TALLAHASSEE, FLORIDA
C. H. COULTER, State Forester

FOREWORD

Through the McSweeney-McNary Act of 1928, Congress authorized the Secretary of Agriculture to conduct a comprehensive survey of the forest resources of the United States. The Forest Survey was organized by the Forest Service to carry out the provisions of the Act through the Regional Forest Experiment Stations. In the Southeastern states the Forest Survey is an activity of the Division of Forest Economics of the Southeastern Forest Experiment Station, Asheville, North Carolina.

The five-fold purpose of the Forest Survey is (1) to make a field inventory of the present supply of standing timber, (2) to ascertain the rate at which this supply is being increased through growth, (3) to determine the rate at which it is being reduced through industrial and domestic uses, fire, and other causes, (4) to determine the present consumption and the probable future trend in requirements for forest products, and (5) to interpret and correlate these finds to aid in the formulation of private and public policies regarding forest land management.

The State of Florida was inventoried by the Forest Survey in the period 1934-36 and reports presenting the findings have been published. Since then, better forest management, more intensive forest use, changes in land use, and other factors have caused changes in the forest growing stock that can only be measured accurately by on-the-ground surveys. Field work on a resurvey of the forest resources of Florida was completed in August 1949. This progress report presents area and volume statistics of the resurvey in Northwest Florida (Survey Unit No. 2). Statistical reports covering Northeast Florida (Survey Unit No. 1) and Central Florida (Survey Unit No. 3) have already been published. When complete statistical data for the State are available, an analytical report will be prepared which will interpret these statistics and focus attention upon the principal forest problems.

ACKNOWLEDGMENTS

The author gratefully acknowledges the assistance received from C. H. Coulter, State Forester, and his staff in facilitating the Survey work and in providing additional personnel to augment and intensify the collection of data in the field.

The Division of Forest Economics is under the direction of James W. Cruikshank. The timber inventory field work was under the supervision of Mackay B. Bryan. Photo interpretation work was done by N. F. Force, R. C. Aldrich, and R. W. Cooper. Sample plot work was under the direction of Fritz Lorentzen, E. W. Vetter, M. W. McClure, W. A. McCarty, H. W. Allen, E. A. Schluter, Ben Juskie, and F. S. Hill.

Office compilation of the data was under the direction of Miss Agnes Creasman, assisted by Mrs. Christine Paxton, Miss Priscilla Walker, and Miss Camilla Young.

FOREST RESOURCES OF NORTHWEST FLORIDA

The data presented in this publication were obtained from a resurvey of the forest resources of Florida during the period from June 1948 to August 1949. This report covers the group of 16 counties in Northwest Florida designated Survey Unit No. 2 (fig. 1). The field work was based on the combined use of aerial photography and ground plot examination to obtain current statistics on forest area and timber volumes. The original Forest Survey of this area was completed in 1934, and by comparing the current statistics with those of the original survey the changes which have taken place in the past 14 years can be determined.

1949 FACTS AND SIGNIFICANT CHANGES

Acreage of forest land: Nearly 6.1 million acres of land in Northwest Florida were classed as forest land in 1949. Of this total, 5.9 million acres were found to be in productive forests. No significant change in the area of forest land occurred between the original survey in 1934 and the resurvey of 1949. The Northwest Florida Survey Unit, with 83 percent of the total land area in forests, has the highest proportion of forest land found in the State.

Area in softwood forest types decreases: Northwest Florida exhibits the same trend in recent type changes that was found in the other areas of the State, but the changes are not as extensive. Since 1934, pine types on commercial forest land have decreased in area from 4.6 million acres to 4.2 million acres, a decline of 9 percent. The area occupied by hardwood types has increased from 1.2 million acres to 1.6 million acres, or 33 percent. Pine types are still predominant, since they occupy 71 percent of the commercial forest land area.

