COPYRIGHT STATEMENT

The copyright law of the United States (Title 17, United States Code) governs the making of photocopies or other reproductions of copyrighted materials including foreign works under certain conditions. In addition, the United States extends protection to foreign works by means of various international conventions, bilateral agreements, and proclamations.

Under certain conditions specified in the law, libraries and archives are authorized to furnish a photocopy or other reproduction. One of these specified conditions is that the photocopy or reproduction is not to be "used for any purpose other than private study, scholarship, or research." If a user makes a request for, or later uses, a photocopy or reproduction for purposes in excess of "fair use," that user may be liable for copyright infringement.

The Columbia University Libraries reserve the right to refuse to accept a copying order if, in its judgement, fulfillment of the order would involve violation of the copyright law.

FRUITS AND NUTS:
BEARING ACREAGES
1919-46

This is the first publication that gives a complete statistical series of estimates of bearing acreages for noncitrus fruit crops for all States. Estimates of bearing acreages for citrus fruits were first published in October 1947 in "Citrus Fruits: Production, Farm Disposition, Value and Utilization of Sales" and for almonds, walnuts, and filberts in "Tree Nuts: Acreage, Production, Farm Disposition, Value, and Utilization of Sales." For most crops and States the acreage estimates in these publications include the years 1919-46. Production estimates corresponding to all of the bearing-acreage series are found in the publications mentioned above and in "Fruits (Noncitrus): Production, Farm Disposition, Value, and Utilization of Sales," for the years 1889 to 1944 dated May 1948 and for 1945 to 1947 dated July 1948.

These estimates include bearing acreages of most of the fruits and bearing acreages of almonds, walnuts, and filberts. Because large numbers of pecan trees are located outside of established orchards, data on tree numbers are very incomplete and are not sufficiently reliable to justify the preparation of estimates of acreages of pecan trees. (Bearing acreage refers to trees of bearing age.)

For California, estimates of bearing acreages have been published annually since 1921. The first detailed coverage by age groups and varieties for all counties was obtained by the extensive Federal-State survey of 1936. Since then, records for this State have been provided through cooperation between the respective county agricultural commissioners and the California Crop and Livestock Reporting Service, partly from new surveys and partly by recording changes from the previous years.

In developing these records for California, most of the field work was done by the county agricultural commissioners and their staffs, while some of the field work and much of the assembling and compilation of data were done by the staff of the California Crop and Livestock Reporting Service. The major year-to-year changes include: acreages removed or abandoned, new plantings made, and the shifting from a nonbearing position to bearing. All improved records obtained from more recent surveys are used each year.

This report includes some revisions of the estimates shown in the annual publications of the California Crop and Livestock Reporting Service. The totals published by that agency are summations of county totals and are shown to the nearest acre. In this publication, these totals have been rounded to the nearest 100 acres except in the case of dates, persimmons, and pomegranates; their totals have been rounded to the nearest 10 acres.

Prepared by Cary D. Palmer, E. O. Schlotzhauer, and P. F. Kiesler under the general direction of R. Royston, from reports submitted by field statisticians of the Bureau of Agricultural Economics and other available data.

FRUITS AND NUTS:
BEARING ACREAGES
1919-46

This is the first publication that gives a complete statistical series of estimates of bearing acreages for noncitrus fruit crops for all States. Estimates of bearing acreages for citrus fruits were first published in October 1947 in "Citrus Fruits: Production, Farm Disposition, Value and Utilization of Sales" and for almonds, walnuts, and filberts in "Tree Nuts: Acreage, Production, Farm Disposition, Value, and Utilization of Sales." For most crops and States the acreage estimates in these publications include the years 1919-46. Production estimates corresponding to all of the bearing-acreage series are found in the publications mentioned above and in "Fruits (Noncitrus): Production, Farm Disposition, Value, and Utilization of Sales," for the years 1889 to 1944 dated May 1948 and for 1945 to 1947 dated July 1948.

These estimates include bearing acreages of most of the fruits and bearing acreages of almonds, walnuts, and filberts. Because large numbers of pecan trees are located outside of established orchards, data on tree numbers are very incomplete and are not sufficiently reliable to justify the preparation of estimates of acreages of pecan trees. (Bearing acreage refers to trees of bearing age.)

For California, estimates of bearing acreages have been published annually since 1921. The first detailed coverage by age groups and varieties for all counties was obtained by the extensive Federal-State survey of 1936. Since then, records for this State have been provided through cooperation between the respective county agricultural commissioners and the California Crop and Livestock Reporting Service, partly from new surveys and partly by recording changes from the previous years.

