FOREWORD

Through the McSweeney-McNary Act of 1928, Congress authorized the Secretary of Agriculture to conduct a comprehensive survey of the forest resources of the United States. The Forest Survey was organized by the Forest Service to carry out the provisions of the Act through the Regional Forest Experiment Stations. In the Southeastern states the Forest Survey is an activity of the Division of Forest Economics of the Southeastern Forest Experiment Station, Asheville, North Carolina.

The five-fold purpose of the Forest Survey is (1) to make a field inventory of the present supply of standing timber, (2) to ascertain the rate at which this supply is being increased through growth, (3) to determine the rate at which it is being reduced through industrial and domestic uses, fire, and other causes, (4) to determine the present consumption and the probable future trend in requirements for forest products, and (5) to interpret and correlate these finds to aid in the formulation of private and public policies regarding forest land management.

The forest resources of the State of North Carolina were originally inventoried by the Forest Survey during the period 1937-38, and these findings have been published. Since that time rapid changes have taken place in the growing stock as the result of timber cutting, forest growth, changes in land use, and better management practices. These changes can be accurately measured only by on-the-ground surveys. A resurvey of the forest resources in the Southern Coastal Plain of North Carolina was started in December 1951 and completed in November 1952. This progress report presents resurvey statistics on forest area, timber volume, growth, and drain for this area, which is designated Survey Unit No. 1.

ACKNOWLEDGMENTS

The Southeastern Station gratefully acknowledges the cooperation of the Department of Conservation and Development and Fred H. Claridge, State Forester, for providing personnel and equipment for field crews to conduct the survey.

The Division of Forest Economics at the Southeastern Station is under the direction of James W. Cruikshank. Field inventory work was under the supervision of Robert W. Larson, and photo interpretation was done by R. C. Aldrich. Office compilation of the data was under the direction of Agnes Nichols, assisted by Louise Shuford, Sammy Wenningham, and Eunice Gable.

FOREST STATISTICS FOR THE SOUTHERN COASTAL
PLAIN OF NORTH CAROLINA, 1952

Statistical data on forest area, timber volume, growth, and drain are presented in this progress report for the 21-county area in the Southern Coastal Plain of North Carolina, designated as Survey Unit No. 1 (fig. 1). The field data were obtained by a survey made during the period December 1951 to November 1952. Ground sample plots distributed among all the individual counties were located to collect detailed information. Procedures used in selecting sample plots and collecting the basic data are outlined briefly on page 45.

Changes in area or timber volume which have taken place since the original survey in 1937 are also pointed out. These changes are based on comparisons of similar statistics obtained in both surveys and they indicate trends which are affecting the forest resource.

1952 HIGHLIGHTS AND SIGNIFICANT CHANGES

Forests occupy two-thirds of the land area.--The Southern Coastal Plain of North Carolina is a heavily wooded area. Some 5.5 million acres, or 65 percent of the total land area, are in forest (fig. 2). Practically all the forest land is capable of producing crops of commercial timber, but there are 91 thousand acres of swampland or pocosin which are so wet or infertile they will not grow timber of usable size. The acreage of forest land is slightly less now than it was in 1937, being down 1.4 percent.

Agricultural land amounts to 2.5 million acres, or 30 percent of the total. The remain-

ing 5 percent of land area includes cities, towns, rights-of-way, coastal beaches, and marshland.

Figure 2.--Land use in the Southern Coastal Plain of North Carolina, 1952

Ninety-two percent of the commercial forest land is in private ownership. Nearly 3.5 million acres, or 64 percent, is in farm woodlands, the remainder being owned by pulp and paper mills, lumber companies, and other private owners. The 455 thousand acres of public forest lands are about equally divided between Federal and State ownership. The bulk of the Federal land is in military establishments, and the State land is mostly in game management areas or in State and school forests.

Pine forests decrease in area.--A comparison of forest type acreages found in 1937 and 1952 shows that pine forests now occur on 743 thousand fewer acres than before. The present distribution of forest area by types is pine 64 percent and hardwoods 36 percent. The 1937 distribution was pine 76 percent and hardwoods 24 percent. Identical forest type definitions were used in both surveys so the resulting data would be comparable.