Saw-timber volume decreases: The total volume of saw timber in 1949 was 6.3 billion board feet. This total includes 525 million board feet in hardwood trees 12 inches d.b.h., which were not considered saw timber in the original survey. To place the data on a comparable basis, the present volume in these 12-inch hardwoods has been omitted.

Table A.--Change in volume of saw timber, 1934 to 1949

Species group	: 1934	: 1949	: Change
	<u>Thousand</u> <u>bd. ft.</u>	<u>Thousand</u> <u>bd. ft.</u>	<u>Percent</u>
Pines	3,982,600	3,822,900	- 4
Hardwoods ^{1/}	2,261,800	1,621,200	-28
Cypress ^{2/}	623,500	369,100	-41
All species	6,867,900	5,813,200	-15

^{1/} Excludes volume of hardwoods 12 inches d.b.h.

^{2/} Includes volume of cedar.

Only 14 percent of forest area is in saw timber: Stands of saw timber containing 1,500 board feet or more per acre were found on only 14 percent of the commercial forest land. Of the remaining forest area, 19 percent is occupied by stands of pole timber, 17 percent by stands of seedlings and saplings, and 50 percent is either unstocked or lightly stocked with scattered trees (see definition of stand size classes, p. 30). No direct comparisons of forest area by stand class are possible between the original and current surveys because different standards were used.

Total sound-tree volume decreases slightly: The net cubic-foot volume of all sound trees 5.0 inches and larger decreased 2 percent during the period. However, the decrease was entirely in the hardwood and cypress species groups and was nearly balanced by an increase in the volume of pine.

The volume of sound wood in cull trees increased heavily in the hardwood species group. This same trend has been found in other areas of the State.

Table B.--Change in volume of all trees 5.0 inches d.b.h. and larger,
1934 to 1949

Species group:	Sound tree volume			Cull tree volume		
	1934	1949	Change	1934	1949	Change
	<u>Million</u> <u>cu. ft.</u>	<u>Million</u> <u>cu. ft.</u>	<u>Percent</u>	<u>Million</u> <u>cu. ft.</u>	<u>Million</u> <u>cu. ft.</u>	<u>Percent</u>
Pines ^{1/}	1,200	1,321	+10	21	25	+ 19
Hardwoods ^{2/}	936	854	- 9	335	769	+130
Cypress	196	110	-44	41	39	- 5
All species	2,332	2,285	- 2	397	833	+110

^{1/} Excluding turpentine butts.

^{2/} Excluding limb volume of sound hardwood trees.

Two-thirds of the forest land is understocked: In this Survey Unit 3.9 million acres are less than 40 percent stocked with sound trees. The understocked areas comprise two-thirds of all the commercial forest land in the Unit. Approximately 2 million acres are seriously understocked, having less than 10 percent of the required stocking of sound trees, and the other 1.9 million acres fall in the range of stocking from 10 to 39 percent.

Turpentine activity decreases: The area in turpentine crops and the number of trees being worked in Northwest Florida show a heavy decline since the original survey. In 1949 there were 104,900 acres in working timber crops compared to 940,000 acres in 1934. The number of turpentine pine trees being worked decreased from 12,081,000 to 2,742,000 during the period.

REASONS FOR AREA AND VOLUME CHANGES

Forest type area changes: The shift in forest area from softwood to hardwood types is a trend found throughout Florida, and is also present in other Southeastern states. Where stands of pine and cypress timber with a hardwood understory are cut over, the hardwoods usually occupy the site unless some measures are used to control them. In many areas, repeated burning, which destroys hardwood reproduction, has been reduced thus permitting greater hardwood competition. In most cases this trend to hardwoods is the result of a natural succession to hardwood types and will continue unless control measures are applied.

Saw-timber volume: The board-foot volumes shown in Table A have been made comparable by the exclusion of the present volume in 12-inch d.b.h. hardwood trees. The 12-inch hardwoods were not considered saw timber in the original survey.