In developing these records for California, most of the field work was done by the county agricultural commissioners and their staffs, while some of the field work and much of the assembling and compilation of data were done by the staff of the California Crop and Livestock Reporting Service. The major year-to-year changes include: acreages removed or abandoned, new plantings made, and the shifting from a nonbearing position to bearing. All improved records obtained from more recent surveys are used each year.

This report includes some revisions of the estimates shown in the annual publications of the California Crop and Livestock Reporting Service. The totals published by that agency are summations of county totals and are shown to the nearest acre. In this publication, these totals have been rounded to the nearest 100 acres except in the case of dates, persimmons, and pomegranates; their totals have been rounded to the nearest 10 acres.

Prepared by Cary D. Palmer, E. O. Schlotzhauer, and P. F. Kiesler under the general direction of R. Royston, from reports submitted by field statisticians of the Bureau of Agricultural Economics and other available data.

For the other States, the estimates of acreages are the joint product of the field and the Washington statisticians of the Bureau of Agricultural Economics. Information on the numbers and acreages by age groups is much less comprehensive for these States than for California. Measures of year-to-year change, such as annual records of removals and new plantings, are not available for most States but all available basic data were used in preparing these estimates. These include the Federal Quinquennial Census of tree numbers, results of the sample surveys of tree numbers and acreages conducted by the Bureau of Agricultural Economics and other agencies, and other available indications. Surveys of tree numbers and acreages similar to the 1936 California survey are needed for nearly all of the other important fruit States.

Trends in Fruit Acreages

The area devoted to fruit crops in the United States has declined one-tenth, but the production has more than doubled during the quarter-century (1919-46) covered by the fruit-acreage estimates given in this report. This decline in bearing acreage has resulted from a combination of several factors, including the abandonment of orchards on poor soils and of orchards with high risks of spring frost. Many of these poorly located orchards came from unwise promotional ventures. The increase in production is due largely to an increased acreage in the irrigated areas of the West and to a decline in the low-yielding, nonirrigated areas of the central and eastern States. Improved cultural practices, increased use of fertilizer, and improved control of insects and diseases, have also been influential in increasing fruit yields. (Fig. 1.)

In this quarter of a century, the area devoted to noncitrus fruit crops has declined materially in the eastern and central States. The decline was sharpest during the late 1930's when the production of fruit was relatively unprofitable. In the western States, the acreage increased until the late 1920's; it declined during the 1930's and has not varied much since the late 1930's, although it showed a slight upward trend during the early 1940's. (Fig. 2.)

Apples: The bearing acreage of apples in the United States has declined steadily since 1919, but still is the largest of any single fruit crop. Total bearing acreage in 1946 was only about half the total bearing acreage in 1919. The largest decline occurred in the central States, which have less than half of the acreage they had a quarter-century ago. The decline was only slightly less drastic in the eastern States. In these areas, farm orchards were planted extensively in the last century and in the early 1900's, but they have declined in importance and are apparently still declining gradually. In the western States, the peak of bearing acreage of apples was reached before 1919. The acreage declined gradually after that until the early 1940's, and at present it appears to be on about a level trend. In all areas, the greatest decline in acreage has occurred in the sections which have proved to be least suited to fruit production. Estimates are available for noncommercial and commercial counties, separately, for the period 1934-46. In this 13-year period the decline in noncommercial areas has been greater than in commercial areas. (Figs. 3 and 4.)

Peaches: The bearing acreage of peaches in the United States reached a peak in the mid-1920's, declined steadily until the late 1930's, and increased during the early 1940's. California, which in 1946 had about 13 percent of the United States bearing acreage of peaches and 43 percent of the production, showed a marked shift in trend during the last quarter of a century. The acreage increased during the 1920's largely because of an increase in Clingstones for canning; it declined from the late 1920's until the early 1940's. The acreage shows considerable increase during the 1940's. Peaches have proved to be profitable in other western irrigated areas, especially in the State of Washington. The acreage in the western States, excluding California, has increased gradually since the late 1920's and still appears to be increasing. In the 10 southern States, which furnish the bulk of the peaches for the June and July markets, the acreage increased until the mid-1920's, declined until the mid-1930's and has gradually increased since then. A noteworthy change within this group of States has been the increase within the past 15 years in South Carolina. In the central States, the acreage devoted to peaches reached a low point in the late 1930's and increased in the early 1940's, largely through new plantings in Michigan. (Figs. 5 and 6.)

