FACTORS FOR CONVERTING ENGLISH UNITS TO INTERNATIONAL SYSTEM UNITS (SI)

For use of those readers who may prefer to use metric units rather than English units, the conversion factors for the terms used in this report are listed below:

Multiply English units	By	To obtain metric units
<u>Length</u>		
feet (ft)	0.3048	meters (m)
inches (in)	25.4	millimeters (mm)
miles (mi)	1.609	kilometers (km)
<u>Area</u>		
acres	.4047	hectares (ha)
square miles (mi ²)	2.590	square kilometers (km ²)
<u>Volume</u>		
acre-feet (acre-ft)	1233	cubic meters (m ³)
acre-feet (acre-ft)	.001233	cubic hectometers (hm ³)
cubic feet (ft ³)	.02832	cubic meters (m ³)
gallons (gal)	3.785	liters (L)
Mgal (million gallons)	3785	cubic meters (m ³)
<u>Specific combinations</u>		
cubic feet per second (ft ³ /s)	.02832	cubic meters per second (m ³ /s)
gallons per minute (gal/min)	.06309	liters per second (L/s)
gallons per minute per foot [(gal/min)/ft]	.2070	liters per second per meter [(L/s)/m]
million gallons per day (Mgal/d)	3785	cubic meters per day (m ³ /d)
<u>Temperature</u>		
degrees Fahrenheit (°F)	5/9 after subtracting 32 from F° value	degrees Celsius (°C)

GROUND-WATER DATA FOR THE DREWSEY RESOURCE AREA, HARNEY AND MALHEUR COUNTIES, OREGON

--

By J. B. Gonthier, C. A. Collins, and D. B. Anderson

--

INTRODUCTION

Appraisals of the resources of selected management areas in eastern Oregon are being made by the U.S. Bureau of Land Management. To provide needed hydrologic information the Bureau of Land Management requested the U.S. Geological Survey Water Resources Division to inventory ground-water data for the Drewsey Resource Area. The inventory included field location of selected wells and springs, measurement of ground-water levels, ground-water temperatures, specific electrical conductance, pH, and collection of ground-water samples at selected localities to determine dissolved chemical constituents.

Included in this data report are well data, drillers' lithologic logs, hydrographs, a summary of observation-well data, and chemical analyses of ground water.

Previous Investigations

Parts of the Drewsey Resource Area are included in previous studies of the geology and ground-water resources of the Harney Basin (Waring, 1909; Piper and others, 1939; and Leonard, 1970). Leonard's report describes the occurrence, distribution, availability, and chemical quality of ground water in the Harney Valley. The area covered by that report is outlined on plate 1, and within that area, no new data have been collected for this report. The Harney Valley report (Leonard, 1970) could serve as a basis for interpretation and evaluation of data presented in this report. A report by Hubbard (1975) describes the surface-water resources of the Harney Valley and includes a detailed water budget for Malheur Lake. Geologic information for the resource area is shown on the "Geologic Map of the Burns Quadrangle, Oregon" (Greene and others, 1972).

Hydrographs of representative wells in Oregon appear in annual reports prepared by the Oregon Water Resources Department (formerly the State Engineer's Office) (Sceva, 1964; Sceva and DeBow, 1965, 1966; Bartholomew and DeBow, 1967, 1970; Bartholomew and others, 1973).

Location and Description of the Area

The Drewsey Resource Area is located in eastern Oregon. Most of the area is in northeastern Harney County, but a small part of Malheur County is also included (fig. 1). The boundary of the Drewsey Resource Area has been established by the Bureau of Land Management, and it does not conform either with

Base from U.S. Geological Survey
1:1,000,000, 1966

Figure 1.—Map showing location and general features of the Drewsey Resource Area, Oregon.

natural, physical, or established political boundaries; it is, however, a land unit within the Bureau of Land Management, Burns District. Land within the Drewsey Resource Area is in both private and public ownership, and a large part is held in public trust by the Bureau of Land Management. The total area included in the Drewsey Resource Area exceeds 2,500 mi².

The cities of Burns and Hines, Oreg., with an estimated combined population of 5,170 persons in 1976 (Oregon Secretary of State, 1977) are near the northwest edge of the resource area. The population density of the resource area is greatest in the Harney Valley near Burns and Hines; elsewhere it is extremely small. Small settlements include Drewsey, and Buchanan in the north, and Lawen, Crane, Princeton, Voltage, and Diamond in the central and south.

