ANAGNI, a town of Latium, capital of the Hernici; which, after a faint reſiſtance, ſubmitting to the Romans, was admitted to the freedom of a city. It was afterwards a colony of Drufus Cæſar, and walled round, and its territory aſſigned to the veterans. Here Antony married Cleopatra, and divorced Octavia. It is thirty-fix miles to the eaſt of Rome. Lat. 42. 48. lon. 13. 45.

ANAGNOSTA, or ANAGNOSTES, *f.* in antiquity, a kind of literary ſervant, retained in the families of perſons of diſtinction, whoſe chief buſineſs was to read to them during meals, or at any other time when they were at leiſure. Cornelius Nepos relates of Atticus, that he had always an anagnoſtes at his meals.

ANAGOGE, *f.* [*αναγωγή*, of *ανα*, again, and *αγω*, to lead, Gr.] An elevation of the mind to ſearch after the hidden meaning of a paſſage, but more eſpecially the myſtical ſenſe of the Holy Scriptures.

ANAGOGETICAL, *adj.* That which contributes or relates to ſpiritual elevation, or religious raptures; myſterious; elevated above humanity.

ANAGO'GICAL, *adj.* [*anagogique*, Fr.] Myſterious; elevated; religiously exalted.

ANAGO'GICALLY, *adv.* [from *anagogical*.] Myſteriously; with religious elevation.

A'NAGRAM, *f.* [from *ανα*, backwards, and *γραμμα*, letter, Gr.] In literature, a tranſpoſition of the letters of ſome name, whereby a new word is formed, either to the advantage or diſadvantage of the perſon or thing to which the name belongs. Thus, the anagram of Galenus is *angelus*; that of Logica, *caligo*; that of Alſtedius, *ſedulitas*, &c. Calvin, in the title of his *Inſtitutions*, calls himſelf *Alcuinus*, which is the anagram of Calvinus, and the name of an eminently learned perſon in the time of Charlemagne. Thoſe who adhere ſtrictly to the definition of an anagram, take

take no other liberty than that of omitting or retaining the letter H, at pleasure; whereas others make no scruple to use ϵ for π , ν for w , s for z , and c for k ; and *vice versa*. But, besides anagrams formed as above, we meet with another kind in ancient writers, made by dividing a single word into several; thus, *fus tinea mus*, are formed out of the word *Justinianus*. Anagrams are sometimes also made out of several words: such is that on the question put by Pilate to our Saviour, *Quid est veritas?* whereof we have this admirable anagram, viz. *Est vir qui adest*. The Cabballists among the Jews are professed anagrammatists; the third part of their art, which they call *themuru*, that is, "changing," being nothing but the art of making anagrams, or of finding hidden and mystical meanings in names; which they do by changing, transposing, and differently combining, the letters of those names. Thus, of נח the letters of Noah's name, they make הן grace; of משיח the Messiah, they make ישעיה he shall rejoice.

ANAGRAMMATISM, *f.* The act or practice of making anagrams.—The only quintessence that hitherto the alchymy of wit could draw out of names, is *anagrammatism*, or *metagrammatism*, which is a dissolution of a name truly written into his letters, as his elements, and a new connexion of it by artificial transposition, without addition, subtraction, or change of any letter into different words, making some perfect sense applicable to the person named. *Camden*.

ANAGRAMMATIST, *f.* [from *anagram*.] A maker or composer of anagrams. Thomas Billon, a provincial, was a celebrated anagrammatist, and retained by Louis XIII. with a pension of 1200 livres, in quality of anagrammatist to the king.

TO ANAGRAMMATIZE, *v.n.* [*anagrammatizer*, Fr.] To make anagrams.

ANAGRAPHE, *f.* [of *αναγραφή*, of *ανα*, and *γραφω*, to write.] A description, a registering or recording of acts; an inventory, a breviate.

ANAGROS, *f.* in commerce, a measure for grain, used in some cities of Spain, particularly at Seville; forty-six anagros make about $10\frac{1}{4}$ quarters of London.

ANAGYRIS, *f.* [*ανagyris*, Gr. from the name of a town in Attica.] In botany, a genus of the decandria monogynia class, ranking in the natural order of papilionaceæ or leguminosæ. The generic characters are—Calyx: perianthium bell-shaped; mouth five-toothed, the upper pair of teeth more deeply divided. Corolla: papilionaceous; standard obcordate, straight, emarginate, broader than the other petals, twice as long as the calyx; wings ovate-oblong, flat, longer than the standard; keel straight, very long. Stamina: filaments parallel, distinct, rising; antheræ simple. Pistillum: germ oblong; style simple, rising; stigma villose. Pericarpium: an oblong, large, roundish, obtuse legume, a little reflex. Seeds: six, or more, kidney-form.—*Essential Character*. Standard and wings shorter than the keel in a papilionaceous corolla. Fruit, a legume.

Species. 1. *Anagyris fœtida*, or stinking bean trefoil: leaves ovate, flowers axillary. This grows wild in the south of France, in Spain, Italy, and Sicily; also about Smyrna. It is a shrub which usually rises to the height of eight or ten feet, and produces its flowers in April and May, which are of a bright yellow colour, growing in spikes somewhat like those of the laburnum. The seeds are never perfected in this country, which is the reason of its present scarcity in England.

2. *Anagyris cretica*: leaves oblong, racemes longer. A native of Candia, and some of the islands of the Archipelago, and is at present very rare in the English gardens. This sort has longer leaves than the former, and flowers later in the summer, so that it never produces seeds. It is probably only a variety.

3. *Anagyris inodora*: leaves pinnate; calyxes inflated, coloured; legumes compressed, straight; racemes terminating, oblong. Native of the woods of Cochinchina.

VOL. I. No. 32.

Propagation and Culture. These may be propagated by laying down their tender branches in the spring, observing to tongue them in the same manner as the layers of carnations, being careful in dry weather to supply them with water; which, if duly performed, the layers will have taken root by the following spring, when they should be cut off from the old plants, a little time before they begin to put out their leaves, and planted in a warm situation; for, if they are too much exposed to cold winds, they will be in danger of being destroyed in a hard winter. This method of propagating these plants, is to supply their defect in not producing ripe seeds in this country; for the plants which are produced from seeds will be much handsomer, and will rise to a much greater height. If you propagate these plants from seeds, you should sow them on a moderate hot-bed the beginning of March; or in a border of good rich earth, in a well-sheltered place, sifting over them about half an inch of fine mould, and covering them with a common frame, to protect them in case of severe weather. If the seeds are good, the plants will appear in a month after the seeds are sown; when they should be inured by degrees to the open air, into which they should be removed towards the end of May, placing them in a sheltered situation; for this purpose the seeds may be sown in pots, and plunged into a hot-bed, because the plants do not bear transplanting well till the spring following: and, as they are impatient of cold while young, the two first winters it will be proper to shelter them under a common frame, where the glasses may be drawn off every day in mild weather, that the plants may enjoy the open air, which will prepare them for planting abroad when they have acquired proper strength; it will be very proper to keep these plants in pots three years, in which time they will have advanced to be in proper condition for planting them into the places where they are intended to remain; the best time for this is about the beginning of April, just before the plants begin to put out new leaves: at which time they should be turned out of the pots, preserving good balls of earth to their roots, planting some of them against warm aspected walls, where they will not be in danger of suffering by frost; and the others may be planted in warm situations, where, if they are protected in severe winters by covering the surface of the ground about their roots with tanner's bark, and screening their heads with mats, they may be preserved several years. The fourth year from sowing, these plants will begin to produce their flowers, will continue flowering every year after, and will be very proper to intermix with other flowering shrubs of the same growth in warm situations. See *CYTISUS LABURNUM*.

ANAGYRIS, or **ANAGYRUS**, the name of a place in Attica, of the tribe Erechtheis, where a fetid plant, called *Anagyris*, probably the same with the foregoing, grew in great plenty.

ANAITIS, a surname of Venus among the Armenians; where the virgins consecrated to her service esteemed themselves more dignified by public prostitution. Diana was also worshipped under this name by the Lydians.

ANAK, [אנאק Heb. i. c. a collar.] The father of the Anakims, was the son of Arba, who gave his name to Kirjath-arba, or Hebron, Josh. xiv. 15. Anak had three sons, Shefhai, Ahiman, and Talmi, chap. xv. 14. and Numb. xiii. 22. who, as well as their father, were giants; and who, with their posterity, all terrible for their fierceness and extraordinary stature, were called *Anakims*; in comparison of whom the Hebrews, who were sent to view the land of Canaan, reported that they were but as grasshoppers, Numb. xiii. ult. Caleb, assisted by the tribe of Judah, took Kirjath-arba, and destroyed the Anakims, Judg. i. 20. and Josh. xv. 14. in the year of the world 2559.

ANALCES, *f.* [from *a neg.* and *αλην*, strength, Gr.] Weak, effeminate. Hippocrates uses this word as an epithet for the Asiatic nations.

ANALECTA, *f.* [of *αναλεκτα*, of *ανα*, and *λεγομαι*, to

to gather, Gr.] Fragments, or crumbs gathered up from the table. Collections, or scraps collected out of authors.

ANALEMMA, *f.* A planisphere, or projection of the sphere, orthographically made on the plane of the meridian, by perpendiculars from every point of that plane, the eye supposed to be at an infinite distance, and in the east or west point of the horizon. In this projection, the solstitial colure, and all its parallels, are projected into concentric circles, equal to the real circles in the sphere; and all circles whose planes pass through the eye, as the horizon and its parallels, are projected into right lines equal to their diameters; but all oblique circles are projected into ellipses, having the diameter of the circle for the transverse axis. This instrument, having the furniture drawn on a plate of wood or brass, with an horizon fitted to it, is used for resolving many astronomical problems; as, the time of the sun's rising and setting, the length and hour of the day, &c. It is also useful in dialling, for laying down the signs of the zodiac, with the lengths of days, and other matters of furniture upon dials. The oldest treatise we have on the analemma, was written by Ptolemy, which was printed at Rome in 1562, with a commentary by F. Commandine. Pappus also treated of the same. Since that time, many other authors have treated very well of the analemma; as, Aguilonius, Taquet, Dechaies, Witty, &c.

ANALEPSIA, *f.* That species of epilepsy which proceeds from the stomach being disordered. It is by some put synonymously with epilepsy in general.

ANALEPTICS, *f.* [*αναλεπτικα*, Gr.] To recover and regain vigour after sickness. Restorative or nourishing medicines, particularly such as exhilarate the spirits, and promote flesh and strength. Dr. Cullen says, they are medicines suited to restore the force of the body when lost, and sometimes employed with respect to stimulus; but more commonly with respect to those substances which supply a deficient nourishment. Besides the nutritious quality of restoratives, they have a sweet, fragrant, subtil, oleous, principle, which immediately affects the nerves, and gives a kind of friendly motion to the fluids. In diseases, the speediest way to restore strength, is to remove the cause occasioning the debility; but this is not to be done merely by the force of medicines, which increase the vital heat; for, in convulsions and fevers, the motions are very strong, and yet the natural strength is languid: whence it is concluded, that true strength depends upon congruous aliments, turned into laudable blood and juices, yielding plenty of animal heat, the true and only source of firmness and vigour. Cordial flowers and herbs, musk, ambergris, oil of cinnamon made into olea sacchara, chocolate, shell-fish, &c. are *analeptic*.

ANALGESIA, *f.* [*α neg.* and *αλγος*, Gr. pain, or grief.] Indolence, or absence of pain and grief. A state of ease.

ANALOGAL, *adj.* Analogous; having relation.—When I see many *analogal* motions in animals, though I cannot call them voluntary, yet I see them spontaneous, I have reason to conclude, that these in their principle are not simply mechanical. *Hale*.

ANALOGICAL, *adj.* Used by way of analogy. It seems properly distinguished from *analogous*, as words from things; *analogous* signifies having relation, and *analogical* having the quality of representing relation.—It is looked on only as the image of the true God, and that not as a proper likeness, but by *analogical* representation. *Stillington*.—When a word, which originally signifies any particular idea or object, is attributed to several other objects, not by way of resemblance, but on the account of some evident reference to the original idea, this is peculiarly called an *analogical* word; so a sound or healthy pulse, a sound digestion, sound sleep, are so called, with reference to a sound and healthy constitution; but, if you speak of sound doctrine, or sound speech, this is by way of resemblance to health, and the words are metaphorical. *Watts*.

Analogous; having resemblance or relation.—There is placed the minerals between the inanimate and vegetable province; participating something *analogical* to either. *Hale*.

ANALOGICALLY, *adv.* In an analogical manner; in an analogous manner.—I am convinced, from the simplicity and uniformity of the Divine Nature, and of all his works, that there is some one universal principle, running through the whole system of creatures *analogically*, and congruous to their relative natures. *Chayne*.

ANALOGICALNESS, *f.* The quality of being analogical; fitness to be applied for the illustration of some analogy.

ANALOGISM, *f.* [*αναλογισμος*, Gr.] An argument from the cause to the effect.

To **ANALOGIZE**, *v. a.* To explain by way of analogy; to form some resemblance between different things; to consider something with regard to its analogy with something else.—We have systems of material bodies, diversely figured and situated, if separately considered; they represent the object of the desire, which is *analogized* by attraction or gravitation. *Chayne*.

ANALOGOUS, *adj.* [*ανα* and *λογος*, Gr.] Having analogy; bearing some resemblance or proportion; having something parallel.—Exercise makes things easy, that would be otherwise very hard; as, in labour, warchings, heats, and colds; and then there is something *analogous* in the exercise of the mind to that of the body. It is folly and infirmity that makes us delicate and froward. *L'Estrange*.—It has the word *to* before the thing to which the resemblance is noted.—This incorporeal substance may have some sort of existence, *analogous* to corporeal extension: though we have no adequate conception hereof. *Locke*.

ANALOGY, *f.* [from *ανα*, *per*, by, and *λογος*, *ratio*, reason.] Resemblance between things with regard to some circumstances or effects; as *learning* is said to *enlighten* the mind; that is, it is to the mind what light is to the eye, by enabling it to discover that which was hidden before.—From God it hath proceeded, that the church hath evermore held a prescript form of common prayer, although not in all things every where the same, yet, for the most part, retaining the same *analogy*. *Hooker*.—When the thing to which the analogy is supposed, happens to be mentioned, *analogy* has after it the particles *to* or *with*; when both the things are mentioned after *analogy*, the particle *between* or *betwixt* is used.—If the body politic have any *analogy* to the natural, an act of oblivion were necessary in a hot disordered state. *Dryden*.—By *analogy* with all other liquors and concretions, the form of the chaos, whether liquid or concrete, could not be the same with that of the present earth. *Burnet*.—If we make Juvenal express the customs of our country, rather than of Rome, it is when there was some *analogy* *betwixt* the customs. *Dryden*.—By grammarians, it is used to signify the agreement of several words in one common mode; as, from *love* is formed *loved*; from *hate*, *hated*; from *grieve*, *grieved*, &c.

ANALYSIS, *f.* [*analyse*, Fr. *αναλυσις*, Gr. of *ανα* and *λυσις*, a solution.] A separation of a compound body into the several parts of which it consists.—There is an account of dew falling in the form of butter, or grease, which grows extremely fetid; so that the *analysis* of the dew of any place, may, perhaps, be the best method of finding such contents of the soil as are within the reach of the fun. *Arbutnot*.—A consideration of any thing in parts, so as that one particular is first considered, then another.—*Analysis* consists in making experiments and observations, and in drawing general conclusions from them by induction, and admitting of no objections but such as are taken from experiments, or other certain truths. *Newton*.—A solution of any thing, whether corporeal or mental, to its first elements; as, of a sentence to the single words; of a compound word, to the particles and words which form it; of a tune, to single notes; of an argument to simple propositions.—We cannot know any thing of nature, but by an *analysis* of its true initial causes; till we know the first springs

springs of natural motions, we are still but ignorants. *Glanville.*

ANALYSIS, in mathematics, is properly the method of resolving problems by means of algebraical equations; whence we often find that these two words, *analysis* and *algebra*, are used as synonymous.

Mathematical analysis may be distinguished into the *ancient* and the *modern*. The ancient analysis, as described by Pappus, is the method of proceeding from the thing sought as *taken* for granted, through its consequences, to something that is *really* granted or known; in which sense it is the reverse of synthesis or composition, in which we lay that down *first* which was the *last* step of the analysis, and tracing the steps of the analysis back, making that antecedent here which was consequent there, till we arrive at the thing sought, which was taken or assumed as granted in the first step of the analysis. This chiefly respected geometrical enquiries. The principal authors on the ancient analysis, as recounted by Pappus, in the 7th book of his Mathematical Collection, are—*Euclid*, in his *Data*, *Porismata*, & *de Locis ad Superficem*; *Apollonius* de *Sectione Rationis*, de *Sectione Spatii*, de *Tactionibus*, de *Inclinationibus*, de *Locis Planis*, & de *Sectionibus Conicis*; *Ariflaus*, de *Locis Solidis*; and *Eratosthenes*, de *Mediis Proportionalibus*; from which Pappus gives many examples in the same book. To these authors we may add Pappus himself. The same sort of analysis has also been well cultivated by many of the moderns; as *Fermat*, *Viviani*, *Getaldus*, *Snellius*, *Huygens*, *Simpson*, *Stewart*, *Lawson*, &c. and more especially *Hugo d'Omerique*, in his *Analysis Geometrica*, in which he has endeavoured to restore the analysis of the ancients. And, on this head, *Dr. Pemberton* tells us, that *Sir Isaac Newton* used to censure himself for not following the ancients more closely than he did; and spoke with regret of his mistake, at the beginning of his mathematical studies, in applying himself to the works of *Descartes*, and other algebraical writers, before he had considered the *Elements* of *Euclid* with that attention so excellent a writer deserves: that he highly approved the laudable attempt of *Hugo d'Omerique* to restore the ancient analysis.

In the application of the ancient analysis in geometrical problems, every thing cannot be brought within strict rules; nor any invariable directions given, by which we may succeed in all cases; but some previous preparation is necessary, a kind of mental contrivance and construction, to form a connexion between the *data* and *quæsitæ*, which must be left to every one's fancy to find out; being various, according to the various nature of the problems proposed. Right lines must be drawn in particular directions, or of particular magnitudes; bisecting perhaps a given angle, or perpendicular to a given line; or perhaps tangents must be drawn to a given curve, from a given point; or circles described from a given centre, with a given radius, or touching given lines, or other given circles; or such-like other operations. Whoever is conversant with the works of *Archimedes*, *Apollonius*, or *Pappus*, well knows that they founded their analysis upon some such previous operations; and the great skill of the analyst consists in discovering the most proper affections on which to found his analysis: for the same problem may often be effected in many different ways: of which it may be proper to give here an example or two. Let there be taken, for instance, this problem, which is the 155th prop. of the 7th book of Pappus.

From the extremities of the base *A, B*, of a given segment of a circle, it is required to draw two lines *AC, BC*, meeting at a point *C* in the circumference, so that they shall have a given ratio to each other, suppose that of *F* to *G*. The solution of this problem, as given by Pappus, is thus:

ANALYSIS.

Suppose the thing done, and that the point *C* is found: then suppose *CD* is drawn a tangent to the circle at *C*, and meeting the line *AB* produced in the point *D*. Now by

the hypothesis $AC : BC :: F : G$, and also $AC^2 : BC^2 :: DA : DB$, as may be thus proved:

Since *DC* touches the circle, and *BC* cuts it, the angle *BCD* is equal to *BAC* by *Euc. iii. 32*; also the angle *D* is common to both the triangles *DCA, DCB*; these are therefore similar, and so, by *vi. 4*, $DA : DC :: DC : DB$, and hence $DA^2 : DC^2 :: DA : DB$, by *cor. vi. 20*. But also, by *vi. 4*, $DA : AC :: DC : CB$, and by permutation $DA : DC :: AC : BC$, or $DA^2 : DC^2 :: AC^2 : BC^2$; and hence, by equality, $AC^2 : BC^2 :: DA : DB$. But the ratio of AC^2 to BC^2 is given by *Prop. LVII.* of *Simpson's* edition of the *Data*, because the ratio of *AC* to *BC* is given, and consequently that of *DA* to *DB* is given. Now since the ratio of *DA* to *DB* is given, therefore also by *Data vi.* that of *DA* to *AB*, and hence by *Data ii.* *DA* is given in magnitude. And here the analysis properly ends. For it having been shewn that *DA* is given, or that a point *D* may be found in *AB* produced, such, that, a tangent being drawn from it to the circumference, the point of contact will be the point sought; we may now begin the composition or synthetical demonstration; which must be done by finding the point *D*, or laying down the line *AD*, which, it was affirmed, was given in the last step of the analysis.

SYNTHESIS.

Construction. Make as $F^2 : G^2 :: AD : DB$, (which may be done, since *AB* is given, by making it as $F^2 - G^2 : G^2 :: AB : DB$, and then by composition it will be as $F^2 : G^2 :: AD : DB$); and then from the point *D*, thus found, draw a tangent to the circle, and from the point of contact *C* drawing *CA* and *CB*, the thing is done.

Demonstration. Since, by the constr. $F^2 : G^2 :: AB : DB$, and also $AD : DB :: AC^2 : BC^2$, which has been already demonstrated in the analysis, and might be here proved in the same manner. Therefore $F^2 : G^2 :: AC^2 : BC^2$, and consequently $F : G :: AC : BC$. *Q. E. D.*

Here we see an instance of the method of *resolution* and *composition*, as it was practised by the ancients, the solution given being that of Pappus himself. But as the method of referring and reducing every thing to the *Data*, and constantly quoting the same, may appear now to be tedious and troublesome: and indeed it is unnecessary to those who have already made themselves masters of the substance of that valuable book of *Euclid*, and have by practice and experience acquired a facility of reasoning in such matters; therefore it remains only to shew how we may abate something of the rigour and strict form of the ancient method of solution, without diminishing any part of its admirable elegance and perspicuity. And this may be done by the instance of another solution, of the many more which might be given, of the same problem, as follows.

ANALYSIS.

Let us again suppose that the thing is done, viz. $AC : BC :: F : G$, and let there be drawn *BH*, making the angle *ABH* equal to the angle *ACB*, and meeting *AC* produced in *H*. Then, the angle *A* being also common, the two triangles *ABC* and *ABH* are equiangular, and therefore, by *vi. 4* $AC : BC :: AB : BH$, in a given ratio; and, *AB* being given, therefore *BH* is given in position and magnitude.

SYNTHESIS.

Construction. Draw *BH* making the angle *ABH* equal to that which may be contained in the given segment, and take *AB* to *BH* in the given ratio of *F* to *G*. Draw *ACH*, and *BC*.

Demonstration. The triangles *ABC, ABH*, are equiangular,

gular, therefore, vi 4, $AC : CB :: AB : BH$, which is the given ratio by construction.

Modern analysis consists chiefly of algebra, arithmetic of infinites, infinite series, increments, fluxions, &c. These form a kind of arithmetical and symbolical analysis, depending partly on modes of arithmetical computation, and partly on rules peculiar to the symbols made use of, and partly on rules drawn from the nature and species of the quantities they represent, or from the modes of their existence or generation. The modern analysis is a general instrument by which the finest inventions and the greatest improvements have been made in mathematics and philosophy, for near two centuries past. It furnishes the most perfect examples of the manner in which the art of reasoning should be employed; it gives to the mind a wonderful skill for discovering things unknown, by means of a small number that are given; and, by employing short and easy symbols for expressing ideas, it presents to the understanding things which otherwise would seem to lie above its sphere. By this means geometrical demonstrations may be greatly abridged: a long train of arguments, in which the mind cannot, without the greatest effort of attention, discover the connection of ideas, is converted into visible symbols; and the various operations which they require are simply effected by the combination of those symbols. And, what is still more extraordinary, by this artifice, a great number of truths are often expressed in one line only: instead of which, by following the ordinary way of explanation and demonstration, the same truths would occupy whole pages or volumes. And thus, by the bare contemplation of one line of calculation, we may understand in a short time whole sciences, which otherwise could hardly be comprehended in several years.

It is true, that Newton, who best knew all the advantages of analysis in geometry and other sciences, laments, in several parts of his works, that the study of the ancient geometry is abandoned or neglected. And indeed the method employed by the ancients in their geometrical writings, is commonly regarded as more rigorous than that of the modern analysis: and though it be greatly inferior to that of the moderns, in point of dispatch and facility of invention; it is nevertheless highly useful in strengthening the mind, improving the reasoning faculties, and in accustoming the young mathematician to a pure, clear, and accurate, mode of investigation and demonstration, though by a long and laboured process, which he would with difficulty have submitted to if his taste had before been vitiated, as it were, by the more piquant sweets of the modern analysis. And it is principally on this that the complaints of Newton are founded, who feared lest, by the too early and frequent use of the modern analysis, the science of geometry should lose that rigour and purity which characterise its investigations, and the mind become debilitated by the facility of our analysis. This great man was therefore well founded in recommending, to a certain extent, the study of the ancient geometricians: for, their demonstrations, being more difficult, give more exercise to the mind, accustom it to a closer application, give it a greater scope, and habituate it to patience and resolution, so necessary for making discoveries. But this is the only or principal advantage from it; for, if we should look no farther than the method of the ancients, it is probable that, even with the best genius, we should have made but few or small discoveries, in comparison of those obtained by means of the modern analysis. And even with regard to the advantage given to investigations made in the manner of the ancients, namely, of being more rigorous, it may perhaps be doubted whether this pretension be well founded. For to instance in those of Newton himself, although his demonstrations be managed in the manner of the ancients; yet at the same time it is evident that he investigates his theorems by a method different from that employed in the demonstrations, which are commonly analytical calculations, disguised by substituting the name of lines for their algebraical value: and, though it be true

that his demonstrations are rigorous, it is no less so that they would be the same when translated and delivered in algebraic language; and what difference can it make in this respect, whether we call the line AB , or denote it by the algebraic character a ? Indeed this last designation has this peculiarity, that, when all the lines are denoted by algebraic characters, many operations can be performed upon them, without thinking of the lines or the figure. And this circumstance proves of no small advantage: the mind is relieved, and spared as much as possible, that its whole force may be employed in overcoming the natural difficulty of the problem alone. Upon the whole therefore the state of the comparison seems to be this: That the method of the ancients is fittest to begin our studies with, to form the mind and to establish proper habits; and that of the moderns to succeed, by extending our views beyond the present limits, and enabling us to make new discoveries and improvements.

Analysis is divided, with respect to its object, into that of *finites* and that of *infinites*. Analysis of finite quantities is what is otherwise called *algebra*, or *specious arithmetic*. Analysis of infinites, called also the *new analysis*, is that which is concerned in calculating the relations of quantities which are considered as infinite, or infinitely little; one of its chief branches being the *method of fluxions*, or the *differential calculus*. And the great advantage of the modern mathematicians over the ancients, arises chiefly from the use of this modern analysis.

ANALYSIS of POWERS, is the same as resolving them into their roots, and is otherwise called *evolution*. *Analysis of Curve Lines*, shews their constitution, nature, and properties, their points of inflexion, station, retrogradation, variation, &c.

ANALYSIS, in chemistry, is the term used for decomposing any mixed body, and reducing it into its constituent parts; and this indeed is the chief object of the art of chemistry. The chemists make use of two modes of analyzation. 1. By fire. 2. By menstrua. Indeed the modes of decomposing bodies, are all founded on the difference of the properties belonging to the different principles of which the body to be analyzed is composed. Suppose, for instance, a body be composed of several principles, possessed of different degrees of volatility, and of some which are fixed, the volatile parts will rise in proportion to the degrees of volatility which they possess; the most volatile first, on the application of gradual heat; then the next in degree, whilst the fixed, capable of resisting the action of the fire, will remain at the bottom of the vessel. This is called *analysis by fire*. But when a body is compounded of several substances; one of which for instance is soluble only by spirits of wine; a second is soluble only by water; and a third is soluble only by æther; these substances may be very easily separated from each other, by submitting successively the compound body to the action of these menstrua, each of which dissolves that particular substance to which it has an affinity, and from which it may afterwards be readily separated. This is called the *analysis by menstrua*. In anatomy, the dissection of the human body is also called *analysis*.

ANALYSIS, in rhetoric, is that which examines the connections, tropes, figures, and the like, inquiring into the proposition, division, passions, arguments, and other apparatus of rhetoric. Several authors, as Fregius and others, have given analyses of Cicero's Orations, wherein they reduce them to their grammatical and logical principles; strip them of all the ornaments and additions of rhetoric which otherwise disguise their true form, and conceal the connection between one part and another. The design of these authors is to have those admired harangues just such as the judgment disposed them, without the help of imagination; so that here we may coolly view the force of each proof, and admire the use Cicero made of rhetorical figures to conceal the weak part of a cause. A collection has been made of the analyses formed by the most celebrated authors of the 16th century, in 3 vols. folio.

ANALYSIS is also used for a kind of syllabus, or table, of the principal heads or articles of a continued discourse, disposed in their natural order and dependency. Analyses are more scientific than alphabetical indexes; but they are less used, as being more intricate.

ANALYSIS is likewise used for a brief, but methodical, illustration of the principles of a science; in which sense it is nearly synonymous with what we otherwise call a *Synopsis*.

ANALYTICAL, *adj.* That which resolves any thing into first principles; that which separates any compound. That which proceeds by analysis, or by taking the parts of a compound into distinct and particular consideration.—Descartes hath here infinitely outdone all the philosophers that went before him, in giving a particular and *analytical* account of the universal fabric: yet he intends his principles but for hypotheses. *Glanville*.

ANALYTICALLY, *adv.* In such a manner as separates compounds into simples.

ANALYTIC, *adj.* [*ανλυτικος*, Gr.] The manner of resolving compounds into the simple constituent or component parts; applied chiefly to mental operations.—*Analytic* method takes the whole compound as it finds it, whether it be a species or an individual, and leads us into the knowledge of it, by resolving into its first principles, or parts, its generic nature and its special properties; and therefore it is called the method of resolution. *Watts*.

To **ANALYZE**, *v. a.* [of *ανα* and *λυω*, Gr. to loosen.] To resolve a compound into its first principles.—Chemistry enabling us to deposite bodies, and, in some measure, to *analyze* them, and take asunder their heterogeneous parts, in many chemical experiments, we may, better than in others, know what manner of bodies we employ; art having made them more simple or uncompounded, than nature alone is wont to present them to us. *Boyle*.—To *analyze* the immorality of any action into its last principles; if it be enquired, why such an action is to be avoided, the immediate answer is, because it is sin. *Norris*.—When the sentence is distinguished into subject and predicate, proposition, argument, act, object, cause, effect, adjunct, opposite, &c. then it is *analyzed* analogically and metaphysically. This last is what is chiefly meant in the theological schools, when they speak of *analyzing* a text of scripture. *Watts*.

ANALYZER, *f.* That which has the power of analyzing.—Particular reasons incline me to doubt, whether the fire be the true and universal *analyzer* of mixt bodies. *Boyle*.

ANAMABO'A, a populous town of the kingdom of Fantin, in Guinea. The country at Anamaboa is full of hills, beginning at a good distance from the town, and affording a very pleasant prospect. Indian corn and palm-wine are in great plenty. They have a green fruit called *papas*, as big as a small melon, and which has a taste like cauliflower. Anamaboa is much frequented by the English ships for corn and slaves, which last are sometimes to be had in great numbers. The English fort is a large edifice, flanked by two towers, and fortified towards the sea with two bastions. It is mounted with twelve pieces of cannon and twelve patereroes, and defended by a garrison under the command of the chief factor. The natives sometimes treat the garrison of this fort with great insolence. In 1701, they declared war against the English; and, having assembled in a tumultuous manner before the fort, they set fire to the exterior buildings, and went on with their outrages, till they were dispersed by a discharge of the cannon from the batteries. The night following the English took their revenge, by setting fire to the town of Anamaboa; and thus hostilities continued for twenty days, till at last the natives were obliged to sue for peace. This fort was abandoned in 1733; but has been resumed by the English, who have maintained it ever since.

ANA'MELECH, an idol of the Sepharvites, who are said in Scripture to have burned their children in honour of Adramelech and Anamelech. These idols probably signified the sun and moon. Some of the rabbins represent

Anamelech under the figure of a mule, others under that of a quail or pheasant.

ANA'MIM, the second son of Mizraim (Gen. x. 13). Ananim, if we may credit the paraphrast Jonathan the son of Uzziel, peopled the Marcotis; or the Pentapolis of Cyrene, according to the paraphrast of Jerusalem. Bochart is of opinion, that these Ananimus were the people that dwelt in the parts adjacent to the temple of Jupiter Ammon, and in the Nafamonitis. Calmet thinks the Amnians and Garamantes to be descended from Ananim.

ANAMNES'TICA, *f.* [*ανα*, and *μνησται*, Gr. *recordor*, to remember.] Medicines which are said to improve the memory, or restore it when lost. This is a general title, and seems, like many others, to have no foundation at all, but confounds the practice of physic; for, as this defect of memory may depend upon different causes, and such as may require different, nay opposite, remedies, students cannot be properly instructed, unless remedies are pointed out as suited to the particular cause and peculiar circumstances of the disease; and this observation will hold good in a variety of other instances.

ANAMOR'PHOSIS, *f.* [of *ανα* and *μορφωσις*, of *μορφη*, Gr. form or shape.] In perspective drawings, is a deformed or distorted portrait or figure, generally confused and unintelligible to the common unassisted view; but when seen to a certain distance and height, or as reflected from a plain or curved mirror, will appear regular and in right proportion.

ANANAS, *f.* in botany. See BROMELIA.

ANANC'TIS, *f.* in antiquity, a kind of figured stone, otherwise called *synochitic*, celebrated for its magical virtue of raising the shadows of the infernal gods.

ANAN'DRIA, *f.* in botany. See TUSSELLAGO.

ANANI'AH, [עֲנַיִה, Heb. of עָנָה a cloud or answer, and ה' the Lord, i. e. the cloud or divination of the Lord.] A proper name of a man.

ANANI'AS, a Sadducee, high-priest of the Jews, who put to death St. James the brother of our Lord, and was deposed by Agrippa.

ANANISAB'TA, or **ANANISAP'TA**, *f.* a magical word frequently found inscribed on coins and other amulets, supposed to have a virtue of preserving the wearer from the plague.

ANANTHOCY'CLUS, *f.* in botany. See COTULA.

ANAPÆST, *f.* [*αναπαυστος*, Gr. of *ανα* again, and *παυω*, to strike.] In ancient poetry, a foot consisting of two short syllables and one long. Such is the word "scôpûlôs." It is just the reverse of the dactyl.

ANAPÆSTIC VERSES, those consisting wholly or chiefly of anapæsts.

ANA'PHE, an island which spontaneously emerged out of the Cretan sea, near Thera; now called *Nanfio*. Its name is from the sudden appearance of the new moon to the Argonauts in a storm.

ANAPHONE'SIS, *f.* [from *ανα*, and *φωνη*, vox.] A species of exercise which consisted in vociferation. It exercises the breast and organs of speech, increases the natural heat, improves the complexion, and is useful for the phlegmatic. It is commended to those who have the heart-burn, bad digestion, and want of appetite, the cachectic, &c. but singing is yet a gentler exercise. See Hieron Mercurialis de Arte Gymnastica.

ANA'PHORA, *f.* [*αναφορα*, Gr. of *ανα*, and *φερω*, to bear.] A figure, when several clauses of a sentence are begun with the same word or sound; as, "Where is the wife? Where is the scribe? Where is the dispenser of this world?"

ANAPHORA, in astrology, the second house, or that part of the heavens which is thirty degrees from the horizon. The term *anaphora* is also sometimes applied promiscuously to some of the succeeding houses, as the fifth, the eighth, and the eleventh. In this sense *anaphora* is the same as *epanaphora*, and stands opposed to *cataphora*.

ANAPHORA, among physicians, the throwing off purulent matter by the mouth.

ANAPHRODISIA, *f.* [from *α neg.* and *αφροδισια*, Gr. ventry; called also *agenesia*, *atchnia*.] Impotence with respect to venereal commerce. This inability and sterility arises from various causes, either from an abolition of all passionate desires, appetite, or power of action, necessary for the propagation of our species, from a defect in erection, emission, or want of fertile semen. Sauvages has given us five species, which Dr. Cullen thus divides. The *true species* are the paralytic and gonorrhoeic; the *spurious species*, or where impediments occur to prevent the act, from piles, or some fault in the urethra; what is called *false* or *fictional*, that is, supposed to arise from magic. See Sauvages Nosologia Methodica, vol. i. 770. The cure of this disease depends upon the removal of its separate causes; when it arises from paralysis, such medicines as are necessary for the conquering that complaint must be had recourse to, particularly eating stimulants. Sauvages gives us an account of a man being cured by immersing the penis often in the day in a strong decoction of mustard-seed. If it is occasioned by simple gonorrhoea, such aids are to be called in as are calculated to invigorate the system, tonics and corroborants are to be made use of, particularly cold bathing, avoiding high-seasoned foods and cordial stimulants. If from the piles, or faults in the urethra, such means must be used as the nature and particular circumstances of the case demand.

ANAPLASIS, *f.* [from *αναπλασσω*, Gr. to restore to the original form.] Hippocrates uses this word for the replacing a fractured bone, and for a restoration of flesh.

ANAPLERO'SIS, *f.* [from *αναπληρω*, Gr. to fill up.] The restitution of any wasted part. Incarnatives are called *anaplerotica*.

ANAPLEU'SIS, *f.* [from *αναπλευ*, Gr. to fluctuate or float upon, or wash out.] Hippocrates used this word to express when faulty humours rot the bone, so that it falls out of its joint, as happens to the jaw sometimes. Vogel expresses by this word, the scaling or separation of the carious parts of a bone.

ANAPODOPHYLLUM, *f.* in botany. See **PODOPHYLLUM**.

A'NARCH, *f.* [*αναρχος*, Gr. of *α priv.* and *αρχη*, government.] An author of confusion:

Him thus the *anarch* old,
With fault'ring speech, and visage compos'd,
Answer'd.

Milton.

ANAR'CHI, *f.* [*αναρχος*, Gr.] In antiquity, a name given by the Athenians to four supernumerary days in their year, during which they had no magistrates. The Attic year was divided into ten parts, according to the number of tribes, to whom the presidency of the senate fell by turns. Each division consisted of thirty-five days; what remained after the expiration of these, to make the lunar year complete, which according to their computation consisted of 354 days, were employed in the creation of magistrates, and called *αναρχοι ημεραι*, and *αρχαιρεσιν*.

ANAR'CHICAL, *adj.* Confused; without rule or government.—In this *anarchical* and rebellious state of human nature, the faculties belonging to the material world presume to determine the nature of subjects belonging to the supreme Spirit. *Chayne*.

A'NARCHY, *f.* [*αναρχια*, Gr.] Want of government; a state in which every man is unaccountable; a state without magistracy:

Where eldest Night
And Chaos, ancestors of nature, hold
Eternal *anarchy*, amidst the noise
Of endless wars, and by confusion stand.

Milton.

Arbitrary power is but the first natural step from *anarchy*, or the savage life; the adjusting power and freedom being an effect and consequence of maturer thinking. *Swift*.

ANARCHY is also applied to certain troublesome and disorderly periods, even in governments otherwise regular.

In England, the period between the death of Cromwell and king Charles's restoration is commonly represented as an *anarchy*. Every month produced a new scheme or form of government. Enthusiasts talked of nothing but annulling all the laws, abolishing all writings, records, and registers, and bringing all men to a primitive level. The Jewish history presents numerous instances of anarchies in that state, usually denoted by this phrase, that "in those days there was no king in Israel, but every man did that which was right in his own eyes;" which is a just picture of an anarchy.

ANARE'TA, *f.* with astrologers, a name given to the fatal planet in the nativity, which threatens death.

ANAR'RHICAS, *f.* in ichthyology, a genus of fishes of the order of apodes. There is but one species of this genus, viz. the *annarrhicas lupus*, or sea-wolf; which seems to be confined to the northern parts of the globe. We find it in the seas of Greenland; in those of Iceland and Norway; on the coasts of Scotland and of Yorkshire; and lastly, in that part of the German ocean which washes the shores of Holland, the most southern of its haunts that we can with any certainty mention. It is a most ravenous and fierce fish, and, when taken, fastens on any thing within its reach: the fishermen, dreading its bite, endeavour as soon as possible to beat out its fore-teeth, and then kill it by striking it behind the head. Schonevelde relates, that its bite is so hard, that it will seize on any anchor, and leave the marks of its teeth in it; and the Danish and German names of *steenbider* and *steinbeisser*, express the sense of its great strength, as if it were capable of crushing even stones with its jaws. It feeds almost entirely on crustaceous animals and shell-fish, such as crabs, lobsters, prawns, muscles, scollops, large whelks, &c. these it grinds to pieces with its teeth, and swallows with the smaller shells. It does not appear they are dissolved in the stomach, but are voided with the feces; for which purpose the aperture of the anus is wider than in other fish of the same size. It is full of roe in February, March, and April, and spawns in May and June; but it has so disagreeable and horrid an appearance, that nobody at Scarborough except the fishermen will eat it, and they prefer it to holibut. They always before dressing take off the head and skin.

The sea-wolf grows to a large size: those on the Yorkshire coast are sometimes found of the length of four feet; according to Dr. Gronovius, they have been taken near Shetland seven feet long, and even more. The head is a little flattened on the top; the nose blunt; the nostrils very small; the eyes small, and placed near the end of the nose. The teeth are very remarkable, and finely adapted to its way of life. The fore-teeth are strong, conical, diverging a little from each other, stand far out of the jaws, and are commonly six above and the same below, though sometimes there are only five in each jaw: these are supported within-side by a row of smaller teeth, which makes the number in the upper jaw seventeen or eighteen, in the lower eleven or twelve. The sides of the under jaw are convex inwards, which greatly adds to their strength, and at the same time allows room for the large muscles with which the head of this fish is furnished. In the centre are two rows of flat strong teeth, fixed on an oblong basis upon the bones of the palate and nose. The teeth of the *annarrhicas* are often found fossil; and in that state are called *busonites*, or *load-stones*: these were formerly much esteemed for their imaginary virtues, and were set in gold, and worn as rings.

The body of this fish is long, and a little compressed sideways; the skin smooth and slippery: it wants the lateral line. The pectoral fins consist of eighteen rays. The dorsal fin extends from the hind part of the head almost to the tail; the rays in the fresh fish are not visible. The anal fin extends as far as the dorsal fin. The tail is round at its end, and consists of thirteen rays. The sides, back, and fins, are of a livid lead colour; the two first marked downwards with irregular obscure dusky lines: these in different fish have different appearances. The young are

of a greenish cast, resembling the sea-wrack, amongst which they reside for some time after their birth.

ANARRHOE'A, *f.* [from *ανω*, upward, and *ρηνω*, to flow.] A flux of humours from below upwards.

ANAR'THROI, *f.* [from *α* neg. and *αρθρον*, a joint.] Fat, even to be bloated, so that the joints are obliterated.

ANAS, in ornithology, a genus of birds belonging to the order of anseres; the distinguishing characters of which are; bill lamellar and toothed, convex, obtuse; tongue ciliate, obtuse. This very extensive genus includes the swans, the geese, the ducks, the sheldrakes, the shouclers, the wigsons, the garganeys, and the teals, forming in all one hundred and twenty-four species; of which the following are the most remarkable and curious.

1. The *cygnus-ferus* or wild swan, and the *cygnus-manfuetus* or tame swan, constitute the most elegant of this genus; and have, on this account, been celebrated by the most distinguished poets and ornithologists, in all ages of the world. It has shewn, that the lion and the tiger on the earth, the eagle and vulture in the air, assume their reign amid the horrors of war, and extend their dominion by cruelty and rapine, while the stately swan upholds his empire on the water in gentleness and peace. Endowed with strength and vigour, but restrained by a sense of moderation and justice, he knows to fight and conquer, yet never urges an attack. Pacific king of the water-fowls, he braves the tyrants of the air: he awaits the eagle, without provoking and without fearing the encounter. He repels his assaults, and opposes to his talons the attack of rapid strokes of a vigorous wing, which serves him as a shield; and often does victory crown his exertions. This is his only formidable enemy; all the other ravenous birds respect him; and he is at peace with all nature. Indeed the swan is the only bird we know of that dares contend with the eagle. He lives rather the friend than the monarch amidst the numerous tribes of aquatic birds, which submit to his law. He is only the chief, the principal inhabitant, of a peaceful republic; nor have his citizens aught to fear from a ruler who exacts no more than he grants, and whose sole wish is to enjoy tranquility and freedom.

The graces of figure, and the beauty of shape, correspond in the swan to the mildness of his disposition: he pleases every eye; he decorates every place that he frequents; he is beloved and admired; and no species more deserves our applause. On none has nature diffused so many of those noble and gentle graces, which recal the image of her most charming productions: elegant fashion of body; roundness of form; softness of outline; whiteness resplendent and pure; motions full of flexibility and expression; attitudes, sometimes animated, sometimes gently languishing: all the features and actions of the swan breathe the voluptuousness, the enchantment which wrap our soul at the sight of grace and beauty; all declare and paint it the bird of love; all justify the ingenious and sprightly fable, that made this delightful bird the father of the most beautiful of women.

The noble ease and freedom of its motions on the water bespeak it not only the first of the winged sailors, but the finest model presented by nature for the art of navigation. Its raised neck and its round swelling breast exhibit the prow of a ship cleaving the waves; its broad stomach represents the keel; its body, pressed down before, rises behind into the stern; the tail is a genuine rudder; its feet are broad oars; and its wings, half opened to the wind, and gently inflated, are the sails which impel the animated machine. Thus she is finely described by our poet Milton:

The swan, with arched neck
Between her white wings mantling proudly, rows
Her state with oary feet.

Proudly of its superiority, and emulous of distinction, the swan seems forward to unveil its beauties; seeks to charm the spectators, and to command their applause. And the sight indeed captivates the eye, whether we behold the

winged fleet at a distance gliding through the water, or view one, invited by signals, approach the shore and display its elegance and grace by a thousand pleasing undulating motions. To these endowments bestowed by nature, the swan joins the possession of liberty. He is none of those slaves which we can constrain or imprison. Even on our artificial lakes, he retains so much of the spirit of independence as to exclude every idea of servitude and captivity. He roves at will on the water, lands on the shore, wanders to a distance, or shelters himself under the brink; lurks among the rushes, or retires to the remotest inlets: then, leaving solitude, he returns to society and to the enjoyment which he receives by approaching man; provided we are hospitable and friendly, not harsh and tyrannical. Among our ancestors, too simple, or too wise, to fill their gardens with the frigid beauties of art, instead of the lively beauties of nature, the swans formed the ornament of almost every piece of water. They cheered the gloomy ditches round castles, they decorated most of the rivers, and even that of the capital, the stately-rolling Thames, which even to this day affords an anniversary to some of its magistrates, to survey and protect their swannery. The swan swims so fast, that a man, walking with hasty strides along the banks, can hardly keep pace with it. What Albin says of this bird "that it swims well, walks ill, and flies indifferently," is true only of the flight of the swan degraded by domestication; for when free, and especially when wild, it flies very loftily and vigorously. Hesiod gives it the epithet of *αεγιπτιος*, or bird that soars above the clouds; Homer classes it with the great migratory birds, the cranes and the geese; and Plutarch attributes to two swans what Pindar sung of two eagles, that Jupiter dispatched them from the opposite extremities of the world, to discover the middle by their meeting. The swan, superior in every respect to the goose, which lives only on herbs and grain, procures itself a rarer and more delicate food. It continually practises wiles to ensnare and catch fish; it assumes a thousand different attitudes, and draws every possible advantage from its dexterity and strength. It evades and resists its enemies: an old swan fears not in the water the strongest dog: a stroke of its wing has been known to break a man's leg; and they will easily beat down and trample upon youths of thirteen or fourteen years of age. Nor does the swan dread the ambush of any foe; for its courage equals its address and its force.

The wild swans fly in great flocks, and the tame swans walk and swim in company. Every thing marks their social instinct; and that instinct, the most agreeable in nature, bespeaks innocent manners, peaceful habits, and that delicate and sensible disposition which seems to bestow on the actions that flow from it, the merit of moral qualities. The swan also prolongs its placid existence to extreme old age. All observers ascribe to it prodigious longevity: some represent it as even passing the term of three centuries; which must certainly be an exaggeration. But Willoughby saw a goose, which was proved to have lived an hundred years; and he concludes from analogy that the period of the swan must extend farther; both because it is larger, and because its eggs require longer time to hatch: for incubation in birds corresponds to gestation in quadrupeds, and bears some relation, perhaps, to the body's growth, which is proportional to the duration of life. The swan requires two years to attain its full size, which is a very considerable time; since, in birds, the development is much quicker than in quadrupeds. The female swan sits six weeks at least; she begins to lay in the month of February; and, as with the goose, there is a day's interval between the dropping of each egg. She lays from five to eight, but most commonly six or seven; they are white and oblong, covered with a thick shell, and are of a very considerable size. The nest is placed sometimes on a bed of dry herbs on the bank; sometimes on a heap of broken reeds, heaped and even floating on the water. The amorous pair lavish the sweetest caresses, and seem in their pleasures

tures to seek all the gradations of voluptuousness. They begin by entwining their necks; and thus breathe the intoxication of a long embrace; they communicate the fire which kindles in their veins; and after the male has fully indulged his appetite, the female still burns; she pursues, and even excites him anew; and then leaves him, with regret, to wash in the water, and quench her remaining ardour. The fruits of these embraces are tenderly cherished and fostered. The mother gathers, night and day, the young under her wings, and the father is ready to defend them with intrepidity against every assailant. But his courage, on such occasions, bears no comparison to the fury with which he attacks a rival that intrudes on the possession of his beloved object. He then forgets his mildness, becomes ferocious, and fights with obstinate rancour; and a whole day is often insufficient to terminate the quarrel. They begin with striking violently their wings, then join close, and persist till commonly one of them is killed; for they strive to stifle each other by locking the neck, and forcibly holding the head under water. It was probably these combats that made the ancients imagine that the swans devoured one another. Nothing is wider of the truth; only in this, as in other cases, furious passions originate from a passion the most delicious; and it is love that begets war. At every other time, their habits are peaceful, and all their sentiments are attuned to love. As attentive to neatness as they are addicted to pleasure, they are assiduous each day in the care of their person: they arrange their plumage, they clean and smooth it; they take water in their bill, and sprinkle it on their back and wings with an attention that implies the desire of pleasing, and which can only be repaid by the consciousness of being loved. The only time when the female neglects her attire, is that of incubation; her maternal solicitude then entirely occupies her thoughts, and hardly does she spare a few moments for the relief and support of nature.

The cygnets are hatched very ugly, and covered only with a grey or yellowish down like goslings. Their feathers do not sprout till a few weeks after, and are still of the same colour. This unsightly plumage changes after the first moult, in the month of September: they assume many white feathers, and others rather flaxen than grey, especially on the breast and the back. This laced plumage drops at the second moult, and it is not till eighteen months, or even two years, that these birds are invested with their robe of pure and spotless white; nor before that age can they have young. The cygnets follow their mother the first summer, but they are compelled to leave her in the month of November, being chased away by the adult males, who wish to enjoy entirely the company of the females. These young birds, thus exiled from their family, unite in one body, and never separate till they pair.

As the swan often eats marsh-plants, and particularly the algæ, it prefers rivers of a smooth and winding course, whose banks are well clothed with herbage. The ancients have cited the Meander, the Mincio, the Strymon, the Cayster, as streams covered with swans. Paphos, the loved isle of Venus, was filled with them. Strabo speaks of the swans of Spain; and according to Ælian they were seen, at times, on the sea of Africa. From this and other accounts, we may conclude, that the species penetrates into the regions of the south: yet the north seems the true country of the swan, where it breeds and multiplies. With us wild swans are scarcely ever seen, but in the hardest winters. Gesner says, that in Switzerland, a long and severe winter is expected, when many swans arrive on the lakes. In the same cold season, they appear on the coasts of France and of England, and on the Thames. Many of our tame swans would then join the wild ones, did we not clip the great feathers of their wings. Yet some swans nestle and pass the summer in the northern parts of Germany, in Prussia, and Poland; and on nearly the same parallel of latitude, they are found on the rivers about Azof and Astracan; in Siberia, among the Jacutes; in Seleginskki, and as far as Kamtschatka. During the

breeding season, they are found in immense numbers on the streams and lakes of Lapland: there they feed on the larvæ of the gnat, which cover the surface of the water. The Laplanders see them arrive in the spring from the German Ocean: part stop in Sweden, and especially in Scania. Horrebow affirms, that they continue the whole year in Iceland, and inhabit the sea when the fresh waters are frozen. But, if a few do remain, the bulk of them follow the common law of migration, and fly from a winter, which, as the shoals of ice are driven from Greenland, is attended with greater rigour in Iceland than in Lapland. In August they lose their feathers, and are not able to fly, when the natives of Iceland and Kamtschatka hunt them with dogs, which catch them by the neck, and easily secure them in this defenceless state. The eggs are accounted good food, and the flesh is much esteemed by the inhabitants. These birds are as numerous in the northern parts of America as in those of Europe. They inhabit Hudson's Bay, and are likewise very numerous in Canada, from whence they appear to migrate for winter quarters into Virginia and Louisiana.

The differences which subsist between the wild or whistling swan, and the tame or mute swan, which is bred in England, have led to the opinion that they form two distinct and separate species. The whistling swan carries its neck quite erect, the other swims with it arched. It is also far inferior in size, and has twelve ribs on a side, the mute only eleven. But the most remarkable is the strange figure of the windpipe; which falls into the chest, then turns back like a trumpet, and afterwards makes a second bend to join the lungs. Thus it is enabled to utter a loud and shrill note. The mute swan, on the contrary, is the most silent of birds: it can do little more than hiss, which it does on receiving any provocation. The vocal kind emits its loud notes only when flying or calling. Its sound is very loud and shrill, but not disagreeable when heard far above one's head and modulated by the winds. The natives of Iceland compare it to the notes of a violin. In fact, they hear it, says Mr. Pennant, at the end of their long and gloomy winter, when the return of the swans announces the return of summer; every note must be therefore melodious which prefaces the speedy thaw, and the release from their tedious confinement. The tame swan is, however, regarded as a breed derived anciently and originally from the wild species. Klein, Frisch, and Linnaeus, have formed this opinion; though Willoughby and Ray pretend the contrary. The figure of the wild swan given in the annexed plate, may be depended upon as an exact copy of nature. The drawing was made from the real bird by the ingenious Mr. Edwards, and placed in his valuable and elegant collection of subjects in natural history.

Belon reckons the swan to be the largest of the aquatic birds; which is true, excepting, however, that the pelican has a much greater alar extent, that the albatross is as bulky, and that the flamingo is taller on its legs. The tame swans are invariably thicker and larger than the wild: some of them weigh twenty-five pounds, and measure, from the bill to the tail, four feet and an half; the breadth of the wings eight feet. The female is, in every dimension, rather smaller than the male. The bill usually exceeds two inches in length, and, in the tame kind, has above its base a fleshy tubercle, inflated and prominent, which gives a sort of expression: this tubercle is covered with a black skin; and the sides of the face, under the eyes, are covered with a skin of the same colour. In cygnets of the domestic breed, the bill is of a leaden cast, and afterwards becomes yellow or white, with the point black. In the wild kind, the bill is entirely black, with a yellow membrane on the front; its form seems to be copied in the two most numerous families of the palmipede birds, the geese and ducks. In all of these the bill is flat, thick, indented on the edges, rounded into a blunt tip, and terminated on the upper mandible by a nail of horny substance.

Swans, almost mute, like ours in the domestic state, could

ANAS.

Plate I.

The Teal or Whistling Swan.

could not be those melodious birds which poets and orators have celebrated and extolled. But the wild swan appears to have better preserved its prerogatives; and, with the sentiment of entire liberty, it has also the tones. The bursts of its voice form a sort of modulated song; yet the shrill and scarcely diversified notes of its loud clarion sounds, differ widely from the tender melody, the sweet and brilliant variety, of our singing birds. But it was not enough that the swan sung admirably; the ancients ascribed to it a prophetic spirit. It alone, of all animated beings, chanted in the moment of its agony, and, with harmonious sounds, prepared to breathe the last sigh. When about to expire, they said, and to bid a sad and tender adieu to life, the swan poured forth those accents so sweet, so affecting, and which, like a gentle and doleful murmur, with a voice low, plaintive, and melancholy, formed its funeral song. This fearful music was heard at the dawn of day, or when the winds and the waves were still: and they have been seen expiring with the notes of their dying hymn. No fiction of natural history, no fable of antiquity, was ever more celebrated, oftener repeated, or better received. It occupied the soft and lively imagination of the Greeks: even philosophers and historians adopted it as a truth too pleasing to be doubted. And well may we excuse such fables; they were amiable and affecting; they were worth many dull insipid truths; they were pleasing emblems to feeling minds. The swan, doubtless, chants not its approaching end; but, in speaking of the last flight, the expiring effort of a fine genius, we shall ever, with tender melancholy, recal the classical and pathetic expression, *It is the song of the swan!*

In former times, swans were served up at every great feast, when the elegance of the table was measured by the size and quantity of the good cheer. Cygnets are to this day fattened at Norwich about Christmas, and are sold for a guinea a-piece. Indeed swans were formerly held in such great esteem in England, that by an act of Edward IV. c. 6. "no one that possessed a freehold of less clear yearly value than five marks, was permitted to keep any, other than the son of our sovereign lord the king." And by the eleventh of Henry VII. c. 17. the punishment for taking their eggs was imprisonment for a year and a day, and a fine at the king's will. We shall now notice the other most remarkable species belonging to this genus.

2. The cygnoides, with a semicylindrical bill, gibbous wax, and tumid eye-brows, is the swan-geese of Ray, from Guinea. There is likewise a variety of this species, of a less size, called the *goose of Muscovy*. They are found wild about the Lake Baikal in the east of Siberia, and in Kamtschatka. They are also kept tame in most parts of the Russian empire. These birds likewise inhabit China, and are common at the Cape of Good Hope. This is no doubt the species mentioned by Kolben, called *crop-geese*; who says, that the sailors make tobacco-pouches and purses of the membrane which hangs beneath the throat, as it is sufficiently tough for such purposes, and will hold two pounds of tobacco. They are sufficiently common in Britain, and readily mix with the common goose; the breeds uniting as freely, and continuing to produce as certainly, as if no such mixture had taken place. They are much more noisy than the common tame geese, taking alarm at the least noise; and even without disturbance will emit their harsh and disagreeable scream the whole day through. They walk very erect, with the neck much elevated; and, as they bear a middle line between that of the swan and goose, they have not improperly been called *swan-geese*.

3. The tadorna, or sheldrake, has a flat bill, a compressed forehead, a greenish black head, and the body is variegated with white. This species is found as far as Iceland to the north. It visits Sweden and the Orkneys in the winter, and returns in spring. It is found in Asia about the Caspian Sea, and all the salt lakes of the Tartarian and Siberian deserts, as well as in Kamtschatka. Our voyagers, if right in the species, have also met with

it at Falkland Isles and Van Diemen's Land. It breeds in deserted rabbit holes, or occupies them in the absence of the owners, who, rather than make an attempt at dislodging the intruders, form others; though, in defect of ready-made quarters, these birds will frequently dig holes for themselves. They lay fifteen or sixteen roundish white eggs. These are placed at the farther end of the hole, covered with down supplied from the breast of the female, who sits about thirty days. She is very careful of her young, and will often carry them from place to place in her bill: "this we are certain of," says Mr. Latham, "from a young one having been dropt at the foot of an intelligent friend unhurt, by the mother flying over his head." When a person attempts to take their young, the old birds show great address in diverting his attention from the brood: they will fly along the ground as if wounded, till the former are got into a place of security, and then return and collect them together. From this instinctive cunning, Turner, with good reason, imagines them to be the *chenalopex*, or *fox-geese* of the ancients. The natives of the Orkneys to this day call them the *fly-geese*, from an attribute of that quadruped. The young, as soon as hatched, take to the water, and swim rapidly; but do not come to their full plumage till the second year. This species, Mr. Latham informs us, may be hatched under a tame duck, and the young readily brought up; but are apt, after a few years, to attempt the mastery over the rest of the poultry. In a state of nature, the food seems chiefly to be small fish, marine insects, and shells; herbage has likewise been found in their stomachs. In a tame state they will eat bread, grain, and greens. Their great beauty would tempt us to endeavour at domesticating the race; but it will not thrive completely, except in the neighbourhood of salt-water, which seems almost essential to its well-being. The flesh is rather unfavourable, though the eggs have at all times been thought very good.