This change in forest composition is typical of many areas in the Southeast. The cause can usually be traced to cutting practices which remove the preferred pine timber from the stands and leave the less desirable hardwoods to occupy the site. Under current definitions which divide the forest into types on the basis of cubic volume or number of stems, pine types occupy only 54 percent of the commercial forest land.

Stocking of young timber improves.--A comparison of the number of sound trees found at the time of each survey reveals a very significant increase in the number of small trees, particularly pines. Increases in the number of 6-, 8-, and 10-inch pines since 1937 amount to a total of 41 million trees (fig. 3). Small hardwoods in the same diameter range have also increased sharply during the period between surveys. These improvements in timber stocking may be largely attributed to improved fire protection, which has cut down the loss of young trees.

Figure 3.--Change in number of pole timber and larger trees by diameter class and species group

Figure 3 also shows the effect of heavy demand for the larger, more valuable trees, and the preference for pine timber. In the 12-inch and larger diameter classes the number of pine trees has decreased nearly 4 million, or about 8 percent, since 1937. There have also been decreases in the number of gums and other soft-textured hardwoods above the 18-inch diameter class. Only among the oaks and other hard-textured hardwoods are there now more large trees than in 1937.

Pine sawtimber volume down 10 percent.--Heavy utilization of pine sawtimber has reduced the volume from 7.6 billion board feet in 1937 to 6.8 billion feet in 1952, a decrease of 10 percent. During the same period hardwood sawtimber trees have added 10 percent to their volume, while cypress remained about the same (table A). These opposite trends in the volume of pine and hardwood sawtimber volume have had a balancing effect resulting in an over-all reduction in volume of only 2 percent.

Table A.--Change in volume of sawtimber, 1937 to 1952

Species group	1937 ^{1/}	1952	Change
	<u>Million</u> <u>bd. ft.</u>	<u>Million</u> <u>bd. ft.</u>	<u>Percent</u>
Pines	7,591	6,810	-10
Hardwoods	4,649	5,129	+10
Cypress	552	560	+ 1
All species	12,792	12,499	- 2

^{1/} Original survey volumes have been recomputed to allow for differences in standards between the two surveys and to provide a uniform basis for comparison. Thus, the 1937 estimate shown here will not agree with volumes previously published.

Softwood species make up 59 percent of the present sawtimber volume. Loblolly pine with 4.7 billion board feet, or 38 percent of the total, is the predominating species. Pond pine, occupying the low, wet areas, is next in importance, followed by longleaf pine and cypress. In the hardwood species group, blackgum, tupelo, and sweetgum account for 2.8 billion feet, 23 percent of the total volume. Different varieties of oak make up most of the remaining sawtimber.

Three-fourths of the board-foot volume is found in stands having a minimum volume of 1,500 board feet per acre. Stands of large sawtimber average 7,680 board feet per acre, and small sawtimber stands average 4,480 feet. The rest of the board-foot volume is scattered throughout stands of poles and smaller trees. Nearly half of the pine sawtimber volume is in trees in the 10- and 12-inch diameter classes.

Quality of large sawtimber trees good.--In the 1952 survey, logs in each sawtimber tree were graded to determine quality, and the results have been summarized by tree-size class (table 7). Sawlogs in softwood trees were graded under the Crossett log grade rules described in USDA Technical Bulletin No. 861, while "Hardwood Log Grades for Standard Lumber" (Forest Products Laboratory publication No. D1737) were used for all hardwoods. In the pines 73 percent of the board-foot volume is in grade 1 and 2 logs. However, about half the volume in trees 16 inches and larger d.b.h. is in grade 1 logs as compared to only 12 percent in trees 10 to 14 inches in diameter. This relationship shows that quality is closely associated with tree size.

The quality of hardwood sawlogs in large sawtimber trees compares favorably with that of softwoods, 42 percent of the volume being in grade 1 and 33 percent in grade 2 logs. In the smaller 12- and 14-inch hardwood trees there is practically no volume in grade 1 and only 32 percent in grade 2. The remaining two-thirds of the volume in this class is composed of low-quality factory lumber logs, or logs from which only crossties and timbers can be manufactured.

Growing stock volume increases 6 percent.--The total growing stock volume increased 6 percent between 1937 and 1952, but the increase was confined to the hardwood species. Pine and cypress volumes show little change (table B).