Good highways cross part of the study area, but much of it is accessible only during the summer and fall months by using four-wheel-drive vehicles.

The Drewsey Resource Area includes most of the Harney Valley, a flat, featureless plain, and uplands that border the valley on the north, east, and south. The Steens Mountains, in the southeastern part of the area, attain an altitude of more than 9,000 ft and are the highest of the uplands. The Harney Valley is a closed basin, and streams draining the bordering hills discharge into Malheur Lake located near the south center of the valley. The principal streams entering the Harney Valley are the Silvies River, which drains the upland north of the Drewsey Resource Area and the Donner und Blitzen River which drains the western ramplike slope of the Steens Mountains and flows northward into Malheur Lake. The Malheur River and its tributaries drain the uplands in the northern and eastern parts of the Drewsey Resource Area and ultimately discharge into the Snake River to the east.

General Geology

The uplands bordering the Harney Valley consist of volcanic and pyroclastic rocks and sediments derived from volcanic rocks. The uplands are cut by numerous faults, and the rock strata slope gently toward the Harney Valley, which is both an erosional and a structural basin. Unconsolidated valley-fill deposits underlie the Harney Valley floor to a maximum depth of about 250 ft (Leonard, 1970). The valley-fill deposits consist chiefly of clay, but contain lenticular deposits of sand and gravel in alluvial fans built by the principal streams. Beneath the valley-fill deposits are a large but unknown thickness of consolidated rocks similar in composition to those exposed in the bordering uplands.

Occurrence of Ground Water

Large quantities of ground water are withdrawn by numerous wells from sand and gravel and from consolidated rock aquifers in the Harney Valley east of Burns. Wells in that area produce as much as several hundred gallons of water per minute, and the water is used chiefly for irrigation. The distribution of the consolidated rock aquifers beneath the valley-fill deposits is generally poorly known. Ground water in the Harney Valley is generally confined beneath beds of clay or other rocks of low hydraulic conductivity such

as welded tuff or dense crystalline basalt. Locally, ground water in shallow sand and gravel aquifers is unconfined.

Ground-water recharge in the uplands is chiefly by direct infiltration of precipitation, and locally along streams by infiltration of streamflow during periods of high runoff. Each spring, snowmelt runoff from upland streams floods large areas of the Harney Valley floor and recharges the valley-fill deposits. Upward movement of ground water from the underlying consolidated rocks also provides small quantities of recharge to the valley-fill deposits.

The general direction of movement of ground water in the Drewsey Resource Area is from upland recharge areas toward valley areas where the ground water is discharged by seepage to springs, by diffuse seepage to streams, by evapotranspiration, or by wells. In the Harney Valley, ground water in the valley-fill deposits is moving toward Malheur Lake. Most of this ground water is discharged in the valley by direct evapotranspiration of shallow ground water before it reaches Malheur Lake. Evapotranspiration of shallow ground water probably is the cause of large areas of alkali soil in the valley.

Locally in the Harney Valley, wells and springs yield warm geothermally heated ground water; some of these occurrences are described by Leonard (1970). Two warm springs outside the Harney Valley were visited during this study, and the data are listed in the accompanying tables.

EXPLANATION OF DATA

Well- and Spring-Numbering System

Wells and springs are assigned a number based on their location according to the rectangular system for subdivision of public lands. In successive order, the numerals represent the township, range, and section. Thus, well 25S/36E-16ccc is in township 25 south, range 36 east, section 16. The letters following the section number show the location within the section, the first letter designating the quarter section (160 acres), the second letter the quarter-quarter section (40 acres), and the third letter the quarter-quarter-quarter section (10 acres). Where two or more wells are in the same 10-acre subdivision, serial numbers are added after the third letter, as shown in figure 2. For a spring, a lower case (s) in parentheses is appended to the number as described.