4. The *spectabilis*, has a compressed bill gibbous at the base, a black feathery carina, and a hoary head. It is the grey-headed duck of Edwards, and the king-duck of Pennant. This beautiful species is found at Hudson's Bay, at Churchill River, and at York Fort; in winter it is met with as far south as New York. It is pretty frequent in the north of Siberia and Kamtschatka; it is found also on the coast of Norway, and has been killed in the Orkneys. It is common in Greenland; where the flesh is accounted excellent, and the crude gibbous part of the bill a great delicacy. It produces a down equally valuable as the eider. The skins are sewed together, and make warm garments. The natives kill them with darts, and use the following method to succeed: A number of men in canoes, falling in with a flock while swimming, on a sudden set up a shouting, making as much noise as they can; on which, the birds being too much frightened to fly away, dive under the water; but, as the place at which they are to rise again is known by the bubbling of the water above, the hunters follow them up as close as possible; and, after acting this three or four times over, the birds become so fatigued as to be easily killed. This species builds on the sides of ponds and rivers, making its nest of sticks and moss, and lining it with feathers from the breast. It lays four or five whitish eggs, as large as those of the goose. The young fly in July. The food consists chiefly of worms and grubs.

5. The *fusca*, or velvet duck, is of a blackish colour, has a white spot behind the eyes, and a white line on the wings. The male of this species is distinguished by a gibbosity at the base of the bill. It is the black duck of Ray, and is in length about twenty inches. This species frequents Hudson's Bay in summer, where it breeds. The nest is composed of grubs; in which it lays from four to six white eggs, and hatches in July. It feeds on grubs, and is known by the name of *cus cusi qua tum*. It retires south in winter, when it is frequently seen as far as New York. Our late navigators met with it at Aconalashka. It is now and then seen on the coasts of England, but it

is not common. It is more frequent on the continent, inhabiting Denmark and Russia. In some parts of Siberia it is very common; and it enters the list of those found at Kamtschatka. In breeding-time, it goes far inland to lay its eggs; which are eight or ten in number, and white. After the season is over, the males are said to depart; the females staying behind till the young are able to fly, when the two last go likewise off, but to what part is not certain. It is found in great plenty at Ochotska, especially about the equinox. Fifty or more of the natives go in boats and surround the whole flock, driving them in the flood up the river Ochotska; and, as soon as it ebbs, the whole company fall on them at once with clubs, and often knock so many of them on the head, that each man has twenty or thirty for his share.

6. The *nigra*, or scoter, is totally black, and has a gibbosity at the base of the bill; the tail resembles a wedge; the female is brownish. It is the lesser black diver of Ray, and measures in length twenty-two inches. These birds are found on the northern coasts of England and those of Scotland in the winter season; but no where so common as on the French coasts, where they are seen in prodigious numbers from November to March, especially if the wind be to the north or north-west. Their chief food is a glossy bivalve shell, near an inch long, called by the French *vaimeaux*. These they are perpetually diving after, frequently to the depth of some fathoms; and an usual method of catching them is, by placing nets under the water in such places as the shells are most numerous; by which means thirty or forty dozen of them have been taken in one tide. The day seems to be spent by these birds between diving and flying to small distances over the water, which it does so low as frequently to dip the legs therein. It swallows the food whole, and soon digests the shells, which are found quite crumbled to powder among the excrements. It has been kept tame for some time, and will feed on soaked bread. The flesh tastes fishy to an extreme; on which account it is allowed by the Roman Catholics to be eaten on fast-days and in lent; and indeed must be a sufficient mortification. These birds abound in all the northern parts of the continent, Lapland, Sweden, Norway, and Russia; and are found in great plenty on the great lakes and rivers of the north and east of Siberia, as well as on the sea-shores. It likewise inhabits North America, being met with at New York; and, in all probability, much more to the north on that continent and that of Asia, Osbeck having met with them in thirty and thirty-four degrees south latitude, between the island of Java and St. Paul, in the month of June.

7. The *anser*, *ferus et mansuetus*; or grey lag, and tame goose. The *grey lag*, or *wild goose*, is two feet nine inches in length, and five feet in extent. The bill is large and elevated; of a flesh-colour, tinged with yellow; the head and neck cinereous; breast and belly whitish, clouded with grey or ash colour; back, grey; the legs of a flesh-colour. This species resides in the fens the whole year; breeds there, and hatches about eight or nine young, which are often taken, easily tamed, and esteemed most excellent meat, superior to the domestic goose. Towards winter they collect in great flocks, but in all seasons live and feed in the fens. On the continent they are migratory, changing place in large flocks often 500 or more; in this case, the flock is triangular in shape, with one point foremost; and, as the goose which is first is tired soonest, it has been seen to drop behind, and another to take his place. In very small flocks, however, they are sometimes seen to follow one another in a direct line. Geese seem to be general inhabitants of the globe. The *mansuetus*, is the grey lag in a state of domestication, and from which it varies in colour, though much less so than either the mallard or cock, being ever more or less verging to grey; though, in all cases, the whiteness of the vent, and upper tail coverts, is manifest. It is frequently found quite white, especially the males; and doubts have arisen, which of the two colours should have the preference in point of

eating. Tame geese are kept in great multitudes in the fens of Lincolnshire; a single person will have one thousand old geese, each of which will rear seven; so that, towards the end of the season, he will become possessed of eight thousand. During the breeding season, these birds are lodged in the same houses with the inhabitants, and even in their very bed-chambers: in every apartment are three rows of coarse wicker pens, placed one above another; each bird has its separate lodge divided from the other, which it keeps possession of during the time of sitting. A person called a *gozzard*, i. e. *goose-herd*, attends the flock, and twice a day drives the whole to water; then brings them back to their habitations, helping those that live in the upper stories to their nests, without ever misplacing a single bird. The geese are plucked five times in the year: the first plucking is at Lady-day, for feathers and quills; and the same is renewed, for feathers only, four times more between that and Michaelmas. The old geese submit quietly to the operation, but the young ones are very noisy and unruly. If the season proves cold, numbers of them die by this barbarous custom. Vast numbers of geese are driven annually to London, to supply the markets; among them, all the superannuated geese and ganders, which, by a long course of plucking, prove uncommonly tough and dry. The goose in general breeds only once in a year; but will frequently have two hatches in a season, if well kept. The time of sitting is about thirty days. They will also produce eggs sufficient for three broods, if they are taken away in succession. It is said to be very long-lived, as we have authority for their arriving at no less than 100 years. The common price of geese, in many counties, is regulated by that of mutton, both being the same by the pound, without the feathers. The usual weight of a fine goose is fifteen or sixteen pounds; but it is scarcely credible how far this may be increased, by cramming them with bean-meal, and other fattening diet. The victims destined for this furfeit, are by some nailed to the floor by the webs of the feet, which causes no pain, and is meant to prevent the least possibility of action: to which, we are told, the French add the refinement of putting out their eyes; but what end this last part of barbarity is meant to answer, is hard to conjecture. To what weight they arrive in France, is not said; but we have been well informed, that twenty-eight or even thirty pounds, is no uncommon thing in England.

8. The *bean-geese* is two feet seven inches in length; in extent four feet eleven. The bill, which is the chief distinction between this and the former, is small, much compressed near the end, whitish, and sometimes pale red in the middle, and black at the base and nail: the head and neck are cinereous brown, tinged with ferruginous; breast and belly dirty white, clouded with cinereous; the back of a plain ash colour; feet and legs of a saffron colour; claws, black. This species arrives in Lincolnshire in autumn, and is called the *bean-geese*, from the likeness of the nail of the bill to a horse-bean. They always light on corn-fields, and feed much on the green wheat. They never breed in the fens, but all disappear in May. They retreat to the sequestered wilds of the north of Europe; in their migration they fly to a great height, cackling as they go. They preserve a great regularity in their motions; sometimes forming a straight line; at others, assuming the shape of a wedge, which facilitates their progress through the air.

9. The *erythropus*, or laughing-geese of Edwards, is a native of Europe and America. The length of this species is about two feet four inches, the extent four feet six; the bill is elevated, of a pale yellow colour, with a white ring at the base; the forehead is white; the breast and belly are of a dirty white, marked with great spots of black; and the legs yellow. These visit the fens, and other parts of England, during winter, in small flocks; they keep always in marshy places, and never frequent the corn-lands. They disappear in the earliest spring, and none are seen after the middle of March. Linnæus makes

The Egyptian Goose and Cider Duck.

London Published as the act directs, Nov. 8-1802, by J. Wilkes.

J. Page sculp.

this goose the female of the *bernacle*; but Mr. Pennant thinks this opinion not well-founded. The *bernacle* is two feet one inch in length, the breadth four feet five inches; the bill is black; the forehead and cheeks are white; from the bill to the eyes there is a black line; the hind part of the head, the whole neck, and upper part of the breast and back, are of a deep black; the tail is black, the legs are of the same colour, and small. These birds appear in vast flocks during winter, on the north-west coasts of this kingdom: they are very shy and wild; but, on being taken, grow in a few days as familiar as our tame geese. In February they quit our shores, and retire as far as Lapland, Greenland, and even Spitzbergen, to breed. They live to a great age: the Rev. Dr. Buckworth, of Spalding, had one which was kept in the family above thirty-two years, but was blind during the two last; what its age was when first taken, was unknown. These are the birds that about 200 years ago were believed to be generated out of wood, or rather a species of shell that is often found sticking to the bottoms of ships, or fragments of them, and were called *tree-geese*. These were also thought by some writers to have been the *chenalopeces* of Pliny; they should have said *chenerotes*, for those were the birds which that naturalist said were found in Britain; but, as he has scarcely left us any description of them, it is difficult to say which species he intended. Mr. Pennant imagines it to be the following; which is far inferior in size to the wild-geese, and very delicate food, in both respects suiting his description of the *cheneros*.

10. The race-horse, or loggerhead goose, is in length thirty-two inches, and weighs from twenty to thirty pounds. The bill is three inches long, and of an orange colour; the irides are orange, surrounded with black, and then with orange; the head, neck, and upper parts of the body, are of a deep ash-colour; the outer edge of the secondaries white, forming a band of the same on the wing; the under parts of the body dusky down the middle; over the thighs, cinereous blue; vent, white; quills and tail, black; the wings are very short, not reaching to the rump; on the bend of the wing is a yellow knob, half an inch in length; the legs are brownish orange, the webs dusky, and the claws black. These inhabit Falkland Islands, Staaten Land, &c. and were mostly seen in pairs, though sometimes they were observed in large flocks. From the shortness of the wings they were unable to fly; but they made considerable use of them when in the water, on which they seemed as it were to run, at least they swam, with the assistance of the wings used as oars, at an incredible rate, inasmuch that it was a most difficult thing to shoot them while on that element: to catch them, the sailors used to surround a flock with boats, and drive them on shore; where, unable to raise themselves from the ground, they ran very fast; but soon growing tired, and squatting down to rest, were easily overtaken, and knocked on the head. Their flesh was sometimes eaten by the sailors, in defect of that of the bustard goose; but it was not much relished, being rank and fishy, and thought more fit for the hogs, which ate it greedily; and fatted well upon it, boiled.

11. The snow-geese is in length two feet eight inches, and weighs between five and six pounds. The bill is somewhat ferrated at the edges; the upper mandible scarlet, the lower whitish: the general colour of the plumage is snow white, except the first ten quills, which are black, with white shafts; the legs are of a deep red. The young are of a blue colour, till they are a year old. These are very numerous at Hudson's Bay, and called by the natives *way-way*, and *wapa-whi-why*. They visit Severn River in May, and stay a fortnight; but go farther north to breed: they return to Severn Port the beginning of September, and stay till the middle of October, when they depart for the south, and are observed to be attended with their young, in flocks innumerable. At this time many thousands are killed by the inhabitants, who pluck them, and take out the entrails, and, putting the bodies into holes dug in the ground, cover them with earth, which, freezing

above them, keeps them perfectly sweet throughout the severe season; during which, there is no more to do than occasionally to open one of those storehouses, when they find them sweet and good. They seem to occupy also the western side of America. In the summer months, they are plenty on the arctic coast of Siberia, but never migrate beyond longitude 130. They are supposed to pass the winter in more moderate climes, as they have been seen flying at a great height over Silesia; probably on their passage to some other country, as it does not appear that they continue there. In like manner, those of America pass the winter in Carolina. Here they arrive in vast flocks; and feed on the roots of sage and grass. It used to be a common practice in that country, to burn a piece of a marsh, which enticed the geese to come there, as they could then more readily get at the roots, which gave the sportsman opportunity of killing as many as he pleased. This species is the most numerous and the most stupid of all the goose race. They seem to want the instinct of others, by their arriving at the mouths of the arctic Asiatic rivers before the season in which they can possibly subsist. They are annually guilty of the same mistake, and annually compelled to make a new migration to the south in quest of food, where they pass their time till the northern estuaries are freed from the bonds of ice. They have so little of the shyness of other geese, that they are taken in the easiest manner imaginable, about Yakut, and the other parts of Siberia, which they frequent. The inhabitants first place, near the banks of the rivers, a great net, in a straight line, or else form a hovel of skins sewed together. This done, one of the company dresses himself in the skin of a white rein-deer, advances towards the flock of geese, and then turns back towards the net or hovel; and his companions go behind the flock, and by making a noise drive them forward. The simple birds mistake the man in white for their leader, and follow him within reach of their net, which is suddenly pulled down and captivates the whole. When he chooses to conduct them to the hovel, they follow in the same manner; he creeps in at a hole left for that purpose, and out at another on the opposite side, which he closes up. The geese follow him through the first; and, as soon as they are got in, he passes round, and secures every one.

12. The great goose is of a very large size, weighing near twenty-five or thirty Russian pounds. The bill is black; base of it tawny; body, dusky; the under parts are white; the legs, scarlet. It is found in the east of Siberia, from the river Lena to Kamtschatka; and is taken in great numbers, together with the red-necked geese, in glades, as we do woodcocks here, but on a larger scale.

13. The ruficollis, or red-breasted goose, is in length twenty-one inches; weight about three pounds. The bill is small, and brown; the tail black; the irides are yellow brown; round the eyes fringed with brown; fore part of the head and crown black, passing backwards in a narrow stripe quite to the back; on the breast is a narrow band of white feathers with black ends, forming a band of white and another of black; the sides are striped with black; back and wings black, the last even with the tail; legs black. This most elegant of geese, is found to breed from the mouth of the Ob, along the coasts of the icy Sea, to that of the Lena. Its winter quarters are not certainly known. Small flocks are observed in the spring, flying from the Caspian Sea along the Volga northward; and are seen about Zarizyn, between the sixth and tenth of April. They rest a little time on the banks of the Sarpa, but soon resume their arctic course. Their winter retreat is probably in Persia. They are highly esteemed for the table, being quite free from any fishy taste.

14. The casarca, or ruddy goose, is larger than a mallard, and seems even larger than it really is, from the length of wing, and standing high on its legs. The bill is black; the irides yellowish brown; forehead, cheeks, and throat, yellowish; fore part of the neck ferruginous, encircled with a collar of black, inclining to deep rufous

on the throat; the breast and sides are pale rufous; the belly is obscure; the back is pale; the lower part is undulated, hoary, and brown, not very distinct; the rump and tail are greenish black; the legs long and black. This species is found in all the southern parts of Russia and Siberia, in plenty. In winter it migrates into India, and returns northward in the spring. It makes the nest in the craggy banks of the Wolga, and other rivers, or in the hollows of the deserted hillocks or marmots; making it after the manner of the sheldrake, and is said to form burrows for itself in the manner of that bird. It has been known also to lay in a hollow tree, lining the nest with its own feathers. It is monogamous: the male and female sit in turns. The eggs are like those of the common duck. When the young come forth, the mother will often carry them from the place of hatching to the water with her bill. They have been attempted to be domesticated, by rearing the young under tame ducks; but without success, as they are ever wild, effecting their escape the first opportunity; or, if the old ones are taken and confined, they lay their eggs in a dispersed manner, and never sit. The voice is not unlike the note of a clarinet, while flying; at other times they cry like a peacock, especially when kept tame; and now and then cluck like a hen. It is very choice of its mate; for, if the male be killed, the female will not leave the gunner till she has been two or three times shot at. The flesh is very good food.

15. The bernicle, is of a brown colour, with the head, neck, and breast, black, and a white collar. These birds, like the bernacles, frequent our coasts in winter; and are particularly plenty, at times, on those of Holland and Ireland, where they are taken in nets placed across the rivers. In some seasons they have resorted to the coasts of Picardy, in France, in such prodigious flocks, as to prove a pest to the inhabitants; especially in the winter of the year 1740, when these birds destroyed all the corn near the sea-coasts, by tearing it up by the roots. A general war was for this reason declared against them, and carried on in earnest, by knocking them on the head with clubs; but their numbers were so prodigious, that this availed but little: nor were the inhabitants relieved from this scourge till the north wind, which had brought them, ceased to blow, when they took leave. They easily become tame; and, being fatted, are thought to be a delicate food. They breed pretty far north, returning southward in autumn. They fly in the shape of a wedge, like the wild geese, with great clamour. They are called in Shetland, *Horra geese*, from being found in that sound. They are common also in America; breeding in the islands, and along the coast, and feed about high-water mark. Their food consists of plants, such as the small bistort, and black-berryed heath, sea-worms, berries, and the like. They are apt to have a fishy taste, but are in general thought good food. The same fable has been told of this bird as of the bernicle, in respect to its being bred from trees. It is called at Hudson's Bay, *Wetha may pa wew*.

16. The canadensis is brown; its neck and head are black, and the throat is white. It measures three feet and half in length. It is found during the summer in Hudson's Bay, and parts beyond; also in Greenland; and, in the summer months, in various parts of North America, as far as Carolina. Numbers breed at Hudson's Bay, and lay six or seven eggs; but the major part retire still farther north. Their first appearance in the Bay is from about the middle of April to about the middle of May, when the inhabitants wait for them with impatience, being one of the chief articles for food, and many years kill as many as three or four thousand, which are salted and barrelled. Their arrival is the harbinger of spring, and the month is named by the Indians the *goose moon*. The British send out their servants, as well as Indians, to shoot these birds on their passage. It is in vain to pursue them; they therefore form a row of huts made of boughs, at musket-shot distance from each other, and place them in a line across the vast marshes of the country. Each ho-

vel, or, as they are called, *fland*, is occupied by only a single person. These attend the flight of the birds, and on their approach mimic their cackle so well, that the geese will answer, and wheel, and come nearer the stand. The sportsman keeps motionless, and on his knees, with his gun cocked, the whole time; and never fires till he has seen the eyes of the geese. He fires as they are going from him, then picks up another gun that lies by, and discharges that. The geese which he has killed he sets upon sticks, as if alive, to decoy others; he also makes artificial birds for the same purpose. In a successful day a single Indian will kill 200. Notwithstanding every species of goose has a different call, yet the Indians are admirable in their imitation of every one. In this point, however, they must be very careful to secrete themselves; for the birds are very shy, and on the least motion fly off directly. On their return south, which is from the middle of August to the middle of October, much havoc is made among them; but these are preserved fresh for winter store, by putting them, feathers and all, into a large hole dug in the ground, and covering them with mould; and these, during the whole time of the frost's lasting, are found perfectly sweet and good. The Indians at Hudson's Bay call them *api/si/si/si*. This species is now pretty common, in a tame state, both on the continent and in England; on the great canal of Versailles, hundreds are seen mixing with the swans with the greatest cordiality; and the same at Chantilly. In England, likewise, they are thought a great ornament to the pieces of water in many gentlemen's seats, where they are very familiar, and breed freely. The flesh of the young birds is accounted good; and the feathers equal to those of other geese, inasmuch as to prove an article of commerce much in favour of those places where they are in sufficient numbers.

17. The mollissima, or eider-duck, is double the size of the common duck, has a cylindrical bill, and the wax is divided behind, and wrinkled. The feathers, which are very soft and valuable, fall off during incubation. The male is white above, but black below and behind; the female is greenish. This species is found in the Western Isles of Scotland, particularly on Oranfa, Barra, Rona, and Heisker, and on the Farn Isles; but in greater numbers in Norway, Iceland, and Greenland; from whence a vast quantity of the down, known by the name of *eider*, or *edder*, which these birds furnish, is annually imported. Its remarkably light, elastic, and warm, qualities, make it highly esteemed as a stuffing for coverlets. This down is produced from the breast of the birds in the breeding season. It lays its eggs among the stones or plants near the shore; and prepares a soft bed for them, by plucking the down from its own breast; the natives watch the opportunity, and take away both eggs and nest; the duck lays again, and repeats the plucking of its breast: if she is robbed after that, she will still lay; but the drakes must supply the down, as her stock is now exhausted: but, if her eggs are taken a third time, she wholly deserts the place. These birds are not numerous on the isles; and it is observed, that the drakes keep on those most remote from the sitting-places. The ducks continue on their nests till you come almost close to them; and, when they rise, are very slow fliers. The number of eggs in each nest are from three to five, warmly bedded in the down; of a pale olive colour; and very large, glossy, and smooth. They sometimes, however, lay as many as eight; for Van Troil informs us, that no less than sixteen have been found in one nest, with two females, who agree remarkably well together. In America, this bird is found as far south as New York, and breeds on the desert isles of New England; but most common every where to the north. They are said to be constant to the same breeding-places, and that a pair has been observed to occupy the same nest for twenty years together. They take their young on their backs instantly to sea; then dive, to shake them off, and teach them to shift for themselves. It is said, that the males are five years old before they come to their full colour;

colour; that they live to a great age, and will at length grow quite grey. Their food is shells, for which they dive to great depths. They are very numerous in the Esquimaux lands, where, and in Greenland, they are called *metteh*. The natives kill them on the water with darts, striking them the moment they appear after diving; and know the place, from their being preceded by the rising of bubbles. The flesh is said to be much valued.

18. The maula, or scaup-duck, is less than the common duck. The bill is broad, flat, and of a greyish blue colour; the head and neck are black, glossed with green; the breast is black; the back, the coverts of the wings, and the scapulars, are finely marked with numerous narrow transverse bars of black and grey; the legs are dusky. Mr. Willughby acquaints us, that these birds take their name from feeding on scaup, or broken shell-fish; they differ infinitely in colour, so that in a flock of forty or fifty there are not two alike.

19. The moschata, or Muscovy duck of Ray, has a naked papillous face, and is a native of India. It is bigger than the wild duck, being in length two feet. This species is pretty common in a domesticated state in almost every nation; and the breed ought to be encouraged, as there is more flesh on it than the common duck, and of a very fine flavour. The eggs are rounder than those of a duck, and, in young birds, frequently incline to green. They lay more eggs, and sit oftener, than other ducks. In an unconfined state, they make their nest on the stumps of old trees, and perch during the heat of the day on the branches of such as are well clothed with leaves. When kept tame, they are sufficiently docile; and the male will not unfrequently associate and produce a mongrel breed with the common ducks. The name of Muscovy duck was given them from their exhaling a musky odour, which proceeds from the gland placed on the rump in common with other birds.

20. The clypeata, or shoveler of Ray, has the end of its bill broad, rounded, and furnished with a small hook. It is in length twenty-one inches; the female a trifle smaller. Both sexes are apt to vary much in colour: the male likewise differs from the female inwardly, having, just above the divarication of the wind-pipe, where it passes into the lungs, an enlargement, or, as it is called by some, a *labyrinth*. This bird is now and then met with in England, though not in great numbers. It is said to come into France in February, and some of them to stay during the summer. It lays ten or twelve rufous-coloured eggs, placed on a bed of rushes, in the same manner as the summer-teal; and departs in September, at least the major part of them, for it is rare that one is seen in the winter. Their chief food is insects, for which it is continually muddling in the water with its bill. It also is said dexterously to catch flies which pass in its way over the water. Shrimps, among other things, have been found in its stomach on dissection. This species is also found in most parts of Germany; throughout the Russian dominions, as far as Kamtschatka; and in North America, in New York and Carolina, during the winter season. With us it is accounted pretty good food.

21. The strepera, or gad-wall, has the wings variegated with black, white, and red. It inhabits England in the winter months, and is also found at the same season in various parts of France and Italy. It migrates as far as Sweden, as summer advances, in order to breed; and is found throughout Russia and Siberia, except in the eastern part of the last, and Kamtschatka. Being a very quick diver, it is difficult to be shot. It feeds morning and evening only, being hid among the reeds and rushes during the day. The noise it makes is not unlike that of the mallard, but louder. The flesh is good.

22. The clangula, or golden-eye of Ray, is variegated with black and white, and the head is interspersed with blackish green feathers: it has a white spot near the mouth; and the eyes are of a shining gold colour. It is not unfrequent on our sea-coasts in winter, and appears in

small flocks; but passes to the north in spring, in order to breed. It inhabits Sweden and Norway during the summer. It is an excellent diver, and feeds on small shells. It is mostly seen in the water, as it is very awkward in walking. It has been attempted to be domesticated, but seems out of its element on land. With difficulty it can be brought to eat any thing but bread; and the feet soon grew injured, inasmuch as at last to hinder it from walking. The flesh is much esteemed, and the birds are often seen in the markets at the proper season. This species is found in America; in winter, as low as New York; in summer, at Hudson's Bay, where it frequents the fresh-water lakes, and makes in hollow trees a round nest of grass, lined with feathers from its breast; lays from seven to ten white eggs.

23. The meria, or Ural duck of Pallas, is somewhat bigger than the common teal. The bill is large, broad, very tumid above the nostrils, and bifid in the adult bird, the end marked with diverging striæ; colour blue; the head, and part of the neck, are white; on the crown is a large patch of black; the middle of the neck is black; the fore-parts of the body are a yellowish brown, undulated with black; the back is clouded with a cinereous and pale yellow, powdered with brown; the wings are small; the tail longish, wedge-shaped, and black; the legs are brown, on the fore-part bluish, and placed as far back as in the diver genus. This species is not unfrequent in the greater lakes of the Ural mountains, and the rivers Ob and Irtysh. It is not seen on the ground; for, from the situation of its legs, it is unable to walk; but it swims very well and quick; at which time the tail is immersed in the water as far as the rump, serving by way of rudder, contrary to the common method of a duck's swimming. The nest is formed of reeds, and floats, something like to that of the grebe.

24. The American wigeon, (*le canard jensen* of Buffon), is rather larger than our wigeon. The bill is of a lead-colour; the crown and forehead of a yellowish white; the hind-part of the head and neck is black and white, speckled; and behind the eye is a black mark, changing in some lights to green; the back and scapulars are of a pale rust-colour, waved with transverse black lines; in the middle of the wing-coverts there is a large bed of white; the quills and tail are deep brown; the legs dusky. It inhabits North America, from Carolina to Hudson's Bay; but is no where a common bird. It is called at New York the *pheasant duck*. It is more plenty at St. Domingo and Cayenne, where it is called *vingeon* or *gingeon*. At Martinico, great flocks of them often take short flights, from one rice-plantation to another, where they make much havoc, particularly during the rainy season. They are said to perch on trees. They feed in company; and have a centinel on the watch, like some other birds. They are seldom seen during the day, lying hid in places shaded from the sun; but, so soon as that luminary disappears, they come forth from their hiding-places to feed; and, during this, make a particular kind of noise, by which the sportsman is directed in his search after them; at other times, their note is a soft kind of whistle, which is often imitated in order to decoy them within reach of the gun. They sit in January, and in March the young are seen running about. They lay many eggs. Sometimes they are hatched under hens; in which case they are, while young, familiar, though, when grown up, exceedingly quarrelsome with other ducks: their flesh is most excellent, especially such as are brought up tame. They appear upon the coast of Hudson's Bay in May, as soon as the thaws come on, chiefly in pairs: they lay there only from six to eight eggs; and feed on flies and worms in the swamps. They depart in flocks in autumn. They are known by the name of *atheikimo asheep*.

25. The acuta, pin-tail, or sea-pheasant of Ray, has a long acuminate tail, black below, with a white line on each side of the back part of the head. It is a native of Europe. Mr. Hartlib, in the appendix to his *Legacy*,

tells us, that these birds are found in great abundance in Connaught, in Ireland, in the month of February only; and that they are much esteemed for their delicacy.

26. The glacialis, or long-tailed duck, is inferior in size to the former. The bill is short, black at the tip and base, orange-coloured in the middle; the cheeks are of a pale brown; the hind part of the head, and the neck both before and behind, are white; the breast and back are of a deep chocolate colour; the four middle feathers of the tail are black, and two of them near four inches longer than the others, which are white; the legs dusky. These birds breed in the most northern parts of the world, and only visit our coasts in the severest winters. It breeds in Hudson's Bay and Greenland, among the stones and grafs, making its nest, like the eider, with the down of its own breast, which is equal in value to that of the eider, if it could be got in equal quantity; but the species is scarcer. It lays five eggs; swims and dives admirably, and feeds on shell-fish, which it gets in very deep water. It flies irregularly, sometimes showing its back, sometimes its belly. It continues in Greenland the whole year, in unfrozen places; but there are seasons so very severe, as at times to force them towards the south. Those which breed between Lapland and the polar circle, are often driven into Sweden and the neighbourhood of Petersburg; those from the coast of the Icy Sea, as low as latitude 55: but, on the setting-in of frost, they retire still farther south, unless where some open spots remain in the rivers. They visit the fresh-water lakes in the Orkneys in October, and continue there till April. At sun-set they are seen in great flocks, returning to and from the bays, where they frequently pass the night, and make such a noise as to be heard some miles in frosty weather.

27. The ferina, pochard, or red-headed wigeon of Ray, has a lead-coloured bill: the head and neck are of a bright gay colour: the breast and part of the back where it joins the neck, are black: the coverts of the wings, the scapulars, back, and sides under the wings, are of a pale grey, elegantly marked with narrow lines of black: the tail consists of twelve short feathers, of a deep grey colour: the legs are lead-coloured; and the irides of a bright yellow, tinged with red. The head of the female is of a pale reddish brown. With us, these birds frequent the fens in the winter season, and are brought up to the London markets sometimes in considerable numbers, where they are known by the name of *dun birds*, and are esteemed excellent eating. In winter, they pass pretty far to the south, being found in Egypt, about Cairo. They come into France the end of October in small flocks, from twenty to forty; and are found in Carolina in winter. They feed on small fish and shells. Their flight is rapid and strong; but the flocks form no particular shape in flying.

28. The querquedula, gargeny, or first teal of Aldrovandus, has a green spot on the wings, and a white line above the eyes. It frequents the fresh waters of Europe. In many places it is called the *summer teal*.

29. The creca, or common teal, has a green spot on the wings, and a white line both above and below the eyes. It is of a small size, only fourteen inches in length. The teal is frequent in the London markets along with the wild-duck. It is met with in Duddington-loch, a fresh-water lake, within a mile of Edinburgh. In France it stays throughout the year, and makes a nest in April among the rushes, on the edges of ponds; it is composed of the tenderest stalks of them, with the addition of the pith, and a quantity of feathers. The nest is of a large size, and placed in the water, so as to rise and fall with it. The eggs are the size of those of a pigeon, of a dirty white, marked with small hazel spots. It is said to feed on the grafs and weeds which grows on the edges of the ponds which it frequents, as well as the seeds of the rushes; it will also eat small fish. The flesh is accounted excellent. It is found to the north as high as Iceland; and is mentioned as inhabiting the Caspian Sea to the south.

30. The histrionica, or dusky spotted duck of Edwards,

is of a brown colour, variegated with white and blue; it has a double line on the ears and temples; the collar is white, and there is a white streak on the neck. It inhabits from Carolina to Greenland: in the last it frequents, during summer, the rapid rivers, and the most shady parts; nestling on the banks, among the low shrubs. It swims and dives admirably. In winter it seeks the open sea, flies high and swiftly, and is very clamorous. It feeds on shell-fish, spawn, and the larvæ of gnats. Is found in Iceland, and as low as Sondmor. It is common from the lake Baikal to Kamtschatka; and breeds there, as well as every where else, about the most rocky and rapid torrents.

31. The minuta, or little white and brown duck of Edwards, is of a greyish colour, with white ears, and the prime feathers of the wings blackish. This and the former, according to Latham, are found both on the old and new continents. On the first, it is seen as far south as the lake Baikal, and from thence to Kamtschatka, particularly up the river Ochotka; also in Iceland, and as low as Sondmor. In America, it is found from Carolina to Newfoundland, and Hudson's Bay; also in Greenland, where it frequents, during summer, bays and rivers, especially near their mouths; and is a very noisy species. It is fond of shady places, and makes the nest on the shore among the shrubs. Its food is small shells, eggs of fishes, and particularly the larvæ of gnats. It swims well, even in the most rapid streams; and dives to admiration: it likewise flies swift, and to a great height: from which circumstances it is not easily taken. Our late navigators met with it at Aoonalashka. It is pretty frequent in the small rivulets of Hudson's Bay, about ninety miles inland; seldom in large rivers. It lays ten or more white eggs, like those of the pigeon, on the grafs; and the young brood are specked in a very pretty manner. It migrates south in autumn.

32. The boschas, common wild-duck of Ray, or mallard; the intermediate tail-feathers of the drake are turned backward, and the bill is strait. It frequents the lakes of different countries, and feeds upon frogs and several sorts of insects. The wild-ducks pair in the spring; build their nests among rushes near the water, and lay from ten to sixteen eggs. The female is a very artful bird; and does not always make the nest close to the water, but frequently at a good distance from it; in which case the duck will take the young in its beak or between its legs. It is known sometimes to lay the eggs in a high tree, in a deserted magpie's or crow's nest. At moulting-time, when they cannot fly, they are caught in great numbers. They abound particularly in Lincolnshire, the great magazine of wild-fowl in this kingdom; where prodigious numbers are taken annually in the decoys. Birds with flat bills, that find their food by groping, have three pair of nerves that extend to the end of their bills: these nerves are remarkably conspicuous in the head and bill of the wild-duck, and are larger than those of a goose or any other bird yet known: this is the reason they grope for food more than any other bird whatever. The common tame species of ducks take their origin from this, and may be traced to it by unerring characters. The drakes, howsoever they vary in colours, always retain the curled feathers of the tail, and both sexes the form of the bill, of the wild kind. Nature sports in the colours of all domestic animals; and for a wise and useful end, That mankind may the more readily distinguish and claim their respective property. In France this species is not often seen, except in winter; appearing in October, and going north in spring. They are caught in various manners; among the reeds, in decoys, as in England; the chief place for which is Picardy, where prodigious numbers are taken, particularly on the river Somme. It is also customary there to wait for the flocks passing over certain known places, and the sportsman having a wicker cage, containing a quantity of tame birds, lets out one at a time, at a convenient season, which enticing the passengers within gun-shot, five or six are often killed at once by an expert marksman. They are now and then taken also by a hook

The Chinese Teal.

London, Published as the Act directs, 28 Aug 1796 by J. Williams.

a hook baited with a piece of sheep's lights, which swimming on the water, the bird swallows the bait, and with it the hook. Various other means of catching ducks and geese are peculiar to certain nations; of which one seems worth mentioning from its singularity: the person wishing to take these wades into the water up to the chin, and, having his head covered with an empty calabash, approaches the place where the ducks are; when they, not regarding an object of this sort, suffer the man freely to mix with the flock; after which he has only to pull them by the legs under the water, one after another, till he is satisfied, returning as unsuspected by the remainder as when he first came among them. This method is frequently put in practice on the river Ganges, using the earthen vessels of the Gentoos instead of the calabashes: these vessels are what the Gentoos boil their rice in, and are called *kutchiaree* pots: after these are once used, they look upon them as defiled, and throw them into the river as useless; and the duck-takers find them convenient for their purpose, as the ducks, from constantly seeing these vessels float down the stream, look upon them as objects of full as little regard as a calabash. The above, or some such method, is also practised in China as well as in India. The Chinese, however, though they make great use of ducks, do not prefer the wild sort, being in general extremely fond of tame ones; the major part of which are hatched by artificial heat; the eggs, being laid in boxes of sand, are placed on a brick hearth, to which is given a proper heat during the time required for hatching. The ducklings are fed with little crawfishes and crabs, boiled and cut small, and afterwards mixed with boiled rice; and in about a fortnight flit for themselves, when the Chinese provide them an old step-mother, who leads them where they are to find provender for themselves; being first put on-board a sampane or boat, which is destined for their habitation, and from which the whole flock, often to the amount of three or four hundred, go out to feed, and return at command. This method is used nine months out of twelve, for in the colder months it does not succeed; and is so far from a novelty, that it may be every where seen; but more especially about the time of cutting the rice and gleaming the crop, when the masters of the duck sampans row up and down the river according to the opportunity of procuring food, which is found in plenty, at the tide of ebb, on the rich plantations, as they are overflowed at high water. It is curious to see how the ducks obey their master; for some thousands, belonging to different boats, will feed at large on the same spot, and on a signal given will follow their leader to their respective sampans, without a stranger being found among them. This is still more extraordinary, if we consider the number of inhabited sampans on the Tigris, supposed to be no less than 40,000, which are moored in rows close to each other, with a narrow passage at intervals for boats to pass up and down the river. The Tigris, at Canton, is somewhat wider than the Thames at London, and the whole river is there covered in this manner for the extent of at least a mile.

33. The sponia, or summer-duck of Catesby, is a most elegant species. It has a depending green crest, variegated with blue and white; the back is also variegated with blue and white; the breast is grey, and spotted with white; and the throat is white. It inhabits Mexico, and some of the West-India-isles, migrating in the summer season as far north as forty degrees, or a little beyond. It appears at New York early in the spring, and breeds there; making its nest in the decayed hollows of trees, or such as have been made by woodpeckers; and often between the forks of the branches; and, when the young are hatched, the mother takes them on her back to the water. The flesh is much esteemed by the Americans. This is the species, the neck of which the natives of Louisiana use to ornament their pipes or calumets of peace; and at the last-named place it is found throughout the year. These birds are often kept tame in our menageries, and will breed there.

34. The arborea, or black-billed whistling duck of Ed-

wards, is of a reddish brown colour, with a sort of crest on the head; the belly is spotted with black and white. It is a native of America. Sloane informs us, that this duck perches on trees; that it is about twenty inches long from the end of the bill to the point of the tail; and that it makes a kind of whistling noise, from which circumstance it has received its name.

35. The fuligula, or tufted duck of Ray, has a hanging crest, a black body, and the wings and belly spotted with white. This species is found in Europe as far as Norway. In the winter-months it is not unfrequent in England; being met with in the markets in that season, and is much esteemed. It is common also throughout Russia, going northward to breed. Is frequent in Kamtschatka. The male disappears during the incubation of the female.

36. The *galericulata*, or Chinese teal of Edwards, has a hanging crest; and, on the hinder part of the back, on both sides, there is a crooked, flat, elevated, feather; the crest is green and red; and the back is brown, and spotted with blue; and erect feathers on the back are red and blunt; one edge of the inmost wing-feather, when the wings are shut, is raised over the back, and is red, and like a sickle before. This most singular and elegant species is a native of China and Japan, where it is kept by the inhabitants for the sake of its beauty. It is not so common in China as many other kinds, or perhaps they are politically held dear to the European purchasers: they are frequently exposed to sale at Canton in cages, and the common price is from six to ten dollars per pair. They are not unfrequently brought into England alive; but require care, as they seem more tender than our species. Attempts have been made to breed them in this country, but without success, though they are familiar enough. The bird is known in Japan by the name of *himmodsi*. The English in China give it the name of *mandarin duck*. As it is a singularly curious and elegant species, we have given Mr. Edwards's representation of it, which was copied from the living bird, at Sir Mat. Decker's, at Richmond, Surrey.

ANASAR'CHA, *f.* [from *ana*, through, and *σαρξ*, Gr. flesh.] A species of dropsy. See MEDICINE.

ANASCHOUA'DI, *f.* in botany. See ELEPHANTOPUS.

ANAS'CIS, the son of Castor and Phoebe, had a statue at Corinth, erected in the temple, built in honour of his father.

ANAS'SA, *f.* in botany. See BROMELIA.

ANAS'SUS, or ANAX'US; a river in the territory of Venice; now the *Piave*, which, rising from the mountains of Tyrol, not far from the borders of Carinthia, runs from north to south, through the territories of Cadorina, Belluno, Feltre, and, after running from west to east, through Treviso, falls into the Adriatic, thirteen miles to the south-east of Venice.

ANASTA'SIS, *adv.* [from *αναστημι*, Gr. to cause to rise.] A term among ancient physicians, for a rising up to go to stool. It also signifies the passage of any humour, when expelled from one part, and obliged to remove to another.

ANASTA'SIUS I. emperor of the east, succeeded Zeno in the year 491. The Manicheans and Arians were greatly in hopes of being supported by the new emperor; the former because his mother was their friend; and favoured their sect; the latter because the emperor's uncle was of their opinion: but, if Anastasius did not persecute them (as we do not find he ever did), yet it does not appear that he supported either of these sects. But, in order to maintain the peace of the church, he declared, that such bishops or other clergymen who should disturb the public tranquillity, by maintaining with too much heat either side of the question for or against the council of Chalcedon, should be deprived of their benefices. Accordingly, the disputes concerning Eutychianism running to a very great height, and Euphemius being deeply concerned in them, the emperor expelled him from his see, and chose Macedonius in his stead. The hatred which the different parties entertained against one another occasioned often such

tumults and seditions at Constantinople as threatened the life of the emperor himself; who, to keep the people in awe, ordered that the governor of the city should be present at all church-assemblies and public processions. This was so much the more necessary, because these tumults were chiefly occasioned by a kind of doxology or short hymn which used to be sung at divine service. This doxology consisted only of the following words, Ἄγιος ὁ Θεός, ἅγιος ἰσχυρός, ἅγιος ἀθάνατος, that is, "Holy God, holy the powerful, holy the immortal;" for which reason it was called τριῳαγιος, *trisagius*, "three times holy;" because the word *holy* was therein three times repeated. The orthodox used to sing that hymn without any addition, or by adding only to it, Ἄγια Τριάς, ἐλεησον η̅μ̅ας, i. e. "Holy Trinity have mercy upon us." But Peter the Fuller, bishop of Antioch, pretended to add these words to it, viz. ὁ σωπῶν δι' η̅μ̅ας, i. e. "who hast been crucified for us;" and it was supposed that the first holy related to the Father, the second to the Son, the third to the Holy Ghost, the adding these words, *who hast been crucified for us*, seemed to insinuate that the whole consubstantial Trinity had suffered; for which reason the orthodox were resolved not to admit this addition. Anastasius, desiring to have those fatal words added to that hymn whenever it should be sung at Constantinople, occasioned a terrible sedition in the city, as though the very fundamentals of Christianity had been overthrown. Macedonius and his clergy are said to have raised that sedition, which came to such a height, that the emperor himself was obliged to come, without his crown on his head, and in a most humble manner, to the Circus, where he declared to the people that he was very willing to quit the imperial throne; but he told them at the same time, that they could not all enjoy the sovereign power, which does not admit of a partnership; and that one person still must govern them if he resigned the crown. This discourse had such a power over the raging multitude, that, as if they had been divinely inspired, they immediately requested the emperor to take up his crown, promising that they would be quiet and obedient for the future. As to the civil government of Anastasius, it is confessed that at the beginning of his reign he shewed himself a very good prince; he eased the people of a very heavy tax called *chrysargyrum*, under which they had groaned for a long time; he prohibited the fighting of wild beasts; he raised several buildings; and he avoided war. He reigned twenty-seven years; and died July 10, 518, in the eighty-eighth year of his age.

ANASTASIUS, surnamed *Bibliothecarius*, a Roman abbott, library-keeper of the Vatican, and one of the most learned men of the ninth century, assisted in 869 at the fourth general council, the acts and canons of which he translated from the Greek into Latin. He also composed the lives of several popes, and other works; the best edition of which is that of the Vatican.

ANASTA'TICA, *f.* [ἀναστατικός, Gr. from its quality of reviving in water.] In botany, a genus of the tetradynamia filiculosa class, ranking in the natural order of siliquosæ or cruciformes. The generic characters are—Calyx: perianthium four-leaved, deciduous; leaflets ovate-oblong, concave, erect, deciduous. Corolla: tetrapetalous, cruciform; petals roundish, flat, spreading; with claws nearly the length of the calyx, but more spreading. Stamina: filaments six, subulate, the length of the calyx, form erect spreading; antheræ roundish. Pistillum: germ bifid, very small; style subulate, the length of the stamens, permanent; stigma capitate. Pericarpium: a very short silicle; partition ending in a subulate point, oblique, and longer than the silicle itself; the valves parallel, making a cell of the lower half, but standing out from the upper, rounded, concave, gaping, oblique, hence having the form of a sheep's hoof. Seeds: solitary, roundish.—*Essential Character.* Silicle retuse, crowned at the edge with valves, twice as long as the partition; style intermediate, pointed, oblique; cells one-seeded.

Species. 1. *Anastatica hierochuntica*, or common *anastatica* or rose of Jericho: leaves obtuse; spikes axillary, very short; filicles hooped, thorny. This plant grows naturally on the coasts of the Red Sea; in Palestine and near Cairo, in sandy places. The stalks are ligneous, though the plant is annual; it rises five or six inches high, dividing in many irregular branches. The flowers, which are small and white, are disposed in short spikes at the wings of the stalks, and have little beauty; these are succeeded by short prickly pods, having two cells, in each of which are two seeds. It is preserved in botanic gardens for the variety, and in some curious gardens for the oddness, of the plant, which, if taken up before it is withered, and kept entire in a dry room, may be long preserved; and, after being many years in this situation, if the root is placed in a glass of water a few hours, the buds of flowers will swell open, and appear as if newly taken out of the ground.

2. *Anastatica Syriaca*, or Syrian *anastatica*: leaves acute, spikes longer than the leaf, filicles ovate, beaked. It is a native of Austria, Stiria, Carniola, Syria, and Sumatra; and was introduced in 1788 by M. Thouin. Flowers in May and June.

Propagation and Culture. These plants being annual can only be propagated by seeds, which rarely ripen in England, unless they be sown on a hot-bed in the spring, and the plants afterward put into pots, which should be plunged into another hot-bed to bring them forward; for, although the seeds will come up in the full ground where the soil is dry, yet the plants rarely rise to any size, nor do they perfect seeds unless the summer is very hot and dry: but, if the plants are kept in a frame, giving them free air in warm weather, they will flower in June, and the seeds will ripen in September.

ANASTOICHEIOSIS, *f.* [from ἀνείησις, Gr. a principle, or element, of which bodies are composed.] A wasting of the solids or fluids of the body.

ANASTOMOSIS, *adv.* [from ἀναστομω, Gr. or ἀνα, *per*, and στομα, a mouth, also *exanastomosis inosculatio*.] To relax or open the mouths of the vessels. The opening of the mouths of the vessels to discharge their contained fluids. Anatomists use the word to express the inosculatio of the arteries and veins, or their running into one another. The menes, &c. discharged, are said to be discharged per *anastomosis*, i. e. by opening the mouths of the vessels. The blood transuding through the sides of the vessels, the discharge is said to be per *diapedesis*, transudation. If the vessels are corroded by acrid humours, the discharge is by *diabrosis*, erosion.

ANASTOMATICS, *f.* Medicines supposed to have the power of opening the mouths of the vessels, and promoting the circulation; such as deobstruent, cathartic, and sudorific, medicines.

ANASTROPHE, *f.* [ἀνατροπή, Gr. of ἀνα and τρεφω, to turn.] In rhetoric and grammar, denotes the inversion of the natural order of the words: such is, *saxa per et scopulos*, for *per saxa et scopulos*.

ANASTROUS SIGNS, *f.* in astronomy, a name given to the *duodecatemoria*, or the twelve portions of the ecliptic, which the signs possessed anciently, but have since deserted by the precession of the equinox.

ANASUS, or ANISUS, now the *Ens*, a river of Germany; which, rising on the borders of the territory of Salzburg, then separating Upper Stiria from Upper Austria, and washing the town of Ens, falls, at the distance of a mile below it, into the Danube, in a course from south to north.

ANATHEMA, *f.* [anatheme, Fr. of ἀνάθημα, of ἀνατίθημι, Gr. to renounce or give up to.] Among ecclesiastical writers, it imports whatever is set apart, separated, or divided; but is most usually meant to express the cutting off a person from the privileges of society and communion with the faithful. The anathema differs from excommunication in the circumstances of being attended with curses and execrations. It was practised in the primitive

motive church against notorious offenders; and the form of that pronounced by Senecius against Andronicus is as follows: "Let no church of God be open to Andronicus, but let every sanctuary be shut against him. I admonish both private men and magistrates to receive him neither under their roof nor to their table; and priests more especially, that they neither converse with him living, nor attend his funeral when dead." Several councils have also pronounced anathemas against such as they thought corrupted the purity of the faith; and their decisions have been conceived in the following form: *Si quis dixerit, &c. anathema sit.* There are two kinds of anathemas, the one judiciary and the other abjuratory. The former can only be denounced by a council, a pope, or a bishop; the latter makes a part of the ceremony of abjuration, the convert being obliged to anathematize the heresy he abjures.

ANATHEMA, in heathen antiquity, was an offering or present made to some deity, and hung up in the temple. Whenever a person left off his employment, it was usual to dedicate the tools to the patron deity of the trade. Persons too who had escaped from imminent danger, as shipwreck and the like, or had met with any other remarkable instance of good fortune, seldom failed to testify their gratitude by some present of this kind.

ANATHEMA'TICAL, *adj.* That which has the properties of an anathema; that which relates to an anathema.

ANATHEMA'TICALLY, *adv.* In an anathematical manner.

To ANATHEMATIZE, *v. a.* To pronounce accursed by ecclesiastical authority; to excommunicate.—They were therefore to be *anathematized*, and, with detestation, branded and banished out of the church. *Hammond.*

ANA'THOTH, a village of Palestine, very near Jerusalem, about three miles and a half to the north; the ruins of which are still to be seen. It was the birth-place of the prophet Jeremiah, and one of the Levitical towns in the tribe of Benjamin.

ANATIFERA CON'CHA, *f.* the trivial name of a species of the *lepas*, a testaceous animal. See *LEPAS*.

ANATIFEROUS, *adj.* [from *anas* and *fero*, Lat.] Producing ducks. Not in use.—If there be *anatiferos* trees, whose corruption breaks forth into barnacles; yet, if they corrupt, they degenerate into maggots, which produce not them again. *Brown.*

ANA'TOCISM, *f.* [*anatocismus*, Lat. of *ανατοκισμος*, Gr. of *ανα* and *τοκος*, usury.] An usurious contract, wherein the interests arising from the principal sum are added to the principal itself, and interest exacted upon the whole. *Anatocisin* is what we properly call *interest upon interest*, or *compound interest*. This is the worst kind of usury, and has been severely condemned by the Roman law, as well as by the common laws of most other nations.

ANATO'MICAL, *adj.* Relating or belonging to anatomy.—When we are taught by logic to view a thing completely in all its parts, by the help of division, it has the use of an *anatomical* knife, which dissects an animal body, and separates the veins, arteries, nerves, muscles, membranes, &c. and shews us the several parts which go to the composition of a complete animal. *Watts.*—Proceeding upon principles taught in anatomy; considered as the object of anatomy.—There is a natural involuntary distortion of the muscles, which is the *anatomical* cause of laughter; but there is another cause of laughter, which decency requires. *Swift.*—Anatomized; dissected; separated.—The continuation of solidity is apt to be confounded with, and, if we will look into the minute *anatomical* parts of matter, is little different from, hardness. *Locke.*

ANATO'MICALLY, *adv.* In an anatomical manner; in the sense of an anatomist; according to the doctrine of anatomy.—While some affirmed it had no gall, intending only thereby no evidence of anger or fury, others have construed *anatomically*, and denied that part at all. *Brown.*

ANA'TOMIST, *f.* [*anatomiste*, Fr. *anatomicus*, Lat. of *ανατομικος*, Gr.] He that studies the structure of animal bodies, by means of dissection; he that divides the bodies of animals, to discover the various parts.—*Anatomists* adjudged, that if nature had been suffered to run her own course, without this fatal interruption, he might have doubled his age. *Howel.*

To ANA'TOMIZE, *v. a.* [of *ανατεμνω*, Gr. to cut up; *anatomiser*, Fr.] To dissect an animal; to divide the body into its component or constituent parts.—Our industry must even *anatomize* every particle of that body, which we are to uphold. *Hooker.*—To lay any thing open distinctly, and by minute parts.—I speak but brotherly of him, but should I *anatomize* him to thee as he is, I must blush and weep, and then must look pale and wonder. *Shakespeare.*

Then dark distinctions reason's light disguis'd,
And into atoms truth *anatomiz'd*. *Denham.*

ANATOMY.

ANATOMY, *f.* [from *ανατομη*, Gr. of *ανα*, through, *περνω*, to cut.] The art of dissecting an animal, especially the human body, in order to demonstrate the matter, shape, structure, connection, and situation, of the parts; this, though it does not teach to cure, hath a tendency to make the cure proceed both more safely and agreeably. In short, whatever perfection the art of healing might have risen to, by the aid of practical experiments and observation, it cannot be denied that its greatest lights were received from anatomy and physiology. To know the peculiar structure of each part, its use, what functions it performs, what connection it hath with other parts, and influence on them, whether near or remote, are advantages too obvious to be denied. The greatest geniuses have found that their enquiry cannot be too minute in this branch of physic; and the most eminent professors and practitioners have in consequence become more laudably emulous to encrease their knowledge and acquaintance therein.

Vol. I. No. 33.

The human body is composed of firm and liquid parts, commonly called *solids* and *fluids*. The solid parts are the chief subject of anatomy properly so called; by which term we understand not only an artful decomposition of the parts of the body, but also a methodical demonstration and description of the several parts when dissected. The history of the fluid parts comes into a system of anatomy only occasionally; because it properly belongs to what is called *physiology*, or the *animal economy*.

Anatomists ordinarily reduce all the solid parts under certain general classes, expressed by the common or general names of *bone*, *cartilage*, *ligament*, *fibre*, *membrane*, *vessel*, *artery*, *vein*, *nerve*, *muscle*, *gland*, *fat*, *viscus*, *organ*, &c. These terms are anatomical words, which express several parts that have nearly the same structure to outward appearance; and, as they are often mentioned, we shall here give a brief explanation of them.

A *bone* is that hard, solid, and most inflexible, part of the body, which assists in forming the great frame-work

of the human machine. All bones are covered by a membrane, named on that account *periosteum*; and except where muscles, cartilages, or ligaments, are inserted into the periosteum, its external surface is connected to the surrounding parts by thin cellular membranes, which can easily be stretched considerably, but shorten themselves whenever the stretching force is removed. When these membranes are cut off or broken, they collapse into such a small space, that the surface of the periosteum seems smooth and equal.

The *internal periosteum* is an extremely fine membrane lining the inside of the bone. It hath processes entering into the transverse pores of the bones, where probably they are continued to form the intermediate canals for the marrow distributed through the substance of the bones; and along with them vessels are sent, as from the external periosteum, into the bone. These processes being of a very delicate texture, the adhesion of this membrane to the bone is so small, that it separates commonly more easily from the bone than from the marrow which it contains: wherefore one might call it the common membrane of the marrow, rather than by the name it now has. But whether the one or the other designation ought to be given it, is not worthy a dispute.

The *marrow* is the oily part of the blood, separated by small arteries, and deposited in these cells. Its colour and consistence may therefore vary according to the state of the vessels, and their distribution on the membranes of the cells. The marrow is bloody in children, oily and balmy in middle age, and thin and watery in old people. By experiments made on the marrow when bones of living animals are opened or cut through, and from the racking pain with which suppurations within bones are frequently attended, we have sufficient proof that the membranes here are sensible, and consequently have nerves distributed to them. Hippocrates might therefore say justly, that a wound penetrating into the cavity of a bone may produce a delirium.

Cartilages are solid, smooth, white, elastic, substances, between the hardness of bones and ligaments, and covered with a membrane, named *perichondrium*; which is of the same structure and use to them, as the periosteum is to the bones. While cartilages are in a natural state, it is to be remarked, 1st, That they have no cavity in their middle for marrow. 2dly, That their outer surface is softest, which renders them more flexible. 3dly, That they do not appear to change their texture near so much by acids, as bones do. And, lastly, That as the specific gravity of cartilages is near a third less than that of bones; so the cohesion of their several plates is not so strong as in bones; whence cartilages, laid bare in wounds or ulcers, are not only more liable to corrupt, but exfoliate much sooner than bones do.

Ligaments are white flexible bodies, thicker and firmer than membranes, and not so hard or firm as cartilages, without any remarkable cavity in their substance, difficultly stretched, and with little elasticity; serving to connect one part to another, or to prevent the parts to which they are fixed from being removed out of that situation which is useful and safe. Authors generally say that ligaments are insensible; and consequently it may be inferred, that they have no nerves bestowed on them. But the violent racking pain felt on the least motion of a joint labouring under a rheumatism, the seat of which disease seems often to be in the ligaments, and the insufferable torture occasioned by incisions of ligaments, and by a collection of acrid matter in a joint, or by tophi in the gout, persuade us that they are abundantly supplied with nerves. Part of the capsular ligaments is composed of the periosteum, continued from one bone to another, and their internal layer is continued on the parts of the bone or cartilage which the ligament includes. Besides these common capsular ligaments of the joints, there are particular ones in several places, either for the firmer connection of the articulated bones, or for restraining and confining the mo-

tion to some one side; such are the *cross* and *lateral* ligaments of the knee, the *round* one of the thigh, &c.

Synovia is the liquor which principally serves to moisten the ligaments and cartilages of the articulations, and is supplied by glands, which are commonly situated in the joint, after such a manner as to be gently pressed, but not destroyed by its motion. By this means, when there is the greatest necessity for this liquor, that is, when the most frequent motions are performed, the greatest quantity of it must be separated. These glands are soft and pappy, but not friable: in some of the large joints they are of the conglomerate kind, or a great number of small glandules are wrapt up in one common membrane. Their excretory ducts are long, and hang loose, like so many fringes, within the articulation; which, by its motion and pressure, prevents obstructions in the body of the gland or its excretories, and promotes the return of this liquor, when fit to be taken up by the absorbent vessels, which must be in the joints, as well as in the other cavities of the body; and, at the same time, the pressure on the excretory ducts hinders a superfluous unnecessary secretion, while the fimbriated disposition of these excretories does not allow any of the secreted liquor to be pushed back again by these canals towards the glands. Very often these fountains of slimy liquor appear only as a net-work of vessels. Frequently they are almost concealed by cellular membranes containing the fat; and sometimes small simple mucous folliculi may be seen. The different joints have these organs in different numbers and sizes: the conglomerate ones do not vary much, especially as to situation, in the similar joints of different bodies; but the others are more uncertain.

The name of *fibre* is given to small filaments, which appear to be the most simple parts of the body, and which, by their different disposition and connections, compose all the other parts. The fibres differ in substance, being either membranous, fleshy, tendinous, or bony; in direction, being either straight, oblique, longitudinal, transverse, circular, or spiral; and in size, being either large, small, long, or short.

By *membrane*, we understand a pliable texture of fibres interwoven or disposed together in the same plane. They differ in thickness, according to the smallness of their fibres and number of their planes. These particular planes are termed *laminae*, and are distinguished into external, internal, middle, &c. The difference of membranes in general depends on that of the fibres, of which they are composed. Small portions of membranes, especially when they are very thin, are called *pelliculae*; and some membranous laminae are united together by the intervention of a particular substance, composed of this sort of pellicles, and called the *cellular* or *spongy substance*.