The decrease in the board-foot volume of pine is slight and may not be significant. The data indicate that the higher growth rate of this species group has replaced nearly all of the volume cut or removed for various uses. The decreases in the volumes of hardwood and cypress are much greater and result from heavy cutting of these species in proportion to total volume, a slower rate of growth or replacement, and a larger number of cull hardwood trees.

Cubic volume: The data shown in Table B have also been made comparable. The net cubic-foot volume of all sound trees 5.0 inches d.b.h. and larger decreased 2 percent during the period. By species groups it was found that the cubic volume of pines increased 10 percent, indicating a reduction in trees of larger sizes (see Table A) and an increase in the number of trees of pole size. This change is the result of better stocking in pine stands and a more rapid growth rate.

In hardwoods, the decrease of 9 percent in cubic volume and 28 percent in saw-timber volume indicates a reduction of trees in the larger diameter classes which was partially offset by an increase in the number and volume of pole-size trees. This is not the case with cypress, where the decreases in both board-foot and cubic-foot volumes are about equal. The cypress stands are apparently being replaced by hardwoods as they are cut over, and the cypress is not restocking.

Cull volume: The changes in cull volumes of pine and cypress are relatively small and may not be significant. However, the volume of sound material in cull hardwood trees has more than doubled. During the original survey about one-fourth of the total hardwood volume was found to be in cull trees. In the resurvey, nearly half (47 percent) of the hardwood volume was in cull trees.

This increase in the volume of cull hardwoods is due to increases in the volume of both scrub oak and rotten cull trees. Excluding scrub oak, there was no significant change in the volume of other rough culls. More than one-fourth of the increase was accounted for by scrub oak, while rotten cull trees made up the remainder. Many hardwood trees which contained rot in some degree at the time of the original survey have since become too rotten to qualify as sound trees. This trend is augmented by cutting practices which seldom remove hardwoods with any marked degree of cull from the stand. The proportion of volume in cull trees in cut-over hardwood stands thus tends to become increasingly greater.

Table 1.--Gross area^{1/} by broad use class, 1949

Class of use	Area

Table 17.--Number^{1/} of turpentine pine trees by working status
and tree size, 1949

(in thousands of trees)

Working status	Pole size trees	Small saw-timber trees	Large saw-timber trees	All trees
Round timber ^{2/}	112,874	28,783	1,152	142,809
Working timber ^{3/}	323	2,403	16	2,742
Resting timber	162	4,451	233	4,846
Abandoned timber	560	1,923	256	2,739
Worked-out timber	139	1,747	--	1,886
All classes	114,058	39,307	1,657	155,022

^{1/} Includes sound and rough cull trees.

^{2/} In 1934 there were 11,945,000 round trees 9.0 inches d.b.h. and larger compared to 29,935,000 in 1949.

^{3/} In 1934 there were 12,081,000 working trees compared to 2,742,000 in 1949.

Table 18.--Area of turpentine timber crops by working status,
1949

Crop working status	Area	
	Acres	Percent
Round timber	410,200	45.0
Working timber		
Front-faced	59,700	6.5
Back-faced	45,200	5.0
Resting timber	186,000	20.4
Abandoned timber	108,900	11.9
Worked-out timber	102,500	11.2
All classes	912,500	100.0

Table 19.--Area of stump land and tonnage of wood naval stores stumps
by availability class, 1949

Availability class	Area	Tonnage ^{1/}
	<u>Acres</u>	<u>Thousand tons</u>
Merchantable area	2,249,800	^{4/} 5,016
Marginal area ^{2/}	91,900	79
Potential area ^{3/}	317,600	836
Inaccessible area	38,300	38
All classes	2,697,600	5,969

^{1/} Includes stumps on agricultural land.

^{2/} Stump-land areas less than 25 acres in extent and partially worked areas.

^{3/} Unworkable at present due to density of timber stands.

^{4/} A check on the tons of stumps harvested under existing practices indicates the recoverable tonnage is approximately two-thirds of the merchantable volume shown.

^{1/} Sound wood and bark, excluding volume of palms. Limbs of sawlog-size hardwoods are included in cull volumes.