Records of Wells and Springs

Records for 88 wells and springs in the Drewsey Resource Area outside that area studied by Leonard (1970) are listed in table 1. Well records for the Harney Valley are included in Leonard's (1970) report. Most of the wells for which drillers' reports were available have been field located; their locations are shown on plate 1. Most of these well locations are also plotted on Geological Survey 1:24,000-scale quadrangle maps, and these field maps are on file in the Geological Survey Oregon District Office. Table 1 also includes some data on selected springs; wherever possible the discharge of the

Figure 2. — Well-numbering system

spring was measured at the time of the visit. Little or no data were available, however, for estimating the annual range of discharge of each spring.

Drillers' Logs of Wells

Drillers' logs of wells are obtained from reports submitted by drillers to the Oregon Water Resources Department since 1956 and from records supplied by the Bureau of Land Management. Drillers' terminology for the materials penetrated vary from driller to driller. Therefore, the logs in table 2 have been edited for consistency, but they otherwise remain unchanged.

Hydrographs of Observation Wells

Hydrographs in figure 3 show fluctuations of ground-water levels in four representative observation wells in the Drewsey Resource Area. The period of record for two of the wells extends from 1928 and 1930 to the present, and the other two are for shorter periods. Ground-water levels generally rise each year when the ground-water reservoir is recharged and ground-water storage is increased. Water levels decline during periods of no recharge as ground-water storage decreases. If over a period of time, ground-water discharge exceeds the rate of recharge, water levels gradually decline and the hydrographs show a declining trend. Conversely, a rising trend occurs when ground-water recharge exceeds ground-water discharge. In most of the Drewsey Resource Area no rises nor declining trends are apparent and ground-water levels are more or less stable. This suggests that ground-water recharge and discharge in the area generally are in balance. Ground-water pumpage in some of the area near Burns, however, is gradually increasing and some observation wells show declining trends.

Table 4 is a summary of the observation-well data for 35 wells in the Drewsey Resource Area and bordering area. The locations of the observation wells are shown on plate 1, and well records are in table 1 in this report or in the report by Leonard (1970). Hydrographs of water levels for each observation well are available from the Oregon Water Resources Department or from the Oregon District of the Geological Survey.

Chemical Quality of Ground Water

Chemical analyses were made by the Geological Survey of 16 ground-water samples from the Drewsey Resource Area. The source and significance of the chemical constituents and physical properties are summarized in table 4, and the analyses are listed in table 5.

Chemical diagrams for each analysis are shown on plate 1. The scale of the diagrams is similar to those presented in Leonard's report (1970); therefore, a visual comparison of the areal variation of the chemical quality of the ground water is possible.

Data from table 4 are plotted on a salinity diagram (fig. 4) which shows the classification of the ground water for irrigation use.

Figure 3. — Hydrographs of selected observation wells.

Figure 4. — Classification of irrigation waters. Numbers of plotted circles correspond to sample numbers in table 5. Sample number 7 plots off the upper and of the diagram.

GLOSSARY OF SELECTED TERMS

Aquifer.--A formation, group of formations, or part of a formation that contains sufficient saturated permeable material to yield significant quantities of water to wells or springs.

Confined ground water.--Ground water that is under pressure significantly greater than atmospheric. In a well that taps a confined ground-water body, the static water level is above the top of the aquifer.

Drawdown.--The lowering of ground-water level caused by pumping. It is the difference, generally, in feet or meters, between the static water level and the pumping water level in a well.

Evapotranspiration.--Water withdrawn from a land area by evaporation from water surfaces and moist soil and by plant transpiration.

Hydraulic conductivity.--The volume of water that will move in unit time under a unit hydraulic gradient through a unit area measured at right angles to the direction of flow.

Hydraulic gradient.--The change in static head per unit of distance in a given direction. The direction generally is understood to be that of the maximum rate of decrease in head.

Intermittent (or seasonal) stream.--A stream that flows only at certain times of the year when it receives water from springs or from some surface source such as melting snow in mountainous areas.

Perched ground water.--Unconfined ground water separated from an underlying body of ground water by an unsaturated zone.

Perennial stream.--A stream that flows continuously.

Potentiometric surface.--A surface that represents the static head. In an aquifer it is defined by the levels at which water stands in tightly cased wells.

Runoff.--That part of the precipitation that appears in surface streams.

Specific capacity.--The rate of discharge of water in a well divided by the drawdown of water level within the well. It is an approximate index of the capability of an aquifer to transmit water.