By *vessels* are meant tubes, ducts, or canals, more or less flexible, composed of different membranes, the frata of which are generally termed *tunica* or *coats*. Some of them are divided into branches, and these again into rami and ramifications, which gradually diminish, but still remain hollow. The general design of the vessels is to contain fluids; from the diversity of which they are distinguished into blood-vessels, vasa lactea, lymphatica, &c. The last and smallest extremities of all sorts of vessels are generally termed *capillaries*. The *blood-vessels* are of two kinds; one of which receives the blood from the heart, and distributes it to all the parts of the body, and are named *arteries*; the other brings the blood back again from all parts to the heart, and are called *veins*; and some of these have the name of *sinuses*. The arteries are thicker than the veins, and may be distinguished by this mark in dissected dead bodies; and in living bodies they are known by a certain beating called the *pulse*. The trunks of the veins lie nearer the surface of the body than the arteries, and are furnished with valves, that is, with small membranous sacculi, fixed at different distances to the sides of their cavities. The openings of these valves are broad, and turned toward the heart; but their bottoms are turned the contrary

contrary way. In some places these valves are single, in others double, triple, &c.

By *nerves*, anatomists mean the white ropes which proceed from the cerebrum, cerebellum, and spinal marrow, and are spread over all the parts of the body by filaments and ramifications. Each nervous rope may be considered as a membranous vessel, the cavity of which is filled by a great number of membranous longitudinal septa, and by medullary filaments which lie between the septa.

Muscles are bundles of fibres, called by anatomists *fibræ motrices*, of a reddish colour, and of different lengths. The middle portion of the moving fibres is the principal, and differs from the extremities in being red, thick, soft, and capable of contraction. This middle portion of each moving fibre is said to be fleshy, and forms what is properly called *flesh*. The extremities are called *tendinous*, and the substance formed by them *tendons*.

Glands are clusters or molecule, distinguishable from all the other parts of the body by their form, consistence, texture, and connection. They are, in general, composed of arteries, veins, nerves, and other particular vessels, and of a substance which unites all these together in their different folds, contortions, and intertextures, all invested by a membranous covering. The office of glands is to separate from the mass of blood, by means of certain secretory vessels, fluids, which they discharge, either immediately or by other vessels termed *excretory*; and these fluids are either accumulated in particular reservoirs, collected in the common cavities, or forced out of the body.

Fat and *marrow* are equivocal terms. By the first we generally understand an oily, soft, white, or yellowish, substance, of different consistences, collected between the skin and the muscles, in the interstices of the muscles about the viscera, &c. and composed partly of a cellulous or spongy substance, purely membranous, and partly of an oily matter of different thickness. This oily matter is called *fat*, especially when separated from the cellulous substance, and likewise *corpus adiposum* by anatomists. Marrow differs from fat only in the fineness of the membranous texture, in the subtility of the oily matter, and its situation within the bones.

By *viscera*, we commonly understand parts contained in a great cavity, without being connected to it through their whole extent or circumference. Such are the stomach, intestines, &c. in the abdomen; and the lungs in the thorax. *Organ* or *instrument* is a term given to every part capable of any function, whether it be simple or complex; and in this sense we say, organ of sight, respiration, &c.

The *HUMAN BODY* is commonly divided into the *head*, *trunk*, and *extremities*. The trunk is again subdivided into the *neck*, *thorax*, and *abdomen*; and the extremities into *superior*, called the *arms*, and *inferior*, called the *legs*. The ancients divided the body into the three great cavities, which they termed *venters*, and into four extremities. They called the head the *upper venter*, the thorax the *middle venter*, and the abdomen the *lower venter*. The neck was by some joined to the head; by others, to the thorax. But the most natural and plainest division of the body, is into the head, neck, thorax, abdomen, arms, and legs; each of which portions may afterwards be subdivided. Each portion is to be examined not only with regard to its surface or external conformation, but also with regard to its internal structure or composition, and to the viscera or organs which it contains or supports. This is what gave occasion to the antients to divide the body into parts containing and parts contained; and to subdivide the containing parts into common and proper. The common containing parts have been named *integuments*, by which they meant chiefly the skin and fat.

The *head*, viewed on the outside, is divided into the *hairy scalp* and *face*. The inner parts of the head are surrounded by the bones of the cranium. The *hairy scalp* covers the upper part of the os frontis, the ossa parietalia, the os occipitis, and the upper and lower portions of the ossa temporum. The uppermost part of the hairy scalp is

termed the *vertex* or *fontanella*; the back part *occiput*; the lateral parts the *temples*. The vertex is known from the occiput by contorted hair, and from the temples by the ears.

The *face* comprehends all that portion of the surface of the head which lies between the hairy scalp and the neck, viz. the forehead, eyebrows, palpebræ, eyes, nose, mouth, chin, cheeks, and ears. The external parts of the *eye* are: the anterior portion of the globe of the eye, the membrana conjunctiva, the cornea lucida, caruncula lachrymalis, angles of the palpebræ, and the cilia, or hairs of each palpebra. The internal parts are: the globe of the eye, the iris and pupil, the tunica sclerotica or cornea opaca, the choroides, arachnoides, crystalline, vitreous humour, aqueous humour, the anterior and posterior chambers, the muscles, and the optic nerve. The external parts of the *ear* are: the great concha, the convex side of this concha or hinder part of the ear, the great border, the fold or helix, the concavity, the broad eminence or antihelix, the small anterior eminence or tragus, the small posterior eminence or antitragus, the lobe or lower extremity of the ear, and the meatus. The external parts of the *nose* are: the upper extremity or root of the nose, the arch or back, the sides of that arch, the tip of the nose, the alæ, the nares, and the septum narium. The internal parts are, the cavity and bottom of the nares, the convolutions, the maxillary, sphenoidal, frontal, and ethmoidal, sinuses. The external parts of the *mouth* are: the lips, one upper, the other lower, the angles or commissures of the lips, the border or edge of each lip, the fossula which runs from the septum narium to the edge of the upper lip, and the transverse fold which separates the upper lip from the chin. The internal parts of the *mouth* are, the palate, the septum palati, the uvula; the amygdalæ, gums, fræna of the lips, the tongue, its apex, roots, sides, and frænum. The other internal parts of the mouth, eye, nose, and ear, such as the glands, membranes, muscles, nerves, veins, &c. must be referred to the particular descriptions of these parts. The *cheeks* are the lateral parts of the face, reaching downward from the eyes and temples, between the nose and ears. The upper prominent part of the cheek is commonly termed *mala*. The *chin* is the anterior protuberance, by which the lower part of the face is terminated, from whence it runs all the way to the neck. The under part of the chin is termed the *basis*; and it is distinguished from the throat by a transverse fold, which reaches from ear to ear. In the middle of the chin there is sometimes a fossula or depression.

The *cranium* comprehends all that portion of the head which reaches from the upper part of the orbit to the upper and back part of the neck; at the sides it extends as low as the passages into the ears. It is lined internally by the dura mater, and divided by a process of that membrane into a large upper cavity and a small under one. The upper cavity contains the cerebrum, the under one contains the cerebellum and the medulla oblongata.

The *neck*, in general, is divided into the anterior part or throat, and posterior part or nape. The throat begins by an eminence, and terminates by a fossula. The nape begins by a fossula, which, as it descends, is gradually lost. The neck contains the larynx, a part of the trachea arteria, the pharynx, a part of the œsophagus, and a portion of the medulla spinalis.

By the *thorax* we commonly understand all that part of the body which answers to the extent of the sternum, ribs, and vertebræ of the back, both outwardly and inwardly. The thorax is divided into the anterior part, called commonly the *breast*; the posterior part, called the *back*; and the lateral parts, called the *right* and *left sides*. The external parts of the thorax, besides the skin and membrana adiposa, are principally the mammae, and the muscles which cover the ribs and fill the spaces between them. In the mammae we see the papillæ or nipples, and a small coloured circle which surrounds them. The internal parts of the thorax are contained in the large cavity of that portion of the trunk which the ancients called the *middle venter*;

but

but the moderns name it simply the *cavity of the breast*. The cavity is lined by a membrane named *pleura*, and divided into two lateral cavities by a membranous septum named *mediastinum*, which is a production or duplicature of the *pleura*. These parts are the heart, pericardium, trunk of the aorta, beginning of the carotid and subclavian arteries, the superior portion of the descending aorta, the intercostal arteries, the vena cava superior, vena azygos, termination of the subclavian veins, a portion of the *aspera arteria*, and of the *œsophagus*; the *ductus lacteus* or *thoracicus*, the lungs, pulmonary artery, pulmonary veins, &c. The cavity of the thorax is terminated downward by the diaphragm, which parts it from the abdomen.

The *abdomen* begins immediately under the thorax, and terminates at the bottom of the pelvis of the *ossa innominata*. Its circumference or outer surface is divided into regions; of which there are three anterior, viz. the epigastric or superior region, the umbilical or middle region, and the hypogastric or lower region. There is but one posterior region, named *regio lumbaris*. The *epigastric region* begins immediately under the appendix *eniformis* at a small superficial depression called the *pit of the stomach*, and in adult subjects ends above the navel at a transverse line supposed to be drawn between the last false ribs on each side. This region is sub-divided into three parts, *epigastrium*, already named; and two lateral regions, termed *hypochondria*. The epigastrium takes in all that space which lies between the false ribs of both sides, and the hypochondria are the places covered by the false ribs. The *umbilical region* begins in adults above the navel, at the transverse line already mentioned; and ends below the navel at another transverse line, supposed to be drawn parallel to the former, between the two *cristæ* of the *os ilium*. This region is likewise divided into three parts; one middle, which is properly the *regio umbilicalis*; and two lateral, called *ilia* or the *flanks*; and they comprehend the space between the false ribs and upper part of the *os ilium* on each side. The *hypogastric region* is extended downward from the inferior limit of the umbilical region, and is divided into three parts; one middle, called *pubis*; and two lateral, called *inguina* or the *groins*. The *lumbal region* is the posterior part of the abdomen, and comprehends all that space which reaches from the lowest ribs on each side, and the last vertebra of the back, to the *os sacrum* and neighbouring parts of the *os ilium*. The lateral parts of this region are termed the *loins*, but the middle part has no proper name in men. Lastly, the bottom of the abdomen, which answers to the pelvis of the skeleton, is terminated anteriorly by the *pudenda* or parts of generation; and posteriorly by the *clunes* or buttocks, and anus. The buttocks are separated by a fossa, which leads to the anus, and each buttock is terminated downward by a large fold which distinguishes it from the rest of the thigh. The space between the anus and parts of generation is called *perinaum*; and is divided into two equal lateral parts by a very distinct line, which is longer in males than in females. The cavity of the abdomen, formed by the parts already mentioned, and covered by the skin and *membrana adiposa*, is lined on the inside by a particular membrane, called *peritoneum*. It is separated from the cavity of the thorax by the diaphragm, and terminated below by the *musculi levatores ani*. This cavity contains the stomach and the intestines; which are commonly divided into three final portions, named *duodenum*, *jejunum*, and *ileum*; and three large, called *cæcum*, *colon*, and *rectum*. It contains likewise the mesentery, mesocolon, omentum, liver, gall-bladder, spleen, pancreas, glands of the mesentery, *vasa lactea*, *receptaculum chyli*, kidneys, renal glands, ureters, bladder, and the internal parts of generation in both sexes.

The whole *arm* is divided, as in the skeleton, into the shoulder, the arm properly so called, the fore-arm, and the hand. To these we must add the shoulder, the axilla or arm-pit, the elbow, the fold of the arm, and the hollow of the hand. What is called the shoulder, is formed by

the fleshy belly of the *musculus deltoideus*; and the axilla, by the corresponding edges of the *pectoralis major* and *latissimus dorsi*. The elbow answers to the *olecranon*; the fold of the arm is on the fore-side of the articulation of the *os humeri*, with the bones of the fore-arm, and the hollow of the hand is in the middle of the palm.

The *lower extremities* of the whole body are divided into the thigh, leg, and foot. The *thigh* begins anteriorly on one side of the fold of the groin; and posteriorly, a little above the lower half of the buttock. It terminates anteriorly at the patella on the knee, and posteriorly at the poples or ham. It is formed chiefly by the muscles which surround the *os femoris*. The *leg* has but very few muscles on the fore-part, but a great many large ones behind; where the *gastrocnemii* and *soleus* form a kind of belly, called the *calf of the leg*. The leg begins anteriorly at the knee below the patella, and posteriorly at the poples; and it terminates below at the ancles. The convex part of the foot, near its articulation with the leg, is termed the *neck of the foot*; and the under part, which is the basis of the whole lower extremity, the *sole of the foot*. The fleshy parts are more considerable on the foot than on the hand.

Thus the human system is made up of a variety of parts formed of matter apparently under very different kinds of modification; and these constitute a whole, the different parts of which are susceptible of various degrees of impressions from powers, to the action of which they are subjected. This entirely arises from the mode of their organization. The bones, from the nature of their fabric, are perhaps less susceptible of the action of powers applied to them, than any other part of the system; they appear designed to form the basis of the body; they support the soft parts; they defend and contain the more delicate and noble organs. Though liable to disease, they are not subject to injury like the other parts; and even after death, that rapid and spontaneous decomposition does not take place in them which we perceive in the rest of the system. They may be exposed for ages, without losing their original form; and they seem to bear a considerable analogy to inorganised matter.

Anatomical research, however, fully proves, that bone is as truly organised matter as any other part of the body. This indeed is a conclusion which we might have drawn *a priori*, from the consideration, that inorganised matter could not possibly form a part of an animated system. The anatomist proves the truth of the assertion. He shews that the bones are supplied with blood-vessels, as well as the fleshy parts. He exhibits their structure, and points out their periods of growth and decay, which can only be effected by the action of depositing and absorbing vessels; and in short, fully proves, that they are as truly organised matter as the rest of the body. But their organisation is so constituted, as to be exactly fitted for the purpose they are destined to serve. In fact, we observe, that bones are formed of a system of vessels, in the interstices of which, a seemingly earthy matter, mixed with mucus, is deposited. This earthy matter, which gives hardness and strength to the bones, is in reality inorganised and dead matter, a true phosphate of lime, liable to no alteration when separated from the body, excepting by the operation of the laws of chemical attraction. The bones are also supplied with nerves. They may be observed, in small threads, entering into the substance of the bones. Small nerves may also be seen entering into each bone, along with its nutritious vessels; and in some cases we observe them passing through large holes in bones, as the nerves which go into the jaws to supply the teeth. But, notwithstanding that anatomists can demonstrate the existence of nerves in the bones, yet the fact has been doubted, because the bones seem insensible to pain. It is true, the periosteum may be scraped from a bone, a bone may be cut through, as in amputation, or in the operation of trepanning, or caustics may be applied to bone; and the patient, in all these cases, scarcely feels pain. It must, however, be admitted, that bone, even in the

the healthy state, possesses a low degree of sensibility. The actual cautery, which, in former periods, was much employed by surgeons, is known to produce a sensation in the bone, though said to be rather pleasant than painful. This, however, is a sufficient proof, that the bones are not absolutely incapable of feeling. But the sensibility of bone is sufficiently obvious in the diseased state: injuries of various kinds will excite inflammation in it, as well as in the soft parts; and we observe the same phenomena produced in both. An increased determination of blood to the part swelling, a spongy looseness of texture, suppuration, and ulcer, take place in bone, in a manner precisely similar to what we observe in the soft parts. And, as in the latter the organization is destroyed, so also in the former we observe the bone eroded, and discharged by ulceration. During the progress of such a disease, the sensibility of the bone is astonishingly increased. Thus in the parts which possess the most acute feeling, we observe the sensibility increased by disease. In like manner the bones, ligaments, bursæ, and other parts, in which, during health, the feeling is scarcely perceptible, become, by disease, extremely sensible, so as to give the most exquisite pain in many cases, superior to what is experienced in a similar disease of the soft parts.

In every view that we can take of the subject, bone appears to be as perfectly organized matter as any other part of the body. It receives its share of the sanguiferous and absorbent vessels; it is supplied with nerves, and by all of them is immediately and intimately connected with the system at large. It is produced by the animalizing process; it is liable to disease and death; it is susceptible of impressions from stimuli; and by their operation is excited to action. Thus the bones are constructed upon a plan admirably calculated for the purpose they are intended to serve in the body. In order to give them hardness and inflexibility, they are chiefly composed of an earthy salt. This salt is deposited by circulating vessels, which enter their substance; and when it has remained for a certain period, it is absorbed and carried out of the system by vessels destined for that purpose. Thus a continual deposition and absorption is going on in the bones, as well as in any other part of the body. The nerves with which bone is supplied, are doubtless intended to supply the vessels which are ramified through its substance; as we cannot suppose that they have any use with respect to the inorganic earthy salt, of which bone is chiefly formed. Upon the whole, then, it appears, that bone must be less capable of sensation, and less liable to be acted upon, than perhaps any other part of the body, as it is only the vessels and nerves which belong to it that are capable of sensation.

Cartilage possesses a degree of organization somewhat inferior to that of bone. This substance is interposed between bones, particularly at the joints, with the view of abating friction, and preventing those injuries which might be expected from the collision of the harder bony matter. Hence they are so constituted as to possess a degree of elasticity, by which they yield to the weight of the body, and are restored to their original size when that weight is removed. Cartilage was at one time supposed to be a mere concrete, having little or no connection with the other parts of the system, except by mechanical cohesion. But, in the original formation of bone, it appears that cartilage is organized matter, and as truly connected with the system as any other part of the animal. Thus we observe, that the bones are terminated at their articulations by a thin cartilage; and the periosteum is extended over the surface of the cartilage. The circulation in cartilage is indeed not very active, but sufficient to preserve it in the living state. Had the powers of life been considerable in cartilaginous matter, had its feelings been acute, it must have produced very considerable inconveniences to the animal: it would have been liable to frequent inflammation, and other disorders. But, having received a peculiar

mode of organization, in which the feeling is obscure, and the excitability dull, it is admirably fitted to perform all the motions of the body, and is subjected to the friction of the joints, without being liable to injury.

The cellular substance, like bone and cartilage, possesses a low degree of sensation, and its excitability is obscure. This matter, under various modifications, is employed to unite, cover, and defend, the other parts of the system. In all the forms in which it subsists in the body, it possesses little sensibility; and may, when compared with the muscular and nervous solids, be almost considered as inanimate matter: that is, when in the healthy state, like bone and cartilage, its excitability is in a very low degree. Both mechanical and chemical stimulants, when applied to it, give but little sense of pain.

First, the cellular substance is extended over the whole body, and interposed between all the parts. Formed into an infinite multitude of cells, which contain fat and a thinner fluid, it is happily constructed to allow the parts to glide and move easily. It penetrates into the muscles, and keeps their fibres at a proper distance, so that the action of each may be duly exerted. It appears also to support and lubricate the muscular fibre, inasmuch that the strength of the system in health, and its weakness in disease, have been supposed in some degree to depend upon the proper or improper state of the cellular matter. It has generally been admitted, that the thinner fluid contained in the cells is designed to render the play of the fibres easy and free; and that the fat is intended to support the fibres in their action, to lubricate them, and to give a plumpness to the body. It has also been suggested, that it may be reabsorbed for various uses in the system. It is probable; however, that the sebaceous matter, like the phosphate of lime in the bones, can only be applied to its proper uses in the system for a certain period. By degrees it becomes unfit for the purposes of the animal economy. It is secreted and deposited in the cells, and, when reabsorbed, is probably, with other excrementitious matter, thrown out of the system. Secondly, a modification of the cellular substance is employed as a covering to the bones. The periosteum appears to be a condensation of the cellular substance applied in successive layers, so as to produce a thick membrane, which conveys the blood-vessels, &c. to the bones. Thirdly, the tendons of the muscles are produced by a mere continuation of the periosteum, from which they are evidently derived, and not from the muscles, as the old anatomists imagined. Fourthly, the tendinous matter somewhat differently modified, so as to form a thin membranous sheet, is employed to cover the muscles forming the vagina or fascia of the muscles. The cellular substance which lies under the fascia, and which immediately surrounds the muscle, appears to be only more loosely attached laminae of the fascia. It is from the fascia that the cellular matter is derived which penetrates into the muscles. Fifthly, the periosteum, formed into a thicker membrane, and strengthened by the adhesion of surrounding parts, is employed for the capsules of the joints. Sixthly, the bursæ mucosæ derive their origin from the same substance. The bursæ are formed in those parts where a tendon plays over a bone. The upper surface of the bursa is formed by the tendon itself; the lower surface of the same bursa is produced from the periosteum of the bone; and the sides of the bursa are formed by the common cellular substance. The bursæ mucosæ and capsular ligaments do not materially differ in their nature. They contain precisely the same kind of liquor, and they frequently communicate with each other. Thus, under a variety of modifications, the cellular substance is applied to many useful purposes in the system. It joins the bones to each other, it unites the muscles to the bones, it gives security and firmness to their motions by the fluids which it contains, it lubricates the joints and muscular fibre, and it is further employed to give a plumpness and agreeable shape to the limbs. For all these purposes it appears

to be peculiarly fitted, by possessing a degree of sensibility much inferior to that of the more important parts of the system. Under all the modifications which we have now mentioned, cellular substance appears to have few blood-vessels, and no nerves; at least no nerves are visible. But we must conclude, that the few blood-vessels which convey nutrition to the cellular substance must be accompanied with nerves, however minute. And the feeling which can, by disease, be awakened in these parts, must lead us to infer, that they are in some degree supplied with nerves; as we cannot conceive that sensation can be produced, except by the agency of nerve. The paucity, however, of blood-vessels and nerves in the cellular substance, sufficiently evinces, that these parts can be little susceptible of the action of stimuli; and the fact which we thus discover from the structure of the parts, is strikingly evidenced by experiment. Under all its different modifications, cellular substance in the healthy state appears to be insensible to the action both of mechanical and chemical stimulants. The tendons of animals have been cut and pierced, they have been pinched and torn, the actual cautery, as well as the chemical, have been applied, without inducing the least indication of pain in the animal subjected to the experiment. The most violent chemical stimuli have been applied to the various parts of a joint, without producing any appearance of an uneasy sensation. In like manner, in surgical operations, the various modifications of the cellular substance may be operated upon without producing any degree of pain to the patient. Nay, it appears that little pain is induced by the accidental laceration of the ligaments and tendons. We cannot indeed say that these parts are entirely without feeling. Their sensibility is indeed dull. They receive the impressions of stimuli very slowly; but when, by disease, the organization of the part is deranged, the feeling is astonishingly increased, and the patient suffers a more acute pain than what we observe in almost any other part of the system. One thing, however, is obvious, the organ of sensation in these parts must be precisely the same as in the rest of the body. It is only to the nerves that we can ascribe this quality. They may, in the cellular substance, during the state of health, be peculiarly sheathed and defended from impressions to which they become exposed when the organization of the part is injured by disease.

In the muscular and nervous fibre, we perceive the powers of life exerted with much greater activity than in those parts which we have hitherto noticed; or, more properly speaking, muscular and nervous fibre are much more susceptible of the action of stimuli, than bone, cartilage, or cellular substance. It is by impressions upon these, by the operation of various agents, that every power of the body is awakened and called into action. The muscular and nervous systems appear to be so intimately connected, that some physiologists have imagined that muscular fibre is a mere continuation of the nervous matter. Anatomy instantly refutes this opinion: the nerves enter into the muscles in every possible direction; and we may trace their branches and ramifications perfectly distinct from the muscular fibre. We cannot indeed trace their course to their termination, because they become deprived of their external coats, mere medullary matter remains, and disappears among the muscular fibres. It is perhaps still more clear, that muscular fibre is not a continuation of nerve, because muscles in the limbs of animals do not diminish in magnitude, although the nerves entering these muscles have been cut through for a considerable period. Yet there certainly exists an intimate and universal connection between the muscular fibre and the nerves; because neither the one nor the other can be acted upon by any stimulus, without the whole body being affected in a greater or smaller degree, according to the nature of the part, and the powers of the stimulus applied. We find then that both muscular and nervous fibre are susceptible of impressions from stimuli: but it is also true, that the

effects produced on these two substances in some respects vary. These differences will appear from the short account which we shall here give, beginning with muscular fibre.

Every distinct muscle is formed of a congeries of longitudinal fibres, which are connected together, as we have already hinted, by the cellular substance. They are extended from bone to bone, and from part to part, so as to form an almost universal covering to the bones, and are at the same time the instruments by which all the motions of the bones are performed. Each congeries of muscular fibre appears distinct from the rest, being terminated at its origin and insertion by its proper tendons, which, as we have said, are a modification of the cellular substance. Those muscles which are not inserted into any of the bones, as the sphincters and muscular membranes of the viscera and vessels have commonly no tendons. Those, again, the origin and insertion of which are on different bones, and in the more moveable extremities, are generally supplied with long tendons, which pass round the joints and heads of the bones to be inserted in the more moveable part. But, however distinct the different muscles appear, there is an universal connection, which depends upon the universal distribution of the nerves; one or more of which enter into each muscle, and thus form an indivisible whole.

The muscles are also abundantly supplied with arteries and veins, which enter within the cellular coat that surrounds the muscular fibres, and, running in company with each other, are subdivided, and form a kind of reticular work. From the smaller of these vessels a vapour and sebaceous matter are secreted into the cellular substance, and which are again absorbed by lymphatics, the presence of which is also perfectly obvious, both on the surface and in the substance of the muscles. The ultimate fibres of the muscles appear to be small soft threads: when subjected to the microscope, they exhibit a kind of wave or zigzag appearance. This form has been attributed to the impressions made by the vessels, cellular substance, and nerves, upon the fibre. Dr. Monro has however demonstrated a similar appearance in the tendons and nerves; and he is of opinion, that these undulations are a kind of folds or joints, which serve to accommodate the parts to the different states of flexion and extension. In proof of this, he observes, that these appearances are only present when the parts are in a relaxed state, and that they entirely lose it when much stretched.

Many opinions have been entertained with respect to the structure of the muscular fibre: it has been supposed that they are solid; again it is said that they are hollow, being formed of a series of vessels or rhomboidal chains communicating with each other; and lastly, it has been alleged, that they are full of a kind of down or woolly substance. The fact cannot be determined by the eye or the microscope, and therefore we conceive it not worth while to engage in the dispute. Indeed, as far as we can discover, the muscular fibre, when washed from the blood contained in the vessels which accompany it, appears a white soft solid. These delicate fibres, formed into bundles of different magnitudes, and variously disposed, supplied with blood-vessels and absorbents, joined together, and supported by cellular substance, and united together, so as to form one grand system, by the distribution of nerves, are destined to perform the most important offices in the body. Every motion is produced by their operation. They possess a kind of contractile power, by which they are fitted to propel the blood from the heart, and direct its course through all the numberless channels in which it flows throughout the body. They produce the action of the lymphatics, by which absorption is carried on; by their energy, every secretion and excretion of the system is performed; the important function of respiration depends upon their exertion; and they effect the various motions of the body, which are of so much utility in the different avocations of life. To render them capable of producing these effects, they are in a high degree endowed with that

susceptibility of the action of stimuli, upon which the commencement and continuance of life depends.

The brain, or that mass which fills the cavity of the cranium, is at once the origin and point of union to the whole nervous system. This general mass is divided into three particular portions, the cerebrum, the cerebellum, and the medulla oblongata; and a continuation of the latter forms the medulla spinalis, which fills the cavity of the vertebrae. This organ, and the various branches derived from it, form one of the most important parts of the animal economy. It is essential to all the nobler species of animals; but its importance is more peculiarly evident in man than in any other. In the human race, it bears a much larger proportion to the size of the animal than in any of the inferior orders. The nerves, which form the various organs of sensation, and upon which ultimately the action of muscular fibre depends, are derived from the brain in the inferior animals, as well as in man; but, from the much larger size of this organ in the latter, it appears destined to perform some other and more important purposes in him than in the former. The whole of the nerves, it has been observed, bear but a small proportion to the mass of medullary substance contained in the brain, being at least an hundred times as large as the diameters of all the nerves of the head and spinal marrow. It does not appear that the large size of the brain gives to man more acute sensations, or a greater power to produce muscular motion, than other animals possess in which the brain is proportionally much less. Thus, the brain of a large ox has been found to weigh not more than one fourth part of the human brain, whilst the weight of the ox was probably six times greater than that of the man; or the brain of the man was, in proportion to his weight, twenty-four times heavier than that of the ox. At the same time, the nerves of the muscles of an ox are in their size proportioned to the bulk of the animal's muscles, and those of the organs of sensation, as the eye and nose, are proportioned to the extent of these organs. Thus the olfactory nerve of an ox is many times larger than that of a man. Again we observe, that three fourths of the nerves originate from the medulla spinalis; yet it is only a small part of the brain which is elongated, and passes down the vertebral canal. We have reason therefore to conclude, that to give origin to the nerves is not the sole use of the brain: it is the seat of intellect; the medium by which impressions made on the organs of sensation are conveyed to the mind.

The whole of the nerves, then, arise from one common source; and the brain must be considered as the central point, at which they all unite. Arising from this point they are transmitted to every part of the body, they are interwoven in every organ of sensation, every muscle, vessel, and bone, and thus unite the various parts so as to constitute an uniform system. Possessed of a peculiar organization, by which they are highly susceptible of impressions from various stimuli, they receive impressions on every part, which appear to be instantaneously transmitted to the central point, the sensorium commune. Hence it is, that the action of a stimulant upon a particular part does not affect that part only to which it is applied, but operates on a greater or smaller degree upon the whole system. Minute anatomy evidences, by an infinite variety of circumstances, the peculiar fitness of the brain and nervous system for producing these effects. We have already observed, that the brain is formed of three portions, the cerebrum, cerebellum, and medulla oblongata, to which a fourth may be added, the medulla spinalis. The whole of these are covered by their peculiar membranes, the pia mater and dura mater. These serve for their protection, and to convey blood-vessels for their nourishment and support. The brain is supplied with numerous blood-vessels from the carotid and vertebral arteries; and, by the many convolutions which they make before they pass through the dura mater, and the vast number of communicating branches into which they are divided in the pia mater,

and its processes, it appears, that the blood must move more slowly and equally in those vessels than in those of other parts. We may also add, that the arteries in other parts are in some degree acted upon by the labouring muscles, and the pressure of the atmosphere, by which the blood is propelled with additional force. But the arteries which supply the brain, after they enter the cranium, are not subjected to the operation of these powers. We observe then, in this distribution of the blood-vessels of the brain, a provision made against those injuries which must have infallibly taken place in so delicate an organ, if it had been possible for the blood to have been driven into it with great violence. A very considerable quantity of blood is transmitted to the brain; it is derived from trunks which arise near the heart; and, according to the opinion of Haller, a sixth part, or, as Dr. Monro supposes, not less than a tenth part, of the circulating mass, is transmitted to the brain. From the ample supply of this fluid which the brain receives, it appears that perpetual and important changes take place in the substance of the brain and nerves, as well as in other parts.

The cerebrum, cerebellum, and spinal marrow, are naturally divided into the external part, the cortex or cineritious substance, and the internal part, or medullary matter. The minute branches of the blood-vessels, by the assistance of injections and the microscope, are found to pass from the pia mater into the cortical part in vast numbers; in fact, it appears to be almost wholly formed of vessels; but into the medullary substance we only observe longitudinal vessels entering. The veins which return the blood from the brain are of a peculiar structure, evidently designed to facilitate that return. Their coats are of peculiar strength: they form innumerable anastomoses with one another; and, when collected so as to form considerable trunks, they are lodged in canals, which prevent them from being subjected to compression. A provision therefore is evidently made to prevent an injurious accumulation of the blood in this organ. It has been doubted, whether the brain is supplied with lymphatics? They may certainly be demonstrated upon the pia mater; and from analogy drawn from every other part of the body, we scarcely suppose that the brain is destitute of lymphatics. Indeed modern physiologists in general admit the existence of lymphatics in the brain.

From the blood-vessels, as we have already hinted, the cortical part of the brain receives its origin. Anatomical injections fully prove, that the greater part of it consists of vessels which are inserted from the small branches of the pia mater. These vessels, however, in the natural state, do not convey red blood, but a thinner fluid; although in some diseases, and in death by strangling, particularly in brutes and birds, the red blood is propelled into them. No anatomist has, indeed, succeeded in filling every portion of the cortex with injected matter; yet it is probable, that it is altogether vascular. We observe no dissimilarity of parts in it when in the entire or natural state, so that we cannot imagine that it is partly vascular and partly solid.

As the cortical substances originate from the vessels of the pia mater, so the white medullary matter is derived from the cortex. The continuity of the medulla with the cortex, is distinctly seen by the microscope, and may even be observed by the naked eye. Minute portions of the medulla may be observed proceeding from the cortex; and its gradual increase may be traced, becoming more broad and abundant till it makes up the whole oval section of the brain, and is bounded only by the convolutions of the cortex. The medulla is extremely soft, and of a fibrous texture. The fibres are visible in several parts of the human brain, and still more evidently in the brains of fishes, especially in their thalami optici. The fibres of the medullary substance are simply extended, so as to form the white fibrous cords which are distributed to every part of the body, and which are universally termed the nerves. That the fibres of the nerves are merely a continuation

of those of the medulla, is distinctly seen in the seventh, fourth, and fifth, pairs of nerves.

The nerves, then, are composed of many fibrous threads, lying parallel, or nearly so, to each other, as they shoot off from the medulla. At the origin of most of the nerves within the skull, this fibrous texture is perceptible; and, in the cauda equina of the spinal marrow, they may be divided into threads so exceedingly minute, that they are scarcely visible to the naked eye; yet even these fibres, when examined with a microscope, appear to be formed of a considerable number of fibrils, much more minute. It is perhaps not possible to estimate the size of the smallest of these fibres. Were the nerves, which are divided over the whole body, conjoined into a cord, the diameter would not be an inch; yet even the most minute part of the body is sensible: and this must depend on each particular point being supplied with nerve. We must therefore be convinced, that the nervous fibrils are astonishingly small. Nay, it has been demonstrated, from the extreme minute portions of matter which are visible to the sight, that each fibre in the retina of the eye cannot exceed in diameter the thirty-two thousand four hundredth part of a hair. The medullary matter, of which the nervous fibrils are formed, is exceedingly delicate and soft. They are therefore connected together by cellular substance, and protected from injury by coats formed of the dura and pia mater. These nervous cords are so liberally supplied with blood-vessels, that, when their arteries only are injected, the whole cord appears to be tinged with the colour of the injected liquor.

The nerves, after being given out by the brain or spinal marrow, are generally, like the blood-vessels, divided into branches: but they pass off, or separate, from each other, in acute angles, and often in a retrograde direction. The fibrils of the nerves, however, are not split at these divisions so as to form smaller threads; but the original fibres, continued from the brain itself, recede from each other by an opening of the cellular substance by which they are united: so that, after the nervous fibril has left the brain, it appears, in fact, to undergo no change till its ultimate termination. The nervous cords generally appear to grow softer during their course, till at length, at their termination, they seem to be lost in a mucus or pulp. Hence it has been supposed, that during their progress they deposit the coats which they had received from the pia and dura mater; and that, to be capable of sensation, or the other purposes which the nerve is to effect in the system, it is necessary that the medullary part should be laid perfectly bare at its termination. It is however alleged, that every filament of a nerve retains, at its termination, a covering of the pia mater, by the vessels of which it is nourished and preserved in that state, upon which the faculty of receiving impressions, and the power of action, depend.

In some instances we observe different nerves uniting so as to form one cord; this, in some measure, resembles the anastomoses which take place in the sanguiferous system. After such an union, we frequently find, particularly in those which are distributed to the bowels, a hard knot is formed, considerably larger than the nerves which are thus united into a cord. These knots are generally termed ganglions: they have thicker coats, and are more liberally supplied with blood-vessels, than the nerves. Dr. Monro observes, that they are full of nervous fibrilli, intermixed with a yellowish or reddish brown substance, somewhat similar to the cortical substance of the brain. Hence he supposes, that they are sources of nervous matter or energy.

Derived from this origin, (the brain,) we find forty pairs of nerves distributed through the body, viz. ten which immediately proceed from the encephalon, and thirty which pass off from the medulla spinalis. Of these we find four proceeding immediately from the brain, which are destined to receive various impressions from external objects, by which the sensations of sight, hearing, smell, and taste, are produced. The rest are distributed to the various muscles, and extended on the surface of the body,

affecting the motion of the muscular solid, and producing, in every part of the system, by impressions from different substances, that sensation which we call feeling. To whatever purpose the nerve is applied, whether to receive sensation, or to excite motion, we do not perceive any difference in its structure; it is in every instance formed of the same soft medullary fibre. We perceive, indeed, that the optic nerve, at its termination, is extended into a delicate web, which covers the surface of the eye. The portio mollis, also, of the auditory nerve, is extended in a very soft pulpy form on the inner camera of the ear; but, excepting these two, we observe no variations in the external appearance of the nerves at their terminations: nor do we discover, even in these, any peculiarities of structure, by which we can be able to assign a reason why the one should receive the rays of light, reflected from surrounding bodies, by which the sensation of sight is produced; or why the other should be affected by percussions of the air, so as to communicate the different sensations of sound. We observe, indeed, that several of the nerves which are designed to communicate particular sensations to the mind, are furnished with peculiar apparatus. Such we observe in the wonderful structure of the eye; and in the striking contrivance exhibited in the vestibule, cochlea, and semicircular canals of the ear. That these apparatus are essentially requisite to enable the nervous matter to receive particular sensations, cannot be doubted; but it must remain as a question which probably will never be determined, whether the medullary matter itself does not undergo some modification, by which it is fitted respectively to receive impressions from light, sound, odorous or sapid substances: to distinguish the nature of other substances by what we call feeling; or to excite the muscular action. Whatever may be in this, we are certain, that sensation altogether, and muscular motion in a great measure, are produced by the operation of various agents upon the nervous system. If a nerve is irritated, acute pain is induced; and, in proportion to the number of nerves with which any part of the body is supplied, it is possessed of a greater or smaller sensibility. Thus, in the eye and the penis, which are plentifully supplied with nerves, the feeling is extremely acute; and the tendons, ligaments, bones, and cartilages, into which few nerves enter, have in the sound state little or no sensation. But if, on the other hand, the communication between the sentient extremities of the nerves and the sensorium commune is obstructed, as by the division of the nerve, the sensation of the part beyond the division is entirely destroyed.

Having thus taken a cursory view of the outline of anatomy, with the physiology appertaining thereto, we shall now proceed to the dissection of the human subject; noting by the way the most recent and important discoveries, calculated to improve the knowledge and success of medical practice.

Of the BONES, or HUMAN SKELETON.

However solid and compact adult bones are, yet they were once cartilages, membranes, nay, a mere jelly. This needs no farther proof than repeated observations of embryos when dissected: and how much more tender must the bones be before that time, when neither knife nor eye is capable to discover the least rudiments of them? By degrees they become more solid, then assume the nature of gristles, and at last ossify; the cohesion of their plates and fibres always increasing in proportion to their increased solidities; as is evident from the time necessary to unravel the texture of bones of people of different ages, or of dense and of spongy bones, or of the different parts of the same bone, and from the more tedious exfoliations of the bones of adults than of children. As the solidity of bones increases, their periosteum more easily separates from them. When bones are membranous, the periosteum cannot be distinguished; they appear to be the same substance. When they are cartilages, their membrane adheres so firmly to them, that it is difficult to separate it from them. Where the

the bony fibres are rigid, the periosteum is easily taken off.

The ossification of bones depends principally on their vessels being so disposed, and of such diameters, as to separate a liquor, which may easily turn into a bony substance, when it is deprived of its thinner parts; as seems plain from the observation of the callous matter separated after fractures and ulcers, where part of the bone is taken out: for, in these cases, the vessels extending themselves, and the liquors added to them, are gradually formed into granulated flesh, which fills up all the space where the bone is taken from, then hardens till it becomes as firm as any other part of the bone. This happens frequently, even when the ends of the diseased bone are at a considerable distance from each other.

The induration of bones is also greatly assisted by their being exposed more than any other parts to the strong pressure of the great weights they support, to the violent contraction of the muscles fixed to them, and to the force of the parts they contain, which endeavour to make way for their own further growth. By all this pressing force, the solid fibres and vessels of bones are thrust closer, and such particles of the fluids conveyed in these vessels as are fit to be united to the fibres are sooner and more firmly incorporated with them, while the remaining fluids are forcibly driven out by the veins, to be mixed with the mafs of blood. In consequence of this, the vessels gradually diminish as the bones harden. From which again we can understand one reason why the bones of young animals sooner re-unite after a fracture than those of old, and why cattle that are too soon put to hard labour, seldom are of such large size as others of the same brood who are longer kept from labour.

That the ossifying of bones greatly depends on pressure, seems to be evinced from the frequent examples we meet with of other parts turning bony, when long exposed to the pressing force of the surrounding parts, or when they are subjected to the like circumstances by their own frequent and violent contraction. Witness the bones found frequently near the base of the heart in some old men, and in several other creatures. Nay, the muscular substance of the heart has been ossified in such, and the arteries of old men often become bony. The cartilages of the larynx are generally ossified in adults. In beasts of burden, the cartilages between the vertebræ of the back very often change into complete bones; and, being intimately united with the vertebræ, the whole appears one continued bone: nor is the periosteum exempted from such an induration.

From the effects of pressure only it is that we can account for the bones of old people having their sides much thinner, yet more dense and solid, while the cavities are much larger than in those of young people; and for the prints of muscles, vessels, &c. being so much more strongly marked on the surfaces of the former than of the latter, if they belong to people of near the same condition in life. Pressure must likewise be the cause which, in people of equal ages, make these prints stronger in the bones of those who had much labour and exercise, than they are in people who have led an indolent and inactive life.

Perhaps the causes of ossification may be assisted by the nature of the climate people live in, and the food they use. Whence, in hot countries, the inhabitants sooner come to their height of stature than in the northerly cold regions: and thence seems to have arisen the common practice among the ladies, of making puppies drink brandy or spirit of wine, and of bathing them in these liquors, to prevent their growing big. Nay, it has been observed, that much use of such spirits has occasioned parts, naturally soft, to petrify in some, and to ossify in other people of no great age.

To express the connection of bones, anatomists have contrived a great number of technical terms; about the meaning, propriety, and classing, of which, there has unluckily been variety of opinions. Some of these terms it is necessary to retain, since they serve to express the various circumstances of the articulations, and to understand the

writers on this subject. The articulations are most commonly divided into three classes, viz. Symphysis, Synarthrosis, and Diarthrosis.

First, *Symphysis*, which properly signifies the conception or growing together of parts, when used to express the articulations of bones, does not seem to comprehend, under the meaning generally given to it, any thing relating to the form or motion of the conjoined bones; but by it most authors only denote the bones to be connected by some other substance; and as there are different substances which serve this purpose, therefore they divide it into the three following species. 1. *Synchondrosis*, when a cartilage is the connecting substance: thus the ribs are joined to the sternum; thus the bodies of the vertebræ are connected to each other; as are likewise the ossa pubis. 2. *Synneurosis*, or *syndesmosis*, when ligaments are the connecting bodies, as they are in all the moveable articulations. 3. *Syffarcosis*, when muscles are stretched from one bone to another, as they must be where there are moveable joints.

The second class of articulations, the *synarthrosis*, which is said to be the general term by which the immoveable conjunction of bones is expressed, is divided into three kinds. 1. The *suture* is that articulation where two bones are mutually indented into each other, or as if they were sewed together; and is formed by the fibres of two bones meeting while they are yet flexible and yielding, and have not come to their full extent of growth; so that they mutually force themselves into the interstices of each other, till, meeting with such resistance as they are not able to overcome, they are stopped from sprouting out farther, or are reflected; and therefore these indentations are very different both in figure and magnitude: thus the bones of the head are joined; thus epiphyses are joined to the bones, before their full connection and union with them. Under this title of *suture*, the *harmonia* of the ancients may be comprehended; scarcely any unmoved bones being joined by plain surfaces. 2. *Gomphosis* is the fixing one bone into another, as a nail is fixed in a board: thus the teeth are secured in their sockets. 3. *Schindylesis* or *ploughing*, when a thin lamella of one bone is received into a long narrow furrow of another: thus the processus azygos of the sphenoid, and the nasal process of the ethmoid, bone, are received by the vomer.

The third class, or *diarthrosis*, is the articulation where the bones are so loosely connected as to allow large motion. This is subdivided into three kinds. 1. *Enarthrosis*, or the ball and socket, when a large head is received into a deep cavity; as the head of the os femoris is into the acetabulum coxendicis. 2. *Arthrodia*, when a round head is received into a superficial cavity; as in the articulation of the arm bone and scapula. These two species of diarthrosis allow motion to all sides. 3. *Ginglimus*, which properly signifies the hinge of a door or window; in it the parts of the bones mutually receive and are received, and allow of motion two ways: workmen call it *charnal*.

The ginglimus is generally divided into three kinds; to which some give the name of *contiguous*, *distant*, and *compound*. The first kind of ginglimus is when a bone has several protuberances and cavities, which answer to as many cavities and processes of the other bone with which it is articulated; as in the conjunction of the femur with the tibia. The second species is, when a bone receives another at one end, and is received by the same bone at the other end; as in the radius and ulna. The last sort is, when a bone receives another, and is received by a third; as in the oblique processes of the vertebræ.

With regard to the different opinions concerning the use of these technical names, it has been said, that symphysis should be the name for the immoveable articulations, and synarthrosis should be understood to be the conjunction of bones by some connecting medium. Those who have taken symphysis in the sense of its expressing the conjunction of bones with a connecting substance, have disagreed in their definition of it; some inserting, and others leaving out, its allowing motion. When they have agreed in their

definition, they have not been of the same mind concerning the species of it: for several think the *syllarcosis* and *syndesmosis* applicable to so many joints which are universally allowed to be classed under the *diarthrosis*, that it must create confusion to name them by any species of the *symphysis*. Few keep to such a general definition of the *synchondrosis*; and whether they determine it to allow no motion, or an obscure or a manifest one, they bring themselves into difficulties, because there are examples of all these three kinds. Some again, by too nicely distinguishing obscure and manifest motions of bones, have blended the *synarthrosis* and *diarthrosis*; and from thence have branched out the different compound species of articulations that may be formed of them, so far, that they could find no examples in the body to illustrate them by. It would be tedious to enumerate the jarring opinions, and useless to give a detail of the arguments adopted by the disputants on this occasion.

Before we proceed to the division and particular description of the skeleton, it is to be observed, that, when the bones are put into their natural situation, scarcely any one of them is placed in a perpendicular bearing to another; though the fabric composed of them is so contrived, that, in an erect posture, a perpendicular line, for their common centre of gravity, falls in the middle of their common base. On this account, we can support ourselves as firm as if the axis of all the bones had been a straight line perpendicular to the horizon; and we have much greater quickness, ease, and strength, in several of the most necessary motions we perform. It is true, indeed, that wherever the bones, on which any part of our body is sustained, decline from a straight line, the force required in the muscles to counteract the gravity of that part is greater than was otherwise necessary: but then this is effectually provided for in such places, by the number and strength of the muscles. So long, therefore, as we remain in the same posture, a considerable number of muscles must be in a constant state of contraction; which we know, both from reason and experience, must soon create an uneasy sensation. This we call *being weary of one posture*: an inconvenience that we should not have had in standing erect, if the bearing of all the bones to each other had been perpendicular; but it is more than compensated by the advantages above-mentioned. The human skeleton is generally divided into the *Head*, the *Trunk*, the *Superior*, and the *Inferior*, *Extremities*.

BONES of the HEAD.

By the *head* is meant all that spheroidal part which is placed above the first bone of the neck. It therefore comprehends the cranium and bones of the face.

The *cranium*, *helmet*, or *brain-case*, consists of several pieces, which form a vaulted cavity, for lodging and defending the brain and cerebellum, with their membranes, vessels, and nerves. The cavity of the cranium is proportioned to its contents. Hence such a variety of its size is observed in different subjects; and hence it is neither so broad nor so deep at its fore-part, in which the anterior lobes of the brain are lodged, as it is behind, where the large posterior lobes of the brain, and the whole cerebellum, are contained. The roundish figure of the skull, which makes it more capacious, and better able to defend its contents from external injuries, is chiefly owing to the equal pressure of these contained parts as they grow and increase before it is entirely ossified. It is to be observed, however, that the sides of the cranium are depressed below a spherical surface by the strong temporal muscles, whose action hinders here the uniform protrusion of the bones, which is more equally performed in other parts where no such large muscles are. In children whose muscles have not acted much, and consequently have not had great effects on the bones, this depression is not so remarkable; and therefore their heads are much rounder than in adults. These natural causes, differently disposed in different people, produce a great variety in the shapes of skulls, which

is still increased by the different management of the heads of children when very young: so that one may know a Turk's skull by its globular figure, a German's by its breadth and the flatness of the occiput, Dutch and English by their oblong shapes, &c. Two advantages are reaped from this flatness of the sides of the cranium, viz. the enlargement of our sphere of vision, and more advantageous situation of our ears for receiving a greater quantity of sound, and for being less exposed to injuries.

The external surface of the upper part of the cranium is very smooth and equal, being only covered with the *periosteum* (common to all the bones, but in the skull distinguished by the name of *pericranium*,) the thin frontal and occipital muscles, their tendinous aponeurosis, and with the common teguments of the body; while the external surface of its lower part has its numerous risings, depressions, and holes, which afford convenient origin and insertion to the muscles that are connected to it, and allow safe passage for the vessels and nerves that run through and near it.

The bones of the cranium are composed of two tables, and intermediate cancelli, commonly called their *diploë*. The external table is thickest; the inner, from its thinness and consequent brittleness, has got the name of *vitrea*. Whence we may see the reason of those mischievous consequences which so often attend a collection of matter in the *diploë*, either from an internal or external cause, before any sign of such a collection appears in the teguments which cover that part of the skull where it is lodged.

The cranium consists of eight bones, six of which are said to be proper, and the other two are reckoned common to it and to the face. The six proper are the *os frontis*, two *os parietalia*, two *os temporum*, and the *os occipitis*. The common are the *os ethmoides* and *sphenoides*. The *os frontis* forms the whole fore-part of the vault; the two *os parietalia* form the upper and middle part of it; the *os temporum* compose the lower part of the sides; the *os occipitis* makes the whole hinder part, and some of the base; the *os ethmoides* is placed in the fore-part of the base, and the *os sphenoides* in the middle of it.

These bones are joined to each other by five *sutures*; the names of which are the *coronal*, *lambdoidal*, *sagittal*, and two *squamous*. The coronal suture is extended over the head, from within about an inch of the external canthus of one eye, to the like distance from the other; which being near the place where the ancients wore their *vittæ*, coronæ, or garlands, has thence got its name.

The lambdoidal suture begins farther back than the vertex or crown of the head, whence its two legs are stretched obliquely downwards, and are now generally said to extend themselves to the base of the skull: but formerly anatomists reckoned the proper lambdoidal suture to terminate at the squamous sutures; and what is extended at an angle down from that on each side, where the indentations are less conspicuous than in the upper part of the suture, they called *aditamentum suturæ lambdoidis*. This suture is sometimes very irregular, being made up of a great many small sutures, which surround so many little bones that are generally larger and more conspicuous on the external surface of the skull than internally. These bones are commonly called *triquetra* or *Wormiana*: but some other name ought to be given them, for they are not always of a triangular figure, and older anatomists than Wormius have described them.

The *sagittal* suture is placed longitudinally in the middle of the upper part of the skull, and commonly terminates at the middle of the coronal and of the lambdoidal sutures; between which it is said to be placed, as an arrow is between the string and the bow. However, this suture is frequently continued through the middle of the *os frontis* down to the root of the nose; which, some say, happens oftener in women than in men.

The *squamous agglutinations*, or *false sutures*, are one on each side, a little above the ear, of a semicircular figure, formed by the over-lapping (like one scale upon another) of

of the upper part of the temporal bones on the lower part of the parietal, where, in both bones, there are a great many small ridings and furrows, which are indented into each other; though these inequalities do not appear till the bones are separated. In some skulls, indeed, the indentations here are as conspicuous externally as in other futures; and what is commonly called the posterior part of this squamous future always has the evident serrated form, and therefore is reckoned by some a distinct future, under the name of *additamentum posterius futuræ squamosæ*.

The bones of the skull are joined to those of the face, by schindylefis and futures. The schindylefis is in the partition of the nose. The futures said to be common to the cranium and face are five, viz. the ethmoidal, sphenoidal, transverse, and two zygomatic. The *ethmoidal* and *sphenoidal* futures surround the bones of these names; and in some places help to make up other futures, particularly the *squamous* and *transverse*; and in other parts there is but one future common to these two bones. The *transverse* future is extended quite across the face, from the external canthus of one orbit to the same place of the other, by sinking from the canthus down the outside of the orbit to its bottom; then, mounting upon its inside, it is continued by the root of the nose down to the internal part of the other orbit, and rises up again on its outside to the other canthus. The *zygomatic* futures are one on each side, being short and slanting from above obliquely downwards and backwards, to join a process of the cheek bone to one of the temporal bones, which advance towards the face; so that the two processes thus united, form a sort of bridge or jugum, under which the temporal muscle passes; on which account the processes, and future joining them, have been called *zygomatic*.

It is alleged, that through the futures there is a transpiration of steams from the brain, which was the old doctrine; or some communication of the vessels without and of those within the skull, larger here than in any other part of the cranium, according to some moderns; and therefore cucuphæ, fomentations, cataplasms, cephalic plasters, blisters, are applied, and issues are eroded or cut in the head, at those places where the futures are longest in forming, and where the connection of the bones is afterwards loosest, for the cure of a phrenitis, mania, inveterate head-ach, epilepsy, apoplexy, and other diseases of the head. The favourers of the doctrine of transpiration, or communication of vessels at the futures, endeavour to support it by observations of persons subject to head-achs which caused death, from the futures being too closely united.

The *os frontis* has its name from its being the only bone of that part of the face we call the *forehead*, though it reaches a good deal farther. It has some resemblance in shape to the shell of the concha bivalvis, commonly called the *cockle*: for the greatest part of it is convex externally, and concave internally, with a serrated circular edge; while the smaller part has processes, and depressions, which make it of an irregular figure. Between the internal and external angular processes on each side, an arched ridge is extended, on which the eye-brows are placed. Very little above the internal end of each of these superciliary ridges a protuberance may be remarked, where there are large cavities, called *sinuses*. Between the internal angular processes a small process rises, which forms a part of the nose, and thence is named *nasal*. Some observe a protuberant part on the edge of the bone which they call *temporal* processes; but these are inconsiderable. From the under part of the superciliary ridges, the frontal bone runs a great way backwards: these parts may justly enough be called *orbital* processes, which, contrary to the rest of this bone, are concave externally, for receiving the globes of the eyes, with their nuses, fat, &c. In each of the orbital processes, behind the middle of the superciliary ridges, a considerable sinusity is observed, where the glandula innominata Galeni, or lacrymalis, is lodged. Behind each internal angular process, a small pit may be remarked, where the cartilaginous pully of the musculus

obliquus major of the eye is fixed. Between the two orbital processes, there is a large discontinnuation of the bone, in which the cribriform part of the *os ethmoides* is incased.

The *foramina*, or holes, observable on the external surface of the frontal bone, are three in each side. One in each superciliary ridge, a little removed from its middle towards the nose; through which a twig of the ophthalmic branch of the fifth pair of nerves passes out of the orbit, with a small artery from the internal carotid, to be distributed to the teguments and muscles of the forehead. These vessels, in some skulls, make furrows in the *os frontis*, especially in the bones of children, as has also been observed of another considerable vessel of this bone near its middle; and therefore we ought to beware of transverse incisions on either side of the *os frontis*, which might either open these vessels, or hurt the nerves, while they are yet in part within the bone: for, when vessels are thus wounded, it is difficult to stop the hæmorrhage, because the adhesion of a part of the artery to the bone hinders its contraction, and consequently styptics can have little effect; the sides of the furrow keep off compressing substances from the artery; and we would wish to shun cauteries or escharotics, because they make the bone carious; and nerves, when thus hurt, sometimes produce violent symptoms. Near the middle of the inside of each orbit, hard-by or in the transverse future, there is a small hole for the passage of the nasal twig of the first branch of the fifth pair of nerves, and of a branch of the ophthalmic artery. This hole is sometimes entirely formed in the *os frontis*; in other skulls, the sides of it are composed of this last bone and of the *os planum*. It is commonly known by the name of *orbitalium internum*, through *anterior* should be added, because of the next, which is commonly omitted. This, which may be called *orbitalium internus posterius*, is such another as the former; only smaller, and about an inch deeper in the orbit. Through it a small branch of the ocular artery passes to the nose.

The internal surface of the *os frontis* is concave, except at the orbital processes, which are convex, to support the anterior lobes of the brain. This surface is not so smooth as the external; for the larger branches of the arteries of the dura mater make some furrows in its sides and back parts. The sinusities from the luxuriant risings of the brain are often very observable on its upper part; and its lower and fore parts are marked with the contortions of the anterior lobes of the brain. Through the middle of this internal surface, where always in children, and sometimes in old people, the bone is divided, either a ridge stands out, to which the upper edge of the falx is fastened, or a furrow runs, in which the upper side of the superior longitudinal sinus is lodged; on both these accounts, chirurgical authors justly forbid the application of the trepan here.

The *os frontis* is composed of two tables, and an intermediate diploë, as the other bones of the cranium are. It is of a mean thickness between the *os occipitis* and the parietal bones; and is nearly equally dense throughout, except at the orbital processes, where, by the action of the eye on one side, and pressure of the lobes of the brain on the other, it is made extremely thin and diaphanous, and the medullium is entirely obliterated. In this place there is so weak a defence for the brain, that fences esteem a push in the eye mortal. The diploë is also exhausted in that part above the eye-brows, where the two tables of the bone separate, by the external being protruded outwards, to form two large cavities, called *sinus frontales*. These are divided by a middle perpendicular bony partition. Their capacity in the same subject is seldom equal; in some the right, in others the left, is largest. In some skulls, besides the large perpendicular *septum*, several bony pillars, or short partitions, are found in each sinus: in others these are wanting. For the most part the septum is entire; at other times it is discontinued, and the two *sinuses* communicate. When the sinuses are seen in such skulls as have the frontal bone divided by the sagittal future,

ture, the partition dividing these cavities is evidently composed of two plates, which easily separate. Each sinus commonly opens by a roundish small hole, at the inner and lower part of the internal angular processes, into a sinus formed in the nose, at the upper and back part of the os unguis; near to which there are also some other small sinuses of this bone, the greater part of which open separately near the septum narium, and often terminate in the same common canal with the large ones.

In a natural and sound state, these cavities are of considerable advantage: for, the organ of smelling being thus enlarged, the effluvia of odorous bodies more difficultly escape it; and their impressions, being more numerous, are therefore stronger, and affect the organ more. That odorous particles may be applied to the membrane of the sinuses, is evident from the pain felt in this part of the forehead, when the effluvia of volative spirits, or of strong aromatics, are drawn up into the nose by a quick inspiration. These, and the other cavities which open into the nose, increase the sound of our voice, and render it more melodious, by serving as so many vaults to rebound the notes. Hence people labouring under a coryza, or stoppage of the nose from any other cause, when they are by the vulgar, though falsely, said to speak through the nose, have such a disagreeable voice. The liquor separated in the membrane of these sinuses runs down upon the membrane of the nose to keep it moist.

The upper circular part of the os frontis is joined to the ossa parietalia, from one temple to the other, by the coronal suture. From the termination of the coronal suture to the external angular processes, this bone is connected to the sphenoid by the sphenoidal suture. At the external canthi of the eyes, its angular processes are joined by the transverse suture to the ossa malarum, to which it adheres one-third down the outside of the orbits; whence to the bottom of these cavities, and a little upon their internal sides, these orbital processes are connected to the sphenoidal bone by that same suture.

The frontal bone serves to defend and support the anterior lobes of the brain. It forms a considerable part of the cavities that contain the globes of the eyes, helps to make up the septum narium, organ of smelling, &c. In a ripe child, the frontal bone is divided through the middle; the superciliary holes are not formed; often a small round piece of each orbital process, behind the superciliary ridge, is not ossified; and there is no sinus to be seen within its substance.