^{2/} Includes bay, magnolia, and yellow-poplar.

DEFINITION OF TERMS

Land-Use Classes

Forest. Land bearing forest growth, land from which the forest has been removed and which shows no evidence of any other recent land use, or former agricultural land which now has a five-percent stocking of trees. Subdivided into the following classes:

Commercial: Land bearing, or capable of bearing, timber of commercial character and available now or prospectively for commercial use.

Reserved: Forest land in public ownership upon which commercial timber cutting is prohibited.

Non-productive: Forest land of such low productivity or so inaccessible that commercial timber will not be produced.

Non-forest. Land less than five percent stocked with trees and showing evidence of non-forest use.

Agriculture: Under cultivation or in pasture, including farm yards on active farms.

Idle: Land previously cultivated or pastured but now idle or abandoned. If reverting to forest there must be less than five percent stocking of trees.

Marsh: Low, boggy, non-forested land usually supporting a heavy growth of grass.

Dunes and beaches: Non-forested sand dunes or coastal beaches.

Urban and other: Includes towns, suburban areas being developed for residential or other urban purposes, school yards, cemeteries, industrial sites, roads, railroads, power lines, and other rights-of-way. Scattered areas of timber within exterior boundaries of cities or villages are also included.

Water: Includes both the small ponds and lakes less than 40 acres in size and streams, sloughs, and canals less than ten chains in width classed as "land area" by the Bureau of the Census. Also includes the "inland water" listed by the Census. On coastal areas the water-line is the mean high-tide mark; tidal flats are classed as water.

Forest Types

Longleaf pine. Stands in which coniferous species comprise at least 25 percent of the dominant and codominant trees, with longleaf pine predominating.

Slash pine. Stands in which coniferous species comprise at least 25 percent of the dominant and codominant trees, with slash pine predominating.

Loblolly pine. Stands in which coniferous species comprise at least 25 percent of the dominant trees, with loblolly pine predominating. Stands of shortleaf and spruce pine are also included in this type.

Pond pine. Stands in which coniferous species comprise at least 25 percent of the dominant and codominant trees with pond pine predominating.

Sand pine. Stands in which coniferous species comprise at least 25 percent of the dominant and codominant trees with sand pine predominating.

Cypress. Stands in which coniferous species comprise at least 25 percent of the dominant and codominant trees, with cypress predominating. White cedar is also included with this type.

Lowland hardwoods. Stands in which mixed hardwoods such as tupelo gum, black-gum, sweetgum, white oak, water oak, red maple, and ash comprise at least 75 percent of the dominant and codominant trees. Found along rivers, small streams, and in swamps and bays.

Upland hardwoods. Stands in which mixed hardwoods such as red oak, white oak, post oak, hickory, ash, sweetgum, elm, and yellow-poplar comprise at least 75 percent of the dominant and codominant trees. Found on the drier upland sites and on low rolling hills bordering the flatwood zone.

Scrub oak. Stands in which scrub species such as blackjack, bluejack, turkey and laurel oaks predominate and in which sound commercial species comprise less than five percent of satisfactory stocking.

Palms. Stands in which there is at least a five-percent stocking of merchantable palm trees and less than five-percent stocking of other sound commercial species.

Stand-Size Classes

Saw timber. Stands containing at least 1,500 board feet net, International 1/4-inch log rule, per acre in sound, live, softwood trees 9.0 inches d.b.h. or larger or hardwood trees 11.0 inches d.b.h. or larger. Two classes of saw-timber stands are recognized:

Large saw timber: Stands of saw timber having more than 50 percent of the net board-foot volume in softwood trees 15.0 inches d.b.h. or larger, or hardwood trees 17.0 inches d.b.h. or larger.

Small saw timber: Stands of saw timber having 50 percent or less of the net board-foot volume in softwood trees 15.0 inches d.b.h. or larger, or hardwood trees 17.0 inches d.b.h. or larger.