Static head.--The height above a datum (mean sea level) of the surface of a column of water in a well. The terms "head" and "static water level" are used interchangeably in this report. The static water level in a well represents the average head of the water-bearing materials open to the well bore.

Unconfined ground water.--Ground water in an aquifer that has a water table.

Water table.--The potentiometric surface in an unconfined water body at which the pressure is atmospheric.

Table 1.--Records of selected wells and springs in the Drewsey Resource Area

Well number: See page 7 for description of well- and spring-numbering system.

Type of well: Dr, drilled.

Depth of casing: Depth of casing indicates total length of casing.

Finish: P, perforated; X, open hole.

Character of material: Character of material refers to water-bearing formations as reported by driller.

Altitude: Altitude of land surface at well, in feet above mean sea level, interpolated from topographic maps, generally to the nearest 1 foot.

Water level: Depths to water below land surface given in feet and decimals were measured by personnel of the Geological Survey or the Oregon Water Resources Department; those given in whole feet were reported by well driller or owner.

Specific conductance: Field measurements by Geological Survey personnel. Units used: micromhos per centimeter at 25°C.

pH: See table 4 for explanation of pH.

Type of pump: C, centrifugal; J, jet; N, none; P, piston; S, submersible; T, turbine.

Drawdown: 1/ Drawdown probably less than 1 foot.

Use: H, domestic; I, irrigation; S, stock; U, unused.

Remarks: C, chemical analysis reported in table 5; L, driller's log in table 2. B, bailed; P, pumped; Air test, test pumped using compressed air for indicated time to determine yield under "Well performance." Obs, observation well whose water level is measured periodically. Sc, specific capacity. Values less than 1 are computed to the nearest 100th, values between 1 and 10 are rounded to the nearest 10th, and values greater than 10 are rounded to the nearest whole number. Where drawdown is reported as zero, actual drawdown is assumed to be less than 1 foot.

<u>20S/36E-32bba.</u> Bill Robertson. Altitude 3,550 ft. Drilled by Holloway Drilling, 1966. Casing: 12-in diam to 72 ft; perforated 22-72 ft			Clay, green, sticky-----	48	300
Soil-----	7	7	<u>26S/31E-34ddd.</u> M. J. Haines. Altitude 4,099 ft. Drilled by Rossberg & Son Irrigation, 1959. Casing: 12-in diam to 91 ft; unperforated		
Clay-----	8	15	Soil and hardpan-----	40	40
Rock, gray-----	40	55	Clay, blue-----	20	60
Rock, broken-----	16	71	Sandstone-----	13	73
Rock, black, hard-----	11	82	Gravel, small-----	1	74
Rock, red-----	30	112	Clay, blue-----	6	80