Each of the two *ossa parietalia*, or bones serving as walls to the encephalon, is an irregular square; its upper and fore sides being longer than the one behind or below. The inferior side is a concave arch; the middle part receiving the upper round part of the temporal bone. The external surface of each os parietale is convex. Upon it, somewhat below the middle height of the bone, there is a transverse arched ridge, generally of a whiter colour than any other part of the bone; from which, in bones that have strong prints of muscles, we see a great many converging furrows, like so many radii drawn from a circumference towards a centre. From this ridge of each bone the temporal muscle rises: and, by the pressure of its fibres, occasions the furrows just now mentioned. Below these we observe, near the semicircular edges, a great many risings and depressions, which are joined to like inequalities on the inside of the temporal bone, and form the squamous suture. The temporal bone may therefore serve here as a buttress, to prevent the lower side of the parietal from starting outwards when its upper part is pressed or struck. Near the upper sides of these bones is a small hole in each, through which a vein passes from the teguments of the head to the longitudinal sinus. In some skulls, one of the ossa parietalia has not this hole. In others, there are perhaps two in one bone; and, in some, not one in either. Most frequently this hole is through both tables; at other times the external hole only is perforated. The knowledge of the course of these vessels may be of use to sur-

geons when they make any incision near this part of the head; left, if the vessels are rashly cut near the hole, they shrink within the substance of the bone, and cause an obstinate hæmorrhage, which neither ligatures nor medicines can stop.

The ossa parietalia are the most equal and smooth, and are among the thinnest bones of the cranium; but they enjoy the general structures of two tables and dispoſe the completeſt. These bones are joined at their fore-side to the os frontis by the coronal suture; at their long inferior angles, to the sphenoid bone, by part of the suture of this name; at their lower edge, to the ossa temporum, by the squamous suture, and its posterior additamentum; behind, to the os occipitis, or ossa triquera, by the lambdoid suture; and above, to one another, by the sagittal suture.

The large unossified ligamentous part of the cranium, observable between the parietal bones and the middle of the divided os frontis of new-born children, called by the vulgar the *open of the head*, was imagined by the ancients to serve for the evacuation of the superfluous moisture of the brain: and therefore they named it *bregma*, or the fountain; sometimes adding the epithet *pulsatilis*, or beating, on account of the pulsation of the brain felt through this flexible ligamento-cartilaginous substance. Hence the parietal bones are very frequently called *ossa bregmatis*.

Ossa temporum, so named from the hair's first becoming grey on the temples, and thus discovering people's ages, are each of them equal and smooth above, with a very thin semicircular edge; which, from the manner of its connection with the neighbouring bones, is distinguished by the name of *os squamosum*. Behind this, the upper part of the temporal bone is thicker, and more unequal; and is sometimes described as a distinct part, under the name of *pars mamillaris*. Towards the base of the skull, the temporal bone appears very irregular and unequal; and this part, instead of being broad, and placed perpendicularly, as the others are, is contracted into an oblong very hard substance, extended horizontally forwards and inwards, which in its progress becomes smaller, and is commonly called *os petrosum*.

Three external processes of each temporal bone are generally described. The first, placed at the lower and hind part of the bone, from its resemblance to a nipple, is called *mastoides* or *mamillaris*. It is not solid; but is composed of cancelli, or small cells, which have a communication with the large cavity of the ear, the drum; and therefore sounds, being multiplied in this vaulted labyrinth, are increased before they are applied to the immediate organ of hearing. Into the mastoid process the sterno-mastoid muscle is inserted: and to its back part, where the surface is rough, the trachelo-mastoides and part of the splenius are fixed. About an inch farther forward, the second process begins to rise out of the bone; and, having its origin continued obliquely downwards and forwards for some way, it becomes smaller, and is stretched forwards to join with the os malæ; they together forming the bony jugum, under which the temporal muscle passes. Hence this process has been named *zygomatic*. Its upper edge has the strong aponeurosis of the temporal muscle fixed into it; and its lower part gives rise to a share of the masseter. From under the craggy part of the os temporum, the third process stands out obliquely forwards. The shape of it is generally said to resemble the ancient *stylus scriptorius*; and therefore it is called the *styloid process*. Some authors however contend, that it ought to be named *stelioid*, from its being more like a pillar. Several muscles have their origin from this process, and borrow one half of their name from it; as *stylo-glossus*, *stylo-hyoides*, *stylo-pharyngeus*. This process is often, even in adults, not entirely ossified, but is ligamentous at its root, and is sometimes composed of two or three distinct pieces. Round the root of it, especially at the fore-part, there is a rising of the os petrosum, which some authors have esteemed a process: and, from the appearance it makes with the styliform, have named it *vaginalis*. Others again have, under the name of

auditory process, reckoned among the external processes, that semicircular ridge, which, running between the root of the mastoid and zygomatic processes, forms the under part of the external *meatus auditorius*.

The *sinuosities* or depressions on the external surface of each temporal bone are these: A long fossa at the inner and back part of the root of the mammary process, where the posterior head of the digastric muscle has its origin. Immediately before the root of the zygomatic process, a considerable hollow is left for lodging the crotaphite muscle. Between the zygomatic, auditory, and vaginal processes, a large cavity is formed; thro' the middle of which, from top to bottom, a fissure is observable, into which part of the ligament that secures the articulation of the lower jaw with this bone is fixed. The fore-part of the cavity being lined with the same cartilage which covers the tubercle before it, receives the condyle of the jaw; and in the back-part a small share of the parotid gland, and a cellular fatty substance, are lodged. At the inside of the root of the styloid apophyse, there is a thimble-like cavity, where the beginning of the internal jugular vein, or end of the lateral sinus, is lodged. Round the external *meatus auditorius*, several *sinuosities* are formed for receiving the cartilages and ligaments of the ear, and for their firm adhesion.

The *holes* that commonly appear on the outside of each of these bones, and are proper to each of them, are five. The first, situated between the zygomatic and mastoid processes, is the orifice of a large funnel-like canal, which leads to the organ of hearing; and is therefore called *meatus auditorius externus*. The second gives passage to the portio dura of the seventh pair of nerves; and from its situation between the mastoid and styloid processes, is called *foramen stylo-mastoideum*. Some way before, and to the inside of the styloid process, is the third hole: the canal from which runs first upwards, then forwards, and receives into it the internal carotid artery, and the beginning of the intercostal nerve; where this canal is about to make the turn forwards, one, or sometimes two, very small holes go off towards the cavity of the ear, called *tympanum*. Thro' these Valsalva affirms the proper arteries of that cavity are sent. On the anterior edge of this bone, near the former, a fourth hole is observable, being the orifice of a canal which runs outwards and backwards, in a horizontal direction, till it terminates in the tympanum. The whole canal is named *iter a palato ad aurem*, or *Eustachian tube*. On the external side of the bony part of this canal, and on the top of the chink, in the cavity that receives the condyle of the lower jaw, is the course of the little nerve, called *chorda tympani*, and commonly said to be reflected from the lingual branch of the fifth pair, till it enters the tympanum, to run across this cavity. The fifth hole is very uncertain, appearing sometimes behind the mastoid process; sometimes it is common to the temporal and occipital bones; and in several skulls there is no such hole.

The internal surface of the ossa temporum is unequal; the upper circular edge of the squamous part having numerous small ridges and furrows for its conjunction with the parietal bones; and the rest of it is irregularly marked with the convolutions of the middle part of the brain, and with furrows made by the branches of the arteries of the dura mater. From the under part of this internal surface, a larger transverse hard craggy protuberance runs horizontally inwards and forwards, with a sharp edge above, and two flat sides, one facing obliquely forwards and outwards, and the other as much backwards and inwards. To the ridge between these two sides, the large lateral process of the dura mater is fixed.

The internal proper *foramina* of each of these bones are, first, the internal *meatus auditorius* in the posterior plain side of the petrous process. This hole soon divides into two; one of which is the beginning of the aqueduct of Fallopius; the other ends in several very small canals that allow a passage to the branches of the portio mollis of the seventh pair of nerves, into the vestibule and cochlea.

Through it also an artery is sent, to be distributed to the organ of hearing. The second hole, which is on the anterior plain side of the craggy process, gives passage to a reflected branch of the second branch of the fifth pair of nerves, which joins the portio dura of the auditory nerve, while it is in the aqueduct, small branches of blood-vessels accompanying the nerves, or passing through smaller holes near it. The passage of the cutaneous vein into the lateral sinus, or of a branch of the occipital artery, is seen about the middle of the large fossa for that sinus; and the orifice of the canal of the carotid artery is evident at the under part of the point of the petrous process. The upper round part of the squamous bones is thin, but equal; while the low petrous part is thick and strong, but irregular and unequal, having the distinction of tables and diploë confounded, with several cavities, processes, and bones, within its substance, which are parts of the organ of hearing.

The temporal bones are joined above to the parietal bones by the squamous sutures and their posterior additamenta. Before, to the sphenoid bone, by the suture of that name; to the cheek bones, by the zygomatic sutures; and to the occipital bone, by the lambdoid suture and its additaments.

Os occipitis, so called from its situation, is convex on the outside, and concave internally. Its figure is an irregular square, or rather rhomboid; the lower angle of which is stretched forward in the form of a wedge, and thence is called the *cuneiform* process. The external surface is convex, except at the cuneiform apophyse, where it is flattened. At the base of this triangular process, on each side of the great hole, the large oblong protuberances, named the *condyles*, appear, to serve for the articulation of this bone with the first vertebra of the neck. Though the motion of the head is performed on the condyles, yet the centre of gravity of that globe does not fall between them, but is a good way farther forward; from which mechanism it is evident, that the muscles which pull the head back must be in a constant state of contraction; which is stronger than the natural contraction of the proper flexors, else the head would always fall forwards, as it does when a man is asleep, or labours under a palsy, as well as in infants, where the weight of the head far exceeds the proportional strength of these muscles. This seeming disadvantageous situation of the condyles is, however, of singular use, by allowing sufficient space for the cavities of the mouth and fauces, and for lodging a sufficient number of muscles, which commonly serve for other uses; but may at pleasure be directed to act on the head, and then they have an advantageous lever to act with, so as to be able to sustain a considerable weight, or other force applied to pull the head back.

Somewhat more externally than the condyles, there is a small rising and semilunated hollow in each side, which make part of the holes common to the occipital and petrous bones. Immediately behind this, on each side, a scabrous ridge is extended from the middle of the condyle towards the root of the mastoid process. Into this ridge the *musculus lateralis*, commonly ascribed to Fallopius, is inserted. About the middle of the external convex surface, a large arch runs across the bone; from the upper lateral parts of which the occipital muscles have their rise; to its middle the trapezii are attached; and half-way between this and the great hole, a lesser arch is extended. In the hollows between the middle of these arches the complexi are inserted; and, in the depressions more external and farther forward than these, the *splenii* are inserted.

On the inner surface of the *os occipitis* we see two ridges; one standing perpendicularly, the other running horizontally across the first. The upper part of the perpendicular limb, to which the falx is fixed, is hollowed in the middle, or often on one side, for the reception of the superior longitudinal sinus; and the lower part of it has the small or third process of the dura mater fastened to it, and is sometimes hollowed by the occipital sinus. Each side of

the horizontal limb is made hollow by the lateral sinuses inclosed in the transverse process of the dura mater; the fossa in the right side being generally a continuation of the one made by the longitudinal sinus in the perpendicular limb, and therefore is larger than the left one. The inner surface of the cuneiform apophyse is made concave for the reception of the medulla oblongata, and of the basilar artery. A furrow is made on each side, near the edges of this process, by a sinus of the dura mater, which empties itself into the lateral sinus.

The holes of this bone are commonly five proper, and two common. The first of the proper holes, called *foramen magnum* from its size, is immediately behind the wedge-like process; and allows a passage to the medulla oblongata, nervi accessorii, to the vertebral arteries, and sometimes to the vertebral veins. At each side of this great hole, near its fore part, and immediately above the condyles, we always find a hole, sometimes two, which soon unite again into one, that opens externally; through these the ninth pair of nerves go out of the skull. The fourth and fifth holes pierce from behind the condyle of each side into the fossae of the lateral sinuses; they serve for the passage of the cervical veins to these sinuses. Often one of these holes is wanting, sometimes both, when the veins pass through the great foramen. The two common foramina are the large irregular holes, one in each side, between the sides of the cuneiform process and the edges of the petrous bones.

The occipital bone is among the thickest of the cranium, though unequally so; for it is stronger above, where it has no other defence than the common teguments, than it is below; for, being there pressed by the lobes of the brain and cerebellum on one side, and by the action of the muscles on the other, it is so very thin as to be diaphanous in many skulls: but then these muscles ward off injuries; and the ridges and spines, which are frequent here, make it sufficiently strong to resist ordinary forces. The tables and diploë are tolerably distinct in this bone, except where it is so thin as to become diaphanous.

The occipital bone is joined above to the ossa parietalia, and to the triquetra, when present, by the lambdoid suture; laterally to the temporal bones, by the additamenta of the lambdoid suture; below to the sphenoid bone, by the end of its cuneiform process, in the same way that epiphyses and their bones are joined. For in children a ligamentous cartilage is interposed between the occipital and sphenoid bones, which gradually turns thinner as each of the bones advances, till their fibres at last run into each other; and, about sixteen or eighteen years of age, the union of these two bones becomes so intimate, that a separation cannot be made without violence. The os occipitis is joined by a double articulation to the first vertebra of the neck, each condyle being received into a superior oblique process of that vertebra.

Oss ethmoides, or the *sewe-like* bone, has its name from the great number of small holes with which it is pierced. Its several parts are, the *cribriform lamella* with its process, the *nasal lamella*, *cellulae*, and *ossa spongiosa*. The thin horizontal lamella is pierced obliquely by a great number of small holes, through which the filaments of the olfactory nerves pass. In a recent subject, these holes are so closely lined by the dura mater, that they are much less conspicuous than in the skeleton. From the middle of the internal side of this plate, a thick process rises upwards; and, being highest at the fore-part, gradually becomes lower as it is extended backwards. From some resemblance which this process was imagined to have to a cock's comb, it has been called *crista galli*. The falx is connected to its ridge, and to the unperforated part of the cribriform plate. When the crista is broke, its base is sometimes found to be hollow, with its cavity opening into the nose.

From the middle of the outer surface of the cribriform lamella, a thin solid plate is extended downwards and forwards, having the same common base with the crista galli. Generally it is not exactly perpendicular, but is inclined

to one side or other, and therefore divides the cavity of the nose unequally. Its inclination to one side, and flexure in the middle, is sometimes so great, that it fills up a large share of one of the nostrils, and has been mistaken for a polypus there. At a little distance from each side of this external process, a cellular and spongy bony substance depends from the cribriform plate. The number and figure of the cells in this irregular process, are very uncertain; but they open into each other, and into the cavity of the nose: the uppermost, which are below the aperture of the frontal sinuses, are formed like funnels. The outer surface of these cells is smooth and plain, where this bone assists in composing the orbit; at which place, on each side, it has the name of *os planum*. Below the cells of each side, a thin plate is extended inwards; and then, bending down, it becomes thick and of a spongy texture. This spongy part is triangular, with a straight upper edge placed horizontally, an anterior one slanting from above, downwards and forwards, and with a pendulous convex one below. The side of this pendulous spongy part next to the septum narium is convex, and its external side is concave. These two processes of the ethmoid bone have the name of *ossa spongiosa*, or *turbinata superiora*, from their substance, figure, and situation. All the prominences, cavities, and meanders, of this ethmoid bone, are covered with a continuation of the membrane of the nostrils in a recent subject. The cellular part of each palate-bone is contiguous to each *os planum*, and to the cells backwards. The lower edge of the nasal perpendicular plate is received into the furrow of the vomer. Its posterior edge is joined to the fore-part of the process azygos of the sphenoid bone. Its upper edge joins the nasal process of the frontal and nasal bones; and its anterior one is connected to the middle cartilage of the nose.

The uses of this bone are to sustain the anterior lobes of the brain; to give passage to the olfactory nerves, and attachment to the falx; to enlarge the organ of smelling, by allowing the membrane of the nose a great extent, to straighten the passage of the air through the nose, by leaving only a narrow winding canal, on the sensible membranous sides of which the substances conveyed along with the air must strike; to form part of the orbit of the eyes, and septum narium; while all its parts are so light as not to be in hazard of separating by their weight; and they are so thin as to form a large surface, without occupying much space. This brittle substance, however, is sufficiently protected from external injuries by the firm bones which cover it. If this bone is seized on by any corroding matter, we may easily conceive what destruction may ensue. Hence it is, that an *ozæna* is difficult to cure; and that in violent scurvy, or in the lues venerea, the fabric of the nose, the eyes, and even the life itself, are in danger. The situation of the nasal plate may shew us how dangerous a fracture of the bones of the nose may be, when made by a force applied to their middle fore-part, of a person in whom this nasal plate is perpendicular.

Oss sphenoides, or *wedge-like* bone, has two or three remarkable processes from each side of it, which are all of them again subdivided. The first pair is the two large lateral processes or wings; the upper part of each of which is called the *temporal process*, because they join the temporal bones. That part of the wings which juts out towards the inside, somewhat lower than the temporal apophyses, where it makes up part of the orbit, is thence named *orbital processes*. Behind the edge separating these two processes, there is often a small groove, made by a branch of the superior maxillary nerve, in its passage to the temporal muscle. The lowest and back part of each wing, which runs out sharp to meet the *ossa petrosa*, has been filled the *spinous process*: from near the point of which a sharp-pointed process is frequently produced downwards, commonly called *styloid process*, that affords origin to the pterygopharyngeus externus muscle. From this styloid process a very small groove is extended along the edge of the bone to the hollow at the root of the internal plate of the following processes,

cesses, which forms part of the Eustachian tube. The second pair of external processes of the cuneiform bone, is the two which stand out almost perpendicular to the base of the skull. Each of them has two plates, and a middle fossa facing backwards; and are commonly said to resemble the wings of a bat, and therefore are named *pterygoid* or *aliform* processes. From each side of the external plates the pterygoid muscles take their rise. At the root of each internal plate, a small hollow may be remarked, where the musculus ptery-phalpinus internus or circumflexus palati rises, and some share of the cartilaginous end of the Eustachian tube rests; and, at the lower end of the same plate, is a hook-like rising or process, round which the tendon of the last-named muscle plays, as on a pulley. To these may be added the little triangular thin process, which comes from each side of the body of the sphenoid bone, where the pterygoid processes are rising from it, and are extended over the lower part of the aperture of the sinus as far as the ethmoid bone, while their body hangs down into the nares. Besides these pair of processes, there is a sharp ridge which stands out from the middle of its base: and, because it wants a fellow, it may be called *processus azygos*. The lower part of this process, where it is received into the vomer, is thick, and often not quite perpendicular, but inclining more to one side than the other. The fore-part of this process, where it joins the nasal plate of the os ethmoides, is thin and straight. These two parts have been described as two distinct processes by some writers.

The depressions, sinuities, and fossæ, on the external surface of this sphenoid bone, may be reckoned up to a great number, viz. Two on the temporal apophyses, where the crotaphite muscles lodge; two on the orbital processes, to make way for the globes of the eyes; two between the temporal and spinous processes, for receiving the temporal bones; two between the plates of the pterygoid processes, where the muscoli pterygoidei interni and ptery-phalpylini interni are placed; two between the pterygoid and orbital processes, for forming the holes common to this and to the cheek and maxillary bones; two on the lower ends of the aliform processes, which the palate bones enter into; two at the roots of the temporal and pterygoid processes, where the largest share of the external pterygoid muscles have their rise; two at the sides of the processus azygos, for forming part of the nose, &c.

What are described under the name of *temporal* and *spinous processes* on the outside of the skull, are likewise seen on its inside, where they are concave, for receiving part of the brain; and commonly three apophyses on the internal surface of the sphenoid bone are only mentioned. Two, rising broad from the fore-part of its body, become smaller as they are extended obliquely backwards. The third, standing on a long transverse base, rises nearly erect, and of an equal breadth, terminating often in a little knob on each side. The three are called *clinoid*, from some resemblance which they were thought to have to the supporters of a bed. From the roots of the anterior clinoid processes the bone is extended on each side outwards and forwards, till it ends in a sharp point, which may have the name of the *transverse spinous processes*.

Within the skull, there are two *sinuities* in the internal part of each wing of the sphenoid bone, for receiving the middle part of the brain. One between the transverse spinous processes, for lodging the part of the brain where the crura medullæ oblongatæ are. Immediately before the third or middle clinoid process, a single pit may generally be remarked, from which a fossa goes out on each side to the holes through which the optic nerves pass. The pit is formed by the conjoined optic nerves; and in the fossa these nerves are lodged, as they run divided within the skull. Between that third protuberance and the posterior clinoid process, the larger pit of the glandula pituitaria may be remarked. This cavity, because of its resemblance to a Turkish saddle, is always described under the name of *sella turcica*, or *ephippium*. The holes on each side of the os sphenoides are six proper, and three common. The

first is the round one immediately below the anterior clinoid processes, for the passage of the optic nerve, and of the branch of the internal carotid artery that is sent to the eye. The second is the foramen lacerum, or large slit between the transverse spinous and orbital processes. The outer end of it is formed in the os frontis; and therefore this might be reckoned among the common foramina. Through it the third, fourth, the first branch of the fifth, and the greater share of the sixth, pair of nerves, and an artery from the internal carotid, go into the orbit. Sometimes a small branch of the external carotid enters near its end, to be distributed to the dura mater; and a vein, some call it the *venous duct*, or *Nuck's aqueduct*, returns through it to the cavernous sinus. The third hole, situated a little below, is called *rotundum*, from its shape. It allows passage to the second branch of the fifth pair of nerves, or superior maxillary nerve, into the bottom of the orbit. The fourth is the *foramen ovale*, about half an inch behind the round hole. Through it the third branch of the fifth pair, or inferior maxillary nerve, goes out. Very near the point of the spinous process is the fifth hole of this bone; it is small and round, for a passage to the largest artery of the dura mater, which is often accompanied with a vein. The sixth proper hole cannot be well seen, till the cuneiform bone is separated from all the other bones of the cranium; for one end of it is hid by a small protuberance of the internal plate of the pterygoid process; and by the point of the processus petrosus of the temporal bone. Its canal is extended above the inner plate of the pterygoid process; and where it opens into the cavity of the nose, it is concealed by the thin laminous part of the palate-bone.

The first of the *common holes* is that unequal fissure at the side of the sella turcica, between the extreme point of the os petrosus and the spinous process of the cuneiform bone. This hole only appears after the bones are boiled; for in a recent subject its back-part is covered by a thin bony plate that lies over the internal carotid artery, and farther forward it is filled with a cartilaginous ligament, under which the cartilaginous part of the Eustachian tube is placed. The second common hole is the large discontinuation of the external side of the orbit, left between the orbiter processes of the cuneiform bone, the os maxillare, malæ, and palati. In this large hole the fat for lubricating the globe of the eye and temporal muscles is lodged, and branches of the superior maxillary nerve, with small arteries from the carotid, and veins, pass. The third hole is formed between the base of this bone and the root of the orbital process of the palate-bone of each side. Through this a branch of the external carotid artery, and of the second branch of the fifth pair of nerves, are allowed a passage to the nostrils, and a returning vein accompanies them. Sometimes, however, this hole is proper to the palate-bone, being entirely formed out of its substance.

The os sphenoides is joined by its wings to the parietal bones above, to the os frontis and ossa malarum before, to the temporal bones behind; by the fore-part of its body and spinous processes, to the frontal and ethmoid bones; by its back-part, behind the two sinuses, to the occipital, where it looks like a bone with the epiphyses taken off, and, as was formerly observed in the description of the occipital bone, it cannot be separated without violence in adults; to the palate-bones, by the ends of the pterygoid process, and still more by the fore-part of the internal plates of the pterygoid processes, and of the sinuses; to the maxillary bones; by the fore-part of the external pterygoid plates; to the vomer and nasal plate of the os ethmoides, by the processus azygos.

The *face* is the irregular pile of bones composing the fore and under part of the head, which is divided by authors into the *upper* and *lower maxilla*, or jaws. The *superior maxilla* is the common designation given to the upper immovable share of the face. It consists of six bones on each side; of a thirteenth bone which hath no fellow, placed in the middle; and of sixteen teeth. The thirteen bones

bones are, two *ossa nasi*, two *ossa unguis*, two *ossa malarum*, two *ossa maxillaria*, two *ossa palati*, two *ossa spongiosa inferiora*, and the vomer. The *ossa nasi* are placed at the upper part of the nose; *ossa unguis* are at the internal canthi of the orbits; *ossa malarum* form the prominence of the cheeks; *ossa maxillaria* form the side of the nose, with the whole lower and fore-part of the upper jaw, and the greatest share of the roof of the mouth; *ossa palati* are situated at the back part of the palate, nostrils, and orbits; *ossa spongiosa* are seen in the lower part of the nares; and the vomer helps to separate these two cavities.

The bones of the upper jaw are joined to the bones of the skull by the *schindylefis* and sutures already described as common to the cranium and face, and they are connected to each other by *gomphosis* and fifteen sutures. The *gomphosis* is only where the teeth are fixed in their sockets, and the *schindylefis* is only where the edges of the vomer are joined to other bones. The sutures of the face (formerly called *harmonia*) have not such conspicuous indentations as those of the skull; the bones here not having substance enough for forming large indentations, and there being less necessity for security against external injuries, or any internal protruding force, than in the cranium. These sutures often disappear in old people, by the bones running into each other; which can do little prejudice, because the principal use of the bones being so numerous here, is to allow them to be extended into a proper form.

Ossa nasi, are so named, from their situation at the root of the nose. The lower edge of these bones is unequal, and is stretched outwards and backwards, to join the cartilages of the nostrils. Their anterior side is thick, especially above, and unequal, that their conjunction to each other might be stronger; and a small ridge may be remarked on their inner edge, where they are sustained by the septum narium. Their posterior side has externally a depression, where it is a little overlapped by the maxillary bones, while its lower half covers these bones: by which contrivance, they do not yield easily to pressure applied to their fore-part or sides. The nasal bones are firm and solid, with very few cells of cancelli in them. They are joined above to the frontal bone, by the middle of the transverse suture; behind, to the maxillary bones, by the lateral nasal sutures; below, to the cartilages of the nose; before, to one another, by the anterior nasal suture; internally, to the septum narium. The use of these bones is to cover and defend the root of the nose. In an infant they are proportionally shorter, and less thick at their upper part, than in an adult; but are otherwise complete.

Ossa unguis, or *lacrymalia*, are so named, because their figure and magnitude are nearly like those of a nail of one's finger, and because the tears pass upon them into the nose. Their external surface is composed of two smooth concavities and a middle ridge. The depression behind forms a small share of the orbit for the eye-ball to move on; and the one before is a deep perpendicular canal, or *fossa*, larger above than below, containing part of the lacrymal sac and duct. This is the part that ought to be pierced in the great operation for the fistula lacrymalis. This fossa of the bone is cribriform, or has a great number of small holes through it, that the filaments for the membrane which lines it insinuating themselves into these holes, might prevent a separation of the membrane, and secure the bone in its natural situation. The ridge between these two cavities of the os unguis is the proper boundary of the orbit at its internal canthus; and beyond which surgeons should not proceed backwards in performing operations here. The internal or posterior surface of this bone consists of a furrow in the middle of two convexities. The substance of the os unguis is as thin as paper, and very brittle; which is the reason that those bones are often wanting in skeletons, and need little force to pierce them in living subjects. Each of these bones is joined, above, to the frontal bone, by part of the transverse suture; behind, to the os planum of the ethmoid bone, by the same suture; before, and below, to the maxillary bone, by the lacrymal suture. Internally, the

ossa unguis cover some of the sinus ethmoidales; nay, are really continuous with the bony lamellæ which make up the sides of these cells; so that they are as much part of the ethmoid bone as the *ossa plana*. Their situation and tender substance make a rash operator in danger of destroying a considerable share of the organ of smelling, when he is performing the operation of the fistula lacrymalis; but, when these bones are hurt, they cast off without much difficulty, and consequently the wound is soon cured, unless the patient labours under a general cacothesis, or there is a predisposition in the bones to caries; in which case, a large train of bad symptoms follow, or at best the cure proves tedious.

Ossa malarum was the name given by Celsus to all the upper jaw; but is now appropriated to the prominent square bones which form the cheek on each side. Before, their surface is convex and smooth; backward, it is unequal and concave, for lodging part of the *crotophyte* muscles. The four angles of each of these bones have been reckoned processes by some authors. The one at the external canthus of the orbit, called the *superior orbital* process, is the longest and thickest. The second terminates near the middle of the lower edge of the orbit in a sharp point, and is named the *inferior orbital* process. The third, placed near the lower part of the cheek, and thence called *maxillary*, is the shortest and nearest to a right angle. The fourth, which is called *zygomatic*, because it is extended backwards to the *zygoma* of the temporal bone, ends in a point, and has one side straight and the other sloping. Between the two orbital angles there is a concave arch, which makes about a third of the external circumference of the orbit, from which a fifth process is extended backwards within the orbit, to form near one third of that cavity; and hence it may be called the *internal orbital* process. From the lower edge of each of the *ossa malarum*, which is between the maxillary and zygomatic processes, the masseter muscle takes its origin; and from the exterior part of the zygomatic process, the *musculus distortor oris* rises; in both which places the surface of the bone is rough.

Each of the *ossa malarum* is joined, by its superior and internal orbital processes, to the os frontis, and to the orbital process of the sphenoid bone, by the transverse suture; by the edge between the internal and inferior orbital processes, to the maxillary bone, by the external orbital suture; by the side between the maxillary and inferior orbital process, again to the maxillary bone, by the external orbital suture; by the zygomatic process, to the os temporum, by the zygomatic suture.

Ossa maxillaria superiora are the largest bones, and constitute the far greater part, of the upper jaw, which has appropriated the name of *maxillaria* to them. The processes of each os maxillare may be reckoned seven. The first is the long nasal one at its upper and fore part, which is broad below, and turns smaller as it rises upwards, to make the side of the nose. At the root of this a transverse ridge may be observed within the nostrils, which supports the fore part of the upper edge of the os spongiosum inferius. The second is produced backwards and outwards, from the root of the nasal process, to form the lower side of the orbit; and therefore may be called *orbital*. The edge of this orbital process, and the ridge of the nasal one, which is continued from it, make a considerable portion of the external circumference of the orbit. From the proper orbital process, a very rough triangular surface is extended downwards and outwards, to be connected to the cheek-bone; and therefore may be called the *molar process*, from the lowest protuberant part of which some share of the masseter muscle takes its rise. Behind the orbital process, a large tuberosity or bulge of the bone appears, which is esteemed the fourth process. On the internal part of this we often meet with a ridge, almost of the same height with that in the nasal process, which runs transversely, and is covered by a similar ridge of the palate-bone, on which the back-part of the upper edge of the os spongiosum inferius rests.

That

That spongy protuberance at the lower circumference of this bone, where the sockets for the teeth are formed, is reckoned the fifth. The sixth is the horizontal plate, which forms the greater part of the base of the nostrils, and roof of the mouth: its upper surface, which belongs to the nostrils, is very smooth; but the other below is arched and rough, for the stronger adhesion of the membrane of the mouth, which is stretched upon it; and in chewing, speaking, &c. might otherwise be liable to be separated. The seventh rises like a spine from the inner edge of the last, and forms a small part of the partition of the nostrils.

The *depressions* in each maxillary bone are, 1. A sinusity behind the orbital process, made by the temporal muscle. 2. A pit immediately before the same process, where the origin of the musculus elevator labiorum communis and elevator labii superioris, with a branch of the fifth pair of nerves, are lodged. 3. The hollow arch of the palate. 4. The femicircular great notch, or entry to the lower part of the nostrils. 5. Sockets for the teeth. 6. The lacrymal fossa in the nasal process, which assists the os unguis to form a passage for the lacrymal duct. The part of the bone forming this fossa is so firm and strong, that a surgeon can scarcely perforate it with the ordinary instruments for the fistula lacrymalis; and therefore ought to avoid it in doing this operation. Immediately on the outside of this there is a small depression, from which the inferior or lesser oblique muscle of the eye has its origin. 7. The canal on the upper part of the great tuberosity within the orbit, which is almost a complete hole; in this a branch of the superior maxillary nerve passes. Besides these, the superior surface of the great bulge is concave, to receive the under part of the eye. Immediately above the transverse ridge in the nasal process, a small hollow is formed by the os spongiosum. In some subjects, the nasal process has a small round pit above the lacrymal duct, where the little tendon or ligament of the orbicular muscle of the eyelids is inserted. It is this tendon, and not the tendon of the larger oblique muscle of the eye, which there is some hazard of cutting in the operation of the fistula lacrymalis.

The *holes* of this bone are two proper and two common. The first of the proper is the external orbital, immediately below the orbit. The second is the foramen incisivum, just behind the fore teeth. Through them small arteries and veins, and a twig of the second branch of the fifth pair of nerves, pass, and make a communication between, or join the lining coats of the nose and mouth. In some subjects, Steno's duct may be traced some length on the side of these passages next to the nose, and small orifices may be observed opening into the mouth. The first common hole is that which appears at the inner side of the back part of the tuberosity and of the sockets of the teeth; and is formed by a fossa in this bone, and a corresponding one in the os palati: through it a nerve, which is a branch of the second branch of the fifth pair, runs to the palate. The other common hole is the great slit in the outside of the orbit.

All the *body* of the maxillary bone is hollow, and leaves a large *sinus* like the frontal and sphenoid, which is commonly, but unjustly, called *antrum Highmorianum*. When the os maxillare is single, or separated from all the other bones of a skeleton, its antrum appears to have a large aperture into the nostrils; but, in a recent subject, it is so covered at its back-part by the palate-bone, in the middle by the os spongiosum inferius, before by a strong membrane, that one or sometimes two holes, scarcely so large as a crow-quill, are only left at the upper part; which, after a short winding process, open into the nostrils between the two ossa spongiosa. At the bottom of this cavity, we may often observe some protuberances, in which the small points of the roots of the teeth are contained. This cavern and the sockets of the teeth are often divided by the interposition only of a very thin bony plate, which is liable to be eroded by acrid matter collected in the antrum, or to be broken in drawing a tooth. The symptoms

of a collection of matter here naturally led us to the practice of pulling out the teeth, and piercing through this plate into the antrum, to procure an evacuation of the collected matter, by which considerable service is frequently done.

The maxillary bones are joined above, by the upper ends of their nasal processes to the os frontis, by the transverse future; at the sides of these processes, to the ossa unguis, by the lacrymal futures; to the nasal bones, by the lateral nasal futures; by their orbital processes, to the cheek-bones, by the external orbital future; by the internal sides of the internal orbital processes, to the ossa plana, by part of the ethmoidal future; by the back part of the tuberosities, to the palate-bones, by the future palato-maxillares; by the posterior edges of their palatine lamellæ, to the ossa palati, by the transverse palate future; by their nasal spines, to the vomer, by the spinous future; by their socket, to the teeth, by the gomphosis; by the internal edge of the palate-plate, to one another, by the longitudinal palate future, on the upper and fore part of which a furrow is left for receiving the cartilage which forms the partition of the nostrils; between the fore-part of the nostrils and mouth, to each other, by the mystachial future: sometimes they are connected to the ossa spongiosa inferiora, by a plain concretion or union of substance.

These bones form the greater part of the nose and of the roof of the mouth, and a considerable share of the orbit. They contain sixteen teeth, and give rise to muscles, transmission to nerves, &c.

Ossa palati are commonly described as two small square bones, at the back-part of the palate or roof of the mouth, though they are of much greater extent, being continued up the back-part of the nostrils to the orbit. Each palate-bone may therefore be divided into four parts, the palate square-bone, the pterygoid process, nasal lamella, and orbital process. The *square-bone* is unequally concave, for enlarging both the mouth and cavity of the nose. The upper part of its internal edge rises in a spine. Behind, this bone is somewhat in form of a crescent, and thick, for the firm connection of the velum pendulum palati; the internal point being produced backwards, to afford origin to the palato-staphylinus or azygos muscle. This square-bone is well distinguished from the pterygoid process by a perpendicular fossa, which, applied to such another in the maxillary bone, forms a passage for the palatine branch of the fifth pair of nerves; and by another small hole behind this, through which a twig of the same nerve passes. The *pterygoid process* is somewhat triangular, having a broad base, and ending smaller above. The back-part of this process has three fossæ formed in it; the two lateral receive the ends of the two plates of the sphenoid bone; the middle fossa makes up a part of what is commonly called the *fossa pterygoidea*; the fore-side of this palatine pterygoid process is an irregular concave, where it receives the back-part of the great tuberosity of the maxillary bone. The *nasal lamella* of this bone is extremely thin and brittle, and rises upwards from the narrow extremity of the pterygoid process; where it is so weak, and at the same time so firmly fixed to the maxillary bone, as to be very liable to be broken in separating the bones. From the part where the plate rises, it runs up broad on the inside of the tuberosity of the maxillary bone, to form a considerable share of the sides of the maxillary sinus, and to close up the space between the sphenoid and the great bulge of the maxillary bone, where there would otherwise be a large slit opening into the nostrils. From the middle internal side of this thin plate, a cross ridge, placed on such another of the maxillary bone, is extended; on it the back-part of the os spongiosum inferius rests.

The palate-bones are joined to the maxillary, by the fore-edge of the palate square bone, by the transverse palate future; by their thin nasal plates, and part of their orbital processes, to the same bones, by the palato-maxillares futures; by their pterygoid processes, and back-part of the nasal plates, to the alæ vespertilionum, by the sphenoid future; by the transverse ridges of the nasal palates, to

the ossa spongiosa inferiora, by contact; hence there frequently is an intimate union of the substance of these bones in aged skulls; by the orbital processes, to the ossa plana and cellulae ethmoidae, by the ethmoid future; to the body of the sphenoid bone, by the sphenoid future; by the internal edge of the square bones, to each other by the longitudinal palate future; and by their nasal spines, to the vomer, by the spinous future. The palate-bones form part of the palate, nostrils, orbits, and fossae pterygoideae; and they cover part of the sinus maxillares, sphenoidales, and ethmoidi. When we are acquainted with the history of these bones, the reason is evident, why the eyes are so much affected in ulcers of the palate, as to be often attended with blindness, which frequently happens in an ill-managed lues venerea; or why, on the other hand, the palate suffers from an ægylops.

Ossa turbinata, or *spongiosa inferiora*, resemble the superior ossa spongiosa in shape and substance, but have their anterior and upper edges contiguous to the transverse ridges of the nasal processes of the maxillary and palate bones. From their upper straight edge, two small processes stand out: the posterior, which is the broadest, descends to cover some of the antrum Highmorianum; the anterior rises up to join the os unguis, and to make part of the lacrymal duct. The names of these bones sufficiently declare their spongy substance, which has no firm external plate covering it. They are joined to the ossa maxillaria, palati, and unguis, in all subjects, by a firm union of substance; and, as this often happens in people of no great age, some authors are of opinion, that they should be esteemed part of the palate-bones; others think, that, since their upper edge is continued by a plate to part of the os ethmoides, they ought to be esteemed part of this bone. Their use is, to straighten the nostrils, to afford a large surface for extending the organ of smelling, to cover part of the antra maxillaria, and to assist in forming the under part of the lacrymal ducts, the orifices of which into the nose are concealed by these bones.

Vomer, or bone resembling a plough-share, is the thirteenth of the upper jaw, and is without a fellow, forming the lower and back parts of the partition of the nose. The figure of this bone is an irregular rhomboid. Its sides are flat and smooth. Its posterior edge appears in an oblique direction at the back-part of the nostrils. The upper one is firmly united to the base of the sphenoid bone, and to the nasal plate of the ethmoid; and is hollow, for receiving the processus azygos of the sphenoid. The anterior edge has a long furrow in it, where the middle cartilage of the nose enters. The lower edge is firmly united to the nasal spines of the maxillary and palate bone. The vomer is convex at its upper part, and then is straight, as it is extended downwards and forwards, where it is composed of two plates, the edges of which have a great number of small processes, disposed somewhat like the teeth of a saw, but more irregularly, and several of them are reflected back. Between these plates a deep fossa is left, which, as far as the top of the curvature, is wide, and has strong sides, for receiving the processus azygos of the sphenoid bone. Beyond the arch forwards, the fossa is gradually narrower and shallower to the point of the bone, receiving for some way the nasal lamella ethmoidae; which, after the ossification is complete, is so closely united to the vomer by the little processes piercing its substance, as to prevent any separation; on which account it has been esteemed by some authors a part of the ethmoid bone. The middle cartilage of the nose fills up what remains of the fossa at its fore-part. The posterior edge of the vomer, which appears above the back-part of the palate-bones, is broader above; but, as it descends forwards, becomes thinner, though it is still solid and firm. The lower edge of this bone, which rests on the nasal spine of the palate and maxillary bones, has a little furrow on each side of a small middle ridge, answering to the spines of the bones of different sides, and the interstices between them. This and the upper edge meet in the pointed fore-end of this bone.

It is joined above to the sphenoid and ethmoid bones, and to the middle cartilage of the nose by schindyleis; below, to the maxillary and palate bones by the spinous future. The vomer divides the nostrils; enlarges the organ of smelling, by allowing place for expanding the membrane of the nose on its sides; and sustains the palate-plates of the maxillary and palate bones, which otherwise might be in hazard of being pressed into the nostrils.

Maxilla inferior, the lower jaw, consists only of one moveable bone, and sixteen teeth incased in it. This bone is situated at the lower part of the face, so as its convex middle part is forward, and its legs are stretched back. It is commonly divided into the chin, sides, and processes. The *chin* is the middle fore-part; the extent of which to each side is marked on the external surface by the holes observable there, and internally by the beginning of an oblique ridge. Beyond these the *sides* appear; and are continued till the bone, by bending upwards, begins to form the *processes*. On the fore-part of the chin, a transverse ridge appears in the middle; on each side of which the musculi quadrati, or depressores, and the levatores labii inferioris, depress the bone: and below these prints a small rising may be observed, where the depressores commence. On the back-part of the chin, sometimes three, always two, small protuberances appear in the middle. To the uppermost, when it is seen, the frænum of the tongue is connected. From the middle one, the musculi genio-glossi rise; and from the lowest, the genio-hyoidei have their origin. Below the last, we see two rough sinuosities formed by the digastric muscles.

At the lower and fore part of the external surface of each side of the lower jaw, a small eminence may be observed, where the depressor labiorum communis rises. Near the upper edge of the side a ridge runs lengthwise, to which the under-part of the musculus buccinator is connected. Internally, towards the upper edge of each side, another ridge appears, from which the mylo-hyoidei have their origin, and to which the internal membrane of the gums adheres. In the upper edge of both chin and sides, are a great many deep pits or sockets, for receiving the roots of the teeth. The number and magnitude of these sockets are various, because of the different number, as well of the teeth themselves, as of their roots, in different people. These sockets in the lower jaw, as well as in the upper one, are less deep as old age comes on: when freed from the teeth by any means, they are some time after filled up with an osseous net-work, which at last becomes entirely solid, and as smooth as any other part of the bone; so that, in a great many old subjects, we cannot observe a vestige of the sockets: but then the jaw becomes less, and much narrower. Hence we may know why the chin and nose of edentulous people are much nearer than before the teeth were lost; while their lips either fall in towards their mouth, or stand prominent forwards. When new teeth are protruded, new sockets are formed. The lower edge of the chin and sides is smooth and equal, and is commonly called the base of the lower jaw.

The *processes* are two on each side. The anterior sharp thin coronoid ones have the crotaphite muscles inserted into them. The posterior processes or condyles terminate in an oblong smooth head, supported by a cervix. The fore-part of the root and neck of these condyloid processes are a little hollow and rough where the external pterygoid muscles are inserted. The *holes* of the lower jaw are two on each side; one at the root of the processes internally, where a large branch of the third branch of the fifth pair of nerves enters with an artery, and a vein returns. The other hole is external, at the confines of the chin, where branches of the nerve and vessels come out. The canal between these two holes is formed in the middle of the substance of the bone, and is pierced by a great number of small holes, by which the nerves and blood-vessels of the cancelli and teeth pass. This canal is continued a little farther than the external hole at the chin. On account of the vessels and nerves in the lower jaw, fractures of it

may be attended with dangerous symptoms. The *surface* of the lower jaw is hard and firm, except at the spongy sockets, where, however, it is stronger than the upper jaw. Its internal *substance* is cellular, without any solid partition between the cancelli in its middle. At the base, especially of the chin, where this bone is most exposed to injuries, the solid sides of it are thick, compact, and hard.

The lower jaw generally receives the root of sixteen teeth into its sockets, by *gomphosis*; and its condyloid processes, covered with a cartilage, are articulated with the temporal bones, in a manner that is not in general rightly described: for, not only the fore-part of the cavity between the zygomatic, auditory, and vaginal, processes, but also the adjoining tubercle at the root of the zygomatic process of each os temporum, is covered with a smooth cartilage for this articulation. Here also an intermediate moveable cartilage is placed; which being thin in the middle, and thick at the edges, is concave on both sides; and is connected so firmly by ligaments to each condyle, as to follow the motions of the condyle; and so loosely to the temporal bone, as readily to change its situation from the cavity to the tubercle, and to return again; while the common ligament of the articulation affords space enough for such a change of place backwards and forwards: but, like other ligaments of the joints by ginglymus, is strong and short at the sides, to confine the lateral motions. When, therefore, the teeth of both jaws coincide, the condyles are lodged securely in the temporal cavities; but their motions to either side must be confined both by the firmness of the ligaments and the rising brims which are on each side of the cavities. When the jaw is brought directly forwards, the condyle and intermediate cartilages descend and advance forwards upon the tubercles. In this situation, the lateral motions are a little more free than in the former one, from the want of rising brims to stop the condyles. When the fore-teeth of the lower jaw are moved forwards and to a side, the condyle of the opposite side is either advanced from the cavity to the tubercle, while the condyle of the same side remains in the cavity; or, if both condyles are on the tubercles, when the jaw is moved obliquely to a side, the condyle of the side to which the motion is made slides back from the tubercle to the cavity. When the mouth is opened by the descent of the lower jaw, the fore-part of it, where the depressing muscles are fixed, is drawn backwards, as well as downwards, while resistance is made to the angles moving backwards by the masseter and internal pterygoid muscles, and at the same time, the external pterygoid draws the condyles and their moveable cartilages forwards; and therefore, when the mouth is opened, the condyles are carried forwards upon the tubercles, and the axis of motion of the bone is a little above its angles. But in this situation there is less resistance, than in any other, to the condyles luxating forwards; a disease which seldom happens, except when people are gaping too wide; and therefore the common practice of nurses, who support the jaw of infants when they are yawning, is reasonable. In chewing, there is a succession of the motions above described.

The *teeth* are the hard white bodies placed in the sockets of both jaws. Their number is generally sixteen above and as many below; though some people have more, others less. The broad thick part of each tooth, which appears without the socket, is the base or body. The smaller processes, sunk into the maxillæ, are the roots or fangs. At the place where the base ends and the roots begin, there is generally a small circular depression, which some call the neck or collar. Without the gums the teeth are covered with no membrane, and they are said to have no proper periodium within the sockets; but that is supplied by the reflected membrane of the gums, which after a good injection may be evidently seen in a young subject, with the vessels from it penetrating into the substance of the teeth; and it may be discovered in any tooth recently pulled, by macerating it in water. The adhesion of this membrane to these roots is strengthened by the small fur-

rows observable on them. Each tooth is composed of its cortex or enamel, and an internal bony substance. The cortex has no cavity or place for marrow; and is so solid and hard, that saws or files can with difficulty make an impression on it. It is thickest upon the base, and gradually, as the roots turn smaller, becomes thinner, but not proportionally to the difference of the size of the base and roots. The fibres of this enamel are all perpendicular to the internal substance; and are straight on the base, but at the sides are arched with a convex part towards the roots; which makes the teeth resist the compression of any hard body between the jaws with less danger of breaking these fibres than if they had been situated transversely. The bony part of the teeth has its fibres running straight, according to the length of the teeth. When it is exposed to the air, by the breaking or falling off of the hard cortex, it soon corrupts. And thence carious teeth are often entirely hollow within, when a very small hole appears only externally.

The teeth have canals formed in their middle, wherein their nerves and blood-vessels are lodged. The vessels are easily traced as long as they are in the large canal, but can scarcely be observed in their distribution from that to the substance of the teeth of adults. Ruysch however affirms, that after injection he could trace the arteries into the hardest part of the teeth. And Leuwenhoek suspected the fibres of the cortex to be vessels. This plentiful supply of vessels must expose the teeth to the same disorders that attack other vascular parts; and such teeth as have the greatest number of vessels must have the most numerous chances of being seized with these diseases.

Every root of each tooth has a distinct canal, with vessels and nerves in it. These canals in the teeth with more than one root, come nearer each other as they approach the base of the tooth; and at last are only separated by very thin plates, which, being generally incomplete, allow a communication of all the canals; and frequently one common cavity only appears within the base, in which a pulpy substance composed of nerves and vessels is lodged. The condition therefore of the nerves here bears a strong analogy to that of the cutaneous nerves which serve for the sensation of touching. The entry of the canals for these vessels is a small hole placed a little to a side of the extreme point of each root; sometimes, especially in old people, this hole is entirely closed up, and consequently the nerves and blood-vessels are destroyed.

Children are seldom born with teeth; but at two years of age they have twenty; and their number does not increase till they are about seven years old; when the teeth that first made their way through the gums are thrust out by others that have been formed deeper in the jaw, and some more of the teeth begin to discover themselves farther back in the mouth. About fourteen years of age, some more of the first crop are shed, and the number is increased. This shedding of the teeth is of great use: for, if the first had remained, they would have stood at a great distance one from another; because the teeth are too hard in their outer crust to increase so fast as the jaws do. Whereas, both the second layer and the teeth that come out late, meeting, while they are soft, with a considerable resistance to their growth in length, from those situated upon them, necessarily come out broad, and fit to make that close guard to the mouth which they now form.

The teeth are joined to the sockets by *gomphosis*, and the gums contribute to fix them there; as is evident by the teeth falling out when the gums are any way destroyed or made too spongy, as in the scurvy or salivation: whence some authors class this articulation with the *symplicosis*.

Though the teeth so far agree in their structure, yet, because of some things wherein they differ, they are generally divided into three classes, viz. *incisores*, *canini*, and *molars*. The *incisores* are the four fore-teeth in each jaw, receiving their name from their office of cutting our aliment; for which they are excellently adapted, being each formed into a sharp-cutting edge at their base, by their fore-

fore-side turning inwards there, while they are sloped down and hollowed behind; so that they have the form of wedges, and therefore their power of acting must be considerably increased. Seeing, in the action of the incisores, a perpendicular compression is only necessary, without any lateral motion, they are not so firmly fixed in their sockets as the other teeth are, each having only one short root; but that is broader from before backwards than to either side, to have the greatest strength where it is exposed to the strongest force applied to it. The incisores of the upper jaw, especially the two middle ones, are generally broader and longer than those of the under jaw. The *canini*, from the resemblance to dog's tusks, are one on each side of the incisores in each jaw. The two in the upper jaw are called *eye-teeth*, from the communication of nerves which is said to be between them and the eyes. The two in the lower jaw are named *angular* or *wisdom teeth*, because they support the angles of the mouth. The canini are broader, longer, and stronger, than the incisores are; only that the edge rises into a point at the middle. Each of them has generally but one long root, though sometimes they have two. The roots are crooked towards the end. The canini of the upper jaw are larger, longer, and with more crooked roots, than those of the under jaw. The form of their base is fit both for piercing and cutting, and the long crooked root of each makes it secure in the socket. The *dentes molares*, or *grinders*, which have this name because they grind our food, are generally five in the sides of each jaw; in all twenty. Their bases are broader, more scabrous, and with a thinner cortical substance, than the other teeth. They have also more roots; and, as these roots generally divaricate from each other, the partitions of the sockets between them bear a large share of the great pressure they suffer, and hinder it from acting on their points. The base of the first grinder has an edge pointed in the middle, on its outside resembling the canini; from which it slopes inwards till it rises again into a point. It has generally but one root, which sometimes is long and crooked at its point. The second *dens molaris* has two points on its base, rising nearly equally on its out and inside. It has two roots, either separate or run together, but shorter than the root of the first. These two anterior grinders are much smaller than the three that are placed farther back in the mouth. The third and fourth are very broad in their bases, with four or five points standing out; and they have three or more roots. The fifth, commonly called *dens sapientia*, from its coming through the gums later than the other grinders, has four points on its base, which is not so large as the base of the third and fourth, and its roots are less numerous. The incisores of the upper jaw being broader than those of the lower jaw, make the superior grinders to be placed so much farther back than the lower ones, that, when they are brought together, by shutting the mouth, the points of the grinders of one jaw enter into the depressions of the opposite grinders, and they are all equally applied to each other, notwithstanding the inequality of their surface. The numerous roots of the *dentes molares* prevent their loosening by the lateral pressure they suffer in grinding; and as the sockets in the upper jaw are more spongy, and the teeth are more liable, by their situation, to fall out, the grinders there have more numerous and more separated roots than in the lower jaw.

The *os hyoides* is situated horizontally between the root of the tongue and the larynx. It is properly enough named *hyoides*, from the resemblance it bears to the Greek letter *v*; and may, for a clearer demonstration of its structure, be distinguished into its *body*, *cornua*, and *appendices*. The *body* is the middle broad part, convex before and hollow behind. The convex fore-part is divided into two by a ridge, into the middle of which the *mylo-hyoidei*, and into the sides the *stylo-hyoidei*, muscles are inserted. Above the ridge, the bone is horizontal; but pitted in the middle by the insertion of the two *genio-hyoidei* muscles, and a little hollowed more laterally by the *basio-glossi*. Below

the ridge, it is convex; but a little flattened in the middle by the *sterno-hyoidei*, and pitted more externally by the *coraco-hyoidei*. The concavity behind faces backwards and downwards to receive the thyroid cartilage, when the larynx and the *os hyoides* are pulled towards each other by the action of the *sterno-hyoidei* and *hyo-thyroidei* muscles; and, to its upper edge, the ligamentous membranes of the epiglottis, tongue, and thyroid cartilage, are fixed.

The *cornua* of the *os hyoides* are stretched backwards from each side of its body, where often a small furrow points out the former separation; for, in young subjects, the body and cornua are not one continued substance, as they come afterwards to be in adults. These cornua are not always straight, nor of an equal length; their two plain surfaces stand obliquely sloping from above outwards and downwards. Into the external, the *cerato-glossi* is inserted above, and the *thyro-hyoideus* muscle below; and and, to the one behind, the ligamentous membrane of the tongue and larynx adheres. Each of the cornua becomes gradually smaller as it is extended from the base; but ends in a round tubercle, from which a moveable cartilage stands out, which is connected to the upper process of the *cartilago thyroidea*.

Where the body of the *os hyoides* joins on each side with its cornua, a small styloid process, called *appendix*, rises upwards and backwards, into which the *musculi stylo-hyoidei alteri*, and part of the *hyo-glossi* muscles, are fixed. The substance of the *os hyoides* is cellular; but covered with a firm external plate, which is of sufficient strength to bear the actions of so many muscles as are inserted into it. It is not articulated with any bone of the body, except by means of the muscles and ligaments already mentioned. The use of *os hyoides*, is to serve as a solid lever for the muscles to act with, in raising and depressing the tongue and larynx, or in enlarging and diminishing the capacity of the fauces.

BONES of the TRUNK.

The trunk consists of the *spine*, *pelvis*, and *thorax*. The *spine* is the long piles of bones extended from the condyles of the occiput to the end of the rump. It somewhat resembles two unequal pyramids joined in a common base. It is not, however, straight; for, its upper part being drawn backwards by strong muscles, it gradually advances forwards, to support the oesophagus, vessels of the head, &c. Then it turns backwards, to make room enough for the heart and lungs. It is next bent forwards, to support the viscera of the abdomen. It afterwards turns backwards, for the enlargement of the pelvis. And, lastly, it is reflected forwards, for sustaining the lowest great gut. The spine is commonly divided into *true* and *false vertebrae*; the former constituting the long upper pyramid, which has its base below; while the *false vertebrae* make the shorter lower pyramid, whose base is above.

The *true vertebrae* are the twenty-four upper bones of the spine, on which the several motions of the trunk of our bodies are performed; from which use they have justly derived their name. Each of these vertebrae is composed of its body, and processes. The *body* is the thick spongy fore-part, which is convex before, concave backwards, horizontal and plain in most of them above and below. Numerous small holes, especially on the fore and back part of their surface, give passage to their vessels, and allow the ligaments to enter their substance. The edges of the body of each vertebra are covered, especially at the fore-part, with a ring of bone firmer and more solid than the substance of the body any where else. These rings seem to be joined to the vertebrae in the form of epiphyses, but are alleged by some authors to be the ligaments ossified. They are of great use in preventing the spongy bodies from being broken in the motions of the trunk. Between the bodies of each two adjoining vertebrae, a substance between the nature of ligament and cartilage is interposed; which seems to consist of concentric curved fibres, when it is cut horizontally; but, when it is

divided perpendicularly, the fibres appear oblique and decussating each other. The outer part of the intervertebral ligaments is the most solid and hard, and they gradually become softer till they are almost in the form of a glairy liquor in the centre; and therefore these substances were not improperly called mucous ligaments by the ancients. The external fibrous part of each is capable of being greatly extended, and of being compressed into a very small space, while the middle fluid part is incompressible, or nearly so; and the parts of this ligament between the circumference and centre approach in their properties to each other, in proportion to their more solid or more fluid texture. The middle point is therefore a fulcrum or pivot, on which the motion of a ball and socket may be made, with such a gradual yielding of the substance of the ligament, in whatever direction our spines are moved, as saves the body from violent shocks, and their dangerous consequences.

From each side of the body of each vertebra, a bony bridge is produced backwards, and to one side: from the posterior end of which one slanting *process* rises, and another descends; the smooth, and what is generally the flattest, side of each of these four processes, which are called the *oblique*, is covered with a smooth cartilage; and the two lower ones of each vertebra are fitted to, and articulated with, the two upper or ascending oblique processes of the vertebra below, having their articular ligaments fixed into the rough line round their edges. From between the oblique processes of each side, the vertebra is stretched out laterally into a process that is named *transverse*. From the back part of the roots of the two oblique and of the transverse process of each side, a broad oblique bony plate is extended backwards; where these meet, the seventh process of the vertebra takes its rise, and stands out backwards: this being generally sharp-pointed and narrow-edged, is therefore called *spinal* process; from which this whole chain of bones has its name. The substance of the processes is considerably stronger and firmer, and has a thicker external plate, than the bodies of the vertebrae themselves. The seven processes form a concavity at their fore-part, which, joined to the one at the back-part of the bodies, makes a great hole; and the holes of all the vertebrae form a long large conduit, for continuing the spinal marrow. In the upper and lower edge of each lateral bridge, there is a notch. These are so adapted to each other in the contiguous vertebrae, as to form a round hole in each side between each two vertebrae, through which the nerves that proceed from the spinal marrow and its blood-vessels pass.

The articulations, then, of these true vertebrae are plainly double: for their bodies are joined by the intervening cartilage above described; and their oblique processes, being tipped with cartilages, are so connected by their ligaments as to allow a small degree of motion on every side. Hence it is evident, that their centre of motion is altered in different positions of the trunk: for, when we bow forwards, the upper moved part bears entirely on the bodies of the vertebrae; if we bend back, the oblique processes support the weight; if we recline to one side, we rest upon the oblique processes of that side and part of the bodies; if we stand erect, all the bodies and oblique processes have their share in our support.

