Laboratory Evaluations of Candidate Insecticide Residues Against Face Flies and DDT-Resistant House Flies, 1961-1969

BY O. F. BODENSTEIN, J. H. FALES, R. P. HALL, G. D. MILLS, JR., and R. L. WALKER, *Entomology Research Division,
Agricultural Research Service*

In 1960 the face fly (*Musca autumnalis* De Geer) became a serious pest of cattle and horses in central Maryland for the first time. Research undertaken that year on this insect at the Agricultural Research Center, Beltsville, Md., consisted of laboratory rearing studies and field tests with insecticides and repellents (3, 4).¹

The following year laboratory evaluations of insecticide residues against this insect were begun. The same candidate materials were also tested against DDT-resistant house flies (*Musca domestica* L.).

TEST PROCEDURES

The method used to test face and house flies was a modification of the residue jar method described for use with cockroaches (5) and later for house flies (1). This is the same method used for residual tests on face flies (2).

The insecticides were made up in acetone solutions at a concentration of 0.56 mg. per milliliter. The solutions were applied to the entire neck of a pint Mason jar with a pipette and allowed to run down into the jar. As the jar was gently rotated by hand the acetone evaporated and all interior surfaces were evenly coated.

In early tests 5 ml. of the solution were used in the jars resulting in a residue of 10 mg. per 929 cm.² In later tests the beginning dosage was 5 mg. per 929 cm.², which was obtained by using 2.5 ml. of the 0.56-mg. stock solution. Since it was impossible to coat the surface of the jar evenly with less than 2.5 ml., lower dosages were obtained by diluting the stock solutions to obtain the desired dosage when using either 5 or 2.5 ml. of the solution.

A cover of 94-cm.² double-weight window glass was treated on one side at the same dosage as the jar. This was obtained by using the same dilution and treating the cover with 1.75 ml. when 5 ml. were used in the jar and 0.875 ml. when 2½ ml. were used.

Insofar as possible the insects were 3 to 5 days old on a given day of testing. One or two hours after the acetone was evaporated, 20 or more adult flies were selected at random through the opening in the rubber back of a stock cage by means of a shell vial. They were then transferred to a treated jar by first covering it with a piece of cardboard containing an opening of the same diameter as the vial used to catch the flies. The open end of the vial was inserted through the hole in the cardboard and the flies were shaken into the jar. As the cardboard was removed the window-glass cover was quickly slipped over the jar with the treated side covering the mouth.

The jar was inverted on a table for 5 minutes, during which the insects were in continual contact with the treated surface except for occasional flight. Inversion of the jar was necessary since the face flies particularly tended to congregate on the jar lip, which had been difficult to treat. At the end of the exposure period the insects were placed in a 10-inch cubical screen holding cage.

All insects were fed with cotton soaked in a skim milk and water solution (1:1). They were held overnight for mortality counts. Both dead and living insects were sexed, and the percent mortality was recorded for males, females, and the total population. No attempt was made to determine whether some insects may have been killed by fumigation.

When tests were replicated, freshly treated jars and different populations of insects were used. Be-

¹ Italic numbers in parentheses refer to Literature Cited, p. 3.

cause of limited equipment, space, and time, all materials could not be tested on the same day. DDT and malathion were included at each level as a standard against face flies and resistant house flies, respectively. Only the more promising materials were tested at lower dosages.

RESULTS

In table 1, 281 materials are evaluated as insecticide residues against face flies and DDT-resistant house flies. Approximately one-third of the materials tested were equal to or better than their respective standards when compared at the dosage level most closely approximating the LD_{50} —1.25 mg. of DDT against face flies and 5 mg. of malathion against resistant house flies.

The most effective materials against the face fly, based on 100-percent kill with a residue of 0.312 mg. per 929 cm.² or less, were as follows:

<i>Residue (mg.)</i>	<i>Item No.</i>
0.039 -----	84, 121 (isobenzan)
0.156 -----	75 (crotoxyphos), 159, 160, 165, 245 (phoxim)
0.312 -----	2, 107 (Bomyl®), 163, 164, 166, 180, 181, 217, 218, 224 (bromophos), 229, 231, 233, 247 (Dursban®), 255, 271, 272

The most effective materials against DDT-resistant house flies, based on 100-percent kill with a residue of 0.312 mg. per 929 cm.², were items 75 (crotoxyphos), 83, 84, 166, and 272.

The most effective materials against both species were items 75 (crotoxyphos) and 84.

This publication reports research involving pesticides. It does not contain recommendations for their use, nor does it imply that the uses discussed here have been registered. All uses of pesticides must be registered by appropriate State and/or Federal agencies before they can be recommended.

CAUTION: Pesticides can be injurious to humans, domestic animals, desirable plants, and fish or other wildlife—if they are not handled or applied properly. Use all pesticides selectively and carefully. Follow recommended practices for the disposal of surplus pesticides and pesticide containers.

Mention of a proprietary product in this publication does not constitute a guarantee or warranty by the U.S. Department of Agriculture over other products not mentioned.

1/ Average 2 tests.

2/ Average 3 tests.

3/ Average 4 tests.

4/ Mobam^(R) gave erratic results varying from no kill to 100 percent. Unpublished data indicate that aged residues of Mobam^(R) in acetone may be more effective than a fresh residue.