Table B.--Volume comparison, all live trees 5.0 inches d.b.h. and larger, 1937 and 1952

Species group	Growing stock			Cull trees		
	1937 ^{1/}	1952	Change	1937 ^{1/}	1952	Change
	<u>Million</u> <u>cu. ft.</u>	<u>Million</u> <u>cu. ft.</u>	<u>Percent</u>	<u>Million</u> <u>cu. ft.</u>	<u>Million</u> <u>cu. ft.</u>	<u>Percent</u>
Pines	1,952	1,911	- 2.1	84	58	-31.0
Hardwoods	1,360	1,617	+18.9	375	381	+ 1.6
Cypress	130	129	- 0.8	11	11	0.0
All species	3,442	3,657	+ 6.2	470	450	- 4.3

^{1/} See footnote 1, table A.

^{2/} Excludes limb volume of hardwood sawtimber trees.

The total growing stock volume includes all sound trees of pole size (5.0 inches d.b.h. to sawtimber size) as well as the sawtimber trees. Trees smaller than 5.0 inches in size are considered seedlings or saplings and are not assigned volume for inventory purposes.

While the survey results show only a slight decrease in the amount of pine growing stock, there has actually been a considerable shift in volume by tree size. As pointed out in figure 3, heavy increases in the number of small trees have been offset by decreases in trees 12 inches and larger in diameter. The proportion of volume in small trees is now greater than in 1937. Hardwood trees have increased in number throughout the range of diameter classes, creating a 19-percent increase in volume. There has been little actual change in the volume of cull trees.

Planting required to restock some forest land.--In the pine and upland hardwood forest types there are 260,000 acres which are in a poorly stocked condition, and which also lack the necessary seed trees for natural restocking. Most of these areas will need to be planted to bring them back into production within a reasonable length of time. About 76,000 acres can be planted by machine, 104,000 acres can be planted only by hand, and 80,000 acres are so densely covered with brush or are so inaccessible that planting does not appear practical.

Forests composed largely of young timber.--More than 70 percent of the commercial forest land is well stocked or overstocked with sound trees of all sizes; yet the trees which provide this rating are mostly seedlings and saplings, all below volume size. Only 13 percent of the forest land is well stocked with trees 5.0 inches d.b.h. and larger, and the area occupied by well stocked stands of sawtimber is less than 5 percent. These comparisons point out the fact that much of the forest area is now actually deficient in growing stock volume, but at the same time they indicate a better potential stocking in the future as the smaller trees grow into volume size.

Wood naval stores stumps total 2.2 million tons.--Cured, old-growth stumps of longleaf pine useful for the extraction of wood naval stores products are found throughout the area, with the heaviest concentrations in Brunswick, Bladen, Columbus, Pender, and Sampson Counties. They occur on a harvestable area of 1.1 million acres, and the total volume amounts to 2.2 million tons, or an average of 2 tons per acre.

Current timber growth exceeds drain.--In 1952 timber growth exceeded drain both in sawtimber and total growing stock for all species groups (fig. 4). This favorable trend resulted in an estimated annual increase in board-foot volume of 2.6 percent, and a 2.9-percent rise in the volume of growing stock.

Total sawtimber growth amounted to 891 million board feet compared to 563 million feet of drain. Growth of pine sawtimber was 621 million feet, or 70 percent of the total, yet because of heavier drain, the gain

in pine volume amounts to only half the over-all volume increase. The increment in sound growing stock trees 5.0 inches d.b.h. and larger was 106 million cubic feet greater than the drain.

Figure 4.--Timber growth and drain relationship in the Southern Coastal Plain of North Carolina

The estimated volume of growth includes the growth on all sound trees of volume size plus the ingrowth created by smaller trees which reach volume size during the year. Mortality, or the loss of volume in trees which die from natural causes, is deducted. Timber drain volume is based on measurement and tally of stumps found on ground sample plots. Stumps of all trees cut during the past three-year period were recorded by species groups and the measurements were converted into tree volume. The average volume of drain for the three-year period was taken as the annual estimate.

It is interesting to note that the volume of ingrowth makes up a sizable proportion of the total growth estimate. Thirty-seven percent of the net board-foot growth is credited to small trees which grew into sawtimber size during the year. The rate of ingrowth is highest for the pine species in poletimber stands, where it approximates half the growth for this class. Recruitment of trees into pole size accounts for 17 percent of the cubic volume growth on all growing stock. Ingrowth will continue to be an important factor in future growth estimates because of the large number of trees in small diameter classes.