Hence it follows, 1. That, because the joints of which the spine is composed are so numerous, the spinal marrow, nerves, blood-vessels, &c. are not liable to such compression and over-stretching in the motion of the trunk of the body as they would otherwise be, since several vertebrae must be concerned in every motion of the spine; and therefore a very small curvature is made at the conjunction of any two vertebrae. 2. That an erect posture is the surest and firmest, because the surface of contact of the fulcrum is largest, and the weight is most perpendicular to them. 3. That the muscles which move the spine act with greater force in bringing the trunk into an erect posture, than in drawing it to any other; for, in bending forwards, back-

wards, or to a side, the muscles which perform any of these actions are nearer the centre of motion; consequently the lever with which they act is shorter than when the centre of motion is on the part of the vertebra opposite to that where these muscles are inserted; which is the case in raising the trunk. This is extremely necessary; since, in the deflections of the spine from a perpendicular bearing, the weight of the body soon inclines it in the direction we choose; whereas, in raising us erect, this great weight must be more than counteracted. 4. In calculating the force exerted by the muscles which move the spine, we should always make allowance for the action of the cartilages between the vertebrae, which, in every motion from an erect posture, must be stretched on one side, and compressed on the other, to both which they resist; whereas, in raising the trunk, these cartilages assist by their springy force. 5. We are hence naturally led into the reason of our height of stature increasing in the morning, and diminishing at night: for the intermediate cartilages of the vertebrae, being pressed all day long by the weight of our body, become more compact and thin in the evening; but, when they are relieved from this pressure in the night, they again expand themselves to their former thickness: and, seeing the bulk of any part must vary according to the different distension or repletion of the vessels composing it, we may understand how we become taller after a plentiful meal, and decrease after fasting or evacuations. 6. From the different articulations of the bodies and oblique processes of the vertebrae, and the different strength of the ligaments, it is plain that they are formed so as to allow much larger motion forwards than backwards; this last being of much less use, and might be dangerous, by over-stretching the large blood-vessels that are contiguous to the bodies of the vertebrae. 7. The intervertebral cartilages shrivelling as they become more solid by age, is the cause why old people generally bow forwards, and cannot raise their bodies to such an erect posture as they had in their youth.

From this general mechanism of the spine, an account is easily deduced of all the different preternatural curvatures of which the spine is capable. For, if one or more vertebrae, or their cartilages, are of unequal thickness in opposite sides, the spine must be reclined over to the thinner side; which now, sustaining the greatest share of the weight, must still be more compressed, consequently hindered from extending itself in proportion to the other side, which, being too much freed of its burden, has liberty to enjoy a luxuriant growth. The causes, on which such an inequality of thickness in different sides of the vertebrae depends, may vary. For either it may be owing to an over-distension of the vessels of one side, and from thence a preternatural increase of the thickness of that part: or, which is more commonly the case, it may proceed from an obstruction of the vessels, by which the application of proper nourishment to the bony substance is hindered; whether that obstruction depends on the faulty disposition of the vessels or fluids, or if it is produced by an unequal mechanical pressure occasioned by a paralytic weakness of the muscles and ligaments, or by a spasmodic over-action of the muscles on any side of the spine, or by people continuing long, or putting themselves frequently, into any posture declining from the erect one. In all these cases one common effect follows, to wit, the vertebrae, or their cartilages, or both, turn thick on that side where the vessels are free, and remain thin on the other side where these vessels are straitened or obstructed. When once we understand how these crooked spines are produced, there is little difficulty in forming a just prognosis; and a proper method of cure may be easily contrived, which must vary as to the internal medicines, according to the different causes on which the disease depends. But one general indication must be pursued by surgeons; which is, to counteract the bending force, by increasing the compression on the convex part of the curvature, and diminishing it on the concave side. The manner of executing which in particular

cular cases must be different, and requires a very accurate examination of the circumstances both of the disease and patient.

Though the true vertebræ agree in the general structure above described; yet, because of several specialties proper to a particular number, they are commonly divided into three classes, viz. *cervical*, *dorsal*, and *lumbar*. The *cervical* are the seven uppermost vertebræ; which are distinguished from the rest by these marks: Their bodies are smaller and more solid than any others; and flattened on the fore-part, to make way for the œsophagus; or rather this flat figure is owing to the pressure of that pipe, and to the action of the longi colli and anterior recti muscles. They are also flat behind, where small processes rise, to which the internal ligaments are fixed. The transverse processes of these vertebræ are framed in a different manner from those of any other bones of the spine. For, besides the common transverse process rising from between the oblique processes of each side, there is a second one that comes out from the side of the body of each vertebra; and these two processes, after leaving a circular hole for the passage of the cervical artery and vein, unite, and are considerably hollowed at their upper part, with rising sides, to protect the nerves that pass in the hollow; and at last each side terminates in an obtuse point, for the insertion of muscles. The spinal processes of these cervical bones stand nearly straight backwards, are shorter than those of any other vertebræ, and are forked or double at their ends; and hence allow a more convenient insertion to muscles.

The cervical vertebræ have some particular differences, which oblige us to consider them separately. The first, from its use of supporting the head, has the name of *atlas*; and is also called *epistrophe*, from the motion it performs on the second. The atlas, contrary to all the other vertebræ of the spine, has no body; but, instead of it, there is a bony arch. In the convex fore-part of this arch a small rising appears, where the musculus longi colli are inserted; and, on each side of this protuberance, a small cavity may be observed, where the recti interni minores take their rise. The upper and lower parts are rough and unequal, where the ligaments that connect this vertebra to the os occipitis, and to the second vertebra, are fixed. The back-part of the arch is concave, smooth, and covered with a cartilage, in a recent subject, to receive the tooth-like process of the second vertebra.

The superior oblique process of this atlas are large, oblong, hollow, and more horizontal than in any other vertebra. They rise more in their external than internal brim; by which their articulations with the condyloid processes of the os occipitis are firmer. Under the external edge of each of these oblique processes is the fossa, or deep open channel, in which the vertebral arteries make the circular turn, as they are about to enter the great foramen of the occipital bone, and where the tenth pair of nerves go out. The inferior oblique processes, extending from within outwards and downwards, are large, concave, and circular. So that this vertebra, contrary to the other six, receives the bones with which it is articulated, both above and below.

The second vertebra colli is called *dentata*, from the tooth-like process on the upper part of its body. Some authors call it *epistrophe*; but improperly, since this designation is only applicable to the first, which moves on this as on an axis. The body of this vertebra is somewhat of a pyramidal figure, being large, and produced downwards, especially at its fore-side, to enter into a hollow of the vertebra below; while the upper part has a square process, with a small point standing out from it. A ligament likewise goes out in an oblique transverse direction, from each side of the processus dentatus, to be fixed at its other end to the first vertebra, and to the occipital bone; and another ligament rises up from near the point of the process to the os occipitis. The superior oblique processes of this vertebra are large, circular, very nearly in an horizon-

tal position, and slightly convex, to be adapted to the inferior oblique processes of the first vertebra. The inferior oblique processes of this vertebra answer exactly to the description given of those common to all the cervical vertebræ.

The transverse processes of the vertebra dentata are short, very little hollowed at their upper part, and not forked at their ends; and the canals through which the cervical arteries pass are reflected outwards about the middle substance of each process; so that the course of these vessels may be directed towards the transverse processes of the first vertebra. Had this curvature of the arteries been made in a part so moveable as the neck is, while they were not defended by a bone, and fixed to that bone, scarcely a motion could have been performed without the utmost hazard of compression, and a stop put to the course of the liquids, with all its train of bad consequences. Hence we observe this same mechanism several times used, when there is occasion for a sudden curvature of a large artery. The spinal process of this vertebra dentata is thick, strong, and short, to give sufficient origin to the musculus recti majores and obliqui inferiores, and to prevent the contusion of these and other muscles in pulling the head back. This second vertebra consists, at the birth, of four bony pieces. For, besides the three already mentioned as common to all the vertebræ, the tooth-like process of this bone is begun at this time to be ossified in its middle, and is joined as an appendix to the body of the bone. Left this appendix bent or displaced, good nurses keep the heads of new-born children from falling too far backwards, by stay-bands, or some such means, till the muscles attain strength sufficient to prevent that dangerous motion.

The third vertebra of the neck is by some called *axis*; but this name is applied to it with much less reason than to the second. This third, and the three below, have nothing particular in their structure, but all their parts come under the general description formerly given, each of them being larger as they descend. The seventh vertebra of the neck is near to the form of those of the back, having the upper and lower surfaces of its body less hollow than the others. The oblique processes are more perpendicular; neither spinal nor transverse processes are forked. This seventh and the sixth vertebra of the neck have the hole in each of their transverse processes more frequently divided by a small cross bridge, that goes between the cervical vein and artery, than any of the other vertebræ.

The twelve *dorsal* may be distinguished from the other vertebræ of the spine by the following marks: Their bodies are of a middle size, between those of the neck and loins; they are more convex before than either of the other two sorts; and are flattened laterally by the pressure of the ribs, which are inserted into small cavities formed in their sides. This flatness of their sides, which makes the figure of these vertebræ almost an half oval, is of great use; as it affords a firm articulation to the ribs, allows the trachea arteria to divide at a small angle, and the other large vessels to run secure from the action of the vital organs. Their bodies are more concave behind than any of the other two classes. Their upper and lower surfaces are horizontal. The cartilages interposed between the bodies of these vertebræ are thinner than in any other of the true vertebræ; and contribute to the concavity of the spine in the thorax, by being thinnest at their fore-part. The oblique processes are placed almost perpendicularly; the upper ones slanting but a little forwards, and the lower ones slanting as much backwards. Between the oblique processes of opposite sides, several sharp processes stand out from the upper and lower parts of the plates which join to form the spinal processes; into these, strong ligaments are fixed for connecting the vertebræ. The transverse processes of the dorsal vertebræ are long, thicker at their ends than in the middle, and turned obliquely backwards; which may be owing to the pressure of the ribs, the tubercles of which are inserted into a depression near the end of these processes.

ses. The spinal processes are long, small-pointed, and sloping downwards and backwards: from their upper and back part a ridge rises, which is received by a small channel in the fore-part of the spinal process immediately above, which is here connected to it by a ligament. The conduit of the spinal marrow is here more circular, but, corresponding to the size of that cord, is smaller than in any of the other vertebrae; and a larger share of the holes in the bony bridges, for the transmission of the nerves, is formed in the vertebra above than in one below. The connection of the dorsal vertebrae to the ribs, the thinness of their cartilages, the erect situation of the oblique processes, the length, sloping, and connection, of the spinal processes, all contribute to restrain these vertebrae from much motion, which might disturb the actions of the heart and lungs; and, in consequence of the little motion allowed here, the intervertebral cartilages sooner shrivel, by becoming more solid; and therefore the first remarkable curvature of the spine observed, as people advance to old age, is in the least stretched vertebrae of the back; or old people first become round shouldered.

The lowest order of the true vertebrae is the *lumbar*, which are five bones, that may be distinguished from any other by these marks: 1. Their bodies, though of a circular form at their fore-part, are somewhat oblong from one side to the other; which may be occasioned by the pressure of the large vessels, the aorta and cava, and of the viscera. The epiphyses on their edges are larger; and therefore the upper and lower surfaces of their bodies are more concave than in the vertebrae of the back. 2. The cartilages between these vertebrae are much the thickest of any, and render the spine convex within the abdomen, by their greatest thickness being at their fore-part. 3. The oblique processes are strong and deep; those in opposite sides being almost placed in parallel planes; the superior, which are concave, facing inwards, and the convex inferior ones facing outwards. And therefore each of these vertebrae receives the one above it, and is received by the one below; which is not so evident in the other two classes already described. 4. Their transverse processes are small, long, and almost erect, for allowing large motion to each bone, and sufficient insertion to muscles, and for supporting and defending the internal parts. 5. Between the roots of the superior oblique and transverse processes a small protuberance may be observed, where some of the muscles that raise the trunk of the body are inserted. 6. Their spinal processes are strong, straight, and horizontal, with broad flat sides, and a narrow edge above and below; this last being depressed on each side by muscles. And at the root of these edges, we see rough surfaces for fixing the ligaments. 7. The canal for the numerous cords called *cauda equina*, into which the spinal marrow divides, is rather larger in these bones than what contains that marrow in the vertebrae of the back. 8. The holes for the passage of the nerves are more equally formed out of both the contiguous vertebrae than in the other classes; the upper one furnishes, however, the larger share of each hole. The lumbar vertebrae, as they descend, have their oblique processes at a greater distance from each other, and facing more backwards and forwards. Both transverse and spinal processes of the middlemost vertebrae of the loins are longest and thickest; in the vertebrae above and below, they are less. So that these processes of the first and fifth are the least, to prevent their striking on the ribs or os ilium, or their bruising the muscles in the motions of the spine. The epiphyses round the edges of the bodies of the lumbar vertebrae are most raised in the two lowest; which consequently make them appear hollower in the middle than the others are. The body of the fifth vertebra is rather thinner than that of the fourth. The spinal process of this fifth is smaller, and the oblique processes face more backwards and forwards than in any other lumbar vertebra. After considering the structure of the particular vertebrae, and their mutual connection, we may observe a solicitous care taken that they shall not be disjoined without

great difficulty. For, besides being connected by strong ligaments proportioned to the forces which are to be resisted, their bodies either enter so into each other as to prevent their being displaced any way, as in the vertebrae of the neck; or they are propped on all sides, as those of the back are by the ribs; or their surfaces of contact are so broad, as to render the separation almost impracticable, as in the loins: while the depth and articulation of the oblique processes are exactly proportioned to the quantity of motion which the other parts of the bones allow, or the muscles can perform. Yet as these oblique processes are small, and therefore not capable of so secure a conjunction as the larger bodies, they may sooner yield to a disjoining force; but then their dislocation is not of so near bad consequence as the separation of the bodies would be: for, by the oblique processes being dislocated, the muscles, ligaments, and spinal marrow, are indeed stretched; but this marrow must be compressed, or entirely destroyed, when the body of the vertebra is removed out of its place.

The *false vertebrae* compose the under pyramid of the spine. They are distinguished from the bones already described justly enough by the epithet of false; because, though each bone into which they can be divided in young people resembles the true vertebrae in figure, yet none of them contribute to the motion of the trunk of the body; they being intimately united to each other in adults, except at their lower part, where they are moveable; whence they are commonly divided into two bones, *os sacrum* and *os coccygis*.

Os sacrum, is so called, from being offered in sacrifice by the ancients, or rather because of its largeness in respect of the other vertebrae. This bone is of an irregular triangular shape, broad above, narrow below; convex behind, for the advantageous origin of the muscles that move the spine and thigh backwards; and concave before, for enlarging the cavity of the pelvis. Four transverse lines, of a colour different from the rest of the bone which are seen on its fore-part, are the marks of division of the five different bones of which it consists in young persons. The fore-part of the *os sacrum*, analogous to the bodies of the true vertebrae, is smooth and flat, to allow a larger space for the contained bowels, without any danger of hurting them; or this flat figure may be owing to the equal pressure of these bowels, particularly of the last gut. The back-part of it is almost straight, without so large a cavity as the vertebrae have; because the spinal marrow, now separated into the *cauda equina*, is small. The bridges between the bodies and processes of this bone are much thicker, and in proportion shorter, than in the former class of bones.

There are only two oblique processes of the *os sacrum*; one standing out on each side from the upper part of the first bone. Their plain erect surfaces face backwards, and are articulated with the inferior oblique processes of the last vertebra of the loins, to which each of these processes is connected by a strong ligament, which rises from a scabrous cavity round their roots, where mucilaginous glands are also lodged. Instead of the other oblique processes of this bone, four rough tubercles are to be seen on each side of its surface behind, from which the *musculus sacri* has its origin. The transverse processes here are all grown together into one large strong oblong process on each side; which, so far as it answers to the first three bones, is very thick, and divided into two irregular cavities by a long perpendicular ridge. The foremost of the two cavities has commonly a thin cartilaginous skin covering it in the recent subject, and is adapted to the unequal protuberance of the *os ilium*; and a strong ligament connects the circumference of these surfaces of the two bones. The cavity behind is divided by a transverse ridge into two, where strong ligamentous strings that go from this bone to the *os ilium*, with a cellular substance containing mucus, are lodged. The transverse processes of the two last bones of the *os sacrum* are much smaller than the former. At their back-part near their edge, a knob and oblong flat surface

give rise to two strong ligaments which are extended to the os ischium; and are therefore called *sacrociatic*.

The spinal processes of the three uppermost bones of the os sacrum appear short, sharp, and almost erect, while the two lower ones are open behind; and sometimes a little knob is to be seen on the fourth, though generally it is bifurcated, without the two legs meeting into a spine; in which condition also the first is often to be seen; and sometimes none of them meet, but leave a sinus, or rather fossa, instead of a canal. The *musculus latissimus* and *longissimus dorsi*, *sacro-lumbalis*, and *glutæus maximus*, have part of their origins from these spinal processes. At the root of each oblique process of this bone, the notch is conspicuous; by which, and another similar one in the last vertebra of the loins, a passage is left for the twenty-fourth spinal nerve; and, in viewing the os sacrum, either before or behind, four large holes appear in each side, in much the same height as where the marks of the union of its several bones remain. Some of the largest nerves of the body pass through the anterior holes; and superficial grooves, running outwards from them in different directions, shew the course of these nerves. From the intervals of these grooves, the *pyriformis* muscle chiefly rises. The holes in the back-part of the bone are covered by membranes which allow small nerves to pass through them.

The substance of the os sacrum is very spongy, without any considerable solid external plates, and is lighter proportionally to its bulk than any other bone in the body; but it is secured from injuries by the thick muscles that cover it behind, and by the strong ligamentous membranes that closely adhere to it. As this is one of the most remarkable instances of this sort of defence afforded a soft weak bone, we may make this general observation: That, wherever we meet with such a bone, one or other or both these defences are used; the first to ward off injuries, and the second to keep the substance of the bone from yielding too easily. This bone is articulated above to the last vertebra of the loins, in the manner that the lumbar vertebrae are joined. The articulation of the lower-part of the os sacrum to the os coccygis, seems well enough adapted for allowing considerable motion to this last bone, were it not much confined by ligaments. Laterally, the os sacrum is joined to the *os ilium* by an immoveable *synchondrosis*, or what almost deserves the name of a suture. For the cartilaginous crust on the surface of the bones is very thin; and both their surfaces are so scabrous and unequal, as to be indented into each other; which makes such a strong connection, that great force is required to separate them, after all the muscles and ligaments are cut. Frequently the two bones grow together in old people. The uses of the os sacrum are, to serve as the common base and support of the trunk of the body, to guard the nerves proceeding from the end of the spinal marrow, to defend the back-part of the pelvis, and to afford sufficient origin to the muscles which move the trunk and thigh.

The *os coccygis*, or *rump-bone*, is that triangular chain of bones depending from the os sacrum; each bone becoming smaller as they descend, till the last ends almost in a point. The os coccygis is convex behind, and concave before; from which crooked pyramidal figure, which was thought to resemble a cuckow's beak, it has got its name. This bone consists of four pieces in people of middle age. In children, almost the whole of it is cartilage. In old subjects, all the bones are united, and become frequently one continued bone with the os sacrum. The highest of the four bones is the largest, with shoulders extended farther to each side than the end of the os sacrum. From the back of that bulbous part, called its shoulders, a process often rises up on each side, to join with the bifurcated spine of the fourth and fifth bones of the os sacrum, to form the bony bridge mentioned in the description of the os sacrum. Sometimes these shoulders are joined to the sides of the fifth bone of the os sacrum, to form the hole in each side common to these two bones, for the passage of the twenty-ninth pair of spinal nerves. Immediately

below the shoulders of the os coccygis, a notch may be remarked on each side, where the thirtieth pair of the spinal nerves passes.

The three lower bones gradually become smaller, and are spongy; but are strengthened by a strong ligament which covers and connects them. Their ends, by which they are articulated, are formed in the same manner as those of the first bone. To the sides of these bones the *coccygæi* muscles, and part of the *levatoris ani*, and of the *glutæi maximi*, are fixed. The substance of these bones is very spongy, and in children cartilaginous; there being only a part of the first bone ossified in a new-born infant. Since therefore the *intestinum rectum* of children is not so firmly supported as it is in adults, this may be one reason why they are more subject to a *proctidentia ani* than old people. From the description of this bone, we see how little it resembles the vertebrae; since it seldom has processes, never has any cavity for the spinal marrow, nor holes for the passage of nerves. Its connection hinders it from being moved to either side; and its motion backwards and forwards is much confined: yet, as its ligaments can be stretched by a considerable force, it is of great advantage in the excretion of the *fæces alvinæ*, and much more in child-bearing, that this bone should remain moveable; and the right management of it, in delivering women, may be of great benefit to them. The mobility of the os coccygis diminishing as people advance in age, especially when its ligaments and cartilages have not been kept flexible by being stretched, is probably one reason why the women, who are old maids before they marry, have generally difficult parturition.

The second part of the trunk of the skeleton, viz. the *pelvis*, is the cylindrical cavity at the lower part of the abdomen formed by the os sacrum, os coccygis, and *os innominata*. The *os innominata* are two large broad bones, which form the fore-part and sides of the pelvis, and the lower part of the sides of the abdomen. In children, each of these bones is evidently divided into three; which are afterwards so intimately united, that hardly the least mark of their former separation remains. They are nevertheless described as consisting each of three bones, viz. the *os ilium*, *ischium*, and *pubis*.

The *os ilium*, or *haunch-bone*, is situated highest of the three, and reaches as far down as one third of the great cavity into which the head of the thigh-bone is received. The external side of this bone is unequally convex, and is called its *dorsum*; the internal concave surface is by some authors (but improperly) named its *costa*. The semicircular edge at the highest part of this bone, which is tipped with a cartilage in the recent subject, is named the *spine*, into which the external or descending oblique muscle of the abdomen is inserted; and from it the internal ascending oblique, and the transverse muscles of the belly, with the *glutæus maximus*, *quadratus lumborum*, and *latissimus dorsi*, have their origin. From the anterior spinal process, the *sartorius* and *fascialis* muscles have their rise, and the outer end of the doubled tendon of the external oblique muscle of the abdomen, commonly called *Fallopian's* or *Poupart's* ligament, is fixed to it. The inside of the posterior spinal process, and of part of the spine forward from that, is made flat and rough where the *sacro-lumbalis* and *longissimus dorsi* rise; and to its outside are fixed ligaments extended to the os sacrum and transverse processes of the fifth and fourth vertebrae of the loins. Between the sides of the os ilium, and the strong ligament that is stretched over from the os sacrum to the sharp-pointed process of the os ischium of the recent subject, a large hole is formed, through which the *musculus pyriformis*, the great sciatic nerve, and the posterior crural vessels, pass, and are protected from compression.

The external broad side or *dorsum* of the os ilium, is a little hollow towards the fore-part; farther back, it is as much raised; then is considerably concave; and, lastly, it is convex. These inequalities are occasioned by the actions of the muscles that are situated on this surface.

From behind the uppermost of the two anterior spinal processes, in such bones as are strongly marked by the muscles, a semicircular ridge is extended to the hollow passage of the sciatic nerve. Between the spine and this ridge, the glutæus medius takes its rise. Immediately from above the lowest of the anterior spinal processes, a second ridge is stretched to the niche. Between this and the former ridge, the glutæus minimus has its origin. On the outside of the posterior spinal processes, the dorsum of the os ilium is flat and rough, where part of the musculus glutæus maximus and pyriformis rises. The internal surface of the os ilium is concave in its broadest fore-part, where the internal iliac muscle has its origin, and where some share of the intestinum ilium and colon is lodged. From this large hollow, a small sinuosity is continued obliquely forwards, at the inside of the inferior spinal process, where part of the psoas and iliacus muscles, with the crural vessels and nerves, pass. The large concavity is bounded below by a sharp ridge, which runs from behind forwards; and, being continued with such another ridge of the os pubis, forms a line of partition between the abdomen and pelvis. Into this ridge the broad tendon of the psoas parvus is inserted.

The *os ischium*, or *hip-bone*, is of a middle bulk between the two other parts of the os innominatum, is situated lowest of the three, and is of a very irregular figure. Its extent might be marked by a horizontal line drawn nearly through the middle of the acetabulum. From the upper thick part of the os ischium, a sharp process, called by some authors *spinous*, stands out backwards, from which chiefly the musculus coccygæus and superior gemellus, and part of the levator ani, rise; and the anterior or internal sacrosciatic ligament is fixed to it. Between the upper part of this ligament and the bones, it was formerly observed that the pyriform muscle, the posterior crural vessels, and the sciatic nerve, pass out of the pelvis. Immediately below this process, a sinuosity is formed for the tendon of the musculus obturator internus. Below the sinuosity for the obturator muscle, is the great knob or tuberosity, covered with cartilage or tendon. The upper part of the tuberosity gives rise to the inferior gemellus muscle. To a ridge at the inside of this the external or posterior sacrosciatic ligament is so fixed, that between it, the internal ligament, and the sinuosity of the os ischium, a passage is left for the internal obturator muscle. The upper thick smooth part of the *tuber*, called by some its *dorsum*, has two oblique impressions on it. The inner one gives origin to the long head of the biceps flexor tibiæ, and feminovus muscles; and the semimembranosus rises from the exterior one, which reaches higher and nearer the acetabulum than the other. The lower, thinner, more scabrous, part of the knob which bends forwards, is also marked with two flat surfaces; whereof the internal is what we lean upon in sitting, and the external gives rise to the largest head of the triceps adductor femoris. Between the external margin of the tuberosity and the great hole of the os innominatum, there is frequently an obtuse ridge extended down from the acetabulum, which gives origin to the quadratus femoris. As the tuber advances forwards, it becomes smaller, and is rough, for the origin of the musculus transversalis and erector penis. The small leg of it, which mounts upwards to join the os pubis, is rough and prominent at its edge, where the two lower heads of the triceps or quadriceps adductor femoris take their rise.

The *os pubis*, or *share-bone*, is the least of the three parts of the os innominatum, and is placed at the upper fore-part of it. The thick largest part of this bone is employed in forming the acetabulum; from which, becoming much smaller, it is stretched inwards to its fellow of the other side, where it again grows larger, and sends a small branch downwards to join the end of the small leg of the os ischium. The upper fore-part of each os pubis is tuberculous and rough where the musculus rectus and pyramidalis are inserted. From this a ridge is extended along

the upper edge of the bone, in a continued line with such another of the os ilium, which divides the abdomen and pelvis. The ligament of Fallopius is fixed to the internal end of this ridge, and the smooth hollow below it is made by the psoas and iliacus internus muscles passing with the anterior crural vessels and nerves behind the ligament. Some way below the former ridge, another is extended from the tuberculous part of the os pubis downwards and outwards towards the acetabulum; between these two ridges the bone is hollow and smooth, for lodging the head of the pectineus muscle.

Between the os ischium and pubis a very large irregular hole is left, which, from its resemblance to a door or shield, has been called *thyroides*. This hole is filled up, in a recent subject, with a strong ligamentous membrane, that adheres very firmly to its circumference. From this membrane chiefly the two obturator muscles, external and internal, take their rise. The great design of this hole, besides rendering the bone lighter, is to allow a strong origin to the obturator muscles. The bowels sometimes make their way through the niche at the upper part of this thyroid hole; which causes a hernia in this place.

In the external surface of the ossa innominata, near the outside of the great hole, a large deep cavity is formed by all the three bones conjunctly. The brims of this cavity are very high, and are still much more enlarged by the ligamentous cartilage, with which they are tipped in a recent subject. From this form of the cavity it has been called *acetabulum*; and for a distinguishing character the name of the bone that constitutes the largest share of it is added: therefore *acetabulum ossis ischii* is the name this cavity commonly bears. Round the base of the supercilia the bone is rough and unequal, where the capsular ligament of the articulation is fixed. Besides the difference in the height of the brims, the acetabulum is otherwise unequal; for the lower internal part of it is depressed below the cartilaginous surface of the upper part, and is not covered with cartilage; into the upper part of this depression, where it is deepest and of a semilunar form, the ligament of the thigh-bone, commonly, though improperly called the *round* one, is inserted; while, in its more superficial lower part, the large mucilaginous gland of this joint is lodged.

The *ossa innominata* are joined at their back-part to each side of the os sacrum by a sort of suture, with a very thin intervening cartilage, which serves as so much glue to cement those bones together; and strong ligaments go from the circumference of this unequal surface, to connect them more firmly. The ossa innominata are connected together at their fore-part by the ligamentous cartilage interposed between the two ossa pubis. These bones can therefore have no motion in a natural state, except what is common to the trunk of the body, or to the os sacrum.

Thus the pelvis has a large cavity above where it is continued with the abdomen; is strongly fenced by bones on the sides, back, and fore part; and appears with a wide opening below, in the skeleton; but, in a recent subject, a considerable part of the opening is filled by the sacrosciatic ligaments, pyriform, internal obturator, levatores ani, gemini, and coccygæi muscles, which support and protect the contained parts better than bones could have done; so that space is only left at the lowest part of it, for the large excretories, the vesica urinaria, intestinum rectum, and in females the uterus, to discharge themselves.

The *thorax*, or *chest*, reaches from below the neck to the belly; and, by means of the bones that guard it, is formed into a large cavity. The figure of it is somewhat conoidal: but its upper smaller end is not finished, being left open for the passage of the wind-pipe, gullet, and large blood-vessels; and its lower part or base, has no bones, and is shorter before than behind. The bones which form the thorax are the twelve dorsal vertebrae behind, already described; the ribs on the sides, and the sternum before.

The *ribs*, or *costæ*, (as if they were *cylinders*, or guards, to those principal organs of the animal machine, the heart

and lungs,) are the long crooked bones placed at the side of the chest, in an oblique direction downwards in respect of the back-bone. Their number is generally twelve on each side; though frequently eleven or thirteen have been found. Sometimes the ribs are found preternaturally joined or divided. The ribs are all concave internally; where they are also made smooth by the action of the contained parts, which, on this account, are in no danger of being hurt by them; and they are convex externally, that they might resist that part of the pressure of the atmosphere which is not balanced by the air within the lungs during *inspiration*. The ends of the ribs next the vertebrae are rounder than they are after these bones have advanced forwards, when they become flatter and broader, and have an upper and lower edge; each of which is made rough by the action of the intercostal muscles inserted into them. These muscles, being all of nearly equal force, and equally stretched in the interstices of the ribs, prevent the broken ends of these bones, in a fracture, from being removed far out of their natural place, to interrupt the motion of the vital organs. The upper edge of the ribs is more obtuse and rounder than the lower, which is depressed on its internal side by a long fossa, for lodging the intercostal vessels and nerves; on each side of which there is a ridge, where the intercostal muscles are fixed. The fossa is not observable, however, at either end of the ribs; for, at the posterior or root, the vessels have not yet reached the ribs; and, at the fore-end, they are split away into branches, to serve the parts between the ribs: which plainly teaches surgeons one reason of the greater safety of performing the operation of the empyema towards the sides of the thorax, than either near the back or the breast.

At the posterior end of each rib, a little head is formed, which is divided by a middle ridge into two plain or hollow surfaces; the lowest of which is the broadest and deepest in most of them. The two plains are joined to the bodies of two different vertebrae, and the ridge forces itself into the intervening cartilage. A little way from this head, we find on the external surface a small cavity, where mucilaginous glands are lodged; and, round the head, the bone appears spongy, where the capsular ligament of the articulation is fixed. Immediately beyond this a flattened tubercle rises, with a small cavity at, and roughness about, its root, for the articulation of the rib with the transverse process of the lowest of the two vertebrae, with the bodies of which the head of the rib is joined. Advancing farther on this external surface, we observe in most of the ribs another smaller tubercle, into which ligaments connecting the ribs to each other, and to the transverse processes of the vertebrae and portions of the longissimus dorsi, are inserted. Beyond this the ribs are made flat by the sacro-lumbalis muscle, which is inserted into the part of this flat surface farthest from the spine, where each rib makes a considerable curve, called by some its *angle*. Then the rib begins to turn broad, and continues so to its anterior end, which is hollow and spongy, for the reception of, and firm coalition with, the cartilage that runs thence to be inserted into the sternum, or to be joined with some other cartilage.

To the fore-end of each rib a long, broad, and strong, cartilage is fixed, and reaches thence to the sternum, or is joined to the cartilage of the next rib. This course, however, is not in a straight line with the rib: for the cartilages generally make a considerable curve, the concave part of which is upwards; therefore, at their insertion into the sternum, they make an obtuse angle above, and an acute one below. These cartilages are of such a length as never to allow the ribs to come to a right angle with the spine; but they keep them situated so obliquely as to make the angle very considerably obtuse above, till a force exceeding the elasticity of the cartilage is applied. These cartilages, as all others, are firmer and harder internally than they are on their external surface; and sometimes in old people all their middle substance becomes bony, while a thin cartilaginous lamella appears externally. The of-

fification, however, begins frequently at the external surface. The greatest alternate motions of the cartilages, being made at their great curvature, that part remains frequently cartilaginous after all the rest is ossified.

The ribs then are *articulated* at each end, of which the one behind is doubly joined to the vertebrae; for the head is received into the cavities of two bodies of the vertebrae, and the larger tubercle is received into the depression in the transverse process of the lower vertebra. When we examine the double articulation, we must immediately see that no other motion can be allowed here than upwards and downwards; since the transverse process hinders the rib to be thrust back; the resistance on the other side of the sternum prevents the ribs coming forward; and each of the two joints, with the other parts attached, oppose its turning round. But then it is likewise as evident, that even the motion upwards and downwards can be but small in any one rib at the articulation itself. But, as the ribs advance forwards, the distance from their centre of motion increasing, the motion must be larger; and it would be very conspicuous at their anterior ends, were they not resisted there by the cartilages, which yield so little, that the principal motion is performed by the middle part of the ribs, which turns outwards and upwards, and occasions the twist remarkable in the long ribs at the place near their fore-end where they are most resisted.

The ribs are commonly divided into *true* and *false*. The *true* costae are the seven upper ones of each side, whose cartilages are all gradually longer as the ribs descend, and are joined to the breast-bone: so that, being pressed constantly between two bones, they are flattened at both ends; and are thicker, harder, and more liable to ossify, than the other cartilages that are not subject to so much pressure. These ribs include the heart and lungs; and therefore are the proper or true *custodes* of life. The five inferior ribs of each side are the *false* or *bastard*, whose cartilages do not reach to the sternum; and therefore, wanting the resistance at their fore-part, they are pointed; and, on this account, having less pressure, their substance is softer. The cartilages of these false ribs are shorter as the ribs descend. To all these five ribs the circular edge of the diaphragm is connected; and its fibres, instead of being stretched immediately transversely, and so running perpendicular to the ribs, are pressed so as to be often, especially in expiration, parallel to the plane in which the ribs lie. Nay, one may judge by the attachments which these fibres have so frequently to the sides of the thorax a considerable way above where their extremities are inserted into the ribs, and by the situation of the viscera always to be observed in a dead subject laid supine, that there is constantly a large concavity formed on each side by the diaphragm within these bastard ribs, in which the stomach, liver, spleen, &c. are contained; which, being only reckoned among the viscera naturalia, have occasioned the name of *bastard custodes* to these bones. Hence, in simple fractures of the false ribs, without fever, the stomach ought to be kept moderately filled with food, lest the pendulous ribs, falling inwards, should thereby increase the pain, cough, &c. Hence likewise we may learn how to judge better of the seat of several diseases, and to perform the operation of the empyema, and some others, with more safety than we can do if we follow the common practice.

The eight upper ribs were formerly classed into pairs, with particular names to each two, viz. the *crooked*, the *solid*, the *pectoral*, and the *twisted*. But these names are of so little use, that they are now almost obsolete. The first rib of each side is so situated, that the flat sides are above and below, while one edge is placed inwards and the other outwards, or nearly so; therefore sufficient space is left above it for the subclavian vessels and muscles; and the broad concave surface is opposed to the lungs. But then, in consequence of this situation, the channel for the intercostal vessels is not to be found; and the edges are differently formed from all the other, except the second; the lower one being rounded, and the other sharp. The head, of

of this rib is not divided into two plain surfaces by a middle ridge, because it is only articulated with the first vertebra of the thorax. Its cartilage is ossified in adults, and is united to the sternum at right angles. This first rib frequently has a ridge rising near the middle of its posterior edge, where one of the heads of the scalenus muscles rises. Farther forward it is flattened, or sometimes depressed by the clavicle. The fifth, sixth, and seventh, or rather the sixth, seventh, eighth, and sometimes the fifth, sixth, seventh, eighth, and ninth, ribs, have their cartilages at least contiguous: and they are frequently joined to each other by cross cartilages; and most commonly the cartilages of the eighth, ninth, and tenth, are connected to the former and to each other by firm ligaments. The eleventh, and sometimes the tenth, rib, has no tubercle for its articulation with the transverse process of the vertebra, to which it is only loosely fixed by ligaments. The fossa in its lower edge is not so deep as in the upper ribs, because the vessels run more towards the interstice between the ribs. Its fore-end is smaller than its body, and its short small cartilage is but loosely connected to the cartilage of the rib above. The twelfth rib is the shortest and straightest. Its head is only articulated with the last vertebra of the thorax; therefore it is not divided into two surfaces. To its whole internal side the diaphragm is connected.

The *sternum*, or *breast-bone*, is the broad flat bone, or pile of bones, at the fore-part of the thorax. The number of bones into which this should be divided, has occasioned debates among anatomists, who have considered it in subjects of different ages. In adults of a middle age, it is composed of three bones, which easily separate after the cartilages connecting them are destroyed. The two lower bones are frequently found intimately united; and very often, in old people, the sternum is a continued bony substance from one end to the other; though we still observe two, sometimes three, transverse lines on its surface; which are marks of the former divisions. When we consider the sternum as one bone, we find it broadest and thickest above, and becoming smaller as it descends. The internal surface is somewhat hollowed for enlarging the thorax: but the convexity on the external surface is not so conspicuous, because the sides are pressed outwards by the true ribs; the round heads of whose cartilages are received into seven smooth pits formed in each side of the sternum, and are kept firm there by strong ligaments, which on the external surface have a particular radiated texture. The cartilaginous fibres frequently thrust themselves into the bony substance of the sternum, and are joined by a sort of future. The pits at the upper-part of the sternum are at the greatest distance one from another, and, as they descend, are nearer; so that the two lowest are contiguous.

The *substance* of the breast-bone is cellular, with a very thin external plate, especially on its internal surface, where we may frequently observe a cartilaginous crust spread over it. On both surfaces, however, a strong ligamentous membrane is closely braced; and the cells of this bone are so small, that a considerable quantity of osseous fibres must be employed in the composition of it. Whence, with the defence which the muscles give it, and the moveable support it has from the cartilages, it is sufficiently secured from being broken; for it is strong by its quantity of bone, its parts are kept together by ligaments, and it yields enough to elude considerably any violence offered.

The sternum is *joined* by cartilages to the seven upper ribs, unless when the first coalesces with it in an intimate union of substance; and its unequal cavity on each side of its upper end is fitted for the ends of the clavicles. The *uses* of this bone are, to afford origin and insertion to several muscles; to sustain the mediastinum: to defend the vital organs, the heart and lungs, at the fore-part; and, lastly, by serving as a moveable fulcrum of the ribs, to assist considerably in respiration.

Authors are much divided in their opinions about the number of bones of which each superior extremity should be said to consist; some describing the clavicle and scapula as part of it, others classing these two bones with those of the thorax; but since most quadrupeds have no clavicles, and the human thorax can perform its functions right when the scapula is taken away, while it is impossible for us to have the right use of our arms without these bones, it seems evident that they belong to the superior extremities. Each of the superior extremities may be divided into the shoulder, arm, fore-arm, and hand.

The *shoulder* consists of the *clavicle* and the *scapula*. The *clavicle*, or *collar-bone*, is the long crooked bone placed almost horizontally between the upper lateral part of the sternum and what is commonly called the top of the shoulder; which, as a clavis or beam, bears off from the trunk of the body. The clavicle is larger at its two ends than in the middle. The end next to the sternum is triangular: the angle behind is considerably protruded, to form a sharp ridge, to which the transverse ligament, extended from one clavicle to the other, is fixed. The middle of this protuberant end is as irregularly hollowed as the cavity in the sternum for receiving it is raised; but, in a recent subject, the irregular concavities of both are supplied by a moveable cartilage; which is not only much more closely connected by ligaments to the circumference of the articulation than those of the lower jaw are, but it grows to the two bones at their internal and external ends; its substance at the external end being soft, but very strong, and resembling the intervertebral cartilages. From this internal end, the clavicle, for about two-fifths of its length, is bended obliquely forwards and downwards. On the upper and fore-part of this curvature a small ridge is seen, with a plain rough surface before it; whence the *musculus sterno-hyoideus* and *sterno-mastoideus* have in part their origin. Near the lower angle a small plain surface is often to be remarked, where the first rib and this bone are contiguous, and are connected by a firm ligament. From this a rough plain surface is extended outwards, where the pectoral muscle has part of its origin. Behind, the bone is made flat and rough by the insertion of the larger share of the *subclavian muscle*. After the clavicle begins to be bent backwards, it is round; but it soon after becomes broad and thin, which shape it retains to its external end. Along the external concavity, a rough sinusity runs, from which some part of the *deltoid muscle* takes its rise; opposite to this, on the convex edge, a scabrous ridge gives insertion to a share of the *cucullaris muscle*. The upper surface of the clavicle is here flat; but the lower is hollow, for lodging the beginning of the *musculus subclavius*; and towards its back part a tubercle rises; to which, and to a roughness near it, the strong short thick ligament, connecting this bone to the coracoid process of the scapula, is fixed. The external end of this bone is horizontally oblong, smooth, sloping at the posterior side, and tipped, in a recent subject, with a cartilage, for its articulation with the *acromion scapulæ*. Round this the bone is spongy, for the firmer connection of the ligaments. The medullary arteries, having their direction obliquely outwards, enter the clavicles by one or more small passages in the middle of their back-part. The uses of the clavicles are, to keep the scapulæ, and consequently all the superior extremities, from falling in and forward upon the thorax; by which, as in most quadrupeds, the motions of the arms would be much confined, and the breast made too narrow. The clavicles likewise afford origin to several muscles, and a defence to large vessels. From the situation, figure, and use, of the clavicles, it is evident that they are much exposed to fractures; that their broken parts must generally pass each other; and that they are with difficulty kept in their place afterwards.

The *scapula*, or *shoulder-blade*, is the triangular bone situated on the outside of the ribs; with its longest side, called its

its *base*, towards the spinal processes of the vertebrae; and with the angle at the upper part of this side about three inches, and the lower angle at a greater distance, from these processes. The back-part of the scapula has nothing but the thin ends of the *ferratus anticus major* and *subscapularis* muscles between it and the ribs: but, as this bone advances forwards, its distance from the ribs increases. The upper or shorter side, called the *superior costa*, of the scapula, is nearly horizontal, and parallel with the second rib. The lower side, which is named the *inferior costa*, is extended obliquely from the third to the eighth rib. The body of this bone is concave towards the ribs, and convex behind, where it has the name of *dorsum*. Three processes are generally reckoned to proceed from the scapula. The first is the large spine that rises from its convex surface behind, and divides it unequally. The second process stands out from the fore-part of the upper side; and, from its imaginary resemblance to a crow's beak, is named *coracoides*. The third process is the whole thick bulbous fore-part of the bone. Into the oblique space the *musculus patientia* is inserted. At the root of the spine, on the back-part of the base, a triangular plain surface is formed by the pressure of the lower fibres of the *trapezius*. Below this the edge of the scapula is scabrous and rough, for the insertion of the *ferratus major anticus* and *rhomboid* muscles.

The back-part of the inferior angle is made smooth by the *latissimus dorsi* passing over it. This muscle also alters the direction of the inferior costa some way forwards from this angle; and so far it is flattened behind by the origin of the *teres major*. As the inferior costa advances forward, it is of considerable thickness; it is slightly hollowed and made smooth behind by the *teres minor*, while it has a fossa formed into it below by part of the *subscapularis*; and between the two a ridge with a small depression appears, where the *longus extensor cubiti* has its origin. The superior costa is very thin; and near its fore-part there is a semilunar niche, from one end of which to the other a ligament is stretched; and sometimes the bone is continued to form one, or sometimes two, holes, for the passage of the scapular blood-vessels and nerves. Immediately behind this semilunar cavity the *coraco-hyoid* muscle has its rise. From the niche to the termination of the fossa for the *teres minor*, the scapula is narrower than any where else, and supports the third process. This part has the name of *cervix*.

The whole *dorsum* of the scapula is always said to be convex; but, by reason of the raised edges that surround it, it is divided into two cavities by the spine, which is stretched from behind forwards, much nearer to the superior than to the inferior costa. The cavity above the spine is really concave where the *supra-spinatus* muscle is lodged; while the surface of this bone below the spine, on which the *infra-spinatus* muscle is placed, is convex, except a fossa that runs at the side of the inferior costa.

The internal or anterior surface of this bone is hollow, except in the part above the spine, which is convex. The *subscapularis* muscle is extended over this surface, where it forms several ridges and intermediate depressions, commonly mistaken for prints of the ribs; they point out the interstices of the bundles of fibres of which the *subscapularis* muscle is composed.

The spine rises small at the base of the scapula, and becomes higher and broader as it advances forwards. On the sides it is unequally hollowed and crooked, by the actions of the adjacent muscles. Its ridge is divided into two rough flat surfaces: into the upper one the *trapezius* muscle is inserted; and the lower one has part of the deltoid fixed to it. The end of the spine, called *acromion*, or top of the shoulder, is broad and flat, and is sometimes only joined to the spine by a cartilage. The anterior edge of the *acromion* is flat, smooth, and covered with a cartilage, for its articulation with the external end of the clavicle; and it is hollowed below, to allow a passage to the *infra* and *supra spinati* muscles, and free motion to the *os humeri*.

The *coracoid* process is crooked, with its point inclining forwards; so that a hollow is left at the lower side of its root, for the passage of the *infra scapularis* muscle. The end of this process is marked with three plain surfaces: into the internal, the *ferratus minor anticus* is inserted; from the external, one head of the *biceps flexor cubiti* rises; and from the lower one, the *coraco-brachialis* has its origin. At the upper part of the root of this process, immediately before the semilunar cavity, a smooth tubercle appears, where a ligament from the clavicle is fixed. From all the external side of this *coracoid* apophysis, a broad ligament goes out, which becomes narrower where it is fixed to the *acromion*. The sharp pain, violent inflammation, and tedious cure, of contusions in this part, are probably owing to these tendons and ligaments being hurt.

From the *cervix* scapulae the third process is produced. The fore-part of this is formed into a glenoid cavity, which is of the shape of the longitudinal section of an egg, being broad below and narrow above. Between the brims of this hollow and the fore-part of the root of the spine, a large sinuosity is left for the transmission of the *supra* and *infra spinati* muscles; and on the upper part of these brims we may remark a smooth surface, where the second head of the *biceps flexor cubiti* has its origin. The root of the *supercilia* is rough all round, for the firmer adhesion of the capsular ligament of the articulation, and of the cartilage which is placed on these brims, where it is thick, but becomes very thin as it is continued towards the middle of the cavity, which it lines all over. The medullary vessels enter the scapula near the base of the spine. The scapula is connected to the head, or *hyoides*, vertebrae, ribs, and arm-bone, by muscles, that have one end fastened to these bones, and the other to the scapula, which can move it upwards, downwards, backwards, or forwards; by the quick succession of these motions, its whole body is carried in a circle. But, being also often moved as upon an axis perpendicular to its plane, its circumference turns in a circle whose centre this axis is. Whichever of these motions it performs, it always carries the outer end of the clavicle and the arm along with it.

The use of the scapula is, to serve as a fulcrum to the arm; and, by altering its position on different occasions, to allow always the head of the *os humeri* a right-situated socket to move in; and thereby to assist and to enlarge greatly the motions of the superior extremity, and to afford the muscles which rise from it more advantageous action, by altering their direction to the bone which they are to move. This bone also serves to defend the back-part of the thorax, and is often employed to sustain weights, or to resist forces too great for the arm to bear. The base, *acromion*, *coracoid* process, and head of the scapula, are all in a cartilaginous state at birth; and the three first are joined as epiphyses; while the head, with the glenoid cavity, is not formed into a distinct separate bone, but is gradually produced by the ossification of the body of this bone being continued forwards.

The arm has only one bone, called *os humeri*; which is long, round, and nearly straight. The upper end of this bone is formed in a large round smooth head, whose middle point is not in a straight line with the axis of the bone, but stands obliquely backwards from it. It is distinguished by a circular fossa surrounding its base, where the head is united to the bone, and the capsular ligament of the joint is fixed. Below the fore-part of its base, two tubercles stand out: the smallest one has the tendon of the *subscapularis* muscle inserted into it. The larger is divided, at its upper part, into three smooth plain surfaces; into the anterior of which, the *musculus supra-spinatus*; into the middle or largest, the *infra-spinatus*; and into the one behind, the *teres minor*; is inserted. Between these two tubercles, exactly in the fore-part of the bone, a deep long fossa is formed, for lodging the tendinous head of the *biceps flexor cubiti*; which, after passing in a manner peculiar to itself through the cavity of the articulation, is tied

down by a tendinous sheath extended across the fossa; in which, and in the neighbouring tubercles, are several remarkable holes, which are penetrated by the tendinous and ligamentous fibres, and by vessels. On each side of this fossa, as it descends in the os humeri, a rough ridge, gently flattened in the middle, runs from the roots of the tubercles. The tendon of the pectoral muscle is fixed into the anterior of these ridges, and the latissimus dorsi and teres major are inserted into the internal one. A little behind the lower end of this last, another rough ridge may be observed, where the coraco-brachialis is inserted. From the back-part of the root of the largest tubercle a ridge also is continued, from which the brevis extensor cubiti rises. This bone is flattened on the inside, about its middle, by the belly of the biceps flexor cubiti. In the middle of this plain surface, the entry of the medullary artery is seen slanting obliquely downwards. At the fore-side of this plane the bone rises in a sort of a ridge, which is rough, and often has a great many small holes in it, where the tendon of the strong deltoid muscle is inserted; on each side of which the bone is smooth and flat, where the brachii internus rises. The exterior of these two flat surfaces is the largest; behind it a superficial spiral channel, formed by the muscular nerve and the vessels that accompany it, runs from behind forwards and downwards. The body of the os humeri is flattened behind by the extensors of the fore-arm. Near the lower end of this bone, a large sharp ridge is extended on its outside, from which the musculus spinator radii longus, and the longest head of the extensor carpi radialis, rise. Opposite to this, there is another small ridge to which the aponeurotic tendon, that gives origin to the fibres of the internal and external brachial muscles, is fixed; and from a little depression on the fore-side of it, the pronator radii teres rises.

The body of the os humeri becomes gradually broader towards the lower end, where it has several processes; at the roots of which there is a cavity before and another behind. The anterior is divided by a ridge into two; the external, which is the least, receives the end of the radius; and the internal receives the coronoid process of the ulna in the flexions of the fore-arm, while the posterior deep triangular cavity lodges the olecranon in the extensions of that limb. The bone between these two cavities is pressed so thin by the processes of the ulna, as to appear diaphanous in several subjects. The sides of the posterior cavity are stretched out into two processes, one on each side: these are called *condyles*; from each of which a strong ligament goes out to the bones of the fore-arm. The external condyle, which has an oblique direction also forwards in respect of the internal, when the arm is in the most natural posture, is equally broad, and has an obtuse smooth head rising from it forwards. From the rough part of the condyle, the inferior heads of the bicipitis, the extensor digitorum communis, extensor carpi ulnaris, anconeus, and some part of the spinator radii brevis, take their rise; and on the smooth head the upper end of the radius plays. Immediately on the outside of this, a sinuosity is made by the shorter head of the bicipitis muscle, upon which the muscular nerve is placed. The internal condyle is more pointed and protuberant than the external, to give origin to some part of the flexor carpi radialis, pronator radii teres, palmaris longus, flexor digitorum sublimis, and flexor carpi ulnaris. Between the two condyles, is the trochlea or pulley; which consists of two lateral protuberances, and a middle cavity, that are smooth and covered with cartilage. When the fore-arm is extended, the tendon of the internal brachii muscle is lodged in the fore-part of the cavity of this pulley. The external protuberance, which is less than the other, has a sharp edge behind; but forwards, this ridge is obtuse, and only separated from the little head, already described, by a small fossa, in which the joined edges of the ulna and radius move. The internal protuberance of the pulley is largest and highest; and therefore, in the motions of the ulna upon it, that bone would be inclined outwards, were

it not supported by the radius on that side. Between this internal protuberance and condyle, a sinuosity may be remarked, where the ulnar nerve passes. The round head of the os humeri is articulated with the glenoid cavity of the scapula; which being superficial, and having long ligaments, allows the arm a free and extensive motion. The lower end of the os humeri is articulated with the bone of the fore-arm, and carries them with it in all its motions, but serves as a base on which they perform the motions peculiar to themselves.

The *fore-arm* consists of two long bones, the *ulna* and *radius*. The *ulna*, so named from its being used as a measure, is the longest of the two, and situated on the outside of the radius. At the upper end of the ulna are two processes: the posterior is the largest, and formed like a hook, whose concave surface moves upon the pulley of the os humeri, and is called *olecranon*, or top of the cubit. The convex back-part of it is rough and scabrous, where the longus, brevis, and brachii externus, are inserted. The anterior process is not so large, nor does it reach so high, as the one behind; but is sharper at its end, and therefore is named *coronoid*. Between these two processes, a large semicircular or sigmoid concavity is left; the surface of which, on each side of a middle rising, is slanting, and exactly adapted to the pulley of the bone of the arm. Immediately below the olecranon, on the back-part of the ulna, a flat triangular spongy surface appears, on which we commonly lean. At the internal side of this, there is a larger hollow surface, where the musculus anconeus is lodged; and the ridge at the inside of this gives rise to the musculus supinator radii brevis. Between the top of the ridge and the coronoid process is the semilunated smooth cavity, lined with cartilage; in which, and in a ligament extended from the one to the other end of this cavity, the round head of the radius plays. Immediately below it, a rough hollow gives lodging to mucilaginous glands. Below the root of the coronoid process, this bone is scabrous and unequal, where the brachii internus is inserted.

The body of the ulna is triangular. The internal angle is very sharp where the ligament that connects the two bones is fixed: the sides which make this angle are flat and rough, by the action and adhesion of the many muscles which are situated here. At the distance of one-third of the length of the ulna, the passage of the medullary vessels may be seen slanting upwards. The external side of this bone is smooth, somewhat convex, and the angles at each edge of it are blunted by the pressure of the muscles equally disposed about them. As this bone descends, it becomes gradually smaller; so that its lower end terminates in a little head, standing on a small neck. Towards the fore but outer part of which last, an oblique ridge runs, that gives rise to the pronator radii quadratus. The head is round, smooth, and covered with a cartilage on its internal side, to be received into the semilunar cavity of the radius; while a styloid process rises from its outside, to which is fixed a strong ligament that is extended to the os cuneiforme and pisiforme of the wrist. Between the back-part of that internal smooth side and this process, a sinuosity is left for the tendon of the extensor carpi ulnaris. On the fore-part of the root of the process, such another depression may be marked for the passage of the ulnar artery and nerve.

The *radius*, so called from its imagined resemblance to a spoke of a wheel, or to a weaver's beam, is the bone placed on the inside of the fore-arm. Its upper end is formed into a circular little head, which is hollowed for an articulation with the tubercle at the side of the pulley of the os humeri. Below the head, the radius is much smaller; therefore this part, which is made round by the action of the supinator radii brevis, is named its *cervix*. At the external root of this neck, a tuberosity process rises; into the outer part of which the biceps flexor cubiti is inserted. From this a ridge runs downwards and inwards, where the supinator radii brevis is inserted; and a little below, and behind this ridge, there is a rough scabrous surface,

surface, where the pronator radii teres is fixed. The body of the radius is convex on its internal and posterior surfaces; but the surfaces next to the ulna are flattened and rough, for the origin of the muscles of the hand; and both terminate in a common sharp spine, to which the strong ligament extended between the two bones of the fore-arm is fixed. The lower end of the radius is larger than the superior; its back-part has a flat strong ridge in the middle, and fossæ on each side. In a small groove, immediately on the outside of the ridge, the tendon of the extensor tertii internodii pollicis plays. In a large one beyond this, the tendons of the indicator and of the common extensor muscles of the fingers pass. Contiguous to the ulna there is a small depression made by the extensor minimi digiti. On the inside of the ridge there is a broad depression, which seems again subdivided, where the two tendons of the biconis, or extensor carpi radialis, are lodged. The internal side of this end of the radius is also hollowed by the extensors of the first and second joint of the thumb; immediately above which a little rough surface shews where the supinator radii longus is inserted. The ridges at the sides of the grooves, in which the tendons play, have an annular ligament fixed to them, by which the several sheaths for the tendons are formed. The fore-part of this end of the radius is also depressed, where the flexors of the fingers and flexor carpi radialis pass. The external side is formed into a semilunar smooth cavity, lined with a cartilage, for receiving the lower end of the ulna. The lowest part of the radius is formed into an oblong cavity; in the middle of which is a small transverse rising, gently hollowed for lodging mucilaginous glands; while the rising itself is insinuated into the conjunction of the two bones of the wrist that are received into the cavity. The internal side of this articulation is fenced by a remarkable process of the radius, from which a ligament going out to the wrist, as the styloid process of the ulna with its ligament, guard it on the outside. As the head of the radius receives the tubercle of the os humeri, it is not only bended and extended along with the ulna, but may be moved round its axis in any position; and, that this motion may be sufficiently large, the ligament of the articulation is extended, further down than ordinary, on the neck of this bone, before it is connected to it; and it is very thin at its upper and lower part, but makes a firm ring in the middle. This bone is also joined to the ulna by a double articulation. When the palm is turned uppermost, the radius is said to perform the *supination*: when the back of the hand is above, it is said to be *prone*. But then the quickness and large extent of these two motions are assisted by the ulna, which can move with a kind of small rotation on the sloping sides of the pulley. This lateral motion, though very inconsiderable in the joint itself, is conspicuous at the lower end of such a long bone; and the strong ligament connecting this lower end to the carpus, makes the hand more readily obey these motions. When we design a large circular turn of the hand, we increase it by the rotation of the os humeri, and sometimes employ the spine and inferior extremities, to make these motions of pronation or supination of the hand large enough.

The *hand* comprehends all from the joint of the wrist to the points of the fingers. Its back-part is convex, for greater firmness and strength; and it is concave before, for containing more surely and conveniently such bodies as we take hold of. One-half of the hand has an obscure motion in comparison of what the other has, and serves as a base to the moveable half; which can be extended back very little farther than to a straight line with the fore-arm, but can be considerably bent forwards. As the bones that compose the hand are of different shapes and uses, while several of them that are contiguous agree in some general characters; the hand is, on this account, commonly divided into carpus, metacarpus, and fingers; among which last the thumb is reckoned.

The *carpus* is composed of eight small spongy bones,

viz. os scaphoides, lunare, cuneiforme, pisiforme, trapezium, trapezoides, magnum, unciniforme. *Os scaphoides* is convex above, concave and oblong below; from which small resemblance to a boat it has its name. Its smooth convex surface is divided by a rough middle fossa, which runs obliquely across it. The upper largest division is articulated with the radius. The common ligament of the joint of the wrist is fixed into the fossa; and the lower division is joined to the trapezium and trapezoides. The concavity receives more than an half of the round head of the os magnum. The external side of this hollow is formed into a semilunar plane, to be articulated with the following bone. *Os lunare* has a smooth convex upper surface, by which it is articulated with the radius. The internal side, which gives name to the bone, is in the form of a crescent, and is joined with the scaphoid; the lower surface is hollow, for receiving part of the head of the os magnum. On the outside of this cavity is another smooth, but narrow, oblong sinuosity, for receiving the upper end of the os unciniforme; on the outside of which a small convexity is found, for its connection with the os cuneiforme. Between the great convexity above, and the first deep inferior cavity, there is a rough fossa, in which the circular ligament of the joint of the wrist is fixed. *Os cuneiforme* is broader above, and towards the back of the hand, than it is below and forwards; which gives it the resemblance of a wedge. The superior slightly convex surface is included in the joint of the wrist, being opposed to the lower end of the ulna. Below this the cuneiform bone has a rough fossa, wherein the ligament of the articulation of the wrist is fixed. *Os pisiforme* is almost spherical, except one circular plane or slightly hollow surface, which is covered with cartilage for its motion on the cuneiform bone, from which its whole rough body is prominent forwards into the palm; having the tendon of the flexor carpi ulnaris, and a ligament from the styloid process of the ulna, fixed to its upper part; the transverse ligament of the wrist is connected to its internal side; ligaments extended to the unciniform bone, and to the os metacarpi of the little finger, are attached to its lower part; the abductor minimi digiti has its origin from its fore-part; and, at the internal side of it, a small depression is formed, for the passage of the ulnar nerve. *Trapezium* has four unequal sides and angles in its back-part, from which it has its name. Above, its surface is smooth, slightly hollowed, and semicircular, for its conjunction with the os scaphoides. Its external side is an oblong concave square, for receiving the following bone. The inferior surface is formed into a pulley; the two protuberant sides of which are external and internal. On this pulley the first bone of the thumb is moved. *Os trapezoides*, so called from the irregular quadrangular figure of its back-part, is the smallest bone of the wrist except the pisiforme. The figure of it is an irregular cube. It has a small hollow surface above, by which it joins the scaphoides; a long convex one internally, where it is contiguous to the trapezium; a small external one, for its conjunction with the os magnum; and an inferior convex surface, the edges of which are, however, so raised before and behind, that a sort of pulley is formed, where it sustains the os metacarpi indicis. *Os magnum*, so called because it is the largest bone of the carpus, is oblong, having four quadrangular sides, with a round upper end, and a triangular plain one below. The round head is divided by a small rising, opposite to the connection of the os scaphoides and lunare, which together form the cavity for receiving it. On the inside a short plain surface joins the os magnum to the trapezoides.