Pole timber. Stands at least 10 percent stocked with pole-size or larger timber, with at least one-half the minimum stocking in pole sizes, and which have less than 1,500 board feet net per acre of saw timber.

Seedling and sapling. Stands less than 10 percent stocked by pole-size or larger trees and with less than 1,500 board feet net per acre, but at least 40 percent stocked with commercial species. Eight hundred seedlings or saplings per acre are considered full stocking.

Poorly stocked and unstocked. Stands of pole-size or larger trees that are less than 10 percent stocked, seedling or sapling stands less than 40 percent stocked, or nonstocked forest land.

Diameters

D.b.h. (diameter at breast height). Stem diameter in inches, outside bark, measured at $4\frac{1}{2}$ feet above the ground.

Diameter class. All trees were tallied by 2-inch diameter classes, each class including diameters 1.0 inch below and 0.9 inch above the stated midpoint; e.g., trees 7.0 to and including 8.9 inches are in the 8-inch class.

Tree Classification

Sound saw-timber trees. Softwood trees at least 9.0 inches d.b.h. and hardwood trees at least 11.0 inches d.b.h., with not less than one merchantable log 12 feet long, or with less than 50 percent of the gross volume of the tree in sound saw timber.

Sound pole timber trees. Straight-boled trees between 5.0 inches d.b.h. and saw-timber size.

Sound sapling-size trees. Trees 1.0 inch to 4.9 inches d.b.h. which will grow into pole or saw-timber size trees of sound quality.

Rough cull trees. Trees that fail to qualify as sound timber because of poor form, excessive limbiness, or other sound defect. Volumes shown for rough cull trees also include the limbs, in sections four feet long and at least 4.0 inches in diameter inside bark, of sound saw-timber-size hardwoods. Scrub oak and noncommercial species are included in this group.

Rotten cull trees. Trees that fail to qualify as sound timber because of rotten defect.

Palms. All species of Sabal 5.0 inches d.b.h. and larger with at least 12 feet of clear stem. All palm trees were considered to be free of rotten defect.

Species Groups

Softwoods. All of the pines, eastern redcedar, Atlantic white-cedar, pond cypress, and baldcypress.

Soft hardwoods. Black and water tupelos, sweetgum, and soft maple. The other soft-textured hardwoods include sweetbay, cottonwood, willow, basswood, southern magnolia, and yellow-poplar.

Hard hardwoods. All of the oaks, hickories, and ash. The other hard-textured hardwoods include river birch, elm, hackberry, and sycamore.

Volume Estimates

Board-foot volume. The volume in board feet, measured by the International 1/4-inch rule, exclusive of defect, of that portion of saw-timber trees between the stump and the upper limit of merchantability for sawlogs.

Volume in cords. For sound trees the volume in standard cords (including bark) of the sound portion of trees 5.0 inches d.b.h. and larger, between stump and a minimum top-stem diameter of 4.0 inches inside bark. For cull trees similar volumes are included plus the volume in limbs, in sections four feet long and at least 4.0 inches in diameter inside bark, of saw-timber size hardwoods.

Volume in cubic feet. Same as volume shown in cords except bark is not included.

International 1/4-inch log rule. A rule for estimating the board-foot volume of 4-foot log sections, according to the formula $V = .905 (0.22D^2 - 0.71D)$. The taper allowance for computing the volume in log lengths greater than four feet is 0.5 inch per 4-foot section. Allowance for saw kerf is 1/4 inch.

Standard cord. A stacked pile, 4 x 4 x 8 feet, of round or split bolts, estimated to contain, on the average, 90 cubic feet of softwoods (wood and bark) or 80 cubic feet of hardwoods (wood and bark).

Gum Naval Stores Conditions

Round timber. A minimum of 15 longleaf and slash pine trees 9.0 inches d.b.h. or larger per acre that have never been worked for naval stores.

Working. Longleaf and slash pine trees that are now being worked for naval stores.

Front-faced. Turpentine tree species on which the front or first face is now being worked.