Rock, black-----	36	148	Gravel, small-----	4	84
Clay, black-----	72	220	Quicksand-----	3	87
Clay, brown-----	65	285	Basalt-----	28	115
<u>21S/35E-13dbc.</u> Lee Williams. Altitude 3,795 ft. Drilled by Holloway Drilling, 1968. Casing: 6-in diam to 103 ft; perforated 22-100 ft			Cinders, red, hard-----	25	140
Soil, sandy-----	7	7	Cinders, red, loose-----	7	147
Clay, brown-----	23	30	<u>26S/33E-13daa.</u> Lester Thompson. Altitude 4,135 ft. Drilled by Jack McClure Drilling, 1957. Casing: 14-in diam to 40 ft; unperforated. Reconditioned 1968; 12-in liner; perforated to 96 ft		
Clay, blue-----	15	45	Soil-----	11	11
Gravel, small-sized-----	1	46	Clay, yellow-----	23	34
Clay, black-----	174	220	Rock, lava-----	30	64
Clay, green-----	11	231	Cinders, coarse, water-bearing-----	3	67
Sand, green-----	1	232	Clay, red-----	7	74
Clay, green-----	18	250	Rock, yellow-----	4	78
<u>22S/34E-20bba.</u> John Temple. Altitude 4,596 ft. Drilled by Holloway Drilling, 1968. Casing: 8-in diam to 20 ft; unperforated			Clay, yellow-----	5	83
Soil-----	2	2	Rock-----	22	105
Clay-----	22	24	Cinders, water-bearing-----	3	108
Sand-----	1	25	<u>26S/33E-26dcc.</u> U.S. Bureau of Land Management. Altitude 4,105 ft. Drilled in 1955; driller unknown. Casing: 6-in diam to 63 ft; unperforated		
Clay, blue-----	104	129	Clay-----	64	64
Rock, creviced-----	5	134	Rock-----	31	95
<u>22S/35E-17ddc.</u> Joe Fine. Altitude 3,780 ft. Drilled by Skinner & Sons Drilling, 1964. Casing: 6-in diam to 115 ft; perforated 110-115 ft			Rock, soft-----	2	97
Soil-----	6	6	Sand-----	1	98
Sand, fine-----	6	12	Clay-----	11	109
Clay, sandy-----	8	20	Clay, with sand streaks-----	5	114
Gravel, medium-----	12	32	Silt-----	1	115
Clay, blue-----	68	100	<u>26S/33E-28dcb.</u> A. B. Hann. Altitude 4,107 ft. Drilled by W. C. Smoot Drilling, 1957. Casing: 16-in diam to 63 ft; perforated 13-38 ft		
Sand, black, and small gravel-----	10	110	Soil, sandy loam-----	16	16
Rock, red-----	5	115	Quicksand and clay, water-bearing-----	4	20
<u>23S/37E-27dbd.</u> Cliff Blaylock. Altitude 3,325 ft. Drilled by Harold E. Hartling Drilling, 1976. Casing: 8-in diam to 73½ ft; perforated 68-70 ft			Clay and sand-----	8	28
Clay and rock-----	19	19	Sand and silt, blue-----	7	35
Rock, black-----	9	28	Clay, soft, and sand-----	10	45
Rock, broken-----	4	32	Cinders, black, water-bearing-----	10	55
Rock, black, solid-----	31	63	Cinders, red, water-bearing-----	10	65
Rock, black, broken-----	3	66	<u>26S/34E-19cab.</u> F. E. Jones. Altitude 4,115 ft. Drilled by Skinner & Sons Drilling, 1963. Casing: 6-in diam to 20 ft; unperforated		
Rock, black, solid-----	4	70	Soil, brown-----	3	3
Rock, black, porous-----	3	73	Clay, yellow-----	27	30
Clay, brown-----	2	75	Clay, blue, with trace of black sand-----	24	54