Os unciniforme has its name from a thin broad process that stands out from it forwards into the palm, and is hollow on its inside, for affording passage to the tendons of the flexors of the fingers. To this process also the transverse ligament is fixed that binds down and defends these tendons; and the flexor and abductor muscles of the little finger have part of their origin from it. The upper plain surface is small, convex, and joined with the os lunare; the internal side is long, and slightly convex, adapted to the

the contiguous os magnum. The external surface is oblique, and irregularly convex, to be articulated with the cuneiform bone. The lower end is divided into two concave surfaces; the external is joined with the metacarpal bone of the little finger, and the internal one is fitted to the metacarpal bone of the ring finger.

The three first bones of the carpus make an oblong head, by which they are articulated with the cavity at the lower ends of the bones of the fore-arm, so as to allow motion on all sides; and, by a quick succession of these motions, they may be moved in a circle. But as the joint is oblong, and therefore the two dimensions are unequal, no motion is allowed to the carpus round its axis, except what it has in the pronation and supination along with the radius. The articulation of the first three bones of the superior row, with the bones of the inferior, is such as allows of motion, especially backwards and forwards; to the security and caleness of which, the reception of the os magnum into the cavity formed by the scaphoides and lunare considerably contributes; and the greatest number of the muscles that serve for the motion of the wrist on the radius, being inserted beyond the conjunction of the first row of bones with the second, act equally on this articulation as they do on the former; but the joint formed with the radius being the most easily moved, the first effect of these muscles is on it, and the second row of the carpus is only moved afterwards. On account of the many tendons that pass upon the lower end of the fore-arm and the carpus, and of the numerous ligaments of these tendons and of the bones, which have lubricating liquors supplied to them, the pain of sprains here is acute, the parts take a long time to recover their tone, and their swellings are very obstinate.

The *metacarpus* consists of four bones which sustain the fingers. Each bone is long and round, with its ends larger than its body. The upper end, which some call the base, is flat and oblong, without any considerable head or cavity; but it is somewhat hollowed, for the articulation with the carpus; it is made flat and smooth on the sides where these bones are contiguous to each other. Their bodies are flattened on their back-part by the tendons of the extensors of the fingers. The lower ends are raised into large oblong smooth heads, whose greatest extent is forwards from the axis of the bone. At the fore-part of each side of the root of each of these heads, one or two tubercles stand out, for fixing the ligaments that go from one metacarpal bone to another, to preserve them from being drawn asunder: round the heads a rough ring may be remarked, for the capsular ligaments of the first joints of the fingers to be fixed to; and both sides of these heads are flat, by pressing on each other. The metacarpal bones are joined above to the ossa carpi, and to each other by nearly plain surfaces; and they may be distinguished from each other by the following marks: the *os metacarpi indicis* is generally the longest. Its base, which is articulated with the os trapezoides, is hollow in the middle. The small ridge on the internal side is smaller than the one opposite to it, and is made flat on the side by the trapezium. The exterior ridge is also smooth, and flat on its outside, for its conjunction with the os magnum; immediately below which a semicircular smooth flat surface shews the articulation of this to the second metacarpal bone. The back-part of this base is flattened where the long head of the extensor carpi radialis is inserted, and its fore-part is prominent where the tendon of the flexor carpi radialis is fixed. *Os metacarpi medii digiti* is generally the second in length, but often it is as long as the former; sometimes it is longer, and it frequently appears only to equal the first by the os magnum being farther advanced downwards than any other bone of the wrist. Its base is a broad superficial cavity, slanting outwards; the internal posterior angle of which is so prominent, as to have the appearance of a process. The motion of this bone is very little more than that of the former; and therefore these two firmly resist bodies pressed against them by the thumb or fingers, or both. *Os metacarpi digiti annularis* is shorter than the second metacarpal

bone. Its base is semicircular and convex, for its conjunction with the os unciniforme. On its internal side are two smooth convexities, and a middle fossa, adapted to the second metacarpal bone. The external side has a triangular smooth concave surface, to join it with the fourth one. *Os metacarpi minimi digiti* is the smallest and sharpest. Its base is irregularly convex, and rises slanting outwards. Its internal side is exactly adapted to the third metacarpal bone. The external has no smooth surface, because it is not contiguous to any other bone; but it is prominent where the extensor carpi ulnaris is inserted. As this metacarpal bone is furnished with a proper moving muscle, has the plainest articulation, is most loosely connected and least confined, it not only enjoys a much larger motion than any of the rest, but draws the third bone with it, when the palm of the hand is made hollow by its advancement forwards, and by the prominence of the thumb opposite to it.

The *thumb*, and *fingers*, are each composed of three bones. The thumb is situated obliquely in respect of the fingers; and all its bones are much thicker and stronger in proportion to their length. The first bone of the thumb has its base adapted to the double pulley of the trapezium; for, in viewing it from one side to the other, it appears convex in the middle; but, when considered from behind forwards, it is concave there. The articulation of the upper end of this bone is uncommon; for, though it has protuberances and depressions adapted to the double pulley of the trapezium, yet it enjoys a circular motion, as the joints do where a round head of the one plays in the orbicular socket of another; only it is somewhat more confined, and less expeditious, but stronger and more secure, than such joints generally are. The second bone of the thumb has a large base formed into an oblong cavity, whose greatest length is from one side to the other. Round it several tubercles may be remarked, for the insertion of ligaments. Its body is convex or a half-round behind; but flat before, for lodging the tendon of the long flexor of the thumb, which is tied down by ligamentous sheaths that are fixed on each side to the angle at the edge of this flat surface. The articulation and motion of the upper end of this second bone is as singular as that of the former. For, its cavity being joined to the round head of the first bone, it would seem to enjoy motion in all directions; yet, because of the strength of its lateral ligaments, oblong figure of the joint itself, and mobility of the first joint, it only allows flexion and extension, and these are generally much confined. The third bone of the thumb is the smallest, with a large base, whose greatest extent is from one side to the other. This base is formed into two cavities and a middle protuberance, to be adapted to the pulley of the former bone. Its body is rounded behind; but is flatter than in the former bone for sustaining the nail. It is flat and rough before, by the insertion of the flexor tertii internodii. The motion of this third bone is confined to flexion and extension.

The orderly disposition of the bones of the *fingers* into three rows, has made them generally obtain the name of three *phalanges*. All of them have half-round convex surfaces, covered with an aponeurosis, formed by the tendons of the extensors, lumbricales, and interossei, and placed directly backwards, for their greater strength; and their flat concave part is forwards, for taking hold more surely, and for lodging the tendons of the flexor muscles. The ligaments for keeping down these tendons are fixed to the angles that are between the convex and concave sides. The bones of the first phalanx of the fingers answer to the description of the second bone of the thumb; only that the cavity in their base is not so oblong; nor is their motion on the metacarpal bones so much confined; for they can be moved laterally or circularly; but have no rotation, or a very small degree of it, round their axis. The second bone of the fingers has its base formed into two lateral cavities, and a middle protuberance; while the lower end has two lateral protuberances and a middle cavity; therefore

fore it is joined at both ends in the same manner, which none of the bones of the thumb are. The third bone differs nothing from the description of the third bone of the thumb, excepting in the general distinguishing marks; and therefore the second and third phalanx of the fingers enjoy only flexion and extension. All the difference of the phalanges of the several fingers consists in their magnitude. The bones of the middle finger being the longest and largest, those of the fore finger come next to that in thickness but not in length, for those of the ring finger are a little longer. The little finger has the smallest bones. Which disposition is the best contrivance for holding the largest bodies; because the longest fingers are applied to the middle largest periphery of such substances as are of a spherical figure.

OF THE INFERIOR EXTREMITIES.

The *inferior extremities* depend from the acetabula of the ossa innominata; and are commonly divided into three parts, viz. the thigh, leg, and foot.

The *thigh* has only one bone, which is the longest in the body, and the largest and strongest of any of the cylindrical bones. The situation of it is not perpendicular; for the lower end is inclined considerably inwards; so that the knees are almost contiguous, while there is a considerable distance between the thigh-bones above; which is of great use, since sufficient space is thereby left for the external parts of generation, the two great cloacæ of urine and fæces, and for the large thick muscles that move the thigh inwards. At the same time this situation of the thigh-bones renders our progression quicker, surer, straighter, and in less room; for, had the knees been at a greater distance from each other, we must have been obliged to describe some part of a circle with the trunk of our body in making a long step; and, when one leg was raised from the ground, our centre of gravity would have been too far from the base of the other, and we should consequently have been in danger of falling; so that our steps would neither have been straight nor firm, nor would it have been possible to walk in a narrow path, had our thigh-bones been otherwise placed.

The upper end of the thigh-bone is not continued in a straight line with the body of it, but is set off obliquely inwards and upwards, whereby the distance between these two bones at their upper part is considerably increased. This end is formed into a large smooth round head, which is the greater portion of a sphere unequally divided. Towards its lower internal part, a round rough spongy pit is observable, where the strong ligament, commonly, but unjustly, called the *round one*, is fixed, to be extended from thence to the lower internal part of the receiving cavity, where it is considerably broader than near the head of the thigh-bone. The small part below the head, called the *cervix*, of the os femoris, has a great many large holes, into which the fibres of the strong ligament, continued from the capsular, enter, and are thereby firmly united to it; and round the root of the neck, where it rises from the bones, a rough ridge is found, where the capsular ligament of the articulation itself is connected. Below the back-part of this root, the large unequal protuberance, called *trochanter major*, stands out; the external convex part of which is distinguished into three different surfaces; whereof the one on the fore-part is scabrous and rough, for the insertion of the glutæus minimus; the superior one is smooth, and has the glutæus medius inserted into it; and the one behind is made flat and smooth, by the tendon of the glutæus maximus passing over it. The upper edge of this process is sharp and pointed at its back-part, where the glutæus medius is fixed; but forwards it is more obtuse, and has two superficial pits formed in it; into the superior of these the pyriformis is implanted, and the obturator internus and gemini are fixed into the lower one. From the hindmost prominent part of this great trochanter, a rough ridge runs backwards and downwards, into which the quadratus is inserted. In the deep hollow, at the internal

upper side of this ridge, the obturator externus is implanted. More internally, a conoid process, called *trochanter minor*, rises for the insertion of the musculus psoas and iliacus internus; and the pectineus is implanted into a rough hollow below its internal root. The muscles inserted into those two processes being the principal instruments of the rotatory motion of the thigh, have occasioned the name of *trochanters* to be given to those processes. The tendons that are fixed into or pass over the great trochanter, cause bruises, by falls on this part, to be attended with great pain or weakness of the limb, which generally remain long. The fore-part of the thigh-bone is a little flattened above by the beginning of the cruræus muscle, as it is also below by the same muscle and the rectus. Its external surface is likewise made flat below by the vastus externus, where it is separated from the former by an obtuse ridge. The vastus internus depresses a little the lower part of the internal surface. The posterior concave surface has a ridge rising in its middle, commonly called *linea aspera*, into which the triceps is inserted, and the short head of the biceps flexor tibiæ rises from it. At the upper part of it the medullary vessels enter, by a small hole that runs obliquely upwards. A little above which there is a rough fossa, where the tendon of the glutæus maximus is fixed. The lower end of the linea aspera divides into two, which descend towards each side. The two vasti muscles have part of their origin from these ridges; and the long tendon of the triceps is fixed to the internal, by a part of the fascia aponeurotica of the thigh. The lower end of the os femoris is larger than any other part of it, and is formed into a great protuberance on each side, called its *condyles*; between which a considerable cavity is found, especially at the back-part, in which the crural vessels and nerves lie immersed in fat. The internal condyle is longer than the external, which must happen from the oblique position of this bone, to give less obliquity to the leg. Each of these processes seem to be divided into its plain smooth surface. The mark of division on the external is a notch, and on the internal a small protuberance. The fore-part of this division, on which the rotula moves, is formed like a pulley, the external side of which is highest. Behind, there are two oblong large heads, whose greatest extent is backwards, for the motion of the tibia; and from the rough cavity between them, but near to the base of the internal condyle, the strong ligament, commonly called the *cross one*, has its rise.

The thigh-bone being articulated above with the acetabulum of the ossa innominata, which affords its round head a secure and extensive play, can be moved to every side; but is restrained in its motion outwards by the high brims of the cavity, and by the round ligament; for otherwise the head of the bone would have been frequently thrust out at the breach of the brims on the inside, which allows the thigh to move considerably inwards. The body of this bone enjoys little or no rotatory motion, though the head most commonly moves round its own axis; because the oblique progress of the neck and head from the bone is such, that the rotatory motion of the head can only bring the body of the bone forwards and backwards. Nor is the head, as in the arm, ever capable of being brought to a straight direction with its body; so far however, as the head can move within the cavity backwards and forwards, the bone may have a partial rotation. When the thigh-bone resists the actions of its muscles more than the trunk of the body can then do, as in standing, these muscles have their effect on the trunk, causing it to bend forward, raising it up, inclining it to the one or the other side, twisting it obliquely, &c. for which the rolling of the acetabula of the ossa innominata on the round heads of the thigh-bones is well fitted. The nearness of the small neck to the round head of the thigh-bone, and its upper end being covered with very thick muscles, make greater difficulty in distinguishing between a luxation and fracture here, than in any other part of the body.

The leg is composed of two bones, *tibia* and *fibula*, tho' it

it seems to have a very good title to a third, the *rotula*; which bears a strong analogy to the olecranon of the ulna, and moves always with the other two.

The *tibia*, so called from its resemblance to an old musical pipe or flute, is the long thick triangular bone, situated at the internal part of the leg, and continued in almost a straight line from the thigh-bone. The upper end of the tibia is large, bulbous, and spongy, and is divided into two cavities by a rough irregular protuberance, which is hollow at its most prominent part, as well as before and behind. The anterior of the two ligaments that compose the great cross one is inserted into the middle cavity, and the depression behind receives the posterior ligament. The two broad cavities at the sides of this protuberance are not equal; for the internal is oblong and deep, to receive the internal condyle of the thigh-bone; while the external is more superficial and rounder, for the external condyle. In each of these two cavities of a recent subject, a femilunar cartilage is placed, which is thick at its convex edge, and becomes gradually thinner towards the concave or interior edge. The middle of each of these cartilages is broad, and the ends of them turn narrower and thinner as they approach the middle protuberance of the tibia. The thick convex edge of each cartilage is connected to the capsular and other ligaments of the articulation; but so near to their rise from the tibia, that the cartilages are not allowed to change place far; while the narrow ends of the cartilages, becoming almost ligaments, are fixed at the insertion of the strong cross ligament into the tibia, and seem to have their substance united with it; therefore a circular hole is left between each cartilage and the ligament, in which the most prominent convex part of each condyle of the thigh-bone moves. The circumference of these cavities is rough and unequal, for the firm connection of the ligaments of the joint.

Below the fore-part of the upper end of the tibia, a considerable rough protuberance rises, to which the strong tendinous ligament of the *rotula* is fixed. On the internal side of this, there is a broad scabrous slightly-hollowed surface, to which the internal long ligament of the joint, the aponeurosis of the vastus internus, and the tendons of the feminovus, gracilis, and sartorius, are fixed. The lowest part of this surface is therefore the place where the tibia ought to be sawn through in an amputation, so as not to have too long and troublesome a stump, and at the same time to preserve its motions, by saving the proper muscles. Below the external edge of the upper end of the tibia, there is a flat circular surface, covered in a recent subject with cartilage, for the articulation of the fibula; between which and the anterior knob, a rough hollow affords origins to the tibialis anticus and extensor digitorum longus. From this smooth flat surface, a ridge runs obliquely downwards and inwards, to give rise to part of the soleus, tibialis posticus, and flexor digitorum longus, and insertion to the aponeurosis of the semimembranosus which covers the popliteus, and to some of the external fibres of this last-named muscle. At the inside of this ridge an oblique plain surface is left, where the greatest part of the musculus popliteus is inserted. The remaining body of the tibia is triangular. The anterior angle is very sharp, and is commonly called the *spine*, or *spin*. This ridge is not straight; but turns first inwards, then outwards, and lastly inwards again. The plain internal side is smooth and equal, being little subjected to the actions of muscles; but the external side is hollowed above by the tibialis anticus, and below by the extensor digitorum longus and extensor pollicis longus. The two angles behind these sides are rounded by the action of the muscles; the posterior side comprehended between them is not so broad as those already mentioned, but is more oblique and flattened by the action of the tibialis posticus and flexor digitorum longus. A little above the middle of the bone, the internal angle terminates, and the bone is made round by the pressure of the musculus soleus. Near to this the passage of the medullary vessels flants obliquely downwards.

VOL. I. No. 35.

The lower end of the tibia is hollowed, so as to occasion a small protuberance to rise in the middle. The internal side of this cavity, which is smooth, and in a recent subject is covered with cartilage, is produced into a considerable process, commonly named *malleolus internus*; the point of which is divided by a notch, and from it ligaments are sent out to the foot. We ought to observe here, that this internal malleolus is situated more forwards than the internal condyle of the upper end of this bone; which is necessary to be remembered in reducing a fracture of the leg. The external side of this end of the tibia has a rough irregular femilunar cavity formed in it for receiving the lower end of the fibula. The posterior side has two lateral grooves, and a small middle protuberance. In the internal depression, the tendons of the musculus tibialis posticus and flexor digitorum longus are lodged; and, in the external, the tendon of the flexor longus pollicis plays. From the middle protuberance, ligamentous sheaths go out, for tying down these tendons.

The *fibula* is the small long bone, placed on the outside of the leg, opposite to the external angle of the tibia; the shape of it is irregularly triangular. The head of the fibula has a superficial circular cavity formed on its inside, which, in a recent subject, is covered with a cartilage, and it is so closely connected to the tibia by ligaments, as to allow only a small motion backwards and forwards. This head is protuberant and rough on its outside, where a strong round ligament and the musculus biceps are inserted; and, below the back-part of its internal side, a tubercle may be remarked, that gives rise to the strong tendinous part of the soleus muscle. The external surface of the fibula is depressed obliquely from above downwards and backwards by the two peronæi. Its internal surface is unequally divided into two narrow longitudinal planes, by an oblique ridge extended from the upper part of the anterior angle, to join with the lower end of the internal angle. To this ridge the ligament stretched between the two bones of the leg is connected. The anterior of the two planes is very narrow above, where the extensor longus digitorum and extensor longus pollicis arise from it; but is broader below, where it has the print of the nonus Vesalii. The posterior plane is broad and hollow, giving origin to the larger share of the tibialis posticus. The internal angle of this bone has a tendinous membrane fixed to it, from which some fibres of the flexor digitorum longus take their rise. The posterior surface of the fibula is the plainest and smoothest; but is made flat above by the soleus, and is hollowed below by the flexor pollicis longus. In the middle of this surface, the canal for the medullary vessels may be seen slanting downwards.

The lower end of the fibula is extended into a spongy oblong head; on the inside of which is a convex, irregular, and frequently a scabrous, surface, that is received by the external hollow of the tibia, and so firmly joined to it by a very thin intermediate cartilage and strong ligaments, that it can scarcely move. Below this the fibula is stretched out into a smooth coronoid process, covered with cartilage on its internal side, and is there contiguous to the outside of the first bone of the foot, the astragalus, to secure the articulation. This process, named *malleolus externus*, being situated farther back than the internal malleolus, and in an oblique direction, obliges us naturally to turn the fore-part of the foot outwards. At the lower internal part of this process, a spongy cavity for mucilaginous glands may be remarked; from its point ligaments are extended to the astragalus, os calcis, and os naviculare, bones of the foot; and from its inside short strong ones go out to the astragalus. On the back part of it a sinuosity is made by the tendons of the peronæi muscles. When the ligament extended over these tendons from the one side of the depression to the other is broken, stretched too much, or made weak by a sprain, the tendons frequently start forwards to the outside of the fibula.

Rotula is the small flat bone situated at the fore-part of the joint of the knee. Its shape resembles the common

figure of the heart with its point downwards. The anterior convex surface of the rotula is pierced by a great number of holes, into which fibres of the strong ligament, that is spread over it, enter. Behind, its surface is smooth, covered with cartilage, and divided by a middle convex ridge into two cavities, of which the external is largest; and both are exactly adapted to the pulley of the os femoris, on which they are placed in the most ordinary unstraining postures of the leg: but, when the leg is much bent, the rotula descends far down on the condyles; and, when the leg is fully extended, the rotula rises higher in its upper part than the pulley of thigh-bone. The plain smooth surface is surrounded by a rough prominent edge, to which the capsular ligament adheres. Below, the point of the bone is scabrous, where the strong tendinous ligament from the tubercle of the tibia is fixed. The upper horizontal part of this bone is flatted and unequal, where the tendons of the extensors of the leg are inserted. The substance of the rotula is cellular, with very thin external firm plates; but then these cells are so small, and such a quantity of bone is employed in their formation, that scarcely any bone of its bulk is so strong. Besides, it is covered all over with a thick ligament, to connect its substance, and is moveable to either side; therefore it is sufficiently strong to resist the ordinary actions of the large muscles, or any common external force.

On account of the very large surface of the bones forming the joint of the knee, and the many strong ligaments connecting them, luxations seldom happen here. But these very ligaments, the aponeurosis passing over this joint, and the quantity of fat and mucilaginous glands necessary for lubricating it, make it more subject to white swellings, dropsies, and such other disorders, than any other joint of the body.

The foot is divided, as well as the hand, into three parts, viz. *tarfus*, *metatarfus*, and *toes*. The *tarfus* consists of seven spongy bones, viz. the astragalus, os calcis, naviculare, cuboides, cuneiforme externum, cuneiforme medium, and cuneiforme internum. The upper part of the *astragalus* is formed into a large smooth head, which is slightly hollowed in the middle; and therefore resembles a superficial pulley, by which it is fitted to the lower end of the tibia. The internal side of this head is flat and smooth, to play on the internal malleolus. The external side has also such a surface, but larger, for its articulation with the external malleolus. The lower surface of the astragalus is divided by an irregular deep rough fossa; which at its internal end is narrow, but gradually widens as it stretches obliquely outwards and forwards. The smooth surface, covered with cartilage, behind this fossa, is large, oblong, extended in the same oblique situation with the fossa, and concave for its conjunction with the os calcis. The back-part of the edge of this cavity is produced into two sharp-pointed rough processes; between which is a depression that is made by the tendon of the flexor pollicis longus. The lower surface of it before the fossa is convex, and composed of three distinct smooth planes. The long one behind, and the exterior or shortest, are articulated with the heel-bone; while the internal one, which is the most convex of the three, rests and moves upon a cartilaginous ligament, that is continued from the calcaneum to the os scaphoides. Without which ligament the astragalus could not be sustained; but would be pressed out of its place by the great weight it supports, and the other bones of the tarfus would be separated. The fore-part of this bone is formed into a convex oblong smooth head, called by some its *process*, which is received by the os naviculare. Round the root of this head, especially on the upper surface, a rough fossa may be remarked. The astragalus is articulated above to the tibia and fibula, which together form one cavity. Though in this articulation the bones have prominences and cavities, so small as might allow motions in all directions, yet the flexion and extension are the most considerable, the other motions being confined by the malleoli, and, by the strong ligaments which

go out from the points of these processes to the astragalus and os calcis.

The *os calcis* is the largest bone of the seven. Behind, it is formed into a large knob, commonly called the *heel*: the surface of which is rough behind, where the tendon Achillis is inserted; and above that part it is hollow and spongy. Farther forwards, on the upper surface of the calcaneum, there is an irregular oblong smooth convexity, adapted to the concavity at the back-part of the astragalus: and beyond this a narrow fossa is seen, which divides it from two small concave smooth surfaces, that are joined to the fore-part of the astragalus. Behind the posterior of these smooth surfaces, which is the largest, a small sinuosity is made by the tendon of the flexor digitorum longus; at the fore-part of which a small rough protuberance appears, that gives rise to the musculus extensor digitorum brevis. The external side of this bone is flat, with a superficial fossa running horizontally, in which the tendon of the musculus peroneus longus is lodged. The internal side of the heel-bone is hollowed, for lodging the origin of the massa cornea Jac. Sylvii, and for the safe passage of tendons, nerves, and arteries. Under the side of the internal smooth cavity, a particular groove is made by the tendon of the flexor pollicis longus; and, from the thin protuberance of this internal side the cartilaginous ligament that supports the astragalus goes out to the os naviculare; on which ligament, and on the edge of this bone to which it is fixed, the groove is formed for the tendon of the flexor digitorum profundus. The lower surface of this bone is pressed flat at the back-part, by the weight of our bodies; and, immediately before this plane, there are two tubercles, from the internal of which the musculus abductor pollicis, flexor digitorum sublimis, as also part of the aponeurosis plantaris, and of the abductor minimi digiti, have their origin; and the other part of the abductor minimi digiti and aponeurosis plantaris rises from the external. Before these protuberances this bone is concave, for lodging the flexor muscles; and at its fore-part we may observe a rough depression, from which, and a tubercle behind it, the ligament goes out that prevents this bone from being separated from the os cuboides. The fore-part of the os calcis is formed into an oblong pulley-like smooth surface, which is circular at its upper external end, but is pointed below. The smooth surface is fitted to the os cuboides.

Os naviculare, is somewhat circular. It is formed into an oblong concavity behind, for receiving the anterior head of the astragalus. On the upper surface there is a rough fossa. Below, the os naviculare is very unequal and rough; but hollow for the safety of the muscles. On its inside a large knob rises out, from which the abductor pollicis takes in part its origin, the tendon of the tibialis posticus is inserted into it, and to it two remarkable ligaments are fixed; the first is the strong one, which supports the astragalus; the second is stretched from this bone obliquely across the foot, to the metatarsal bones of the middle toe, and of the toe next to the little one. On the outside of the os naviculare there is a semicircular smooth surface, where it is joined to the os cuboides. The fore-part of this bone is all covered with cartilage, and is divided into three smooth planes, fitted to the three ossa cuneiformia. The os naviculare and astragalus are joined as a ball and socket; and the naviculare moves in all directions in turning the toes inwards, or in raising or depressing either side of the foot, though the motions are greatly restrained by the ligaments which connect this to the other bones of the tarfus. A weakness of these ligaments causes sometimes an unnatural turn of the fore part of the foot inwards.

Os cuboides is a very irregular cube. Behind, it is formed into an oblong unequal concavity, adapted to the fore-part of the os calcis. On its internal side, there is a small semicircular smooth cavity, to join the os naviculare. Immediately before which, an oblong smooth plane is made by the os cuneiforme externum. Below this the bone is hollow and rough. On the internal side of the lower surface

face a round protuberance and fossa are found, where the musculus adductor pollicis has its origin. On the external side of this same surface, there is a round knob, covered with cartilage; immediately before which a smooth fossa may be observed, in which the tendon of the peronæus primus runs obliquely across the foot; and on the knob the thin flat cartilage proper to this muscle plays; in place of which sometimes a bone is found. More externally than the knob, a rough hollow is made, for the strong ligaments stretched between this bone and the os calcis. Before, the surface of the os cuboides is flat, smooth, and slightly divided into two planes, for sustaining the os metatarsi of the little toe, and of the toe next to it.

Os cuneiforme externum is much of the shape of a wedge, being broad and flat above, with long sides running obliquely downwards, and terminating in a sharp edge. The upper surface of this bone is an oblong square. The one behind is nearly a triangle, but not complete at the inferior angle, and is joined to the os naviculare. The external side is half of it smooth, for its conjunction with the os cuboides. The other is a scabrous hollow, and in its superior anterior angles a small smooth impression is made by the os metatarsi of the toe next to the little one. The internal side of this bone is quadrangular, with the fore-part of its edge made flat and smooth by the os metatarsi of the toe next to the great one, and the back-part is also flat and smooth where the os cuneiforme medium is contiguous to it. The fore-part of this bone is an oblong triangle, for sustaining the os metatarsi of the middle toe.

Os cuneiforme medium or *minimum* is still more exactly the shape of a wedge than the former. Its upper part is square; its internal side has a flat smooth surface above and behind, for its conjunction with the following bone; with a small rough fossa below; and a considerable share of it is rough and hollow. The external side is smooth and a little hollowed, where it is contiguous to the last-described bone. Behind, this bone is triangular, where it is articulated with the os naviculare; and it is also triangular at its fore-part, where it is contiguous to the os metatarsi of the toe next to the great one.

Os cuneiforme maximum or *internum* differs from the two former in its situation, being more oblique. Besides, its broad thick part is placed below, and the small thin point is above and outwards; while its under broad surface is concave, for allowing a safe passage to the flexor of the great toe. The surface of this os cuneiforme behind, where it is joined to the os naviculare, is hollow, smooth, and of a circular figure below, but pointed above. The external side consists of two smooth and flat surfaces, whose direction is nearly at right angles with each other. With the posterior, that runs obliquely from below forwards and upwards, the os cuneiforme minimum is joined; and with the anterior, whose direction is longitudinal, the os metatarsi of the toe next to the great one is connected. The fore-part of this bone is semilunar, but flat and smooth, for sustaining the os metatarsi of the great toe. The internal side is scabrous, with two remarkable tubercles below, from which the musculus abductor pollicis rises, and the tibialis anticus is inserted into its upper part.

The seven bones of the *tarfus*, when joined, are convex above, and leave a concavity below, for lodging safely the several muscles, tendons, vessels, and nerves, that lie in the sole of the foot. In the recent subject, their upper and lower surfaces are covered with strong ligaments, which adhere firmly to them; and all the bones are so tightly connected by these and the other ligaments, which are fixed to thorough ridges and fossæ mentioned in the preceding description of the particular bones, that notwithstanding the many surfaces covered with cartilage, some of which are of the form of the very moveable articulations, no more motion is here allowed than only to prevent too great a shock of the fabric of the body in walking, leaping, &c. by falling on too solid a base; which, if it were one continued bone, would likewise be much more liable to be

broken. Sprains occasion here, as in the wrist, great pain and obstinate tumours, which too often cause carious bones.

The *metatarsus* is composed of five bones, of which the *os metatarsi pollicis* is by far the thickest and strongest, as having much the greatest weight to sustain. Its base is oblong, irregularly concave, and of a semilunar figure, to be adapted to the os cuneiforme maximum. The inferior edge of this base is a little prominent and rough, where the tendon of the peronæus primus muscle is inserted. On its outside an oblique circular depression is made by the second metatarsal bone. Its round head has generally on its fore-part a middle ridge, and two oblong cavities, for the ossa sesamoidea. *Os metatarsi* of the *second toe*, is the longest of the five, with a triangular base supported by the os cuneiforme medium and the external side produced into a process; the end of which is an oblique smooth plane, joined to the os cuneiforme externum. Near the internal edge of the base, this bone has two small depressions, made by the os cuneiforme maximum, between which is a rough cavity. *Os metatarsi* of the *middle toe*, is the second in length. Its base, supported by the os cuneiforme externum, is triangular, but slanting outwards, where it ends in a sharp-pointed little process; and the angle below is not completed. The internal side of this base is adapted to the preceding bone; and the external side has two smooth surfaces covered with cartilage. *Os metatarsi* of the *fourth toe* is near as long as the former, with a triangular slanting base joined to the os cuboides, and made round at its external angle; having one hollow smooth surface on the outside, where it is pressed upon by the following bone; and two on the internal side, corresponding to the former bone; behind which is a long narrow surface impressed by the os cuneiforme externum. *Os metatarsi* of the *little toe* is the shortest, situated with its two flat sides above and below, and with the ridges laterally. The base of it, part of which rests on the os cuboides, is very large, tuberos, and produced into a long-pointed process externally, where part of the abductor minimi digiti is fixed; and into its upper part the peronæus secundus is inserted. Its inside has a flat conoidal surface, where it is contiguous to the preceding bone. When we stand, the fore-ends of these metatarsal bones, and the os calcis, are our only supporters; and therefore it is necessary that they should be strong, and should have a confined motion.

The bones of the *toes* are nearly similar to those of the thumb and fingers; particularly the two of the great toe are precisely formed as the two last of the thumb; only their position, in respect of the other toes, is not oblique; and they are proportionally much stronger, because they are subjected to a greater force; for they sustain the force with which our bodies are pushed forwards by the foot at every step we make. The three bones in each of the other four toes, compared to those of the fingers, differ from them in these particulars: They are less and smaller in proportion to their lengths; their bases are much larger than their anterior ends; their bodies are more narrow above than below, and flatter on the sides; and the first phalanx is proportionally much longer than the bones of the second and third, which are very short. Of the four, the toe next to the great one has the largest bones in all dimensions, and more externally the toes are less. The little toe, and frequently that next to it, have the second and third bones intimately united into one; which may be owing to their little motion, and the great pressure they are subject to.

The only bones now remaining to complete the description of the skeleton, are the small ones which are found at the joints of the fingers and toes, and in some other parts, called *ossa sesamoidea*. These are of very different figures and sizes, though they are generally said to resemble the seed of the sesamum. They seem to be nothing else than the ligaments of the articulations, or the firm tendons of strong muscles, or both, become bony by the compression which

which they suffer. Thus the sesamoid bones at the beginning of the gastrocnemii muscles, are evidently composed of the tendinous fibres only. These, at the first joint of the great toe, are as plainly the same continued substance with the ligaments and the tendons of the adductor, flexor, brevis, and abductor. That which is sometimes double at the second joint of that toe is part of the capsular ligament; and, if we enumerate the other sesamoid bones that are at any time found, we may observe all of them formed in like manner. Their number, figure, situation, and magnitude, are so uncertain, that it were in vain to insist on the differences of each; and therefore we shall only in general remark: That wherever the tendons and ligaments are firmest, the actions of the muscles strongest, and the compression greatest, there such bones are most commonly found. That, the older the subject is in which they are sought, their number is greater, and their size larger. And, the more labour any person is inured to, he has, *cæteris paribus*, the most numerous and largest ossa sesamoidea.

However, as the two at the first joint of the great toe are much larger than any other, are early formed, and are seldom wanting in an adult, we may judge, that, besides the more forcible cause of their formation, there should also be some particular advantage necessary at this place, rather than elsewhere; which may possibly be, to allow the flexor muscles to send their tendons along this joint, secure from compression in the hollow between the two oblong sesamoid bones; while by removing these tendons from the centre of motion, and giving them the advantage of an angle at their insertion, the force of the muscle is increased; and therefore the great super-incumbent weight of our body in progression is more easily raised.

MARKS of a FEMALE SKELETON.

To finish the description of the bones, is generally to conclude the history of osteology: but, that no part of the subject may be left untouched, it is necessary to subjoin the distinguishing marks of the male and female skeletons; and we have chosen to illustrate them principally in the latter; because women having a more delicate constitution, and affording lodging and nourishment to their tender foetuses till they have sufficient strength and firmness to bear the injuries of the atmosphere, and contact of other more solid substances, their bones are frequently incomplete, and always of a make in some parts of the body different from those of the robust male. The causes of the following specialities of the female bones may be reduced to these three: A weak lax constitution; a sedentary inactive life, increasing that lax constitution; and a proper frame for being mothers.

The bones of women are smaller in proportion to their length than those of men; because the force of their muscles is not so great, nor is such strong external force applied to them to prevent their stretching out in length. The depressions, ridges, scabrous surfaces, and other inequalities made by the muscles, are not so conspicuous in them; because their muscles are neither so thick nor strong, nor so much employed, as to make strong prints on their bones. The *os frontis* is more frequently divided by a continuation of the sagittal suture. Their *clavicles* are less crooked; because their arms have been less forcibly pulled forwards; which, in our European women, especially those of distinction, is more hindered by their dress. Their *sternum* is more raised by long cartilages below, that the thorax might be there widened in some proportion to what it is shortened by the pressure upon the diaphragm when they are with child.

The defect of bone, or the hole, in the middle of the *sternum*, is oftener found in them; and is owing to a lax constitution, by which the ossification is not so soon completed as in men, where the action of the solids is vigorous, and the circulation of the fluids is brisk: for a much smaller hole might have served this purpose; for the

branches of the internal mammary vessels which are sent to the external parts the thorax do not pass here, but between the cartilages of the ribs, before these are joined to the sternum. The *cartilago xiphoides*, is oftener bifurcated in women than in men, for the reason just assigned, viz. a less forcible power of ossification. The superior cartilages of the ribs sooner ossify, to support the weight of the mammae. The middle cartilages are more flat and broad by the weight of the breasts. The inferior cartilages are longer, for enlarging the chest.

Weak women, who have borne many children when young, often have the *vertebrae* of their back bent forwards, and their *sternum* depressed, or become round-shouldered and flat-breasted, by the pressure and weight of the impregnated uterus, and by the strong action of the abdominal muscles. The *os sacrum* is broader, and turned much more backwards, for enlarging the pelvis. The *os coccygis* is more moveable, and much less bent forwards, to facilitate the birth. The *ossa ilium* are more hollow, and more reflected outwards, and consequently further removed from each other, in order to widen the lower part of their abdomen, and for the better support of the impregnated uterus. The ridge on the upper part of the *os pubis* is larger in such women as have borne children, being extended by the strong action of the *musculi recti abdominis*. The cartilage between the two ossa pubis, especially in women who have borne children, is thicker than in men, by which the pelvis is more capacious in females. The *conjoined surfaces* of the *ossa pubis*, and of the *ossa innominata* and *sacrum*, are less, the angle under the *symphysis* of the *ossa pubis* is much larger, and the arches formed below and behind by the *ossa ilium* and *ischium* are wider, which, with the straighter *os sacrum*, and more distant *tubera ischii*, leave a larger passage for the exclusion of the child in birth. The great tuberosity of the *ossa ischium* is flatter in women than in men, because it is more pressed upon in the sedentary life which females mostly lead. In consequence of the *pelvis* of women being wider, the articulations of their thigh-bones must be farther removed from each other; and therefore a larger space is left for the procreation and birth of children; which distance of the thighs may be one reason why women in running shuffle more from one side to the other than men, to preserve the centre of gravity of their bodies from falling too far to a side of the joint of the thigh that supports them when the other is raised, which would endanger their tumbling to the ground.

The annexed Plate represents a front and back View of the Human Bones, or Skeleton, with some of the ligaments and cartilages which connect the bones to each other.

FRONT VIEW.

HEAD and NECK. *a*, *Os frontis*. *b*, *Os parietale*: between *a* and *b*, part of the coronal suture. *c*, The pars squamosa of the temporal bone: between *b* and *c*, the squamous suture: below the pars squamosa, the zygoma: and, lower down above *f*, the mastoid process: between the pars squamosa and the cavity, which contains the eyeball, called *orbit*, the temporal process of the sphenoid bone is seen. *d*, *Os malæ*: above *d*, a portion of the transverse suture. *e*, *Os maxillare superius*, with the eight teeth of the right side. The nasal process of the superior maxillary bone has the *os nasi* joined, by the nasal suture, to its inside; and, at the outside, within the orbit, the *os unguis*. The *os nasi* joined to each other before, by the anterior nasal suture. *f*, *Os maxillare inferius*, with sixteen teeth; the four anterior named *incisores*, the two corner ones *canini*, and the five posterior on each side *molars*: opposite to *f*, the angle of the lower jaw: above *f*, the condyloid process, by which the jaw is connected to the temporal bone, at the root of the zygoma: and, behind the *os malæ*, the coronoid process. *g*, The seven cervical vertebrae, with their intermediate cartilages: opposite to *g*, their transverse processes.

TRUNK. *a*, Sternum: *a*, its middle piece, to which one half of the cartilage that connects the second rib, the whole

whole of the cartilages of the third, fourth, fifth, sixth, and one-half of the seventh, are fixed: above *a*, the first or upper triangular piece, to which the clavicle, and one half of the cartilage that connects the second rib, are fixed: below *a*, the extremity, or third piece, of the sternum, named *cartilago ensiformis*, to which one half of the cartilage that connects the seventh rib is fixed. *b*, The seventh or last true rib. *c*, The twelfth or last of the five false ribs. *d*, The five lumbar vertebræ, with their intermediate cartilages: opposite to *d*, their transverse processes. *e*, The os sacrum, with its five divisions. *f*, Os innominatum, divided into *g*, Os ilium; *h*, Os pubis; *i*, Os ischium: opposite to *i*, the foramen thyroideum.

SUPERIOR EXTREMITY. *a*, The clavicle fixed before, to the first piece of the sternum, and outwards to the acromion of the scapula. *b*, The scapula: above *b*, the cervix of the scapula: opposite to it, the inferior costa; and, below the outward extremity of the clavicle, the superior costa, and coracoid process, are seen. *c*, The os humeri: the upper end of it, which is connected to the cavity of the scapula, named *glenoid*, below the acromion, is named its *head* or *ball*; on each side of which is seen a tubercle, named *external* and *internal*; and, between these, a groove for lodging the long head of the biceps flexor cubiti. *d*, The internal condyle. *e*, The external condyle: between *d* and *e*, the trochlea, upon which the ulna moves. *f*, The radius: the upper end, which moves on the external condyle of the os humeri, is named its *head*; below that, the tubercle for the insertion of the biceps flexor cubiti, and between these the cervix: the inferior end of it is connected to the carpus. *g*, Ulna: the upper end of it forms the coronoid process for the insertion of the brachialis muscle: the inferior end has a process named *styloid*, which is connected to the carpus by a ligament. *h*, The carpus, formed of eight bones. *i*, Metacarpal bone of thumb. *k*, The metacarpal bones of the four fingers. *l*, The two joints of the thumb. *m*, The three joints or phalanges of the fore-finger; and the same are seen in each of the other three.

INFERIOR EXTREMITY. *a*, Os femoris: the upper end of it is named its *head* or *ball*, which is lodged in a deep socket of the os innominatum, named *acetabulum*: between the head and trochanter major, the cervix. *b*, Trochanter major. *c*, Trochanter minor. *d*, Internal condyle. *e*, External condyle. *f*, Patella: the place where it moves upon the os femoris, is named *trochlea*. *g*, Tibia: between the tibia and the condyles of the os femoris, the femilunar cartilages are seen; and, below the joint, the tubercle of the tibia. *h*, Fibula. *i*, Malleolus internus. *k*, Malleolus externus. *l*, Os calcis: between *l* and *m*, the other six bones of the tarsus. *m*, Metatarsal bones of the four toes. *n*, The three joints, or phalanges, of the four toes. *o*, Metatarsal bone of the great toe. *p*, The two joints of the great toe.

BACK VIEW.

HEAD and NECK. *a*, Os parietale, joined to its fellow by the sagittal suture. *b*, The os occipitis, joined to the parietal bones by the lambdoid suture, which is between *a* and *b*. *c*, Os malæ. *d*, Maxilla inferior, with a view of the teeth of both jaws from behind. *e*, The seven cervical vertebræ.

TRUNK. *a*, The seventh or last true rib. *b*, The twelfth or last rib. *c*, The five lumbar vertebræ. *d*, Os sacrum. *e*, Os coccygis. *f*, Os innominatum, divided into *g*, Os ilium; *h*, Os pubis; *i*, Os ischium.

SUPERIOR EXTREMITY. *a*, The clavicle, joined outwards to the acromion of the scapula. *b*, The scapula. *c*, Os humeri. *d*, Internal condyle. *e*, External condyle. *f*, Radius. *g*, Ulna: its upper end, named *olecranon*; and, near the wrist, its *styloid* process. *h*, The eight bones of the carpus. *i*, The metatarsal bone of the thumb. *k*, The metatarsal bone of the four fingers. *l*, The two joints of the thumb. *m*, The three joints or phalanges of the four fingers.

INFERIOR EXTREMITY. *a*, Os femoris. *b*, Trochan-

ter major, and at the inside of it the cervix. *c*, Trochanter minor. *d*, Internal condyle. *e*, External condyle. *f*, Tibia. *g*, Fibula. *h*, Malleolus internus. *i*, Malleolus externus. *k*, The seven bones of the tarsus. *l*, The metatarsus. *m*, The joints or phalanges of the toes.

Of the MUSCLES.

THE muscles are the organs of motion in the human body; though motion is not wholly performed by one individual organ. In every animal and vegetable fibre, even in hair, feathers, membranes, the cellular texture, and in the humid muscular fibre, in short, in animal and vegetable glutes, there is a contractile or elastic power which preserves the fibre in its natural state, preventing it from being too much extended, and restoring it again to its proper dimensions when the stretching power is removed. This power never ceases endeavouring to bring the elementary particles into the closest contact that the mechanism of the part can admit. It continues even many days after death; so that fibres of a divided muscle contract towards each extremity, leaving a wide gap in the middle. An artery, when cut, likewise contracts itself in length. This force may be called *vis mortua*, because it continues to be efficacious after death, and is different from the powers of life. In the living animal, indeed, it is somewhat brisker; for, both from cold and fear, the skin trembles, grows harder, and has its papillæ erected; and along with this hardness it contracts itself in length. Again, the cellular fibres are animated with this perpetual nifus to shorten, always endeavouring to contract themselves. Hence, when the skin or any other membrane is extended, as soon as the cause of extension is taken off, it returns by a gentle effort to its former shortness. But it even somewhat resists the attempt to perpetual distension; and, by a gentle, but continual, approach of its elements to one another, it propels the contained fat, or water, or other bodies accidentally introduced into it. The same power also seems to limit the excretion of vapour; for the fibres and plates of the cellular texture being preternaturally relaxed, an immense quantity, either of fat or of watery humour, is deposited in that texture. And this debility seems to be the principal cause of a dropsy. The same cause being always efficacious, and at work in the heart, joints, and every where throughout the body of the embryo, brings into nearer contact the arteries, auricles, and ventricles; produces flexures; and contracts the heart into the form of a cone. The same cause, by an unknown or hidden power, seems to form the shape of most parts of the human body; and, while it expels the gluten received into the cells, it brings the terrestrial particles nearer to one another, and gives the proper solidity, curvature, and situation, to the different parts. It is the nature of this power to act continually by gentle but uninterrupted efforts. It is common for it also to be excited by poisons, in every membrane, fibre, and in the cellular texture; but never by cutting or puncturing with a sharp instrument. These are the known properties of the red muscular fibre. The structure of this fibre, therefore, we shall now consider.

By the name of *muscular* or *moving fibres* in the human body, we call bundles of reddish-coloured threads, which perform all the motions visible in the human body. When many of these fibres are collected together, and appear more evidently red, they are called a *muscle*. The extreme simplicity of the texture in these parts has been the cause of the obscurity in understanding how a small soft portion of flesh can produce such strong and ample motions as we see in man, and more especially in the crustaceous insects. In every muscle we meet with long soft threads of *fibres*, somewhat elastic, or extensible, and almost constantly disposed parallel with each other; and these, being surrounded with a good deal of cellular substance, are by that fastened together into little bundles, called *lacertuli*; which are again tied together into larger bundles, by a more loose cellular net-work, that contains some fat; and between these we constantly perceive mem-

braneous partitions and stripes of the cellular substance removing them farther from each other, till at last a number of them combined together, either parallel or inclined, are surrounded with a more thin and dense cellular membrane, continuous with that of their partitions; and this being again surrounded by a thicker plate of the cellular substance, parts the whole bundle from the adjacent flesh, and gives it the denomination of a *single* or *entire muscle*. In every one of these threads there appears a smaller series of filaments, which, by oblique extremities, are cemented to others of the same kind, forming together a large fibre.

The generality of the muscles, but more especially those which are inserted into the bones, have other fibres fixed to them; but these are condensed into a more slender, hard, and shining, substance, of a silver colour, which has the name of *tendon*. When the tendinous fibres expand into a broad flat surface, they form what is called an *aponeurosis*. The cellular texture which covers the whole tendon, is called its *vagina* or *sheath*, and resembles the coat of a muscle. That fleshy fibres truly change into such as are tendinous, says Dr. Haller, is evident from comparing a fœtus, in which there are few tendons, with a child of some years growth, in which there are many more; and both with an adult, in which there are the greatest number. But Dr. Wrisberg observes, in opposition to this, that many tendons are found in a fœtus, which could not assume this nature by muscular action; as the tendo Achillis, aponeurosis plantaris, centrum diaphragmatis, &c. Besides, in various parts of the body there are tendons found without corresponding muscles.

Muscles which are not inserted into any of the bones have commonly no tendons, as the sphincters and muscular membranes of the viscera and vessels. But those commonly end in long tendons, which are required to pass round the joints and heads of the bones, to be inserted in those extremities which are more moveable. In a fœtus the muscles are evidently inserted into the periosteum only; but, in adults, where the periosteum is more closely joined with the bone itself, the tendons, being confused with the periosteum, pass together with that even into the foveoli of the bone. The tendinous fibres, indeed, often lie in a straight line with the fleshy ones, and are as it were a continuation of them. But in many parts of the body the fleshy fibres are obliquely inclined to the tendon, and adhere to it; and the tendon itself grows thicker in its progress by continually receiving new fibres. This is called a *tendinous muscle*. Other tendons lie in the middle between two plates of fibres, which are inserted on each side of the tendon at angles obtuse downward; and this is called a *pennated muscle*. There are instances of numerous tendons, pennated in different places, formed into one muscle. There are also other methods by which the tendinous fibres are joined with the fleshy ones.

Within the cellular tunic that surrounds the fibres, the arteries and veins, running in company with each other, are sub-divided into net-works. From the smaller of these vessels a vapour is exhaled into the thinner, and the fat is transfused into the thicker, cellular substance; from whence again they are both absorbed by the lymphatic vessels; which can be distinctly seen both on the surface and in the substance of the muscles. The nerves of the muscles are still more evident. They are commonly very large; and enter by so many branches, that some anatomists have considered the muscular fibres as formed by them. Several arguments are offered against this opinion: one of the strongest is, that muscles in the limbs of animals do not shrink, although the nerves entering these muscles have been cut through for a considerable length of time. The nerves enter the muscles in a way somewhat similar with that of the arteries and veins; but it is impossible to trace them a great way among the fleshy fibres, for they at length deposit their harder covering, and become soft, and disappear before they can be traced to their terminations.

The fabric of the least fibres, which are supposed to be

the elementary particles of a muscle, being investigated by the microscope in man and other animals, is found to be similar to that of the larger fibres, and they are all joined together by the intermediate cellular substance. The surface of the fibres, however, puts on a curious waved or zigzag appearance. This undulated appearance Prof. Chazka thinks is nothing else than impressions made by the vessels and cellular substance, and perhaps by the nerves; but Dr. Monro has described and delineated a similar appearance in the tendons and nerves; and is of opinion, that they are to be considered as folds or joints, serving to accommodate the parts to the different states of flexion and extension. In proof of this, he finds, that those parts which appear thus in their relaxed state, lose it when they are much stretched.

With regard to the nature of the ultimate moving fibres, there have been many disputes. Some anatomists think them solid; others, hollow, formed of a series of vessels or rhomboidal chains communicating with each other. Some, again, have been of opinion, that they are full of a kind of down or woolly substance, &c. It may be asked, Whether they are hollow? whether they are continued from the arteries? or whether the difference between muscular and tendinous fibres, lies in the latter being rendered more dense, and beat closer together by an expulsion of the fluids? That these are not probable, appears from the minuteness of the fibres, which are found less than the red-blood globules, and from the whiteness of a muscle after the blood is washed out of it. The structure of the tendons and aponeuroses agrees in some respects with, but differs in others from, that of the muscles. We observe their fibres regularly disposed, and separated by cellular substance and blood-vessels; and without doubt they have lymphatics and nerves: but the tendinous fibres are closer together than those of the muscles, the cellular substance which separates them is finer, their red vessels are fewer in number, and the nerves cannot be traced, without difficulty, into their substance. It has been doubted whether the fibres of tendons are a continuation of the moving fibres, or of a different nature. Many, both ancient and moderns, have embraced the first opinion, others the second; but, if we consider that the tendinous fibres are not irritable, have no contraction, that they differ little from those which constitute the ligaments, and that they degenerate sometimes into a substance truly cellular, we should be inclined to adopt the latter opinion.

According to Dr. Haller, a muscle is endowed at least with a threefold force. First the *vis mortua*, in common to it with other animal fibres. Another, which he has called the *vis insita*, and which has different phenomena from the former. It is more peculiar to life; and, though it may continue for a few hours after death, yet it disappears much sooner than the former. Again, in most cases, it acts by alternate oscillations; so that, being driven hither and thither, it sometimes contracts the muscle towards the middle; sometimes again it extends the muscle from the middle towards the extremities, and sometimes also it has a reiterated motion. Moreover, it is manifestly quicker, and performs the greatest motions. It is excited both by the pricking with a sharp instrument, and in the hollow muscles by inflated air, by water, and every kind of acrimony, but most powerfully of all by a torrent of electrical matter. Lastly, it is peculiar to the muscular fibre, and is found in no other part of the human body with the qualities above-mentioned. But we must give a more particular explication of its phenomena.

It is natural to every muscle to shorten itself, by drawing the extremities towards its belly or middle. But to discover the moving power of a muscle from the fabric which we have described, it will be of use to consider the appearances observable in the muscular contraction. Every muscle then becomes shorter and broader in its action. But this contraction of its length is various; in some more, in others less; and is very considerable in some of the sphincters, inasmuch that they appear to be contracted more

more than one third of their extent. The intestines are exceedingly tenacious of their *vis insita*, as they continue to contract themselves long after they are taken out of the body, and even after they are cold; and the heart is even more tenacious of this principle than the intestines, as is evident in a young chicken, and in cold animals. Different muscles are best excited into action by different stimuli; as the bladder by urine, the heart by the blood, and the intestines by air. Though the nerves are removed, or the connection, made by them between the muscles and the brain, cut off, the muscles lose but little of their irritable nature. It appears also from the example of the polypi and other insects, that the same irritable disposition extends very widely through the animal fibres. In many of these creatures, neither brain nor nerves can be traced, yet they are exceedingly affected by stimulus. Lastly, we perceive this *vis insita* in vegetables, many of which expand and contract their flowers and leaves according to the different states of the atmosphere; and some plants exert sudden and violent motions from stimuli externally applied, appearing little inferior in this respect to animals. This *vis insita* does not depend upon weight, attraction, or elasticity; for it is seated in a soft fibre, and vanishes as the fibre grows hard.

That the cause of motion is conveyed through the nerves into the muscles, is certain from the experiments made on the brain and nerves. For the nerve alone has feeling; this alone carries the commands of the soul; and of these commands there is neither intimation nor perception in that part, whose nerve is either tied or cut, or which has no nerve. Moreover, on irritating the nerve or spinal marrow, even in an animal that has been dead for some time, the muscles which have nervous branches from those parts are most vehemently convulsed. When the nerve of any muscle is cut or tied, or the basis of the spinal marrow compressed, or that part of the brain from whence the nerve has its origin, the muscle becomes paralytic, and languishes, and cannot by any force be re-called into an action similar to the vital one. But, if the ligature be taken off from the nerve, the force by which the muscle is put into action is again recovered. The nerve being irritated below the place where it is cut, the muscle to which that nerve goes is contracted. This appears from numerous experiments, especially those made on the phrenic and recurrent nerves. This force, called *vis nervæ*, is not the same with the *vis insita*. The former comes to the muscle from without: whereas the other resides constantly in the muscle itself. The nervous power ceases when life is destroyed; the other appears, from certain experiments, to remain for some time after death: it is also suppressed by tying a ligature upon the nerve, by hurting the brain, or by taking opium. The *vis insita* suffers nothing from all these circumstances: it remains after the nerve is tied; it continues in the intestines though they be taken out of the body and cut in pieces; it appears with great strength in such animals as are destitute of brain; that part of the body is moved which has no feeling; and the parts of the body feel which are without motion. The will excites and removes the nervous power, but has no power over the *vis insita*.

In the motion of the muscles, whether owing to the *vis insita* or the *vis nervæ*, the fibres are contracted towards the middle of their belly, and recede from one another outwards; they are also diversified with various transverse wrinkles; the whole muscle also becomes shorter, and draws its extremities towards the middle; hence it draws towards each other those parts with which it was connected; the muscle also swells by its contraction, becoming hard at the same time, and as it were increases its circumference on every side. Haller has never observed it to turn pale. Whether on the whole it is increased in bulk, or acquires more in breadth than it loses in length, is difficult to be known. It draws after it the tendons, which are obsequious to its motions, though of themselves neither moveable nor irritable. The whole muscle is also

capable of being moved at once, or only a part of it; if one extremity is fixed to an immovable part, that only is moved which is capable of yielding.

If it be demanded, Whether the arteries conduce any thing to muscular motion? and whether the palsy of the lower limbs after a ligature upon the aorta be not an argument of this opinion? we answer, No farther than as they conduce to the sound state of the muscle, or to the conservation of the mutual structure and habit of the parts, which they supply with vapour, fat, &c. for the irritation of an artery does not affect or convulse the muscle to which it belongs; nor does a ligature on it cause a palsy, unless after a considerable time, when the muscles begin to be destroyed by a gangrene. Moreover, it is impracticable to explain the motion of peculiar muscles from a cause derived with an equal force from the heart to all parts of the body. Lastly, the influence of the will is confined to the nerves, without residing in the arteries or other solid parts of the body. But the direct manner by which the nerves excite motion in the muscles, is so obscure, that we may almost for ever despair of its discovery. The opinion, that the nervous vesicles swell by a quicker flux of the nervous spirits, is inconsistent with anatomical truth, which demonstrates the least visible fibres to be cylindrical, and in no part vesicular; it is likewise repugnant to the celerity with which muscular motion is performed; and it seems to be completely refuted by the well-known fact, that the bulk of a muscle is rather diminished than increased during its action. Again, the inflation of rhomboidal chains in the fibres is equally repugnant to the celerity of muscular motion, and to anatomy; they would also occasion an immense waste of strength, and after all render the muscle but little shorter. The nerves want that irritable nature which is observed in the muscular fibre. Finally, it is by no means demonstrable, that the fibres, from so few nerves, can be so numerous, or distributed in so many different transverse directions, with respect to the muscular threads, as those hypotheses require to be allowed. A complication of the nerves round the extremities of fibres, so as to contract them by their elasticity, is founded upon a false structure of the muscular fibre, supposing the nerves to be distributed where filaments of the cellular substance only can be demonstrated. Moreover, the phenomena of animals, which, having neither brain nor nerves, are yet very apt for motion, apparently demonstrate the intrinsic fabric of the muscles to be sufficient for their motion, without other assistance from the nerves. Other explanations, derived from spherules of air in the blood, are founded on a false hypothesis, for the blood contains no elastic air. The animal spirits are not of the nature of an electric torrent.

If we may add any thing to these phenomena, we may suppose the nervous fluid to be of a stimulating nature, by which means it forces the elementary particles of the muscular fibre to approach nearer to each other. The motive cause which occasions the influx of the animal spirits into the muscle, so as to excite it into action, seems not to be the soul, but a law derived immediately from God. For animals newly born, or newly transformed, without any attempt, or exercise, know how to execute compound motions very difficultly to be defined by calculation; whereas the soul knows not how to perform any actions until she has learnt, by making experiments, the methods of performing them. A muscle then is contracted when in a given time it receives more of the nervous fluid, whether that be occasioned by the will, or by some irritating cause arising in the brain or applied to the nerve.