Pears: Following the large plantings of pears in the Pacific Coast States during the 1920's and shortly before, the United States bearing acreage of pears reached a peak in the mid-1930's. While acreage was increasing in the western States, it was gradually declining in the central and eastern States, mainly because of the more favorable climate and soils in the irrigated areas of the West. But the ravages of fire blight have eliminated much pear acreage in both the East and the West. The pear acreage in the Pacific Coast States, which in 1946 comprised 47 percent of the U. S. acreage and accounted for 81 percent of the production, more than doubled between 1919 and 1933 but declined about one-fifth between 1933 and 1942. (Figs. 7 and 8.)

Grapes: California dominates the grape industry of the United States. In recent years, this State has produced more than 90 percent of the U. S. grape crop on about four-fifths of the U. S. grape acreage. The bearing acreage of all three types of California grapes (raisin, wine, and table varieties) increased during the 1920's, declined during the 1930's, and has been about stable since the late 1930's. The acreage of raisin and table varieties reached a peak about 1927 and wine varieties about 1929. There has been a decline in acreage on the poorly adapted sites and soils, and an increase in the better adapted areas of California during the last 15 years. In the central and eastern States the bulk of the commercial production is found around the Great Lakes and is utilized mostly for grape juice. The acreage increased until the early 1930's and has declined gradually since then. (Figs. 9 and 10.)

Cherries: The bearing acreage of cherries in the United States is divided into the sour varieties produced primarily for processing and grown in the Great Lakes States, and the sweet varieties produced primarily for fresh market but also for processing, and grown mostly in the Pacific Coast States. The acreage of the sour varieties increased very sharply in the early 1930's principally because of extensive plantings in Michigan. The acreage declined

gradually in the late 1930's when prices were very unsatisfactory to orchardists but has increased gradually since then. In the Pacific Coast States, there was a steady increase in acreage devoted to sweet cherries, between 1919 and 1939. The acreage peak was reached in California in the late 1930's and in Washington and Oregon in the middle 1940's. (Figs. 11 and 12.)

Prunes and Plums: The bearing acreage of prunes for drying in California increased sharply until the early 1930's and has since declined gradually. California prune trees are very old on the average and a continuing decline in acreage seems likely. In the Northwest (Oregon, Washington, and Idaho), total bearing acreage of prunes in 1946 was about equal to that of 1919. In western Oregon and Washington--where prunes are produced primarily for processing and where a large proportion of the crop formerly was produced for drying--acreage reached a peak in the late 1920's. It has declined sharply since then, and appears to be still on a downward trend. In eastern Oregon, eastern Washington, and Idaho, where prunes are produced primarily for fresh market, the acreage has increased since the late 1930's. The plum acreage in California increased until the late 1920's, declined until the early 1940's, and has increased slightly since then. (Fig. 13.)

Tree Nuts: The bearing acreage devoted to tree nuts in the Pacific Coast States has increased sharply during the last 25 years. Between 1919 and 1939 the walnut acreage doubled; since 1939 it has increased slightly. Almond acreage increased sharply in the 1920's, was almost stable in the 1930's, and has been increasing during the last few years. The almond acreage in California has declined in the low-yielding coastal counties and increased in the high-yielding interior valleys. The bearing acreage of filberts, a relatively new crop, has increased from 2,290 acres in 1929 to 18,570 acres in 1946. Practically all of the country's acreage of filberts is located in the Willamette Valley of Oregon and in southwestern Washington. (Fig. 14.)

Citrus: Practically all of the citrus fruits are produced in California, Arizona, Texas, and Florida. The bearing acreage has tripled during the last 25 years. The California acreage averages the oldest with 194,000 acres in 1919 and 321,400 acres in 1946. In contrast, Florida had an increase from 84,100 acres in 1919 to 389,200 acres in 1946. In Texas, where the bulk of the citrus acreage is in grapefruit, large plantings occurred in the late 1920's and early 1930's. The bearing acreage was only 10,400 acres in 1928 but reached 112,900 acres in 1946.

Oranges accounted for about two-thirds of the bearing acreage of citrus in the United States in 1946, when about one-fourth was in grapefruit and nearly a tenth in lemons. Nearly all of the country's lemon acreage is located in California. During the last quarter-century, the orange acreage has increased $2\frac{1}{2}$ times, grapefruit acreage nearly 7 times, and the lemon acreage has nearly doubled. (Figs. 15 and 16.)
