., with not less than one merchantable log 12 feet long, or with less than 50 percent of the gross volume of the tree in sound saw timber.

Sound pole-timber trees: Straight-boled trees between 5.0 inches d.b.h. and saw-timber size.

Sound sapling-size trees: Trees 1.0 inch to 4.9 inches d.b.h. which will grow into pole- or saw-timber size trees of sound quality.

Secondary Growing Stock.

Sound cull trees: Live trees of all sizes that fail to qualify as sound timber because of poor form, excessive limbiness, or

other sound defect. Volumes shown for sound cull trees also include the limbs, in sections four feet long and at least 4.0 inches in diameter inside bark, of sound saw-timber size hardwoods. Scrub oak and noncommercial species such as ironwood, blue beech, sassafras, etc., are included in this group.

Rotten cull trees: Live trees of all sizes that fail to qualify as sound timber because of rotten defect.

Species Groups

Yellow pines. Includes longleaf, slash, loblolly, pond, and shortleaf pine.

Other softwoods. Pond cypress, baldcypress, eastern redcedar, and Atlantic white cedar.

Soft-textured hardwoods. Black and tupelo gum, yellow-poplar, sweetgum, cottonwood, soft maple, basswood, magnolia, sweetbay, and willow.

Hard-textured hardwoods. All of the oaks, hickories, ash, beech, elm, river birch, hackberry, sycamore, black locust, mulberry, black walnut, holly, dogwood, and persimmon.

Volume Estimates

Board-foot volume. The volume in board feet, measured by the International 1/4-inch rule, exclusive of defect, of that portion of sound saw-timber trees between the stump and the upper limit of merchantability for sawlogs.

Volume in cords. For sound trees the volume in standard cords (including bark) of the sound portion of trees 5.0 inches d.b.h. and larger, between stump and a minimum top-stem diameter of 4.0 inches inside bark. Similar volumes are given for cull trees. The volume in limbs, in sections four feet long and at least 4.0 inches in diameter inside bark, of sound saw-timber size hardwoods is included as sound cull material.

Volume in cubic feet. Same as volume shown in cords except bark is not included.

International 1/4-inch log rule. A rule for estimating the board-foot volume of 4-foot log sections, according to the formula $V = .905 (0.22D^2 - 0.71D)$. The taper allowance for computing the volume in log lengths greater than four feet is 0.5 inch per 4-foot section. Allowance for saw kerf is 1/4 inch.

Standard cord. A stacked pile, 4 x 4 x 8 feet, of round or split bolts, estimated to contain, on the average, about 74 cubic feet of solid wood.

Gum Naval Stores Conditions

Round timber. A minimum of 15 longleaf and slash pine trees 9.0 inches d.b.h. or larger per acre that have not been worked for naval stores.

Working. Longleaf and slash pine trees that are now being worked for naval stores.

Front-faced: Turpentine tree species on which the front or first face is now being worked.

Back-faced: Turpentine tree species on which the front face has been worked out and on which a back (second or third, etc.) face is being worked.

Resting. Longleaf and slash pine trees with a worked-out or abandoned front face and on which back-facing has not been started.

Worked-out. Longleaf and slash pine trees on which two or more faces have been worked out and with no possibility of supporting another face.

Stocking

Stocking is the extent to which growing space is effectively utilized by trees. The number of stems present by d.b.h. classes was used as a basis for stocking classification. Areas having the minimum numbers of trees listed below, either in a single diameter class or proportionately in any combinations of diameter classes, were considered fully stocked.

<u>D.b.h.</u>	<u>Minimum number trees per acre</u>
Seedlings	1,000
2 inches	800
4 inches	590
6 inches	400
8 inches	240
10 inches	155
12 inches	115
14 inches	90

RELIABILITY OF FOREST SURVEY DATA

In general, the errors which affect the accuracy of Forest Survey area and timber volume estimates arise from two sources. These may be described as (1) sampling errors which result from using sampling procedures rather than making a complete inventory or canvass, and (2) non-sampling errors which arise from human mistakes in judgment, measurement, recording, or arithmetic.

In Forest Survey work a diligent effort is made to maintain a high degree of accuracy in the collection and compilation of data. The sampling errors are held to a specified minimum through survey design and sampling technique. These errors are the only measurable errors involved in computing the reliability of the data. The non-sampling errors are minimized or eliminated through training, supervision, field check cruises, and complete editing and machine verification in compiling the data.

Forest area. The sampling intensity of the 1951 survey was sufficient to provide an estimate of the total forest acreage in the Unit with a standard error of ± 1.0 percent. The probabilities are two out of three that the estimated forest acreage is within ± 1.0 percent of the actual acreage.

Cubic volume. The standard error of the 1951 net cubic-foot volume in the Unit was ± 2.8 percent. Here again, the probabilities are two out of three that the estimated volume does not vary from the actual volume by more than this percentage. The standard error of the volume in cords was not computed but it should be approximately the same.

Board-foot volume. The standard error of the 1951 estimate of board-foot volume in the Unit was ± 3.1 percent.

Use of county data. The tables showing area and timber volumes by county are included to permit grouping of the data in any desired combinations. The survey was designed so that the number of sample plots taken in each county would provide an estimate of the timber volume in cubic feet which would not exceed ± 15 percent. The actual range of error of the cubic volume estimates by county is from ± 7.0 percent to ± 14.7 percent. The errors of board-foot volume estimates by county range from ± 6.9 percent to ± 15.2 percent, and of forest area from ± 2.3 percent to ± 4.8 percent.

In spite of the accuracy limit set on volume estimates by county, comparison of individual county statistics may be subject to considerable error and should be avoided. Grouping the data for a number of counties will increase the reliability and make the combined estimates sufficiently accurate for general use. For example, grouping the timber volume data for four counties with errors ranging from 11 to 15 percent resulted in a total volume estimate with only 7 percent error.

HOW THE FOREST INVENTORY IS MADE

The present system of inventory is a two-step method which includes land-use classification of points on aerial photographs followed by the cruising of ground sample plots. The county is the basic work unit. The detailed procedure is as follows:

1. Preliminary estimates of the acreage of land in forests and other land-use classes are obtained by classifying points printed on every third aerial photograph in alternate flight lines within a county. The proportion of points falling in each class is used to estimate the acreage. This estimate is later checked and revised through the use of ground plots.

2. Ground sample plots are selected in a systematic manner from the forest land classifications made in Step 1, using an interval which will provide sufficient plots to meet established limits of error per billion cubic feet of timber. This results in a proportional sample of all existing timber stands. Timber cruisers make a detailed description and tally of the ground plots to obtain data on timber volume, quality, stocking, and mortality. Samples of agricultural and other photo classifications are also checked on the ground to verify or adjust the area estimates based on these classifications.

3. Growth estimates are based on increment borings taken proportionally from sample trees of various diameters and species in each forest type and stand class. The volume of timber drain is computed from a tally of the stumps of trees cut on the plots during a specified period.

4. All field data are sent to Asheville for editing and are placed on punch cards for machine sorting and tabulation. Final estimates are based on statistical summaries of the data.