But, though we may suppose the soul to be the cause of the nervous motion, we cannot do the same with regard to that arising from the *vis insita*. The heart and intestines, and also the organs of generation, are governed by a *vis insita*, and by stimuli. These powers do not arise from the will; nor are they lessened, or excited, or suppressed, or changed, by it. No custom nor art can make these organs subject to the will, which have their motions from

from a vis insita; nor can they be made to obey the commands of the soul, like attendants on voluntary motion. It is so certain that motion is produced by the body alone, that we cannot even suspect any motion to arise from a spiritual cause, besides that which we see is occasioned by the will; and, even in that motion which is occasioned by the will, a stimulus will occasion the greatest exertions, when the mind is very unwilling. There seems to be this difference between the muscles obeying the will, and those which are governed by a vis insita; namely, that the latter, being more irritable, are very easily excited into motion by a gentle stimulus; as for instance, the heart and intestines; which organs are most manifestly, and greatly, and constantly, irritable. On the other hand, the muscles, which obey the will, are neither endowed with so great nor so durable a power of this kind. Hence they either stand in need of the power of the will, or of a stronger stimulus; when they are excited by a stimulus, they are animated to motion against the will. Thus it happens, that in apoplexies the muscles which obey the will languish, and become paralytic, as being destitute of all influx from the brain; while the vital muscles, having no occasion for the operation of the brain, continue to be excited into contraction by their stimuli, independent of the will, as the heart by the blood, and the intestines by the air and aliments.

The strength of the muscles is very considerable in all persons, but more especially phrenetic and robust men; since frequently, with the use of a few muscles only, they will raise a weight equal to, or much greater than, that of the whole human body. In a healthy man, very slender muscles suffice to lift two or three hundred pounds: the muscles of the back will even sustain 3000. Notwithstanding this, we see, that much the greater part of the force or power exerted by a muscle is always lost without producing any visible effect. For all the muscles are inserted nearer the point or centre of motion, than the weights they are applied to; and therefore their action is weaker, in the same proportion as they move a shorter part of the lever than that to which the weight is applied. Moreover, in most of the bones, especially those of the limbs, the muscles are inserted at very acute angles; whence again the effect which a muscle exerts in action is proportionally less, as the sine of the angle intercepted between the bone and the muscle is less than the whole sine. Again, the half of all muscular force is lost; because a muscle, like an extended cord, exerts as much force at its fixed as at its moving extremity. Besides, many of the muscles are seated in the angle of two bones; and, when the joint is bent, the muscle becomes also bent; consequently a quantity of force must be first applied to stretch the muscle, before the muscle can act on the bone in which it is inserted. Many of them pass over several joints, each of which they bend in some degree, whereby a less part of their remaining force goes to bend the joint to which they are particularly destined. The fleshy fibres themselves of the muscles frequently intercept angles with the tendon in which they terminate; whence their force is diminished in proportion to the sine of the angle of their insertion. Finally, the muscles move their opposed weights with the greatest velocity and expedition, so as not only to overcome the equilibrium, but likewise to add a considerable celerity to the weight.

All these losses of power being computed, make it evident, that the force exerted by muscles in their contraction, is exceeding great, and almost beyond any mechanical computation. The effect is scarcely one-sixtieth of the whole force exerted by the muscle, and yet only a small number of these muscles, weighing but a few pounds, are able not only to raise some thousands of pounds, but also with a considerable celerity. Nor is this to be reputed any defect of wisdom in the Creator; for all those losses of power were necessary for a just symmetry or proportion of the parts, and for various motions and celerities in different directions. But we may, however, conclude from hence, that the action of the nervous or animal fluid is very power-

ful, since, in an engine so small, it can exert a force equal to some thousand pounds for a considerable time, even for many days together; nor does this seem to be otherwise explicable, than by the incredible celerity by which the influx of this fluid obeys the command of the will. But how or whence it acquires such a velocity, is not in our power to say; it is sufficient that we know the laws of its motion are such, that a given action of the will produces a new and determinate celerity in the nervous fluid.

There are various means by which the motions of the muscles are rendered more safe, certain, and easy. The large long muscles, by which the greater motions of flexure are performed, being included in tendinous capsules or cases, drawn and tightened by other muscles, are thus secured and strengthened; and thus the muscle, in a state of contraction, remains pressed against the bone all the time that the limb is bent, and consequently avoids a considerable loss of its power. The long tendons, which are incurvated or extended over joints in their motion, are received and confined by peculiar ligaments, which retain them within their slippery channels; and in these sheaths a particular liquor is separated for the lubricating of the tendons. Nature makes a similar provision for those muscles which perforate others in their course. In other parts, the tendons are either carried round certain eminences of the bone, in order that they may be inserted at greater angles into the bone which they move; or else they are inserted into another bone, from whence a different tendon descends under a larger angle into the bone to be moved. In other parts, the muscles which are derived from convenient situations, have their tendons carried round in a contrary direction by nature, so that they pass into the part to be moved as it were round a pulley. Nature has likewise surrounded the muscles on all sides with a considerable quantity of fat, which is spread also between the bundles of fibres, and also between the small fibres themselves; which fat, being pressed out by the turgescence of the muscles and fibres, renders them soft, flexible, slippery, and fit for motion. Moreover, the power and action of one muscle is determined by the co-operations or oppositions of others, which serve either to hold firm some part from whence the muscle arises, or to bend it together with the muscle, or else to change its action from the perpendicular to the diagonal, by concurring to assist its force at the same time. Remote muscles often assist each other, the superior muscles keeping the bone, whence the inferior acting muscles arise firm and steady. Therefore, the action of no one muscle can be understood from considering it alone; but all the others, which are either inserted into the muscle itself, or into any of the parts to which the muscle adheres, must likewise be brought into the consideration.

By these muscles, variously conspiring and opposing each other, are performed walking, standing, flexion, extension, deglutition, and all the other gestures and offices of the several parts in the living body. But the muscles have likewise some common actions, by which they are of use to the whole animal. They hasten the return of the venous blood, by pressing it out both from the veins of the muscles themselves, and from the veins which lie between them; for the blood in these vessels, distributed between the turgid bundles of a contracted muscle, is, by the valves, determined towards the heart: they likewise return the fat to the blood; and shake, grind, or condense, the arterial blood, and return it quicker to the lungs; they contribute in a great degree to the secretions and excretions. Again, in the liver, mesentery, womb, &c. they promote the course of the contained blood, bile, and other juices, so as to lessen the danger of their stagnation; they serve also to increase the strength of the stomach, by adding their own strength to it, whereby digestion is promoted; inasmuch that all sedentary and inactive courses of life are contrary to nature, and pave the way to diseases from a stagnation of the humours, or from a corruption or crudity of the aliments. The large muscles, which are generally placed round any of the cavities of the body, propel the blood

blood contained in that cavity, and prefs it towards the heart. By too much exercise or action the muscles themselves grow hard and tendinous on all sides; they render the parts upon which they are incumbent cartilaginous, or else change those which are membranous into a bony nature; they increase the roughness, protuberances, and processes, of the bones which lie next to them, and excavate their flat parts; they dilate the cells of the diploe, and incurvate the bones.

The muscle which the stimulus has ceased to irritate, or for the action of which the mind has no occasion, is relaxed, and grows soft; its wrinkles grow plain; its fibres are rendered longer, receding from the middle towards the fixed extremities; and its swelling falls. Whatever is the cause of additional contraction is then taken away; but the vis inertia remains. It may be asked, What becomes of the spirit that is sent from the brain? A part of it perhaps exhales; a part of it may be suspected to adhere to the fibre; and thus it happens that the muscles grow strong with exercise, and their brawny parts become thicker.

The three noted classes of animal powers, *elasticity*, *irritability*, and *sensibility*, Dr. Wrisberg observes, have been and are yet too much confounded, although it is no difficult task to distinguish these affections from one another. The elasticity and cohesion of the fibres, which in different degrees are found in every part of the body, was fully known to Bellini, Baglivi, Stahl, Pacchioni, Juncker, &c. That power, known to Stahl's followers under the appellation of *tone*, has no similarity to irritability, sensibility, and what is called vital power. It either alone performs the various actions of the animal and vegetable body, or adds strength and vigour to them: the former is manifest in the motion of the ribs and cartilages; and the latter in the construction of the uterus, vessels, and membranes. It by no means depends on the vital powers, but may endure long after death; it is not completely destroyed even by putrefaction. During life it is diminished by various causes, and again restored by several remedies. Irritability, which Haller thought existed in the fibres of the muscles alone, and which indeed was known by name, but not in reality, to Glisson, is a kind of animal power, unknown to earlier anatomists, and is different from that power which Hippocrates calls *ενεργουον*. It is proved, from the experiments of Lups, Haller, Fontana, Hoffman, and several others, to differ from elasticity in its rise, duration, seat, causes, effects, and phenomena. 1. It is most powerful in the muscular fibres of the whole body, but not equally diffused through all; more powerful in the heart, muscles of respiration, and intestines, but becomes gradually weaker among the voluntary muscles; and it exists perhaps, in a small degree, in the vessels and membranes, as appears from the doubts offered by Whyte, De Haen, Van Doeveren, &c. which Haller and the learned Cigna have answered. 2. The phenomena of irritability, and the irritations themselves by which these phenomena are produced, are not always the same. In some parts we constantly perceive a manifest irritability produced by every irritation, as is the case in almost all the muscles. In many other parts, we see the greatest inconstancy and very irregular effects, varying differently, at different times, being sometimes increased and sometimes diminished, at one time yielding to, and at another resisting, the irritations; all which is evident in the skin, viscera, vessels, and iris. The learned pathologists, Eller, Tissot, and Gerhard, have long ago acknowledged the great use of the doctrine of irritability. It would be of much importance to know the remedies, which particularly conduce to excite irritability when it is languid, or to diminish it when it is too great. Opium, and the other narcotics, camphor, cantharides, acrid poisons, bark, the electric shock, shew a clear influx of animal spirits in the production of irritability. That it is different from the sentient faculty, and therefore by no means depends upon the nerves, appears partly from other reasons, and partly from the irritability of vegetables. Though we might take into account some phenomena of

the *dionæa muscipula*, according to Ellis's observations, or of the *hedyfarum* or the *antheræ* of certain other plants, yet we should be averse to compare this contractile power of some parts of vegetables with irritability; for the internal tremor of the constituent parts, which makes the particular character of irritability, is wanting in all vegetables; we see contraction and motion alone, which are also observable in other elastic bodies, where we suppose no irritability to exist. The sentient faculty, depending solely upon the nerves, although it has been regarded as one and the same thing with irritability, has been more strongly opposed by Haller's opponents, De Haen, Whyte, Le Cat, Gerhard, &c. than irritability itself. The sensibility of the parts is to be referred both to the various quantity of the nerves, their situation and state, according to Haller's and Castell's experiments, and to the various violence of irritation, and the nature of the irritating or offending body; for some parts are frequently much affected at one time and less at another, and Haller thinks that some of them may sometimes be altogether insensible. We shall not repeat what has been often offered on the opinion, that a greater pain having preceded, absorbs a less pain following; thus we do not feel the taste of a drop of wine, if we have taken a very small quantity of rectified alcohol upon the tongue a little before. It cannot however be denied, that, in inflammatory diseases, affections of the mind, and other causes, it may happen, that hurt parts may feel, which, under any other condition, seem insensible. The *vital power* of certain learned men of later times, as Vanden Bos, Bikker, Gaubius, Albinus, &c. seems rather compounded of all the animal powers comprehended together; which opinion, except in some minutiae, the great Boerhaave and Simpson have more exactly adopted.

Upon the subject of *irritability*, and the *sentient* principle, as acting upon the human fibre, Dr. Blane, F.R.S. has published some very pertinent remarks. He controverts the doctrine that all muscular irritability depends upon a sentient principle. "There have been several instances (says he) of the production of fœtuses without the brain; and a principal fact in support of this opinion is, the existence of animals without brain or nerves. That there are such, was first observed by Haller, and has been confirmed by Mr. Hunter; who maintains farther, that the stomach is a centre or seat of life more essential to it than the brain. That the stomach should be an organ of so much consequence, seems natural enough from the importance of its function, which is that of assimilation; and life can be more immediately and completely extinguished by an injury to it, such as a blow, than by the same violence to any other part of the body. It is also well known, that the muscular fibres of animals, endowed with a nervous system, will retain their irritability for some time after their separation from the brain and nerves. It is evident likewise, from the phenomena of vegetation, that irritability may exist in nature without sensation, consciousness, or any suspicion of the existence of a nervous system. In favour of this opinion, it is farther observable, that those animals which are destitute of brain and nerves are of the class of *vermes*, the most simple in nature, having only one function, viz. that of assimilation; and therefore not requiring that variety of action, and those perceptions which are peculiar to more complex animals. Lastly, the state of an egg before incubation, and the condition of those animals which become torpid from cold, and afterwards revive, afford facts which favour this opinion; as they shew that there is a certain principle of self-preservation, independent not only of the operation of the nervous system, but even of the circulation; for in this quiescent state, those portions of animal matter are preserved for a great length of time from that corruption to which they would otherwise be liable, and their fluids are prevented from freezing in a degree of cold which would congeal them, were they destitute of every principle of life."

In the course of his reasoning, Dr. Blane considers the nervous system not only as a mere appendage to life, but

as tending to impede its operation, and shorten its existence. "Simple life," he says, "will not only survive sensation, but will survive it longer, if the animal is killed by destroying the nervous system, than if it had been destroyed by hæmorrhage, suffocation, or other violence. If a fish, immediately upon being taken out of the water, be stunned by a violent blow on the head, or by having the head crushed, the irritability and sweetness of the muscles will be preserved much longer than if it had been allowed to die with the organs of sense entire. This is so well known to fishermen, that they put it in practice in order to make them longer susceptible of the operation called *crimping*. A salmon is one of the fishes least tenacious of life, inasmuch that it will lose all signs of life in less than half an hour after it is taken out of the water, if suffered to die without any farther injury; but if, immediately after being caught, it receives a violent blow on the head, the muscles will shew visible irritability for more than twelve hours afterwards."

To the same purpose, he observes, that in warm-blooded animals an excessive exertion of voluntary motion immediately before death, prevents the muscles from being rigid when cold, and renders them more prone to putrefaction. Thus, if an ox is killed immediately after being over-driven, the carcase will not become stiff when it grows cold, nor is it capable of being preserved by means of salt. In confirmation of the same hypothesis, it may be observed, that in some disorders of the brain, such as hydrocephalus, and apopleptic palsy, in which the functions of the brain are suspended, the office of digestion is sometimes better performed than in health. From all which Dr. Blane and Mr. Hunter conclude, that the exercise of sensation is inimical to life, and that a sort of fatigue is induced by this as well as by voluntary motion; "so that all that intercourse carried on through the nerves, whether *towards* the brain in the case of sensation, or *from* the brain in acts of volition, tends to wear out the animal powers. And, as intense and long-continued thought, though not terminating in any outward action, tends also to produce an inability for farther exertions, it would appear that the brain or sensorium is more particularly the organ which is subject to that species of suffering called *fatigue*. From these facts we perceive the necessity of sleep, which consists in a temporary suspension of sensation, volition, and thought, and is a resource of nature, whereby the powers of life recover themselves after satiety and fatigue, which are provided as guards to warn us when nature is in danger of being strained, either by repletion or over-exertion; and it is evident that such barriers were absolutely necessary, in order to set bounds to operations which are only occasionally requisite, and which would otherwise depend on the caprice of the will. The exercise of sensation and voluntary motion in a moderate degree is conformable to the intention of nature, and therefore salutary; and it is only when they are excessive that they tend to wear out the powers of life, and more especially if these are not duly recruited by sleep. It follows, from the same principle, that when life is threatened by certain diseases, of which the chief symptom is *irritation*, any means by which sensation, whether natural or morbid, and muscular motion, whether voluntary or involuntary, convulsive or spasmodic, can be soothed or suspended, will prove salutary, by allowing the powers of life to rally as it were, and to recover themselves. In this consists the operation of narcotic medicines, such as opium; which, in complaints both of a general and local nature, proves useful, not merely as a palliative, by the removal of temporary pain or spasm, or by procuring sleep, but as a principal instrument of recovery, by allowing the powers of life to exert their natural action, in consequence of the removal of irritation." In treating this subject, the doctor considers the effects of opium as affecting simple or sensitive life; and to determine this, he made the following experiments: Having made a solution of opium in water, he put into one portion of it some found living eels, and others with their heads

bruised; and, in a number of trials, it was found that the found eels generally died much sooner than the bruised ones. This, however, was the case only when the solution was of a certain degree of strength, such as half a grain of opium to at least to an ounce of water; for, when only about half this strength, the found eels lived much longer, the time being then protracted to that in which the bruised eels would have died merely in consequence of their injury; but it must be observed, that even the wounded eels died considerably sooner than when put into plain water.

Upon the whole, Dr. Blane concludes, that "the great masses of muscle in the trunk and extremities of the body are the instruments of the mind in acting upon external bodies; and we may therefore rank in the list of stimuli the nervous power by which the will and the passions excite external motions. This is a function sufficiently important for the nerves, without admitting them as the principle on which *irritability* depends."

Having disclaimed all inquiry into the connection between muscular motion and volition, the doctor proceeds to consider the effects of the different passions upon the muscles. Though these are distinct from the motions directly produced by the will, yet he considers them among those arising from consciousness; "for there are emotions of the heart which have visible and powerful effects upon the mind and vascular system, which are organs entirely out of the reach of the will. Not to mention the well-known effects of grief, fear, and joy, which affect the whole circulation, there are certain passions and sentiments which produce partial and local effects. These are established by nature, either to answer some important purpose in nature, as in the case of the congestion of the fluids in the parts of generation, in consequence of the venereal appetite, or to serve as natural expressions, as in the case of blushing or weeping. One of the most striking effects of the passions upon muscular action, is the influence they have upon the strength or mechanical force of the voluntary muscles. Fear produces debility almost amounting to palsy. Courage and order of mind, on the contrary, add to the natural strength. When the mind is agitated by some interesting object, and calls upon the body for an extraordinary exertion to effect its end, the muscles are thereby enabled, as it were by magic, to perform acts of strength of which they would be entirely incapable in cold blood. In circumstances of danger, for instance, where life or honour are at stake, exertions are made for overcoming mechanical resistance which seem incredible, and would be impossible, were not the mind in a sort of phrensy; and it is truly admirable in the œconomy of nature, that an idea in the mind should thus in a moment augment the powers of motion, and inspire additional resources of strength adequate to the occasional calls of life. These considerations would almost lead us to doubt whether or not the accounts we have of the great feats of strength ascribed to individuals in the heroic ages, be fabulous or not. It is also worthy of remark, that, in great and lasting exertions of strength, to which men are impelled by active and generous affections, fatigue is not induced in the same proportion, by many degrees, as by the same quantity of muscular action in the cool and deliberate actions of common life."

Having thus discussed the subject of *internal* stimuli, Dr. Blane next proceeds to take notice of the second class, viz. such as are *external*. These are either immediate or remote, viz. such as are excited by mechanical means, or by acrimony directly and artificially applied to a muscular fibre; or such as occur in the instances of sympathy, and in the case of those instincts which nature has instituted for the purpose of self-preservation in brutes, and in the early part of human life. "There are certain habitudes between outward stimuli and the moving powers whereby natural propensities are constituted, equally necessary to the support of life as the internal functions. Thus, in a new-born animal, the first contact of the external air excites the act of respiration, and the contact of the nipple excites

excites the act of sucking; both of which actions are absolutely necessary to the maintenance of life, and require the nice co-operation of a great number of muscles prior to all experience. Actions of this kind are called *instinctive*; but, though different from those of voluntary motion, they nevertheless run into one another; so that what was at first merely instinctive may afterwards become a matter of deliberate choice. The same muscles are the instruments of both; and they differ from the muscles obeying the internal stimuli, such as the heart, in being liable to fatigue, and thereby concurring with the exercise of sensation and of thought, in rendering sleep necessary. There are no muscles except those of respiration, of which the constant action is necessary to life, and which are void of consciousness in their ordinary exercise, but which are yet in some measure under the controul of the will. The principal end answered by the power of the will over the muscles of respiration in man, is to form and regulate the voice. But, though instinctive motions are in some cases convertible into those which are voluntary, they ought by no means to be confounded together; for, even those animals which are destitute of brain and nerves, are capable of actions evidently of the instinctive kind. A leech, for instance, being brought into contact with a living animal, is impelled by an instinct of its nature to fasten upon it, and suck its blood. There is something very similar to this even in vegetables, as in the case of tendrils and creeping plants being stimulated by the contact of other bodies to cling round them in a particular direction.

It has been demonstrated by Galileo, that in similar unequal bodies, of a cylindrical or prismatic shape, such as the limbs of animals nearly are, the ratio of their efforts to break by their own weight is in the quadruplicate ratio of their lengths; but that the resistance they make to the same force is only the triplicate ratio of their lengths. It follows, from this, that, in order to endow the limbs of animals with the same relative force, it is only necessary that the bones should possess an increased proportion of thickness, in order to give an adequate increase of what may be called the dead strength; but a similar increase of living strength is necessary, by a suitable addition of muscular power, in order to keep pace with the increased size of the bones. Now we observe, in fact, that in large-sized animals, such as the bull and the elephant, the thickness both of their bones and muscles becomes greater in proportion to the length of their limbs than in the smaller animals, and they are therefore of a less elegant form. But nature has not carried this so far as to compensate for the disadvantage arising from the increase of size; for the greater animals have not the same proportional strength, in relation to their bulk, that the smaller animals have. It has been computed, that a flea can draw from seventy to eighty times its own weight, whereas a horse cannot with ease draw more than three times his own weight. This disproportion between size and strength is very observable in different individuals of the human species; for tall men are not muscular, even in the simple proportion of their stature."

OF THE PARTICULAR MUSCLES.

MUSCLES of the TEGUMENTS of the CRANIUM.—The skin that covers the cranium is moved by a single broad digastric muscle, and one small pair, viz. 1. *Occipito-frontalis*, arises fleshy from the transverse protuberant ridge near the middle of the os occipitalis laterally, where it joins with the temporal bone. It is inserted into the orbicularis palpebrarum of each side, and into the skin of the eye-brows, sending down a fleshy slip between them. It pulls the skin of the head backwards; raises the eye-brows upwards; and draws up the wrinkles of the skin of the forehead. 2. *Corrugator supercilii*, arises fleshy from the internal angular process of the os frontis, above the joining of the os nasi, and from thence it runs outwards, and a little upwards. It is inserted into the inner and inferior fleshy part of the occipito-frontalis muscle, where it joins

with the orbicularis palpebrarum. It draws the eye-brow of that side towards the other, and makes it project over the inner canthus of the eye: when both act, they pull down the skin of the forehead, and make it wrinkle, particularly between the eye-brows.

MUSCLES of the EAR.—The muscles of the ear may be divided into three classes, viz. the common, proper, and internal. The common move the whole ear; the proper only affect the particular parts to which they are connected; and the internal, the small bones within the tympanum. The common muscles are, 1. *Attollens aurem*, arises thin, broad, and tendinous, from the tendon of the occipito-frontalis, from which it is almost inseparable, where it covers the aponeurosis of the temporal muscle. It is inserted into the upper part of the ear, opposite to the antihelix, and serves to draw the ear upwards, and make the parts into which it is inserted tense. 2. *Anterior auris*, arises thin and membranous near the posterior part of the zygoma; is inserted into a small eminence on the back of the helix, opposite to the concha; and is used to draw this eminence a little forwards and upwards. 3. *Retrahentes auris*, arise sometimes by three, but always by two distinct small muscles, from the external and posterior part of the root of the mastoid process, immediately above the insertion of the sterno-cleido-muscle; are inserted into that part of the back of the ear which is opposite to the septum that divides the scapha and concha; and serve to draw the ear back, and stretch the concha.

The proper muscles are, 1. *Helicis major*, arises from the upper and acute part of the helix anteriorly; is inserted into its cartilage a little above the tragus; and serves to depress that part, from which it arises a little downwards and forwards. 2. *Helicis minor*, arises from the inferior and anterior part of the helix; is inserted into the crus of the helix, near the fissure in the cartilage opposite to the concha; and is used to contract the fissure. 3. *Tragicus*, arises from the middle and outer part of the concha; is inserted into the point of the tragus; and pulls the point of the tragus a little forwards. 4. *Antitragicus*, arises from the internal part of the cartilage that supports the antitragus; and, running upwards, is inserted into the tip of the antitragus, as far as the inferior part of the antihelix; it turns the tip of the antitragus a little outwards, and depresses the extremity of the antihelix towards it. 5. *Transversus auris*, arises from the prominent part of the concha on the dorsum of the ear; is inserted opposite to the outer side of the antihelix; and draws the parts to which it is connected to each other, and stretches the scapha and concha.

The muscles of the internal ear are three, viz. 1. *Laxator tympani*, arises from the extremity of the spinous process of the sphenoid bone; then runs backwards, along with the nerve called *chorda tympani*, in a fissure of the os temporis that lodges the condyle of the lower jaw. It is inserted into the long process of the malleus, within the tympanum, where it rests upon the edge of the fissure between the pars squamosa and petrosa; and serves to draw the malleus obliquely forwards towards its origin, and consequently the membrana tympani. 2. *Tensor tympani*, arises from the cartilaginous extremity of the Eustachian tube, near the entry of the artery of the dura mater; from thence running backwards near the osseous part of the Eustachian tube, and sends off a slender tendon, which makes a turn into the tympanum along with the nerve called *chorda tympani*. It is inserted into the posterior part of the handle of the malleus, a little lower than the root of its long process; and serves to pull the malleus and membrana tympani inwards towards the pars petrosa, by which the membrane is made more concave and tense. 3. *Stapedius*, arises from a little cavern in the pars petrosa, near the cells of the mastoid process; its tendon passes thro' a small hole in the same cavern, enters the anterior part of the tympanum, and is inserted into the posterior part of the head of the stapes. Its use is to draw the stapes obliquely upwards towards the cavern, by which the posterior part of its base is moved inwards, and the anterior part outwards.

MUSCLES of the EYE-LIDS.—The palpebre or eye-lids, have one muscle common to both, and the upper eye-lid one proper to itself. 1. *Orbicularis palpebrarum*, arises from the outer edge of the orbital process of the superior maxillary bone, and from a tendon near the inner angle of the eye, firmly adhering to the internal angular process of the os frontis, and to the short round tendon which serves to fix the palpebre and muscular fibres arising from it. It is inserted into the nasal process of the superior maxillary bone, covering the anterior and upper part of the lachrymal sac; and serves to shut the eye, by drawing both lids close together, the fibres contracting from the outer angle towards the inner, press the eye-ball, squeeze the lachrymal gland, and convey the tears towards the puncta lachrymalis. The *ciliaris* of some authors is only a part of this muscle covering the cartilages of the eye-lids, called *cilia* or *tarfi*. 2. *Levator palpebræ superioris*, arise from the upper part of the foramen opticum of the sphenoid bone, thro' which the optic nerve passes. It is inserted into the cartilage that supports the upper eye-lid, named *tarfus*; and serves to open the eye, by drawing the eye-lid upwards.

MUSCLES of the EYE-BALL.—The muscles which move the globe of the eye are six, viz. Four *straight* and two *oblique*. 1. *Levatore oculi*, arises from the upper part of the foramen opticum of the sphenoid bone, below the levator palpebræ superioris; and is inserted into the superior and fore-part of the tunica sclerotica, by a broad thin tendon; and is used to raise up the globe of the eye. 2. *Depressor oculi*, arises from the inferior part of the foramen opticum; is inserted opposite to the former; and pulls the globe of the eye down. 3. *Adductor oculi* arises, as the former, between the obliquus superior and depressor, being, from its situation, the shortest. It is inserted opposite to the inner angle, and turns the eye towards the nose. 4. *Abductor oculi*, arises from the bony partition between the foramen opticum and lacerum; is inserted into the globe opposite the outer canthus; and serves to move the globe outwards.

The oblique muscles are two, viz. 1. *Obliquus superior, seu trochlearis*, arises from the edge of the foramen opticum, between the levator and adductor oculi; from thence runs straight along the pars plana of the ethmoid bone to the upper part of the orbit, and runs a little downwards and outwards, inclosed in a loose membranous sheath. It is inserted into the tunica sclerotica; and is used to roll the globe of the eye, and turn the pupil downwards and outwards, so that the upper side of the globe is turned inwards, and the inferior part to the outside of the orbit, and the whole globe drawn towards the inner canthus. 2. *Obliquus inferior*, arises from the outer edge of the orbital process of the superior maxillary bone; and, running obliquely outwards, is inserted into the sclerotica, by a broad thin tendon. Its use is to draw the globe of the eye forwards and inwards; and, contrary to the superior, to turn the pupil upwards, towards the inner extremity of the eye-brow.

MUSCLE of the NOSE.—There is only one muscle on each side proper to the nose; though it is affected by several muscles of the face, viz. *Compressor naris*, arises from the root of the ala nasi externally, and spreads into a number of thin separate fibres, which run up along the cartilage in an oblique manner towards the dorsum of the nose, where it joins with its fellow, and is inserted into the anterior extremity of the os nasi and nasal process of the superior maxillary bone. Its use is to compress the ala towards the septum nasi, particularly when we want to smell acutely; but, if the fibres of the frontal muscle, which adhere to it, act, the upper part of this thin muscle assists to pull the ala outwards. It also corrugates the skin of nose, and assists in expressing certain passions.

MUSCLES of the MOUTH and LIPS.—The mouth has nine pair of muscles, which are inserted into the lips, and a common one formed by the termination of these, viz. three *above*, three *below*, three *outwards*, and the common muscle surrounds the mouth. The three upper are, 1.

Levator anguli oris, arises from the hollow of the superior maxillary bone, and is inserted into the angle of the mouth and under lip, where it joins with its antagonist. It serves to draw the corner of the mouth upwards, and make that part of the cheek opposite to the chin prominent, as in smiling. 2. *Levator labii superioris alæque nasi*, arises by two distinct origins; the first from the external part of the orbital process of the superior maxillary bone; the second, from the nasal process of the superior maxillary bone. The first and shortest portion is inserted into the upper lip and orbicularis labiorum; the second and longest, into the upper lip and outer part of the ala nasi. The first serves to raise the upper lip towards the orbit, and a little outwards; the second portion serves to draw the skin of the nose upwards and outwards, by which the nostril is dilated. 3. *Depressor labii superioris alæque nasi*, arises from the os maxillare superius, immediately above the joining of the gums with the two dentes incisivi, and the dens caninus: from thence it runs up under part of the levator labii superioris alæque nasi; and is inserted into the upper lip and root of the ala nasi. Its use is to draw the upper lip and ala nasi downwards and backwards.

The three lower muscles are, 1. *Depressor anguli oris*, arises from the lower edge of the maxilla inferior, at the side of the chin, and is inserted into the angle of the mouth, joining with the zygomaticus major and levator anguli oris; and serves to pull down the corner of the mouth. 2. *Depressor labii inferioris*, arises from the inferior part of the lower jaw next the chin; runs obliquely upwards; and is inserted into the edge of the under lip, and is lost in its red part. It serves to pull the under lip and skin of the side of the chin downwards, and a little outwards. 3. *Levator labii inferioris*, arises from the lower jaw, at the roots of the alveoli of two dentes incisivi and of the caninus; is inserted into the under lip and skin of the chin; and serves to pull the parts into which it is inserted upwards.

The three outward muscles are, 1. *Buccinator*, arises from the lower jaw, as far back as the last dens molaris and fore-part of the root of the coronoid process; fleshy from the upper jaw, between the last dens molaris and pterygoid process of the sphenoid bone; from the extremity of which it arises tendinous, being continued between both jaws to the constrictor pharyngis superior, with which it joins; from thence, proceeding with straight fibres close to the membrane that lines the mouth, it is inserted into the angle of the mouth within the orbicularis oris; and serves to draw the angle of the mouth backwards and outwards, and to contract its cavity, by pressing the cheek inwards, by which the food is thrust between the teeth.

2. *Zygomaticus major*, arises from the os malæ, near the zygomatic future; and is inserted into the angle of the mouth. Its use is to draw the corner of the mouth and under lip towards the origin of the muscle, and make the cheek prominent, as in laughing. 3. *Zygomaticus minor*, arises from the upper prominent part of the os malæ above the origin of the former muscle; and, descending obliquely downwards, is inserted into the upper lip, near the corner of the mouth, along with the levator anguli oris. It serves to draw the corner of the mouth obliquely outwards, and upwards, towards the external canthus of the eye.

The common muscle is the *orbicularis oris*, which is, in a great measure, formed by the muscles that move the lips; the fibres of the superior descending, those of the inferior ascending, and, decussating each other about the corner of the mouth, run along the lip to join those of the opposite side, so that the fleshy fibres appear to surround the mouth like a sphincter. Its use is to shut the mouth, by contracting and drawing both lips together, and to counteract all the muscles that assist in forming it. There is another small muscle described by Albinus, which he calls *nasalis labii superioris*; but it seems to be only some fibres of the former connected to the septum nasi.

MUSCLES of the LOWER JAW.—The lower jaw has four pair of muscles, viz. two which are seen on the side of

of the face, and two concealed by the angle of the jaw.

1. *Temporalis*, arises from a femicircular ridge of the lower and lateral part of the parietal bone, from all the pars squamosa of the temporal bone, from the external angular process of the os frontis, from the temporal process of the sphenoid bone, and from an aponeurosis which covers it; from these different origins the fibres descend like radii towards the jugum, under which they pass; and are inserted into the upper part of the coronoid process of the lower jaw. This muscle is covered by a tendinous membrane, called its *aponeurosis*, which arises from the bones that give origin to the upper and femicircular part of the muscle; and, descending over it, is inserted into all the jugum, and the adjoining part of the os frontis. The use of this membrane is to give room for the origin of a greater number of fleshy fibres, to fortify the muscle in its action, and to serve as a defence to it. 2. *Masseter*, arises from the superior maxillary bone, where it joins the os malæ; and is inserted into the angle of the lower jaw, serving to pull the lower to the upper jaw, and a little forwards and backwards. 3. *Pterygoideus internus*, arises from the inner and upper part of the internal plate of the pterygoid process, filling all the space between the two plates. It is inserted into the angle of the lower jaw internally; and serves to draw the jaw upwards, and obliquely towards the opposite side. 4. *Pterygoideus externus*, arises from the outer side of the external plate of the pterygoid process of the sphenoid bone, from part of the tuberosity of the os maxillare adjoining to it, and from the root of the temporal process of the sphenoid bone. It is inserted into a cavity in the neck of the condyloid process of the lower jaw; which it pulls forwards, and to the opposite side.

MUSCLES about the ANTERIOR PART of the NECK.—On the side of the neck are two muscles or layers. 1. *Musculus cutaneus, vulgo platysma myoides*, arises from the cellular substance that covers the upper parts of the deltoid and pectoral muscles; in their ascent, they all unite to form a thin muscle, which runs obliquely upwards along the side of the neck, adhering to the skin; and are inserted into the lower jaw, between its angle and the origin of the depressor anguli oris, to which it is firmly connected. It assists the depressor anguli oris in drawing the skin of the cheek downwards; and, when the mouth is shut, it draws all that part of the skin, to which it is connected, below the lower jaw, upwards. 2. *Sterno-cleido-mastoideus*, arises by two distinct origins; the anterior, from the top of the sternum; the posterior, from the upper and anterior part of the clavicle; both unite a little above the anterior articulation of the clavicle, to form one muscle, which runs obliquely upwards and outwards, to be inserted, by a thick strong tendon, into the mastoid process, which it surrounds; and, gradually turning thinner, is inserted as far back as the lambdoid suture. It turns the head to one side, and bends it forwards.

MUSCLES between the LOWER JAW and OS HYOIDES.—There are four layers before, and two muscles at the side. The four layers are, 1. *Digastricus*, arises from the fossa at the root of the mastoid process of the temporal bone, and runs downwards and forwards; then it is fixed by a ligament to the os hyoides; and, having received from that bone an addition of tendinous and muscular fibres, runs obliquely forwards, and is inserted into a rough sinuosity at the inferior and anterior edge of the chin. Its use is to open the mouth; and, when the jaws are shut, to raise the larynx and pharynx upwards, as in deglutition. 2. *Mylo-hyoideus*, arises from the inside of the lower jaw, between the last dens molaris and the middle of the chin, where it joins with its fellow. It is inserted into the lower edge of the basis of the os hyoides, and serves to pull the os hyoides forwards, upwards, and to a side. 3. *Genio-hyoideus*, arises from a rough protuberance in the middle of the lower jaw internally; is inserted into the basis of the os hyoides; and draws this bone forwards to the chin. 4. *Genio-hyo-glossus*, arises from the middle of the lower jaw; its fibres run, like a fan; and are inserted into the tongue,

and base of the os hyoides, near its cornu. It serves to draw the tip of the tongue backwards into the mouth, the middle downwards, and to render its dorsum concave; to draw its root and os hyoides forwards, and to thrust the tongue out of the mouth.

The two muscles at the side are, 1. *Hyo-glossus*, arises from the base, cornu, and appendix of the os hyoides; the fibres run upwards and outwards, to be inserted into the side of the tongue, near the stylo-glossus; and pulls the tongue inwards and downwards. 2. *Lingualis*, arises from the root of the tongue laterally; runs forwards between the hyo-glossus and genio-glossus, to be inserted into the tip of the tongue, along with part of the stylo-glossus. It serves to contract the substance of the tongue, and bring it backwards.

MUSCLES between the OS HYOIDES and TRUNK.—These may be divided into two layers. The first layer consists of two muscles. 1. *Sterno-hyoideus*, arises from the cartilaginous extremity of the first rib, the upper and inner part of the sternum, and from the clavicle where it joins with the sternum. It is inserted into the base of the os hyoides; and its use is to pull the os hyoides downwards. 2. *Omo-hyoideus*, arises from the superior costa of the scapula, near the femilunar notch, and from the ligament that runs across it; thence, ascending obliquely, is inserted into the base of the os hyoides, between its cornu and the insertion of the sterno-hyoideus. Its use is to pull the os hyoides obliquely downwards.

The second layer consists of three muscles. 1. *Sterno-thyroideus*, arises from the whole edge of the uppermost bone of the sternum internally, opposite to the cartilage of the first rib, from which it receives a small part of its origin. It is inserted into the surface of the rough line at the external part of the inferior edge of the thyroid cartilage, and is used to draw the larynx downwards. 2. *Thyro-hyoideus*, arises from the rough line, opposite to the former; is inserted into part of the bases, and almost all the cornu of the os hyoides; and its use is to pull the os hyoides downwards, or the thyroid cartilage upwards. 3. *Crico-thyroideus*, arises from the side and fore-part of the cricoid cartilage, and is inserted by two portions; the first, into the lower part of the thyroid cartilage; the second, into its inferior cornu. It pulls forwards and depresses the thyroid, and elevates and draws back the cricoid, cartilage.

MUSCLES between the LOWER JAW and OS HYOIDES laterally.—These are five in number. These proceed from the styloid process of the temporal bone, from which they have half of their names; and two from the pterygoid process of the sphenoid bone. The three from the styloid process are, 1. *Stylo-glossus*, arises from the styloid process, and from a ligament that connects that process to the angle of the lower jaw. It is inserted into the root of the tongue, runs along its side, and is insensibly lost near its tip. It serves to draw the tongue laterally and backwards. 2. *Stylo-hyoideus*, arises from the middle and inferior part of the styloid process; is inserted into the os hyoides at the junction of the base and cornu; and serves to pull the os hyoides to one side, and a little upwards. Its fleshy belly is generally perforated by the tendon of the digastric muscle, on one or both sides. There is often another accompanying it, called *stylo-hyoideus alter*; and has the same origin, insertion, and use. 3. *Stylo-pharyngeus*, arises from the root of the styloid process; is inserted into the side of the pharynx and back-part of the thyroid cartilage, and serves to dilate and raise the pharynx and thyroid cartilage upwards.

The two from the pterygoid process are, 1. *Circumflexus, or tensor palati*, arises from the spinous process of the sphenoid bone, behind the foramen ovale; it then runs, down the pterygoideus internus, passes over the hook of the internal plate of the pterygoid process, and is inserted into the velum pendulum palati, and the femilunar edge of the os palati, and extends as far as the suture which joins the two bones. Its use is to stretch the velum, to draw it downwards, and to a side towards the hook. It has little effect upon the tube, being chiefly connected to its osseous

part. 2. *Levator palati*, arises from the extremity of the pars petrosa of the temporal bone, and is inserted into the whole length of the velum pendulum palati, as far as the root of the uvula, and unites with its fellow. Its use is to draw the velum upwards and backwards, so as to shut the passage from the fauces into the mouth and nose.

Before we describe the muscles situated about the passage into the throat, it will be necessary to mention the principal parts to which they are connected. Upon looking into any person's mouth, we see a soft curtain hanging from the palate-bones, named *velum pendulum palati*. In the middle of which we likewise observe a papilla projecting from the velum, named *uvula*, or *pap of the throat*. From each side of the uvula, at its root, two arches, or columns, are sent down; the anterior to the root of the tongue, the posterior to the pharynx. Between these arches, on each side, the cellular glands called *amygdalæ*, or *almonds of the ears*, are situated. The common opening behind the anterior arch may be named *fauces*, or *top of the throat*, from which there are six passages, viz. two upwards, being one to each nostril: two at the sides, or one to each ear, called the *Eustachian tubes*: two downwards; the anterior is the passage through the *glottis* and *larynx*, into the *trachea*, which terminates in the lungs; the posterior is the largest, named *pharynx*, or *top of the œsophagus*, which leads to the stomach.

MUSCLES at the ENTRY to the FAUCES.—There are two on each side, and a single one in the middle. The two on each side are, 1. *Constrictor ischmi facium*, arises from the side of the tongue, near its root; from thence running upwards within the anterior arch, before the amygdala, it is inserted into the middle of the velum pendulum palati, at the root of the uvula anteriorly, being connected with its fellow, and with the beginning of the palato-pharyngeus. It draws the velum toward the root of the tongue, which it raises at the same time, and, with its fellow, contracts the passage between the two arches, by which it shuts the opening into the fauces. 2. *Palato-pharyngeus*, arises from the middle of the velum pendulum palati, at the root of the uvula posteriorly, and from the tendinous expansion of the circumflexus palati. It is inserted into the edge of the upper and back part of the thyroid cartilage; some of its fibres being lost between the membrane of the pharynx and the two inferior constrictors. It draws the uvula and velum downwards and backwards; and at the same time pulls the thyroid cartilage and pharynx upwards, and shortens it; with the constrictor superior and tongue, it assists in shutting the passage into the nostrils; and, in swallowing, it thrusts the food from the fauces into the pharynx.

The one in the middle is the *azygos uvula*, which arises from the extremity of the future that joins the palate-bones; runs down the whole length of the velum and uvula; and is inserted into the tip of the uvula. It raises the uvula upwards and forwards, and shortens it.

MUSCLES on the POSTERIOR PART of the PHARYNX.—Of these there are three pair. 1. *Constrictor pharyngis inferior*, arises from the side of the thyroid cartilage, near the attachment of the sterno-hyoideus and thyreo-hyoideus muscles. It is the largest of the three, and is inserted into the white line, where it joins with its fellow; the superior fibres running obliquely upwards, covering nearly one half of the middle constrictor, and terminating in a point; the inferior fibres run more transversely, and cover the beginning of the œsophagus. Its use is to compress that part of the pharynx which it covers, and to raise it with the larynx a little upwards. 2. *Constrictor pharyngis medius*, arises from the appendix of the os hyoides, and from the ligament which connects it to the thyroid cartilage. It is inserted into the middle of the cuneiform process of the os occipitis, before the foramen magnum, and serves to compress that part of the pharynx which it covers, and to draw it and the os hyoides upwards. 3. *Constrictor pharyngis superior*, arises from the cuneiform process of the os occipitis, before the foramen magnum; and, between the jaws, it is continued with the buccinator muscle; and

with some fibres from the root of the tongue, and from the palate. It is inserted into the middle of the pharynx, where it joins with its fellow, and is covered by the constrictor medius. It serves to compress the upper part of the pharynx, and draw it forwards and upwards.

MUSCLES about the GLOTTIS.—They consist generally of four pair of small muscles, and a single one. 1. *Crico-arytenoideus posticus*, arises from the back-part of the cricoid cartilage, and is inserted into the posterior part of the base of the arytenoid cartilage. Its use is to open the rima glottidis, and, by pulling back the arytenoid cartilage, to stretch the ligament so as to make it tense. 2. *Crico-arytenoideus lateralis*, arises from the cricoid cartilage, laterally, where it is covered by part of the thyroid, and is inserted into the side of the base of the arytenoid cartilage near the former. It serves to open the rima glottidis, by pulling the ligaments from each other. 3. *Thyreo-arytenoideus*, arises from the under and back part of the middle of the thyroid cartilage; and, running backwards and a little upwards, along the side of the glottis, is inserted into the arytenoid cartilage, higher up and farther forwards than the crico-arytenoideus lateralis. It serves to pull the arytenoid cartilage forwards, and consequently to shorten and relax the ligament of the larynx or glottis vera. 4. *Arytenoideus obliquus*, arises from the base of one arytenoid cartilage; and, crossing its fellow, is inserted near the tip of the other arytenoid cartilage. When both act, they pull the arytenoid cartilages towards each other. One of these is very often wanting.

The single muscle is the *arytenoideus transversus*. It arises from the side of one arytenoid cartilage, from near its articulation with the cricoid to near its tip. The fibres run straight across, and are inserted, in the same manner, into the other arytenoid cartilage. Its use is to shut the rima glottidis, by bringing these two cartilages, with the ligaments, nearer one another.

Besides these, there are a few separate muscular fibres on each side; which, from their general direction, are named, 1. *Thyreo-epiglottideus*, arises, by a few pale separated fibres, from the thyroid cartilage; and is inserted into the epiglottis laterally. Its use is to draw the epiglottis downwards, and, at the same time, it expands that soft cartilage. 2. *Aryteno-epiglottideus*, arises from the lateral and upper part of the arytenoid cartilage; and, running along the outer side of the external rima, is inserted into the epiglottis along with the former. Its use is to pull that side of the epiglottis towards the external rima; or, when both act, to pull it close upon the glottis. It is counteracted by the elasticity of the epiglottis.

MUSCLES on the ANTERIOR PART of the ABDOMEN.—They consist of three broad layers on each side of the belly; always a long one, and generally a short one, on each side of the linea alba. The three layers are, 1. *Obliquus descendens externus*, arises, by eight heads, from the lower edges of an equal number of inferior ribs, at a little distance from their cartilages: it always intermixes in a fermented manner, with portions of the serratus major anticus; and generally coheres to the pectoralis major, intercostals, and latissimus dorsi: which last covers the edge of a portion of it extended from the last rib to the spine of the os ilium. It is inserted into the whole length of the *linea alba*; becomes thicker towards the lower part of the abdomen, and is perforated in the middle by the umbilicus. On the outside of the rectus muscle, the tendon of the external oblique appears whiter than elsewhere, by its being there connected with the tendons of the internal oblique and transverse muscles; so that this part has been called *linea semilunaris*, from its curved shape. The under part of the tendon divides into two columns, which leaves an oval space between them, named the *ring* of the external oblique muscle, for the passage of the spermatic cord in the male, or round ligament of the womb. From that part, which is named its *anterior superior spinous process*, it is stretched tendinous to the os pubis, and is named *Poupart's* or *Fallopian's* ligament. From this ligament it sends a tendinous

a tendinous layer, which is lost in the membranous fascia of the thigh. It supports and compresses the peritonæum and abdomen; assists the evacuations of fæces and urine, and likewise in the exclusion of the foetus; thrusts the diaphragm upwards, and draws down the ribs in expiration; bends the body obliquely when the ribs are fixed, and raises the pelvis obliquely. 2. *Obliquus ascendens internus*, arises from the spine of the ilium, the whole length between the posterior and superior anterior spinous process; from the os sacrum and the three undermost lumbar vertebræ, by a tendon common to it and to the serratus pecticus inferior muscle; from Poupart's ligament, at the middle of which it sends off the beginning of the cremaster muscle; and the spermatic cord in the male, or round ligament of the womb in the female, passes under its thin edge, except a few detached fibres. It is inserted into the cartilago ensiformis, into the cartilages of the seventh, and those of all the false ribs; but, at the upper part, it is extremely thin, resembling a cellular membrane, and only becomes fleshy at the cartilage of the tenth rib. At its undermost part it is inserted into the fore-part of the os pubis. Its principal use is to assist the former; but it bends the trunk in the reverse direction. 3. *Transversalis*, arises from the inner or back part of the cartilages of the seven lower ribs, where some of its fibres are continued with those of the diaphragm and the intercostal muscles; by a broad thin tendon, connected to the transverse processes of the last vertebra of the back and the four superior vertebra of the loins; fleshy, from the whole spine of the os ilium internally, and from the tendon of the external oblique muscle, where it intermixes with some fibres of the internal oblique. It is inserted into the cartilago ensiformis, and into the whole length of the linea alba, excepting its lowermost part. Its use is to support and compress the abdominal bowels; and it is so particularly well adapted for the latter purpose, that it might be called the *proper constrictor* of the abdomen.

The long muscle in the middle is named *rectus abdominis*. It arises from the ligament of the cartilage which joins the two ossa pubis to each other; runs upwards the whole length of, and parallel to, the linea alba, growing broader and thinner as it ascends. It is inserted into the cartilages of the three inferior true ribs, and often intermixed with some fibres of the pectoral muscle. It serves to compress the fore-part, but more particularly the lower part, of the belly; to bend the trunk forwards, or to raise the pelvis. By its tendinous interfections, it is enabled to contract at any of the intermediate spaces; and, by its connection with the tendons of the other muscles, it is prevented from changing place, and from rising into a prominent form when in action.

The short muscle in the middle is named *pyramidalis*. It arises along with the rectus; and, running upwards within the same sheath, is inserted, by an acute termination, near half-way between the os pubis and umbilicus, into the linea alba and inner edge of the rectus muscle. As it is frequently wanting in both sides, without any inconvenience, its use seems to be to assist the inferior part of the rectus.

MUSCLES OF THE MALE ORGANS OF GENERATION.—The *testicles* are said to have a thin muscle common to both, and one proper to each. The supposed common muscle is called the *dartos*. This appears to be no more than a condensation of the cellular membrane lining the scrotum; yet the skin here is capable of being corrugated and relaxed in a greater degree than in other places.

The muscle proper to each testicle is the *cremaster*. It arises from the internal oblique, where a few fibres of that muscle intermix with the transversalis, near the junction of the os ilium and pubis, over which part it passes, after having pierced the ring of the externus obliquus; and then it descends upon the spermatic cord. It is inserted into the tunica vaginalis of the testicle, upon which it spreads, and is insensibly lost. Its use is to suspend and draw up the testicle, and to compress it in the act of coition.

The penis has three pair of muscles. 1. *Erector penis*,

arises from the tuberosity of the os ischium, and runs upwards, embracing the whole crus of the penis. It is inserted into the strong tendinous membrane that covers the corpora cavernosa penis; and its use is to compress the crura penis, by which the blood is pushed from it into the fore-part of the corpora cavernosa; and the penis is by that means more completely distended. 2. *Accelerator urinæ, seu ejaculator seminis*, arises from the sphincter ani and membranous part of the urethra; and from the crus, nearly as far forwards as the beginning of the corpus cavernosum penis; the inferior fibres run more transversely, and the superior descend in an oblique direction. It is inserted into a line in the middle of the bulb, where it joins with its fellow, by which the bulb is completely enclosed. Its use is to drive the urine or semen forwards; and, by grasping the bulb of the urethra, to push the blood towards its corpus cavernosum and the glans, by which they are distended. 3. *Transversus perinei*, arises from the rough fatty membrane that covers the tuberosity of the os ischium; from thence it runs transversely inwards, and is inserted into the accelerator urinæ, and into that part of the sphincter ani which covers the bulb. It serves to dilate the bulb, and draw the perineum and verge of the anus a little outwards and backwards.

There is often a fourth muscle, named *transversus perinei alter*. It arises behind the former, runs more obliquely forwards, and is inserted into that part of the accelerator urinæ which covers the anterior part of the bulb of the urethra; and serves to assist the former.

MUSCLES OF THE ANUS.—The anus has a single muscle, and one pair. The single muscle is *sphincter ani*. This arises from the skin and fat that surround the verge of the anus on both sides; the fibres are gradually collected into an oval form, and surround the extremity of the rectum. It is inserted, before, by a narrow point, into the perineum, acceleratores urinæ, and transversus perinei; behind, by an acute termination, into the extremity of the os coccygis. It shuts the passage through the anus into the rectum, and pulls down the bulb of the urethra, by which it assists in ejecting the urine and semen. *Levator ani*, arises from the os pubis within the pelvis; from the thin tendinous membrane that covers the obturator internus and coccygeus muscles; from the spinous process of the os ischium; and its fibres run down like rays from a circumference to a centre. It is inserted into the sphincter ani, acceleratores urinæ, and anterior part of the two last bones of the coccygis; surrounds the extremity of the rectum, neck of the bladder, prostate gland, and part of the vesiculæ feminales. It serves to draw the rectum upwards after the evacuation of the fæces, and to assist in shutting it; to sustain the contents of the pelvis, and to help in ejecting the semen, urine, and contents of the rectum; and, perhaps, by pressing upon the veins, to contribute greatly to the erection of the penis.

MUSCLES OF THE FEMALE ORGANS OF GENERATION.—The clitoris has one pair. *Erector clitoridis*, arises from the crus of the os ischium internally, and in its ascent covers the crus of the clitoris as far up as the os pubis. It is inserted into the upper part of the crus and body of the clitoris; and draws the clitoris downwards and backwards, and may serve to make the body of the clitoris more tense, by squeezing the blood into it from its crus.

The vagina has one pair. *Sphincter vaginae*, arises from the sphincter ani, and from the posterior side of the vagina, near the perineum: from thence it runs up the side of the vagina, near its external orifice, opposite to the nymphae, and covers the corpus cavernosum vaginae. It is inserted into the crus and body, or union of the crura clitoridis; and contracts the mouth of the vagina, and compresses its corpus cavernosum.

The perineum has one pair. *Transversus perinei*, arises, as in the male, from the fatty cellular membrane which covers the tuberosity of the os ischium; and is inserted into the upper part of the sphincter ani, and into a white hardish tough substance in the perineum, between the lower

er part of the pudendum and anus. Its use is to sustain and keep the perineum in its proper place.

The anus, as in the male, has a single muscle, and one pair. *Sphincter ani*, arises from the skin and fat surrounding the extremity of the rectum; and is inserted into the white tough substance of the perineum; and into the point of the os coccygis. Its use is to shut the passage into the rectum; and, by pulling down the perineum, to assist in contracting the mouth of the vagina. *Levator ani*, arises, as in the male, within the pelvis, and descends along the inferior part of the vagina and rectum. It is inserted into the perineum, sphincter ani, extremity of the vagina, and rectum. It serves to raise the extremity of the rectum upwards, to contract the inferior part of the rectum, and to assist in contracting and supporting the vagina; and, perhaps, by pressing on the veins, to contribute to the distension of the cells of the clitoris and corpus cavernosum of the vagina.

MUSCLES within the PELVIS.—Of these there are two pair. 1. *Obturator internus*, arises from more than one half of the internal circumference of the foramen thyroideum, formed by the os pubis and ischium: its inside is covered by a portion of the levator ani; and appears to be divided into a number of fasciculi, which unite and form a roundish tendon, that passes out of the pelvis, between the posterior sacro-schiatric ligament and tuberosity of the os ischium; where it passes over the capsular ligament of the thigh-bone. It is inserted into the large pit at the root of the trochanter major; and serves to roll the os femoris obliquely outwards. 2. *Coccygeus*, arises from the spinous process of the os ischium, and covers the inside of the posterior sacro-schiatric ligament; and is inserted into the extremity of the os sacrum, and near the whole length of the os coccygis laterally. Its use is to support and move the os coccygis forwards, and to tie it more firmly to the sacrum.

MUSCLES within the CAVITY of the ABDOMEN.—These consist of a single muscle, and four pair. The *diaphragma*, is a broad thin muscle, which makes a complete septum between the thorax and abdomen, is concave below and convex above; the middle of it on each side reaching as high within the thorax of the skeleton as the fourth rib; it is commonly divided into two portions. 1. The *superior or greater muscle of the diaphragm*, arises, by distinct fleshy fibres, from the cartilago ensiformis, from the cartilages of the seventh, and of all the inferior ribs on both sides. The fibres from the cartilago ensiformis, and from the seventh and eighth ribs, run obliquely upwards and backwards; from the ninth and tenth, transversely inwards and upwards; and, from the eleventh and twelfth, obliquely upwards. From these different origins the fibres run, like radii from the circumference to the centre of a circle; and are inserted into a cordiform tendon, of a considerable breadth, which is situated in the middle of the diaphragm, and in which the fibres from opposite sides are interlaced. Towards the right side the tendon is perforated, by a triangular hole, for the passage of the vena cava inferior; and to the upper convex part of it the pericardium and mediastinum are connected. 2. The *inferior lesser muscle, or appendix, of the diaphragm*, arises from the second, third, and fourth, lumbar vertebrae, by eight heads; of which two in the middle, commonly called its *crura*, are the longest, and begin tendinous. Between the crura, the aorta and thoracic duct pass; and, on the outside of these, the great sympathetic nerves and branches of the vena azygos perforate the shorter heads. The muscular fibres run obliquely upwards and forwards, and form in the middle two fleshy columns, which decussate and leave an oval space between them for the passage of the oesophagus and eighth pair of nerves. It is inserted, by strong fleshy fibres, into the posterior part of the middle tendon. The diaphragm is the principal agent in respiration, particularly in inspiration: for, when it is in action, the fibres, from their different attachments, endeavour to bring themselves into a plane towards the middle tendon, by which

the cavity of the thorax is enlarged, particularly at the sides, where the lungs are chiefly situated; and, as the lungs must always be contiguous to the inside of the thorax and upper side of the diaphragm, the air rushes into them, in order to fill up the increased space. This muscle is assisted by the two rows of intercostals, which elevate the ribs, and the cavity of the thorax is more enlarged. In time of violent exercise, or whatever cause drives the blood with unusual celerity towards the lungs, the pectoral muscles, the *ferrati antei majores*, the *ferrati postici superiores*, and *scaleni* muscles, are brought into action. And, in laborious inspiration, the muscles which arise from the upper part of the thorax, when the parts into which they are inserted are fixed, likewise assist. In expiration, the diaphragm is relaxed and pushed up by the pressure of the abdominal muscles upon the viscera of the abdomen; and at the same time that they press it upwards, they also, together with the *sterno-costales* and *ferrati postici inferiores*, pull down the ribs, and are assisted in a powerful manner by the elasticity of the cartilages that join the ribs to the sternum; by which the cavity of the thorax is diminished, and the air suddenly pushed out of the lungs; and, in laborious expiration, the *quadrati lumborum*, *sacro-lumbales*, and *longissimi dorsi*, concur in pulling down the ribs.

The four pair are, 1. *Quadratus lumborum*, arises from the posterior part of the spine of the os ilium; and is inserted into the transverse processes of all the vertebrae of the loins, into the last rib near the spine, and by a small tendon into the side of the last vertebra of the back. Its use is to move the loins to one side, pull down the last rib, and, when both act, to bend the loins forwards. 2. *Psoas parvus*, arises from the sides of the two upper vertebrae of the loins, and sends off a small long tendon, which ends thin and flat, and is inserted into the brim of the pelvis, at the junction of the os ilium and pubis. Its use is to assist the *psoas magnus* in bending the loins forwards; and, in certain positions, to assist in raising the pelvis. 3. *Psoas magnus*, arises from the side of the body, and transverse process of the last vertebra of the back; and, in the same manner, from all those of the loins, by as many distinct slips. It is inserted into the trochanter minor of the os femoris; and into that bone a little below the same trochanter. Its use is to bend the thigh forwards; or, when the inferior extremity is fixed, to assist in bending the body. 4. *Iliacus internus*, arises from the transverse process of the last vertebra of the loins, from all the inner lip of the spine of the os ilium, from the edge of that bone between its anterior superior spinous process and the acetabulum, and from most of the hollow part of the ilium. It joins with the *psoas magnus*, where it begins to become tendinous; and is inserted along with it. Its use is to assist the *psoas* in bending the thigh, and to bring it directly forwards.