With the exception of pine sawtimber, the drain on the forests as a result of timber cutting was slightly lower in 1952 than in 1937. During the period between surveys the volume of drain has apparently reached higher levels. There is considerable evidence that annual timber drain follows a cyclical pattern, changing with the migration of sawmills, shifts in demand and utilization practices, and the ups and downs of the general business cycle. The current relationship of growth and drain leaves a margin of volume which is building up the growing stock. Whether or not this trend can continue will depend largely on the future demand for wood products and the effectiveness of forest management practices aimed at increasing the supply of timber.

Table 1.--Gross area^{1/} by broad use class, 1952

^{1/} Estimates of timber drain by county are less accurate than inventory volumes, and use of individual county statistics should be avoided. For general use, data for a minimum of 10 counties should be combined.

DEFINITION OF TERMS

Land-Use Classes

Forest land: Includes (a) lands which are at least 10 percent stocked with trees of any size and capable of producing sawtimber or other wood products, and (b) lands from which the trees described in (a) have been removed to less than 10-percent stocking but which have not been developed for other use; subdivided into the following classes:

Commercial: Forest land which is (a) producing, or physically capable of producing, usable crops of wood (usually sawtimber), (b) economically available now or in the future, and (c) not withdrawn from timber use.

Noncommercial: Forest land (a) withdrawn from timber utilization through statute, ordinance, or administrative order but which otherwise qualifies as commercial forest land, and (b) incapable of yielding usable wood products (usually sawtimber) because of adverse site conditions, or so physically inaccessible as to be unavailable economically in the foreseeable future.

Nonforest land: Includes land in the following classes:

Agriculture: Land under cultivation or in pasture including farmyards and work lots, and idle or abandoned farmland which has not reverted to forest.

Marsh: Low, wet areas characterized by a heavy growth of grass and reeds and an absence of timber.

Urban and other areas: Includes towns, residential and industrial suburban areas, school yards, cemeteries, roads, railroads, power lines, and other rights-of-way.

Water: Includes lakes, bays, and estuaries over 40 acres in size, and streams, canals, and sloughs at least one-eighth of a mile in width which are classed as "inland water" by the Bureau of the Census. Smaller lakes and ponds between one acre and 40 acres in size, and waterways between 120 feet and 660 feet in width, which are classed as land area by the Bureau of the Census, are also included as water areas.

Forest Types

Forest type is determined on the basis of cubic volume for all stand sizes except seedlings and saplings (stand size 4), in which case the number of stems are the criteria.

Pine types: Forests in which 50 percent or more of the stand is in pine species. Plurality of volume or number of trees is used to determine the specific type.

Oak-pine type: Forests in which 50 percent or more of the stand is hardwood, usually upland oaks, but in which southern yellow pines make up 25-49 percent of the stand.

Oak-hickory type

Upland hardwood: Forests in which 50 percent or more of the stand is composed of upland oak, hickory, yellow-poplar, maple, gum, and other hardwoods, except where pines comprise 25-49 percent of the stand.

Scrub oak: Upland forests in which 50 percent or more of the stand is composed of scrub oak species, except where pines comprise 25-49 percent of the stand.

Oak-gum-cypress type

Lowland hardwood: Bottomland forests in which 50 percent or more of the stand is tupelo, blackgum, sweetgum, ash, oak, elm, maple, and associated species, except where pines comprise 25-49 percent of the stand.

Cypress: Bottomland forests in which 50 percent or more of the stand is cypress, except where pines comprise 25-49 percent of the stand.

Stand-Size Classes

Sawtimber: Stands containing at least 1,500 board feet net volume per acre, 1/4-inch log rule, in sound, live, softwood trees 9.0 inches d.b.h. or larger, or hardwood trees 11.0 inches d.b.h. or larger. Two classes of sawtimber stands are recognized:

Large sawtimber: Stands of sawtimber having more than 50 percent of the net board-foot volume in trees 15.0 inches d.b.h. or larger.

Small sawtimber: Stands of sawtimber having 50 percent or less of the net board-foot volume in trees 15.0 inches d.b.h. or larger.