Back-faced. Turpentine tree species on which the front face has been worked out and on which a back (second or third, etc.) face is being worked.

Resting. Longleaf and slash pine trees with a worked-out front face at least 5 feet high and on which back-facing has not been started.

Abandoned. Longleaf and slash pine trees on which faces less than 5 feet high were discontinued.

Worked-out. Longleaf and slash pine trees on which two or more faces at least 5 feet high have been worked out and with no possibility of supporting another face.

Stocking

Stocking classifications were based on the number of stems present by d.b.h. classes. Areas having the minimum numbers of trees listed below, either in a single diameter class or in combinations, were considered adequately stocked.

<u>DBH</u>	<u>Minimum number trees per acre</u>
2 inches	800
4 inches	600
6 inches	450
8 inches	300
10 inches	200
12 inches	150
14 inches	110

RELIABILITY OF THE DATA

In general, there are two possible sources of error in estimating timber volumes and land areas in various categories under procedures used by the Forest Survey. These are (1) common mistakes resulting from errors of judgment in classifying or recording data, mistakes made in compiling the information, and errors in the application of techniques, and (2) sampling errors.

In Forest Survey work a diligent effort is made to maintain a high degree of accuracy in the collection and compilation of the data. Common errors are eliminated or minimized through training and frequent check cruises in the field and through complete editing and machine verification of office procedures in compiling the data.

Sampling errors (standard errors of estimate) carry no connotation of faulty work but are theoretical measures of the reliability of the estimates based on the variability exhibited by the sample data. Sampling errors were the only measurable errors involved in computing the reliability of the data.

Forest area. The sampling intensity was sufficient to provide an estimate of the forest acreage of the Unit with a standard error of ± 0.5 percent. This indicates the probabilities are two out of three that the actual forest area is within ± 0.5 percent of the given estimate.

Timber volumes. The standard error of estimate of the board-foot volume of saw timber in the Unit is ± 3.9 percent. Here again, the probabilities are two out of three that the actual volume is ± 3.9 percent of the given estimate. Corresponding errors for the total volume in cords or cubic feet were not computed, but they should be smaller.

Use of county data. The tables showing area and timber volumes by county are included to facilitate the grouping of county data in any combination desired. Statistics for individual counties have a standard error of estimate for forest area ranging from ± 1.4 to ± 3.7 percent, and for board-foot volume from ± 11.3 to ± 18.6 percent. Obviously, detailed comparisons between counties are subject to considerable error and should be avoided. Grouping a number of counties together will increase the reliability of the area and volume estimates and make these data sufficiently accurate for most general purposes.

HOW THE FOREST INVENTORY IS MADE

The present system of inventory is based upon interpretation of aerial photographs supplemented by cruising of randomly selected ground plots. The county is the basic work unit. Steps in the procedure are as follows:

1. Acreages of forest land are estimated with the use of a dot grid placed on every 3rd contact print along flight lines in each county. The proportion of dots falling on forest areas when applied to the gross area of the county yields a preliminary estimate of the acreage of forest land. This is later revised after certain field checks.

2. Every 3rd plot listed as forest in step one is classified into forest type, stand class, and density class by careful stereoscopic analysis of the photographs. The proportion of plots falling in each classification when applied to the forest area of the county gives the area in each classification. These areas are revised following ground checking.

3. Timber cruisers make a detailed on-the-ground tally of every 3rd large saw-timber photo plot, every 4th small saw-timber, every 6th pole timber, every 13th seedling and sapling plot, and every 26th poorly stocked plot, to obtain volume, growth, cull and mortality data, and to check accuracy of photo classification. They also check a sample of the idle and agricultural plots to determine the area reverting to forest.

4. Growth estimates are based on increment borings taken from trees of the various diameters and species in each forest type and stand class.

5. All field data are sent to the Asheville office for editing and are placed on punch cards for machine tabulation. Statistical techniques are used to correct for changes in photo classification, and to determine final figures on areas, volumes, and growth.