^{1/} Refers to latest 10 years of record; where period of record is less than 10 years, no comment is made.

^{2/} Well reportedly flowed at land surface when drilled (Leonard, 1970, p. 36).

Table 4.--Source and significance of chemical and physical characteristics of water

Constituent	Potential source(s)	Significance or definition
Silica (SiO ₂)	Silicate minerals in rocks.	Forms hard scale in high-pressure boilers.
Iron (Fe)	Iron-bearing minerals, well casings, and pipes.	In concentrations greater than 0.3 mg/L, may stain laundry and porcelain plumbing fixtures (National Academy of Sciences, 1974). Larger concentrations may impart objectionable taste to water.
Manganese (Mn)	Manganese-bearing minerals, decomposition of plant tissue.	In concentrations greater than 0.05 mg/L may cause brown to black stain in laundry and porcelain plumbing fixtures (National Academy of Sciences, 1974). Generally has same objectionable features as iron.
Calcium (Ca)	Rocks, soils, and "hardpan" deposits rich in calcium carbonate minerals and from fertilizers.	A constituent of scale deposits in water pipes, boilers, and cookware. Principal cause of water hardness.
Magnesium (Mg)	Ferromagnesium minerals in rocks.	A constituent of scale deposits in water pipes, boilers, and cookware. Second principal cause of water hardness.
Sodium (Na)	Sodium-bearing minerals in rocks; industrial wastes	Large concentrations in combination with chloride give water salty taste. Large concentrations in irrigation water may reduce soil permeability.
Potassium (K)	Potassium-bearing minerals in rocks; present in plant tissue, sewage, industrial wastes, and fertilizers.	Essential plant nutrient.
Bicarbonate (HCO ₃) and carbonate (CO ₃)	Carbon dioxide in air and soil atmosphere, "hardpan" deposits, or cementing material in sediments; also decomposition of organic matter in soil.	In combination with calcium and magnesium, cause carbonate hardness. Carbonates of calcium and magnesium form scale in steam boilers and hot-water facilities and release corrosive carbon dioxide gas.
Sulfate (SO ₄)	Sulfide minerals in rocks, gypsum, precipitation, fertilizers, and sewage.	Sulfates of calcium and magnesium form hard scale. In concentrations greater than about 250 mg/L may have unpleasant taste and be cathartic to some individuals (National Academy of Sciences, 1974).
Chloride (Cl)	Soils and rocks, evaporite minerals, precipitation, animal wastes, and sewage.	Makes water corrosive; more than 250 mg/L may impart salty taste to water (National Academy of Sciences, 1974).
Fluoride (F)	Fluoride-bearing minerals which occur in trace amounts in most rocks.	Optimum concentrations tend to reduce decay of children's teeth; larger concentrations cause mottling of enamel of teeth. Concentration of fluoride in drinking water should not exceed 2 mg/L (U.S. Environmental Protection Agency, 1975).
Nitrate (NO ₃) as N	Bacterial action in soil and plants; concentrated in plant and animal wastes, sewage, and fertilizers.	Essential plant nutrient. In surface water excessive nitrate and phosphates in combination cause algal blooms which may result in organic enrichment of water and depletion of dissolved oxygen. Consumption of water with more than about 10 mg/L of nitrate as N may cause methemoglobinemia in infants (U.S. Environmental Protection Agency, 1975). In excess of average concentrations may indicate pollution by organic wastes.
Phosphorus (P or phosphate (PO ₄))	Phosphorus-bearing minerals present in most rocks in trace amounts. Component of sewage, animal wastes, fertilizers, and some detergents.	Essential plant nutrient. See nitrate.
Boron (B)	Boron-bearing minerals, volcanic gases, thermal springs, and sewage.	Essential in trace amounts to plant nutrition. In concentrations greater than about 2 mg/L, may be toxic even to tolerant crops (National Academy of Sciences, 1974).
Arsenic (As)	Dissolved from arsenic-bearing minerals. Ingredient of many herbicides and insecticides.	Prolonged consumption of water containing more than about 0.05 mg/L of arsenic may lead to chronic poisoning (U.S. Environmental Protection Agency, 1975).
Dissolved solids (residue on evaporation or calculated)		Measure of the concentration of dissolved solids in water.
Specific conductance		Indicator of the ability of a solute to conduct an electrical current. Gives indication of the concentration of dissolved solids in water.
Hardness as (CaCO ₃)	Mainly dissolved calcium and magnesium in water.	Property of water related to the formation of an insoluble curd with soap and the formation of scale in pipes, boilers, and cooking utensils.
pH (hydrogen ion activity)	Hydrogen ions in solution.	Hydrogen ion activity expressed in negative logarithmic units. A measure of the dissociation of water molecules. A neutral solution has a pH of 7.0.
Temperature	Determined by local environment.	Important physical characteristic that affects taste, efficiency of waste-treatment processes, cooling, suitability of habitat for aquatic life, and suitability for irrigation.
SAR (sodium-adsorption-ratio)	Calculated from the following equation: $SAR = \frac{(Na^+)}{\sqrt{\frac{(Ca^{+2}) + (Mg^{+2})}{2}}}$ where: Na ⁺ , Ca ⁺² , Mg ⁺² are in milliequivalents per liter.	Equation predicts the degree to which irrigation water tends to enter into cation-exchange reactions in soil. High SAR values imply a hazard of sodium replacing adsorbed calcium and magnesium; this replacement is damaging to soil structure.

Table 5.--Chemical analyses of ground water in the Drewsey Resource Area

Sample number	Location number	Depth of well (feet)	Date of collection	Milligrams per liter																			pH	Temperature °F °C			
				Silica (SiO ₂)	Iron (Fe)	Manganese (Mn)	Calcium (Ca)	Magnesium (Mg)	Sodium (Na)	Potassium (K)	Bicarbonate (HCO ₃)	Carbonate (CO ₃)	Sulfate (SO ₄)	Chloride (Cl)	Fluoride (F)	Nitrite + nitrate as N	Phosphate, ortho as P	Arsenic (As)	Boron (B)	Dissolved solids, calculated from determined constituents	Hardness as CaCO ₃	Noncarbonate hardness				Specific conductance (micromhos/cm at 25°C)	Sodium-adsorption-ratio (SAR)