Poletimber: Stands failing to meet the minimum sawtimber specifications, but at least 10-percent stocked with trees 5.0 inches d.b.h. or larger and with at least half the minimum stocking in pole-size trees.

Seedling and saplings: Stands not qualifying as sawtimber or poletimber stands, but having at least a 10-percent stocking of trees of commercial species and with half the minimum stocking in seedlings and saplings.

Nonstocked and other areas: Forest areas not qualifying as sawtimber, poletimber, or seedling and sapling stands.

Diameters

D.b.h. (diameter at breast height): Stem diameter in inches, outside bark, measured at 4-1/2 feet above the ground.

Diameter class: All trees were tallied by 2-inch diameter classes, each class including diameters 1.0 inch below and 0.9 inch above the stated midpoint, e.g., trees 7.0 to and including 8.9 inches are included in the 8-inch class. Corresponding limits apply to other diameter classes.

Timber Quality Classification

Growing Stock

Sawtimber trees: Live softwood trees at least 9.0 inches d.b.h. and hardwood trees at least 11.0 inches d.b.h., with not less than one merchantable log 12 feet long, or with less than 50 percent of the gross volume of the tree in sound sawtimber.

Poletimber trees: Straight-boled trees between 5.0 inches d.b.h. and sawtimber size.

Sapling-size trees: Trees 1.0 inch to 4.9 inches d.b.h. which will grow into poletimber or sawtimber size trees of sound quality.

Other Material

Sound cull trees: Live trees of all sizes that are unmerchantable for sawlogs now or prospectively because of species, poor form, excessive limbiness, or other sound defect.

Rotten cull trees: Live trees of all sizes that are unmerchantable for sawlogs now or prospectively because of rotten defect.

Hardwood limbs: The limb volume of all hardwood sawtimber and cull trees to a minimum diameter of 4.0 inches inside bark.

Species Groups

Yellow pines: Includes longleaf, slash, loblolly, pond, and shortleaf pine.

Other softwoods: Pondcypress, baldcypress, eastern redcedar, and Atlantic whitecedar.

Soft-textured hardwoods: Black and tupelo gum, yellow-poplar, sweetgum, cottonwood, soft maple, basswood, magnolia, sweetbay, and willow.

Hard-textured hardwoods: All of the oaks, hickories, ash, beech, elm, river birch, hackberry, sycamore, black locust, mulberry, black walnut, holly, dogwood, and persimmon.

Volume Estimates

Board-foot volume: The volume in board feet, measured by the International 1/4-inch rule, exclusive of defect, of that portion of sound sawtimber trees between the stump and the upper limit of merchantability for sawlogs.

Volume in cords: For sound trees the volume in standard cords (including bark) of the sound portion of trees 5.0 inches d.b.h. and larger, between stump and a minimum top-stem diameter of 4.0 inches inside bark. Similar volumes are given for cull trees. The volume in limbs, in sections four feet long and at least 4.0 inches in diameter inside bark, of all sawtimber size hardwoods is shown separately.

Volume in cubic feet: Same as volume shown in cords except bark is not included.

International 1/4-inch log rule: A rule for estimating the board-foot volume of 4-foot log sections, according to the formula $V = .905 (0.22D^2 - 0.71D)$. The taper allowance for computing the volume in log lengths greater than four feet is 0.5 inch per 4-foot section. Allowance for saw kerf is 1/4 inch.

Standard cord: A stacked pile, 4 x 4 x 8 feet, of round or split bolts, estimated to contain, on the average, about 73 cubic feet of solid wood.

Stocking

Stocking is the extent to which growing space is effectively utilized by trees. The number of stems present by d.b.h. classes was used as a basis for stocking classification. Areas having the minimum numbers of trees listed below, either in a single diameter class or proportionately in any combination of diameter classes, were considered fully stocked.

<u>D.b.h.</u>	<u>Minimum number trees per acre</u>
Seedlings	1,000
2 inches	800
4 inches	590
6 inches	400
8 inches	240
10 inches	155
12 inches	115
14 inches	90

Growth and Drain

Net growth.--The estimated volume of net growth includes growth on the present growing stock plus the ingrowth accrual resulting from smaller trees reaching volume size. It excludes mortality, or loss of volume in trees dying from natural causes. Growth estimates are based on the volume or number of sound trees. Other material is not included.

In board feet: The change during the calendar year in sawtimber volume resulting from growth, ingrowth, and mortality losses.

In cubic feet or cords: The change during the calendar year in the volume of all sound trees 5.0 inches d.b.h. and larger resulting from growth, ingrowth, and mortality losses.

Timber drain.--The volume of timber drain is based on the measurement and tally of stumps found on regular ground sample plots. Stumps of all trees cut during the past three-year period were recorded and the measurements converted into equivalent tree volume. The average volume of drain for the three-year period was then taken as the annual estimate. Board-foot drain volumes include the sawlog portion of all sawtimber-size trees which were cut. Drain in cubic feet or cords includes the entire stem from stump to 4.0-inch top of all sound trees 5.0 inches in diameter and larger.

RELIABILITY OF FOREST SURVEY DATA

In general, the errors which affect the accuracy of Forest Survey area and timber volume estimates arise from two sources. These may be described as (1) sampling errors which result from using sampling procedures rather than making a complete inventory or canvass, and (2) non-sampling errors which arise from human mistakes in judgment, measurement, recording, or arithmetic.

In Forest Survey work a diligent effort is made to maintain a high degree of accuracy in the collection and compilation of data. The sampling errors are held to a specified minimum through survey design and sampling technique. These errors are the only measurable errors involved in computing the reliability of the data. The non-sampling errors are minimized or eliminated through training, supervision, field check cruises, and complete editing and machine verification in compiling the data.

Forest area.--The sampling intensity of the 1952 survey was sufficient to provide an estimate of the total forest acreage in the Unit with a standard error of ± 0.9 percent. The probabilities are two out of three that the estimated forest acreage is within ± 0.9 percent of the actual acreage.

Cubic volume.--The standard error of the 1952 net cubic-foot volume in the Unit was ± 2.2 percent. Here again, the probabilities are two out of three that the estimated volume does not vary from the actual volume by more than this percentage. The standard error of the volume in cords was not computed but it should be approximately the same.

Board-foot volume.--The standard error of the 1952 estimate of board-foot volume in the Unit was ± 2.6 percent.

Use of county data.--The tables showing area and timber volumes by county are included to permit grouping of the data in any desired combinations. The survey was designed so that the number of sample plots taken in each county would provide an estimate of the timber volume in cubic feet which would not exceed ± 15 percent. The actual range of error of the cubic volume estimates by county is from ± 7.4 percent to ± 12.2 percent. The errors of board-foot volume estimates by county range from ± 8.6 percent to ± 12.3 percent, and of forest area from ± 1.6 percent to ± 9.2 percent.

In spite of the accuracy limit set on volume estimates by county, comparison of individual county statistics may be subject to considerable error and should be avoided. Grouping the data for a number of counties will increase the reliability and make the combined estimates sufficiently accurate for general use. For example, grouping the timber volume data for four counties with errors ranging from 7 to 12 percent resulted in a total volume estimate with only ± 5 percent error.

HOW THE FOREST INVENTORY IS MADE

The present system of inventory is a two-step method which includes land-use classification of points on aerial photographs followed by the cruising of ground sample plots. The county is the basic work unit. The detailed procedure is as follows:

1. Preliminary estimates of the acreage of land in forests and other land-use classes are obtained by classifying points printed on every third aerial photograph in alternate flight lines within a county. The proportion of points falling in each class is used to estimate the acreage. This estimate is later checked and revised through the use of ground plots.

2. Ground sample plots are selected in a systematic manner from the forest land classifications made in Step 1, using an interval which will provide sufficient plots to meet established limits of error per billion cubic feet of timber. This results in a proportional sample of all existing timber stands. Timber cruisers make a detailed description and tally of the ground plots to obtain data on timber volume, quality, stocking, and mortality. Samples of agricultural and other photo classifications are also checked on the ground to verify or adjust the area estimates based on these classifications.

3. Growth estimates are based on increment borings taken proportionally from sample trees of various diameters and species in each forest type and stand class. The volume of timber drain is computed from a tally of the stumps of trees cut on the plots during a specified period.

4. All field data are sent to Asheville for editing and are placed on punch cards for machine sorting and tabulation. Final estimates are based on statistical summaries of the data.