MUSCLES on the ANTERIOR PART of the THORAX.—These may be divided into two layers. The first layer consists of one muscle, named *pectoralis major*. It arises from the cartilaginous extremities of the fifth and sixth ribs; from almost the whole length of the sternum, and from near half of the anterior part of the clavicle. It is inserted, by two broad tendons, which cross each other at the upper and inner part of the os humeri, above the insertion of the deltoid muscle, and outer side of the groove for lodging the tendon of the long head of the biceps. Its use is to move the arm forwards, and obliquely upwards, towards the sternum.

The second layer consists of three muscles: 1. *Subclavius*, arises from the cartilage that joins the first rib to the sternum; and is inserted into the inferior part of the clavicle; and serves to pull the clavicle downwards and forwards. 2. *Pectoralis minor*, arises from the upper edge of the third, fourth, and fifth, ribs; and is inserted into the coracoid process of the scapula. It serves to bring the scapula forwards and downwards, or to raise the ribs upwards. 3. *Serratus magnus*, arises from the nine superior ribs, by an equal number of fleshy digitations, resembling

the teeth of a saw; and is inserted into the whole base of the scapula, internally, between the insertion of the rhomboid and the origin of the subscapularis muscles, being folded about the two angles of the scapula. It serves to move the scapula forwards; and, when the scapula is forcibly raised, to draw upwards the ribs.

MUSCLES between the RIBS and within the THORAX.—Between the ribs, on each side, there are eleven double rows of muscles, which are named *intercostals*. These decussate each other like the strokes of the letter X. 1. *Intercostales externi*, arise from the inferior acute edge of each superior rib, and run obliquely forwards, the whole length from the spine to near the joining of the ribs with their cartilages; and are inserted into the upper obtuse edge of each inferior rib, as far back as the spine, into which the posterior portion is fixed. 2. *Intercostales interni*, arise in the same manner as the external: but they begin at the sternum, and run obliquely backwards, as far as the angle of the rib; and are inserted in the same manner as the external. By means of these muscles, the ribs are equally raised upwards during inspiration. Their fibres being oblique, give them a greater power of bringing the ribs near each other, than could be performed by straight ones. But, by the obliquity of the fibres, they are almost brought contiguous: and as the fixed points of the ribs are before and behind, if the external had been continued forwards to the sternum, and the internal backwards to the spine, it would have hindered their motion, which is greatest in the middle, though the obliquity of the ribs renders it less perceptible; and, instead of raising the fibres fixed to the sternum and spine, would have depressed the ribs. The muscles within the thorax are one pair, viz. *triangularis* or *sternocostalis*, arises from the cartilago ensiformis laterally, and from the edge of the lower half of the middle bone of the sternum, from whence its fibres ascend obliquely upwards and outwards. It is inserted, generally by three triangular terminations, into the lower edge of the cartilages of the third, fourth, and fifth, ribs, near where these join with the ribs. Its use is to depress these cartilages, and the extremities of the ribs; and consequently to assist in contracting the cavity of the thorax. This muscle often varies; and is sometimes inserted into the cartilage of the second rib; sometimes into the cartilage of the sixth rib.

MUSCLES on the ANTERIOR PART of the NECK.—These consist of one layer formed by four muscles. 1. *Longus colli*, arises from the bodies of the three vertebrae of the back laterally; and from the transverse process of the third, fourth, fifth, and sixth, vertebrae of the neck; and is inserted into the fore-part of the bodies of all the vertebrae of the neck. Its use is to bend the neck gradually forwards, and to one side. 2. *Rectus capitis internus major*, arises from the anterior points of the transverse processes of the third, fourth, fifth, and sixth, vertebrae of the neck; and is inserted into the cuneiform process of the os occipitis. Its use is to bend the head forwards. 3. *Rectus capitis internus minor*, arises from the fore-part of the body of the first vertebra of the neck; and is inserted near the root of the condyloid process of the os occipitis, under the former muscle. Its use is to bend the head forwards. 4. *Rectus capitis lateralis*, arises from the anterior part of the point of the transverse process of the first vertebra of the neck, and is inserted into the os occipitis, opposite to the foramen stylo-mastoideum of the temporal bone. Its use is to bend the head a little to one side.

MUSCLES on the POSTERIOR PART of the TRUNK.—These may be divided into four layers, and a single pair. The first layer consists of two muscles, which cover almost the whole posterior part of the trunk. 1. *Trapezius superficialis*, arises from the middle of the os occipitis behind; and from the rough curved line that extends from the protuberance towards the mastoid process of the temporal bone; runs down the nape of the neck, and covers the spinous processes of the superior vertebrae of the neck; but rises from the spinous processes of the two inferior, and from the spinous processes of all the vertebrae of the back;

adhering to its fellow the whole length of its origin. It is inserted into the posterior half of the clavicle; into the acromion, and into almost all the spine of the scapula. It moves the scapula according to the three different directions of its fibres; for the upper descending fibres draw it obliquely upwards, the middle transverse straight fibres draw it directly backwards, and the inferior ascending fibres draw it obliquely downwards and backwards. Where it is inseparably united to its fellow in the nape of the neck, it is named *ligamentum nuchæ* or *colli*. 2. *Latissimus dorsi*, arises from the posterior part of the spine of the os ilium, from all the spinous processes of the os sacrum and vertebrae of the loins, and from the seven inferior ones of the vertebrae of the back; also from the extremities of the three or four inferior ribs, by as many distinct slips. The inferior fibres ascend obliquely, and the superior run transversely, over the inferior angle of the scapula, towards the axilla, where they are all collected, twisted, and folded. It is inserted into the inner edge of the groove, for lodging the tendon of the long head of the biceps; and serves to pull the arm backwards and downwards, and to roll the os humeri.

The second layer consists of three pair, two on the back, and one on the neck. On the back, 1. *Serratus posterior inferior*, arises in common with that of the latissimus dorsi, from the spinous processes of the two inferior vertebrae of the back, and from the three superior vertebrae of the loins; and is inserted into the lower edges of the four inferior ribs, at a little distance from their cartilages; and serves to depress the ribs into which it is inserted. 2. *Rhomboideus*. This muscle is divided into two portions: 1. *Rhomboideus major*, arises from the spinous processes of the five superior vertebrae of the back; and is inserted into all the basis of the scapula below its spine. This serves to draw the scapula obliquely upwards and directly inwards. 2. *Rhomboideus minor*, arises from the spinous processes of the three inferior vertebrae of the neck; and from the ligamentum nuchæ; and is inserted into the base of the scapula, opposite to its spine. Its use is to assist the former. On the neck, 3. *Splenius*, arises from the four superior spinous processes of the vertebrae of the back, and from the five inferior of the neck, and adheres firmly to the ligamentum nuchæ. At the third vertebrae of the neck, the splenii recede from each other, so that part of the complexus muscle is seen. It is inserted into the five superior transverse processes of the vertebrae of the neck; and into the posterior part of the mastoid process, and into the os occipitis. Its use is to bring the head and upper vertebrae of the neck backwards laterally; and, when both act, to pull the head directly backwards. Albinus divides this muscle into two; viz. that portion which arises from the five inferior spinous processes of the neck, and is inserted into the mastoid process and os occipitis, he calls *splenius capitis*; and that portion which arises from the third and fourth of the back, and is inserted into the five superior transverse processes of the neck, is called by him *splenius colli*. The single pair, *serratus superior posterior*, arises from the spinous processes of the three last vertebrae of the neck, and the two uppermost of the back; is inserted into the second, third, fourth, and fifth, ribs; and serves to elevate the ribs, and dilate the thorax.

The third layer consists of three pair on the back, and three on the neck. Those on the back are, 1. *Spinalis dorsi*, arises from the spinous processes of the two uppermost vertebrae of the loins, and the three inferior of the back; and is inserted into the spinous processes of the nine uppermost vertebrae of the back. Its use is to erect and fix the vertebrae, and to assist in raising the spine. 2. *Longissimus dorsi*, arises from the side, and all the spinous processes of the os sacrum; from the posterior spine of the os ilium; from all the spinous processes; and from the roots of the transverse processes of the vertebrae of the loins. It is inserted into all the transverse processes of the vertebrae of the back; and serves to extend the vertebrae, and to raise and keep the trunk of the body erect. 3. *Sacro-lumbalis*,

lumbalis, arises, in common, with the *longissimus dorsi*; and is inserted into all the ribs, where they begin to be curved forwards; and from the upper part of the six or eight lower ribs, arise as many bundles of thin fleshy fibres, which soon terminate in the inner side of this muscle. Its use is to pull the ribs down, and assist to erect the trunk of the body. There is a fleshy slip, which runs from the upper part of this muscle into the fourth, fifth, and sixth, transverse processes of the vertebrae of the neck, by three distinct tendons: it is named *cervicalis descendens*; and its use is to turn the neck obliquely backwards, and to one side. On the neck are, 1. *Complexus*, arises from the transverse processes of the seven superior vertebrae of the back, and four inferior of the neck; in its ascent it receives a fleshy slip from the spinous process of the first vertebra of the back; and is inserted into the interior edge of the protuberance in the middle of the *os occipitis*, and into a part of the curved line that runs forwards from that protuberance. Its use is to draw the head backwards, and to one side; and, when both act, to draw the head directly backwards. The long portion of this muscle that is situated next the spinous processes, lies more loose, and has a roundish tendon in the middle of it; for which reason Albinus calls it *biorenter cervicis*. 2. *Trachelo-mastoideus*, arises from the transverse processes of the three uppermost vertebrae of the back, and from the five lowermost of the neck, where it is connected to the *transversalis cervicis*; and is inserted into the middle of the posterior side of the mastoid process. Its use is to assist the *complexus*; but it pulls the head more to a side. 3. *Levator scapulae*, arises from the transverse processes of the five superior vertebrae of the neck; and is inserted into the superior angle of the scapula. It pulls the scapula upwards, and a little forwards.

The fourth layer consists of two pair on the back, two on the posterior part of the neck, four small pair situated immediately below the posterior part of the occiput, and three on the side of the neck. On the back are, 1. *Semi-spinalis dorsi*, arises from the transverse processes of the seventh, eighth, ninth, and tenth, vertebrae of the back, by as many distinct tendons; and are inserted into the spinous processes of all the vertebrae of the back above the eighth, and into the two lowermost of the neck, by as many tendons, which serve to extend the spine obliquely backwards. 2. *Multifidus spinae*, arises from the side and spinous processes of the *os sacrum*, and from the posterior part of the *os ilium*, where it joins with the sacrum; from all the oblique and transverse processes of the vertebrae of the loins; from all the transverse processes of the vertebrae of the back, and from those of the neck, except the three first, by as many distinct tendons, which run in an oblique direction; and are inserted into all the spinous processes of the vertebrae of the loins, of the back, and of the neck, except the first. When the different portions of this muscle act on one side, they extend the back obliquely, or move it laterally; but, if they act together on both sides, they extend the vertebrae backwards. On the posterior part of the neck are, 1. *Semi-spinalis colli*, arises from the transverse processes of the uppermost six vertebrae of the back, by as many distinct tendons, ascending obliquely under the *complexus*, and inserted into the spinous processes of all the vertebrae of the neck, except the first and the last. Its use is to extend the neck obliquely backwards. 2. *Transversalis colli*, arises from the transverse processes of the five uppermost vertebrae of the back, by as many tendinous and fleshy origins; runs between the *trachelo-mastoideus*, and *splenius colli* and *cervicalis descendens*, and is inserted into the transverse processes of all the cervical vertebrae, except the first and the last. Its use is to turn the neck obliquely backward, and a little to one side. Below the posterior part of the occiput are, 1. *Rectus capitis posterior major*, arises from the external part of the spinous process of the second vertebra of the neck; and grows broader in its ascent, which is obliquely outwards. It is inserted into the *os occipitis*, near the *rectus*

capitis lateralis, and the insertion of the *obliquus capitis superior*; and serves to pull the head backwards, and to assist a little in its rotation. 2. *Rectus capitis posterior minor*, arises close to its fellow, from a little protuberance in the middle of the back part of the first vertebra of the neck, its outer edge being covered by the *rectus major*; and is inserted into the sides of a dimple in the *os occipitis*, near its foramen magnum. Its use is to assist the *rectus major* in moving the head backwards. 3. *Obliquus capitis superior*, arises from the transverse process of the first vertebra of the neck; and is inserted into the *os occipitis* behind the back-part of the mastoid process of the temporal bone, and under the insertion of the *complexus* muscle. Its use is to draw the head backwards. 4. *Obliquus capitis inferior*, arises from the spinous process of the second vertebra of the neck; and is inserted into the transverse process of the first vertebra of the neck. Its use is to give a rotatory motion to the head. On the side of the neck are, 1. *Scalenus anticus*, arises from the fourth, fifth, and sixth, transverse processes of the first vertebra of the neck; and is inserted into the upper side of the first rib near its cartilage. 2. *Scalenus medius*, arises from all the transverse processes of the vertebrae of the neck, by as many strong tendons; the nerves to the superior extremity pass between it and the former. It is inserted into the upper and outer part of the first rib, from its root, to within the distance of an inch from its cartilage. 3. *Scalenus posterior*, arises from the fifth and sixth transverse processes of the vertebrae of the neck, and is inserted into the upper edge of the second rib, not far from the spine. The use of the three *scaleni* is, to bend the neck to one side; or, when the neck is fixed, to elevate the ribs, and to dilate the thorax.

There are also a number of small muscles situated between the spinous and transverse processes of contiguous vertebrae; which are accordingly named, 1. *Inter-spinales colli*. The space between the spinous processes of the vertebrae of the neck, most of which are bifurcated, is filled up with fleshy portions; which arise from the spinous processes of the inferior vertebrae of the neck; and ascend to be inserted into the spinous process of the superior vertebra. They are five in number, and their use is to draw these processes nearer to each other. 2. *Intertransversales colli*. They begin from the transverse process of the first vertebra of the back, and fill up the spaces between the transverse processes of the vertebrae of the neck, which are likewise bifurcated; and, consequently, there are six distinct double muscles, which arise from the inferior transverse process of each vertebra of the neck, and first of the back, and are inserted into the superior transverse processes. They serve to draw these processes towards each other, and turn the neck a little to one side. 3, 4, 5. *Inter-spinales dorsi et lumborum*, and the *intertransversales dorsi*, are rather small tendons than muscles, serving to connect the spinal and transverse processes. 6. *Intertransversales lumborum*, are four distinct small bundles of flesh, which fill up the spaces between the transverse processes of the vertebrae of the loins, and serve to draw them towards each other.

MUSCLES OF THE SUPERIOR EXTREMITIES.—These may be divided into the muscles that are situated on the scapula, on the *os humeri*, on the cubit or fore-arm, and on the hand. The muscles situated on the scapula, are called *muscles of the os humeri*; and are three behind, one along its inferior costa, two before, and one beneath it. Behind are, 1. *Supraspinatus*, arises from all that part of the base of the scapula that is above its spine; also from the spine and superior costa; passes under the acromion, and adheres to the capsular ligament of the *os humeri*. It is inserted into that part of the large protuberance on the head of the *os humeri* that is next the groove for lodging the tendon of the long head of the biceps. Its use is to raise the arm upwards; and, at the same time, to pull the capsular ligament from between the bones, that it may not be pinched. 2. *Infraspinatus*, arises from all that part of the base of the scapula that is between its spine and inferior angle; from the spine as far as the cervix of the scapula.

pula. It is inserted into the upper and middle part of the large protuberance on the head of the os humeri. Its use is to roll the humerus outwards; to assist in raising, and in supporting it when raised; and to pull the ligament from between the bones. 3. *Teres minor*, arises from the round edge of the inferior costa of the scapula, and runs forwards along the inferior edge of the infraspinatus muscle, and adheres to the ligament. It is inserted into the back-part of the large protuberance on the head of the os humeri, a little behind, and below the termination of the last-named muscles. Its use is to roll the humerus outwards; to draw the humerus backwards; and to prevent the ligament from being pinched between the bones.

Along the inferior costa of the scapula is, *teres major*, which arises from the inferior angle of the scapula, and from all that portion of its inferior costa that is rough and thicker than the rest; its fleshy fibres are continued over part of the infraspinatus muscle, to which they firmly adhere. It is inserted into the ridge at the inner side of the groove for lodging the tendon of the head of the biceps, along with the latissimus dorsi. Its use is to roll the humerus inwards, and to draw it backwards and downwards.

The two before the scapula are, 1. *Deltoides*, arises from the posterior part of the clavicle that the pectoralis major does not possess; from the acromion, and lower margin of almost the whole spine of the scapula; from these origins it runs in three different directions, and is composed of a number of fasciculi, which form a strong fleshy muscle that covers the anterior part of the joint of the os humeri. It is inserted into a rough protuberance in the outer side of the os humeri, near its middle, where the fibres of this muscle intermix with some part of the brachialis externus. Its use is to pull the arm directly outwards and upwards, and a little forwards and backwards, according to the different directions of its fibres. 2. *Coraco-brachialis*, arises from the fore-part of the coracoid process of the scapula; adhering, in its descent, to the short head of the biceps. It is inserted about the middle of the internal part of the os humeri, near the origin of the third head of the triceps, called *brachialis externus*, where it sends down a thin tendinous expansion to the internal condyle of the os humeri; and serves to raise the arm upwards and forwards. There passes a nerve through this muscle, called *muscula cutaneus*.

The one beneath the scapula is, *subscapularis*, arises from the base of the scapula internally, and from its superior and inferior costæ, being composed of a number of tendinous and fleshy fasciculi, which make prints on the bone; it is inserted into the upper part of the internal protuberance at the head of the os humeri. It serves to roll the humerus inwards, and to draw it to the side of the body; and to prevent the capsular ligament from being pinched.

MUSCLES on the OS HUMERI.—These are called *Muscles of the cubit or fore-arm*. They consist of two before and two behind. Before are, 1. *Biceps flexor cubiti*, which arises by two heads. The first and outermost, called *longus*, begins from the upper edge of the glenoid cavity of the scapula; passes over the head of the os humeri within the joint; and, in its descent without the joint, is inclosed in a groove near the head of the os humeri, by a membranous ligament that proceeds from the capsular ligament and adjacent tendons. The second, or innermost head, called *brevis*, arises from the coracoid process of the scapula, in common with the coraco-brachialis muscle. A little below the middle of the fore-part of the os humeri, these heads unite. It is then inserted into the tubercle of the upper end of the radius internally, and serves to turn the hand supine, and to bend the fore-arm. 2. *Brachialis internus*, arises from the middle of the os humeri, at each side of the insertion of the deltoid muscle; and is inserted into the coronoid process of the ulna. Its use is to bend the fore-arm, and to prevent the capsular ligament of the joint from being pinched. Behind are, 1. *Triceps extensor cubiti*, arises by three heads; the first, called *longus*, from the inferior costa of the scapula, near its cer-

vix. The second, called *brevis*, from the back-part of the os humeri, and a little below its head, outwardly. The third, called *brachialis externus*, from the back-part of the os humeri. These three heads unite lower than the insertion of the *teres major*, and cover the whole posterior part of the humerus; and are inserted into the upper and external part of the process of the ulna, called *olecranon*, and partly into the condyles of the os humeri, adhering firmly to the ligament; and serve to extend the fore-arm. 3. *Anconeus*, arises from the posterior part of the external condyle of the os humeri; is inserted into a ridge on the outer and posterior edge of the ulna, and assists in extending the fore-arm.

MUSCLES on the CUBIT or FORE-ARM.—These may be divided into three classes: first, flexors and extensors of the whole hand; second, flexors and extensors of the fingers; and third, supinators and pronators, or those that roll the radius on the ulna. The first class consists of three flexors, and three extensors. Flexors are, 1. *Palmaris longus*, arises from the internal condyle of the os humeri; and is inserted into the ligamentum carpi annulare, and into a tendinous membrane that is expanded on the palm of the hand, named *aponeurosis palmaris*; which, above, begins at the transverse or annular ligament of the wrist, and, below, is fixed to the roots of the fingers. Its use is to bend the hand, and to stretch the membrane that is expanded on the palm. This muscle is sometimes wanting; but the *aponeurosis palmaris* is always to be found, and a small muscle named *palmaris brevis*, which arises from the ligamentum carpi annulare, and tendinous membrane that is expanded on the palm of the hand; and is inserted into the skin and fat that covers the abductor minimi digiti, and into the os pisiforme. Its use is to assist in contracting the palm of the hand. 2. *Flexor carpi radialis*, arises from the internal condyle of the os humeri, and from the anterior part of the upper end of the ulna; it is inserted into the fore and upper part of the metacarpal bone that sustains the fore finger; and serves to bend the hand, and to assist in its pronation. 3. *Flexor carpi ulnaris*, arises from the internal condyle of the os humeri. It has likewise a small fleshy beginning from the outer side of the olecranon; between which and the condyle the ulnar nerve passes to the fore-arm; and a number of its fleshy fibres arise from the tendinous membrane which covers the fore-arm. It is inserted into the os pisiforme; at a little distance from its insertion, a small ligament is sent off to the metacarpal bone that sustains the little finger. It assists the former in bending the arm.

The extensors are, 1. *Extensor carpi radialis longior*, arises immediately below the supinator radii longus, from the lower part of the external ridge of the os humeri, above its external condyle. It is inserted into the posterior and upper part of the metacarpal bone that sustains the fore-finger; and serves to extend and bring the hand backwards. 2. *Extensor carpi radialis brevior*, arises from the external condyle of the os humeri, and from the ligament that connects the radius to it, and runs along the outside of the radius. It is inserted into the upper and back part of the metacarpal bone that sustains the middle finger, and serves as an assistant to the last-mentioned muscle. 3. *Extensor carpi ulnaris*, arises from the external condyle of the os humeri; and, in its progress, passes over the ulna. Its round tendon is enclosed by a membranous sheath, in a groove which is situated at the extremity of the ulna. It is inserted into the posterior and upper part of the metacarpal bone that sustains the little finger; and assists the former in extending the hand.

Second Class.—The flexors and extensors of the four fingers are two long, and one small, flexor to each finger, and one extensor. 1. *Flexor sublimis perforatus*, arises from the internal condyle of the os humeri; from the coronoid process of the ulna, near the edge of the cavity that receives the head of the radius; from the tubercle of the radius; and from the middle of the fore-part of the radius, where the flexor pollicis longus arises. It is inserted into

the anterior and upper part of the second bone of each finger, being, near the extremity of the first bone, divided for the passage of the perforans. Its use is to bend the second joint or phalanx of the fingers. 2. *Flexor profundus perforans*, arises from the external side and upper part of the ulna, and from a large share of the interosseous ligament. It splits into four tendons, and is inserted into the fore and upper part of the third or last bone of all the four fingers; and serves to bend the last joint of the fingers.

The four small flexors are named *lumbricalis*. They arise from the outside of the tendons of the flexor profundus, a little above the lower edge of the ligamentum carpi annulare; and are inserted into the outer sides of the broad tendons of the interossei muscles, about the middle of the first joint. They increase the flexion of the fingers, while the long flexors are in full action.

The extensors are, *Extensor digitorum communis*, arises from the external condyle of the os humeri, where it adheres to the supinator radii brevis. Before it passes under the ligamentum carpi annulare externum, it splits into four tendons; some of which may be divided into several smaller: and about the fore-part of the metacarpal bones they remit tendinous filaments to each other. They are inserted into the posterior part of all the bones of the four fingers, by a tendinous expansion; and serve to extend all the joints of the fingers.

The *Third Class* consists of four muscles, viz. two *supinators*, and two *pronators*. The supinators are, 1. *Supinator radii longus*, arises from the external ridge of the os humeri, above the external condyle; and is inserted into the outer-side of the inferior extremity of the radius. Its use is to roll the radius outwards, and consequently the palm of the hand upwards. 2. *Supinator radii brevis*, arises from the external condyle of the os humeri; and from the external and upper part of the ulna, and adheres firmly to the ligament that joins these two bones. It is inserted into the head, neck, and tubercle, of the radius, near the insertion of the biceps; and serves to roll the radius outwards, and so bring the hand supine.

The pronators are, 1. *Pronator radii teres*, arises from the internal condyle of the os humeri, and from the coronoid process of the ulna; and is inserted into the middle of the posterior part of the radius. Its use is to roll the radius, together with the hand, inwards. 2. *Pronator radii quadratus*, arises from the lower and inner part of the ulna; and is inserted into the lower and anterior part of the radius, opposite to its origin. Its use is to turn the radius, together with the hand, inwards.

MUSCLES ON THE HAND.—These may be divided into four classes, viz. muscles of the thumb, fore-finger, little-finger, and metacarpal bones. The muscles of the thumb consist of three flexors, three extensors, one abductor, and one adductor. The flexors are, 1. *Flexor longus pollicis manus*, arises from the upper part of the radius, immediately below its tubercle, and is continued down for some space on the fore-part of this bone. It has likewise generally another origin from the internal condyle of the os humeri, which forms a distinct fleshy slip that terminates near the upper part of the origin from the radius. It is inserted into the last joint of the thumb, after having passed its tendon under the ligament of the wrist, and serves to bend the last joint of the thumb. 2. *Flexor brevis pollicis manus*, arises from the os trapezoides, magnum, and unciforme, of the carpus, and is divided into two portions by the tendon of the flexor pollicis longus. It is inserted into the ossa sesamoidea and first bone of the thumb. 3. *Flexor ossis metacarpi pollicis, or opponens pollicis*, arises from the os trapezium and ligamentum carpi annulare, lying under the abductor pollicis; and is inserted into the under and anterior part of the metacarpal bone of the thumb. Its use is to bring the thumb inwards, opposite to the other fingers.

The extensors are, 1. *Extensor ossis metacarpi pollicis manus*, arises from the middle and posterior part of the ulna, immediately below the insertion of the anconæus muscle, from the posterior part of the middle of the radius, and

from the interosseous ligament. It is inserted into the os trapezium, and upper back-part of the metacarpal bone of the thumb, and often joins with the abductor pollicis. Its use is to extend the metacarpal bone of the thumb outwards. 2. *Extensor primi internodii*, arises from the posterior part of the ulna near the former muscle, and from the interosseous ligament; is inserted into the posterior part of the first bone of the thumb; and serves to extend the first bone of the thumb obliquely outwards. 3. *Extensor secundi internodii*, arises from the middle back-part of the ulna, and from the interosseous ligament; its tendon runs through a small groove at the inner and back part of the lower end of the radius, and is inserted into the last bone of the thumb. Its use is to extend the last joint of the thumb obliquely backwards.

Abductor pollicis manus, arises, by a broad tendinous and fleshy beginning, from the ligamentum carpi annulare, and from the os trapezium. It is inserted into the outer side of the root of the first bone of the thumb, and draws the thumb from the fingers. *Adductor pollicis manus*, arises from almost the whole length of the metacarpal bone that sustains the middle finger; and is inserted into the inner part of the root of the first bone, and serves to pull the thumb towards the fingers.

Fore-finger: Indicator, arises from the middle of the posterior part of the ulna; its tendon passes under the same ligament with the extensor digitorum communis, with part of which it is inserted into the posterior part of the fore-finger. *Abductor indicis manus*, arises from the os trapezium, and from the superior part and inner side of the metacarpal bone of the thumb. It is inserted into the outer and back part of the first bone of the fore-finger, and serves to bring the fore-finger towards the thumb.

Little-finger: Abductor minimi digiti manus, arises from the os pisiforme, and from that part of the ligamentum carpi annulare next it. It is inserted into the inner side of the upper end of the first bone of the little finger, and serves to draw this finger from the rest. *Adductor metacarpi minimi digiti manus*, arises from the thin edge of the os unciforme, and from that part of the ligament of the wrist next it. It is inserted into the inner side and anterior part of the metacarpal bone of this finger, and serves to bend and bring the metacarpal bone of this finger towards the rest. *Flexor parvus minimi digiti*, arises from the outer side of the os unciforme, and from the ligament of the wrist which joins with that bone. It is inserted into the inner and anterior part of the upper end of the first bone of this finger; and is used to bend the little finger, and assist the adductor.

Between the metacarpal bones, there are four internal and three external muscles, named *interossei*. Interossei interni are: 1. *Prior indicis*, arises from the upper and outer part of the metacarpal bone that sustains the fore-finger; and is inserted into the outside of that part of the tendinous expansion from the extensor digitorum communis, which covers the posterior part of the fore-finger. Its use is to draw the fore-finger inwards towards the thumb, and extend it obliquely. 2. *Posterior indicis*, arises from the root and inner part of the metacarpal bone that sustains the fore-finger; and is inserted into the inner side of the tendinous expansion which is sent off from the extensor digitorum communis along the posterior part of the fore-finger. It serves to extend the fore-finger obliquely, and to draw it outwards. 3. *Prior annularis*, arises from the root of the outside of the metacarpal bone that sustains the ring-finger; and is inserted into the outside of the tendinous expansion of the extensor digitorum communis which covers the ring-finger. Its use is to extend and pull the ring-finger towards the thumb. 4. *Interosseus auricularis*, arises from the root and outer side of the metacarpal bone of the little finger; and is inserted into the outside of the tendinous expansion of the extensor digitorum communis, which covers the posterior part of the little finger. It serves to extend and draw the little finger outwards.

Interossei externi, seu bicipites: 1. *Prior medii*, arises from

from the roots of the metacarpal bones that sustain the fore and middle fingers externally, and next each other; runs along the outside of the middle finger; and, being conspicuous on both sides of the hand, is inserted into the outside of the tendinous expansion from the extensor digitorum communis, which covers the posterior part of the middle finger. It serves to extend, and to draw the middle finger inwards. 2. *Posterior medii*, arises from the roots of the metacarpal bones, next to each other, that sustain the middle and ring fingers; and is inserted into the inside of the tendinous expansion from the extensor digitorum communis, which runs along the posterior part of the middle finger. Its use is to extend and draw the middle finger outwards. 3. *Posterior annularis*, arises from the roots of the metacarpal bones that sustain the ring and little fingers next each other, and is inserted into the inside of the tendinous expansion of the extensor digitorum communis, which runs along the posterior part of the ring-finger. Its use is to extend and draw the ring-finger inwards.

MUSCLES OF THE INFERIOR EXTREMITIES.—These may be divided into the muscles situated on the *outside* of the *pelvis*, on the *thigh*, on the *leg*, and on the *foot*. The muscles on the outside of the pelvis, which are called *muscles of the thigh*, are composed of *one layer before*, and *three layers behind*. The layer before consists of five muscles: 1. *Psoas magnus*, 2. *Iliacus internus*; both which are already described in page 572. 3. *Pectinalis*, arises from the upper and anterior part of the os pubis or pectinis, and is inserted into the anterior and upper part of the linea aspera of the os femoris, a little below the trochanter minor. Its use is to bring the thigh upwards and inwards, and to give it a degree of rotation outwards. 4. *Triceps adductor femoris*; under which application are comprehended three distinct muscles: i. *Adductor longus femoris*, arises from the upper and inferior part of the os pubis, and ligament of its synchondrosis, on the inner side of the pectinalis; and is inserted near the middle of the posterior part of the linea aspera, being continued for some way down. ii. *Adductor brevis femoris*, arises from the os pubis near its joining with the opposite os pubis below and behind the former; and is inserted into the inner and upper part of the linea aspera, from a little below the trochanter minor, to the beginning of the insertion of the adductor longus. iii. *Adductor magnus femoris*, arises a little lower down than the former, near the symphysis of the ossa pubis; and is inserted into almost the whole length of the linea aspera; into a ridge above the internal condyle of the os femoris; and into the upper part of that condyle, a little above which the femoral artery takes a spinal turn towards the ham, passing between this muscle and the bone. The use of these three muscles or triceps is, to bring the thigh inwards and upwards, according to the different directions of their fibres; and, in some degree, to roll the thigh outwards. 5. *Obturator externus*, arises from the lower fore-part of the os pubis, and fore-part of the inner crus of the ischium, and surrounds the foramen thyroideum. It is inserted into the cavity at the inner and back part of the root of the trochanter major, adhering in its course to the capsular ligament of the thigh-bone; and is used to roll the thigh-bone obliquely outwards, and to prevent the capsular ligament from being pinched.

The muscles behind are: First layer, *gluteus maximus*, arises from the posterior part of the spine of the os ilium; from the whole external side of the os sacrum; from the posterior sacro-ischiatic ligament, over which part of the inferior edge of this muscle hangs in a folded manner; and from the os coccygis. All the fleshy fibres run obliquely forwards, and a little downwards, to form a thick broad muscle, which is divided into a number of strong fasciculi. It is inserted into the upper and outer part of the linea aspera, which is continued from the trochanter major; and its use is to extend the thigh, by pulling it directly backwards, and a little outwards.

The second layer consists of *gluteus medius*, which arises from the anterior superior spinous process of the os ilium,

and from all the outer edge of the spine of the ilium, except its posterior part, where it arises from the dorsum of that bone. It is inserted into the outer and posterior part of the trochanter major; and its use is to draw the thigh-bone outwards, and a little backwards; and to roll the thigh-bone outwards, especially when it is bended.

The third layer consists of four muscles, viz. 1. *Gluteus minimus*, arises from a ridge that is continued from the superior anterior spinous process of the os ilium, and from the middle of the dorsum of that bone as far back as its great niche. It is inserted into the fore and upper part of the trochanter major; and serves to assist the former in pulling the thigh outwards and backwards, and in rolling it. 2. *Pyriformis*, arises within the pelvis, by three tendinous and fleshy origins, from the second, third, and fourth, pieces of the os sacrum; from thence, growing gradually narrower, it passes out of the pelvis along with the posterior crural nerve, below the niche in the posterior part of the os ilium, where it receives a few fleshy fibres. It is inserted into the upper part of the cavity at the inner side of the root of the trochanter major. Its use is to move the thigh a little upwards, and roll it outwards. 3. *Geminus*, arises by two distinct origins; the superior from the spinous process, and the inferior from the tuberosity of the os ischium; also, from the posterior sacro-ischiatic ligament. It is inserted into the cavity at the inner side of the root of the trochanter major, on each side of the tendon of the obturator internus; and its use is to roll the thigh outwards, and to preserve the tendon of the obturator internus from being hurt by the hardness of that part of the ischium over which it passes; also, to hinder it from starting out of its place, while the muscle is in action. 4. *Quadratus femoris*, arises from the outside of the tuberosity of the os ischium; and, running transversely, is inserted into a rough ridge, continued from the root of the large trochanter to the root of the small one. Its use is to roll the thigh outwards.

MUSCLES ON THE THIGH.—These are called *muscles of the leg*; and consist of *one on the outside*, *two on the inside*, *four before*, and *four behind*. On the outside is, *tensor vagina femoris*. It arises from the external part of the anterior superior spinous process of the os ilium; and is inserted a little below the trochanter major, into the inner side of the membranous fascia which covers the outside of the thigh. It stretches the membranous fascia, assists in the abduction of the thigh, and helps its rotation inwards.

On the inside are: 1. *Sartorius*, arises from the anterior superior spinous process of the os ilium, runs down upon the rectus, and, going obliquely inwards, it passes over the vastus internus, and about the middle of the os femoris, over part of the triceps, it runs down farther between the tendon of the adductor magnus and that of the gracilis muscle. It is inserted into the inner side of the tibia, near the inferior part of its tubercle; and serves to bend the leg obliquely inwards, or to bring one leg across the other. 2. *Gracilis*, arises from the os pubis near the symphysis of these two bones. It descends by the inside of the thigh, and is inserted into the tibia under the sartorius; which it assists.

Those before are: 1. *Rectus*, arises from the inferior anterior spinous process of the os ilium, and from the dorsum of the ilium, a little above the acetabulum; runs down over the anterior part of the cervix of the os femoris, the fibres not being straight, but running down like the plume of a feather obliquely outwards and inwards, from a tendon in the middle; and is inserted into the upper part of the patella, from which a thin tendon runs down, on the fore-part of this bone, to terminate in a thick strong ligament, which is sent off from the inferior part of the patella, and inserted into the tubercle of the tibia. Its use is to extend the leg in a powerful manner, by the intervention of the patella, like a pulley. 2. *Vastus externus*, arises from the root of the trochanter major, and upper part of the linea aspera, its origin being continued from near the insertion of the gluteus minimus, the whole length of the linea aspera, by fleshy fibres which run obliquely

obliquely forwards to a middle tendon, where they terminate. It is inserted into a large share of the upper part of the patella; and part of it ends in an aponeurosis, which is continued down to the leg, and in its passage is firmly fixed to the head of the tibia. Its use is to extend the leg. 3. *Vastus internus*, arises from between the fore-part of the os femoris and root of the trochanter minor, and from almost all the inside of the linea aspera, by fibres running obliquely forwards and downwards. It is inserted into the upper and inside of the patella, continuing fleshy lower than the vastus externus. Part of it likewise ends in an aponeurosis continued down to the leg, and fixed in its passage to the upper part of the tibia. The use of this also is to extend the leg. 4. *Cruralis*, arises from between the two trochanters of the os femoris, but nearer the minor, and firmly adhering to most of the fore-part of the os femoris, and connected to both vasti muscles. It is inserted into the upper part of the patella, behind the rectus; and also assists in the extension of the leg. These four muscles before, being inserted into the patella, have the same effect upon the leg as if they were immediately inserted into it, by means of the strong tendon, or rather ligament, which is sent off from the inferior part of the patella to the tibia.

Those behind are: 1. *Semitendinosus*, arises from the posterior part of the tuberosity of the os ischium; and is inserted into the inside of the ridge of the tibia, a little below its tubercle. Its use is to bend the leg backwards and a little inwards. 2. *Seminembranosus*, arises from the upper and posterior part of the tuberosity of the os ischium, and is inserted into the inner and back part of the head of the tibia. Its use is to bend the leg, and bring it directly backwards. These two last muscles form what is called the *inner hamstring*. 3. *Biceps flexor cruris*, arises by two distinct heads. The first, called *longus*, arises, in common with the semitendinosus, from the upper and posterior part of the tuberosity of the os ischium. The second, called *brevis*, arises from the linea aspera, a little below the termination of the gluteus maximus; and is inserted into the upper part of the head of the fibula. Its use is to bend the leg. This is called the *outer hamstring*; and between it and the inner the nervous popliteus and arteria vena poplitea are situated. 4. *Popliteus*, arises from the lower and back part of the external condyle of the os femoris; then runs over the ligament that involves the joint, firmly adhering to it, and part of the semilunar cartilage. It is inserted into a ridge at the upper and internal edge of the tibia, a little below its head; and its use is to assist in bending the leg, and to prevent the capsular ligament from being pinched. After the leg is bent, this muscle also serves to roll it inwards.

MUSCLES of the LEG.—These are called *muscles of the foot*; and may be divided into two classes, viz. *extensors* and *flexors of the foot*; and *common extensors* and *flexors of the toes*. First class: The extensors are, 1. *Gastrocnemius externus, seu gemellus*, which arises by two distinct heads. The first head arises from the upper and back part of the internal condyle of the os femoris, and from that bone, a little above its condyle. The second arises from the upper and back part of the external condyle of the os femoris. 2. *Soleus, seu gastrocnemius internus*, arises by two origins. The first is from the upper and back part of the head of the fibula; the second begins from the posterior and upper part of the middle of the tibia. The flesh of this muscle, covered by the tendon of the gemellus, runs down near as far as the extremity of the tibia; a little above which the tendons of both gastrocnemii unite, and form a strong round cord, which is called *tendo Achillis*. It is inserted into the upper and posterior part of the os calcis; by the projection of which the tendo Achillis is at a considerable distance from the tibia. Its use is to extend the foot, by bringing it backwards and downwards. 3. *Plantaris*, arises from the upper and back part of the root of the external condyle of the os femoris, near the inferior extremity of that bone, adhering to the ligament that

involves the joint in its descent. It is inserted into the inside of the posterior part of the os calcis, below the tendo Achillis; and its use is to assist the former, and to pull the capsular ligament of the knee from between the bones. It seems likewise to assist in rolling the foot inwards.

The flexors consist of four muscles: two belong to the tibia, and two to the fibula. 1. *Tibialis anticus*, arises from the middle of that process of the tibia, to which the fibula is connected above; then it runs down fleshy on the outside of the tibia; from which, and the upper-part of the interosseus ligament, it receives a number of distinct fleshy fibres. It is inserted into the inside of the os cuneiforme internum, and posterior end of the metatarsal bone that sustains the great toe; and serves to bend the foot, by drawing it upwards, and, at the same time, to turn the toes inwards. 2. *Tibialis posticus*, arises from the fore and upper part of the tibia, just under the process which joins it to the fibula; then, passing through a perforation in the upper part of the interosseus ligament, it continues its origin from the back-part of the fibula. It is inserted into the upper and inner part of the os naviculare, and gives some tendinous filaments to the os calcis, os cuboides, and to the root of the metatarsal bone that sustains the middle toe. Its use is to extend the foot, and to turn the toes inwards. 3. *Peroneus longus*, arises from the fore-part of the head of the perone, or fibula, the fibres running straight down; also from the upper and external part of the fibula, where it begins to rise into a round edge; as also, from the hollow between that and its anterior edge, as far down as to reach within a hand's breadth of the ankle, by a number of fleshy fibres, which run outwards towards a tendon, that sends off a long round one, which passes through a channel at the outer ankle, in the back-part of the inferior extremity of the fibula; then, being reflected to the sinus of the os calcis, it runs along a groove in the os cuboides, above the muscles in the sole of the foot. It is inserted into the outside of the root of the metatarsal bone that sustains the great toe, and by some tendinous fibres in the os cuneiforme internum. Its use is to move and extend the foot outwards. 4. *Peroneus brevis*, arises from above the middle of the external part of the fibula; from the outer side of the anterior spine of this bone; as also, from its round edge externally, the fibres running obliquely outwards towards a tendon on its external side. It is inserted into the root and external part of the metatarsal bone that sustains the little toe; and serves to assist the former.

Second class: The common extensors consist of two muscles. 1. *Extensor longus digitorum pedis*, arises from the upper and outer part of the head of the tibia, and from the head of the fibula, and from the interosseus ligament; also from the tendinous fascia, which covers the upper and outside of the leg by a number of fleshy fibres; and from the anterior spine of the fibula, almost its whole length, where it is inseparable from the *peroneus tertius*. It is inserted into the root of the first joint of each of the four small toes; and is expanded over the upper side of the toes, as far as the root of the last joint; and serves to extend all the joints of the four small toes. A portion of this muscle, which arises from the middle of the fibula, continues down to its inferior extremity, and sends its fleshy fibres forwards to a tendon, which passes under the annular ligament, and is inserted into the root of the metatarsal bone that sustains the little toe. It is called by Albini *peroneus tertius*, and by others the *nonus vesalii*. It serves to assist in bending the foot. 2. *Extensor brevis digitorum pedis*, arises from the fore and upper part of the os calcis, and is inserted into the tendinous expansion from the extensor longus, which covers the small toes, except the little one; also into the tendinous expansion from the extensor pollicis that covers the upper part of the great toe. Its use is to extend the toes.

The flexors may be reckoned three. 1. *Flexor brevis digitorum pedis, sublimis perforatus*, arises from the inferior and posterior part of a protuberance of the os calcis, be-

tween the abductors of the great and little toes; and is inserted into the second phalanx of the four smaller toes. Its use is to bend the second joint of the toes. 2. *Flexor longus digitorum pedis, profundus, perforans*, arises from the back part of the tibia, near the entry of the medullary artery; which beginning is continued down the inner edge of this bone by short fleshy fibres, ending in its tendon; also by tendinous and fleshy fibres, from the outer edge of the tibia; and between this double order of fibres the tibialis pollicis muscle lies inclosed. It is inserted into the extremity of the last joint of the four smaller toes; and its use is to bend the last joint of the toes. This muscle is assisted by the *flexor digitorum accessorius, seu massa carnea Jacobii Sylvi*. It arises from the sinuosity at the inside of the os calcis, which is continued forwards for some space on the same bone; also, by a thin tendinous beginning, from before the tuberosity of the os calcis externally; and, soon becoming fleshy, is inserted into the tendon of the flexor longus, just at its division into four tendons. Its use is to assist the flexor longus. 3. *Lumbricales pedis*, arise, by four tendinous and fleshy beginnings, from the tendon of the flexor profundus, just before its division, near the insertion of the massa carnea; are inserted, by four slender tendons, into the inside of the first joint of the four smaller toes, and are lost in the tendinous expansion that is sent from the extensors to cover the upper part of the toes. They increase the flexion of the toes, and draw them inwards.

MUSCLES OF THE FOOT.—These may be divided into the muscles of the great toe, of the little toe, and of the metatarsal bones. The muscles of the great toe are five: 1. *Extensor proprius pollicis pedis*, arises some way below the head and anterior part of the fibula, along which it runs to near its lower extremity, connected to it by a number of fleshy fibres, which descend obliquely towards a tendon. It is inserted into the posterior part of the first and last joint of the great toe, which it serves to extend. 2. *Flexor longus pollicis pedis*, arises from the posterior part of the fibula, some way below its head, being continued down the same bone, almost to its inferior extremity, by a double order of oblique fleshy fibres; and is inserted into the last joint of the great toe, and generally sends a small tendon to the os calcis. Its use is to bend the last joint of this toe. 3. *Flexor brevis pollicis pedis*, arises from the under and fore part of the os calcis, where it joins with the os cuboides, from the os cuneiforme externum, and is inseparably united with the abductor and adductor pollicis. It is inserted into the external os sesamoideum and root of the first joint of the great toe; and serves to bend the first joint. 4. *Abductor pollicis pedis*, arises from the inside of the root of the protuberance of the os calcis, where it forms the heel; and, from the same bone, where it joins with the os naviculare. It is inserted into the internal os sesamoideum, and root of the first joint of the great toe; and serves to separate the great toe from the rest. 5. *Adductor pollicis pedis*, arises from the os calcis, from the os cuboides, from the os cuneiforme externum, and from the root of the metatarsal bone of the second toe. It is inserted into the external os sesamoideum, and root of the metatarsal bone of the great toe; and its use is to bring this toe nearer the rest.

The muscles of the little toe, besides the common extensors and flexors, are two, viz. 1. *Abductor minimi digiti pedis*, arises from the semicircular edge of a cavity on the inferior part of the protuberance of the os calcis, and from the root of the metatarsal bone of the little toe. It is inserted into the root of the first joint of the little toe externally; and serves to draw the little toe outwards from the rest. 2. *Flexor brevis minimi digiti pedis*, arises from the os cuboides, near the sulcus or furrow for lodging the tendon of the peroneus longus; and from the outside of the metatarsal bone that sustains this toe, below its protuberant part. It is inserted into the anterior extremity of the metatarsal bone, and root of the first joint of this toe; and serves to bend the toe.

Muscles from the metatarsal bones, consist of four ex-

ternal, and three internal, interossei; and one muscle, which is common to all the metatarsal bones. Interossei pedis externi, bicipites: 1. *Abductor indicis pedis*, arises from the root of the inside of the metatarsal bone of the fore toe, from the outside of the root of the metatarsal bone of the great toe, and from the os cuneiforme internum. It is inserted into the inside of the root of the first joint of the fore toe; and serves to pull the fore toe inwards from the rest of the small toes. 2. *Adductor indicis pedis*, arises from the roots of the metatarsal bones of the fore and second toe, and is inserted into the outside of the root of the first joint of the fore toe. Its use is to pull the fore toe outwards towards the rest. 3. *Adductor medii digiti pedis*, arises from the roots of the metatarsal bones of the second and third toes, and is inserted into the outside of the root of the first joint of the second toe. Its use is to pull the second toe outwards. 4. *Adductor tertii digiti pedis*, arises from the roots of the metatarsal bones of the third and little toe, and is inserted into the outside of the root of the first joint of the third toe. Its use is to pull the third toe outwards.

Interossei pedis interni: 1. *Abductor medii digiti pedis*, arises from the inside of the root of the metatarsal bone of the middle toe internally, and is inserted into the inside of the root of the first joint of the middle toe, and serves to pull the middle toe inwards. 2. *Abductor tertii digiti pedis*, arises from the inside and inferior part of the root of the metatarsal bone of the third toe, and is inserted into the inside of the root of the first joint of the third toe inwards; and serves to pull the third toe inwards. 3. *Abductor minimi digiti pedis*, arises from the inside of the root of the metatarsal bone of the little toe, and is inserted into the inside of the root of the first joint of the little toe; and serves to pull the little toe inwards.

The muscle which brings the extremities of the metatarsal bones towards each other, is named *transversalis pedis*. It arises from the under part of the anterior extremity of the metatarsal bone of the great toe, and from the internal os sesamoideum of the first joint, adhering to the adductor pollicis. It is inserted into the under and outer part of the anterior extremity of the metatarsal bone of the little toe, and ligament of the next toe; and its use is to contract the foot, by bringing the great toe and the two outermost toes nearer to each other. The muscles situated on the sole of the foot are covered by a strong tendinous aponeurosis, which is extended from the os calcis to the first joints of all the toes, and serves to preserve the subjacent parts from being compressed in standing and walking.

EXPLANATION of the ANATOMICAL PLATES II. III. and IV.

Plate II. represents a Front and Back View of the FIRST LAYER of the MUSCLES, situated immediately under the common Integuments and tendinous Fasciæ.

FRONT VIEW.

MUSCLES ON THE HEAD AND NECK.—*a*, The anterior fleshy belly of the occipito-frontalis situated on the os frontis; above *a*, the tendinous aponeurosis of the occipito-frontalis covering the upper part of the parietal bones. *b*, Attollens aurem: under it, the tendinous aponeurosis covering the temporal muscle: anterior auris, between *c* and the ear. *c*, Orbicularis palpebrarum; its tendon is seen at the inner canthus, fixed to the nasal process of the superior maxillary bone: Levator labii superioris alæque nasi, seen divided into two portions running down along the side of the nose, and, on the outside of it, the levator anguli oris: next this, the zygomaticus minor: farther outwards, zygomaticus major: on the ala and tip of the nose, the compressor naris. *d*, Depressor anguli oris: and, beneath it, a portion of the depressor labii inferioris. *e*, Orbicularis oris. *f*, Platysma-myoides: behind *f*, the sternocleidomastoideus is seen through the platysma-myoides.

TRUNK. *a*, Pectoralis major: the upper part of it is covered

covered by the origin of the platysma-myoides. *b*, Serratus magnus: the other portions resemble this. *c*, Latissimus dorsi. *d*, Obliquus externus descendens. *e*, Linea femularis. *f*, Linea alba: below *f*, umbilicus: between *e* and *f*, the rectus abdominis: and, at the inferior part of the linea alba, opposite to *g*, the pyramidales appear thro' the tendons of the oblique muscles. *g*, Ring of the external muscle; with the spermatic cord passing through it, and covered by the cremaster muscle.

SUPERIOR EXTREMITY. *a*, Deltoides: above the clavicle, a portion of the trapezius is seen. *b*, Biceps flexor cubiti: at the bending of the arm are seen its tendon going towards the radius; and the part, from which the tendinous aponeurosis that covers the fore-arm, is cut off: on the inside of the biceps, part of the triceps extensor cubiti: and, on the outside, part of the brachialis internus. *c*, Supinator radii longus. *d*, Pronator teres. *e*, Palmaris longus. *f*, Palmaris brevis: on the palm of the hand, the aponeurosis palmaris is seen extended from the annular ligament at the wrist to the roots of the metacarpal bones of the four fingers. *g*, Flexor carpi radialis. *h*, Part of the flexor sublimis perforatus. *i*, Insertion of the flexor carpi ulnaris. *k*, Abductor pollicis.

INFERIOR EXTREMITY. *a*, Tensor vaginæ femoris, the vagina or tendinous fascia being cut off: on the outside of it a portion of the glutæus maximus. *b*, Part of the iliacus internus: on the outside of it, between *b* and *c*, part of the psoas magnus. *c*, Pectinalis. *d*, Triceps longus. *e*, Gracilis. *f*, Sartorius. *g*, Rectus cruris: its tendon is seen inserted into the patella, from which a strong tendon is sent to be fixed to the tubercle of the tibia. *h*, Vastus externus. *i*, Vastus internus. *k*, Tibialis anticus. *l*, Peronæus longus: on the outside of it, a portion of the solæus. *m*, Extensor longus digitorum pedis, with the peronæus tertius, and extensor proprius pollicis pedis. *n*, Gastrocnemius externus, seu gemellus. *o*, Solæus. *p*, Ligamentum tarfi annulare. *q*, Abductor pollicis pedis.

BACK VIEW.

HEAD and NECK. *a*, Part of the occipito-frontalis muscle, with its aponeurosis. *b*, Attollens aurem. *c*, Anterior auris. *d*, Retrahentes auris.

TRUNK. *a*, Trapezius, seu cucularis. *b*, Its tendinous edge joining with its fellow in the nape of the neck, which is called *ligamentum nuchæ seu colli*. *c*, The fleshy belly of the latissimus dorsi. *d*, The tendon of the latissimus dorsi, which arises in common with the serratus posticus inferior. *e*, Part of the obliquus externus abdominis.

SUPERIOR EXTREMITY. *a*, Deltoides. *b*, Infra-spinaus, with a portion of the teres minor and major below it. *c*, Triceps extensor cubiti: its tendon is seen inserted into the head of the ulna, called *olecranon*; and, on the inside of it, the *anconæus*. *d*, Extensor carpi radialis longior, covered by a portion of the supinator radii longus; and, under it, a portion of the extensor carpi radialis brevior. *e*, Extensor digitorum communis manus, which splits into four tendons, and pass with the indicator, under the ligamentum carpi annulare externum, at the extremities of the metacarpal bone, under ligaments proper to themselves; and are lost in a broad tendon, which covers the back of the four fingers. *f*, Extensor ossis metacarpi pollicis manus. *g*, Extensor primi internodii pollicis manus. *h*, Extensor secundi internodii pollicis manus. *i*, Extensor carpi ulnaris. *k*, Part of the flexor carpi ulnaris: under it, part of the flexor profundus perforatus: and, on the inside, part of the flexor sublimis perforatus, which are more distinctly seen on the right fore-arm. Likewise, on the right hand, are seen part of the abductor pollicis manus, abductor minimi digiti manus, and the aponeurosis palmaris.

INFERIOR EXTREMITY. *a*, Glutæus maximus. *b*, Part of the glutæus medius. *c*, Part of the tensor vaginæ femoris. *d*, Vastus externus. *e*, The long head of the biceps flexor cruris: and, beneath it, *f*, Part of the short head. *g*, Semitendinosus: and beneath it, on each side,

a portion of the semimembranosus is seen. *h*, Gracilis: on the outside of it, a portion of the adductor magnus is seen. *i*, A small part of the vastus internus. *k*, Gastrocnemius externus, seu gemellus: and, within its outer head, a portion of the plantaris. *l*, Solæus seu gastrocnemius internus. *m*, Tendo Achillis, with the plantaris. *n*, Peronæus longus. *o*, Peronæus brevis: between it and the tendo Achillis, a portion of the flexor longus digitorum pedis. *p*, Tendons of the extensor longus digitorum pedis, with the peronæus tertius passing under the ligamentum tarfi annulare; and the flexor brevis digitorum pedis is seen beneath them. *q*, Abductor minimi digiti pedis: and above it the tendons of the peronæus longus and brevis, passing under proper ligaments of their own.

Plate III. represents a Front and Back View of the SECOND LAYER of the MUSCLES.

F R O N T V I E W.

MUSCLES on the HEAD and NECK. *a*, Corrugator supercilii. *b*, Temporalis. *c*, Masseter. *d*, Levator anguli oris. *e*, Buccinator. *f*, Orbicularis oris: opposite to the right ala nasi, the portion of this muscle which Albinus names *nasalis labii superioris*. *g*, Depressor labii inferioris. *h*, Sterno-cleido-mastoidæus, which is seen below, arising from the sternum and clavicle, by two heads. *i*, Sterno-hyoidæus: on the outside of it, the omo-hyoidæus: further on, a portion of the hyo-thyroidæus. *k*, Levator scapulæ.

TRUNK. *a*, Subclavius. *b*, Pectoralis minor. *c*, Serratus magnus. *d*, Rectus abdominis, divided into several fleshy portions by its tendinous interfections. *e*, Pyramidalis. *f*, Obliquus ascendens internus. *g*, Spermatic cord, with the origin of the cremaster muscle.

SUPERIOR EXTREMITY. *a*, Biceps flexor cubiti. *b*, Short head of the biceps: beneath the upper part of it, a portion of the coraco-brachialis: beneath the under part, a portion of the brachialis internus. *c*, Long head of the biceps: at the bending of the arm, the tendon of the biceps, and the place where the tendinous aponeurosis was cut from it, are seen. *d*, Extensor carpi radialis longior: beneath it a portion of the extensor carpi radialis brevior. *e*, Flexor sublimis perforatus. *f*, Insertion of the extensor carpi ulnaris. *g*, Extensors of the thumb. *h*, Opponens pollicis: on the inside of it, a portion of the flexor pollicis brevis. *i*, Tendon of the flexor longus pollicis manus, after passing through the flexor brevis pollicis manus. *k*, Abductor minimi digiti manus. *l*, Flexor parvus minimi digiti manus. *m*, Ligamentum carpi annulare.

INFERIOR EXTREMITY. *a*, Iliacus internus: between *a* and *b*, part of the psoas magnus. *b*, Pectinalis. *c*, Triceps longus. *d*, Gracilis. *e*, Rectus cruris cut off near its origin. *f*, Tendon of the rectus cruris cut off above the patella, from which a strong tendon is sent to be inserted into a tubercle of the tibia. *g*, Portion of the glutæus medius: on the inside of it, part of the glutæus minimus. *h*, Vastus internus. *i*, Vastus externus. *k*, Cruræus. *l*, Insertion of the biceps flexor cruris into the fibula. *m*, Tendons of the gracilis and semitendinosus inserted into the tibia. *n*, Solæus. *o*, Peronæus longus. *p*, Extensor longus digitorum, with the peronæus tertius on the outside, and extensor pollicis proprius on the inside. *q*, Solæus. *r*, Flexor longus digitorum. *s*, Tendons of the tibialis posticus and flexor longus digitorum pedis. *t*, Flexor brevis digitorum pedis.

BACK VIEW.

HEAD and NECK. *a*, Temporalis; its tendon is seen passing below the zygoma. *b*, Masseter. *c*, Splenius capitis et colli. *d*, Portion of the complexus. *e*, Levator scapulæ, seu musculus patientiæ.

TRUNK. *a*, Rhomboides major. *b*, Rhomboides minor: and immediately above it, the upper edge of the serratus posticus is seen. *c*, The serratus posticus superior on the right side. *d*, Serratus posticus inferior. *e*, Part of the spinalis dorsi. *f*, Part of the longissimus dorsi. *g*, Part

g, Part of the sacro lumbalis. *h*, Serratus magnus. *i*, The broad tendon by which the latissimus dorsi begins, and from which the tendon of the serratus posticus inferior is inseparable. *k*, Part of the obliquus internus ascendens abdominis. *l*, The sphincter ani, fixed to the point of the os coccygis; at the side of which the coccygeus, and a portion of the levator ani, are seen; and lower down, opposite to *l*, part of the transversalis penis.

SUPERIOR EXTREMITY. *a*, Supra-spinatus. *b*, Infra-spinatus. *c*, Teres minor. *d*, Teres major. *e*, Triceps extensor cubiti. *f*, Its head, called *longus*. *g*, The brevis: and, *h*, A small portion of the third head, named *brachialis externus*. *i*, The tendon of the triceps, inserted into the olecranon. *k*, Part of the brachialis internus. *l*, Anconæus, which seems to be continued from that part of the brachialis externus immediately above it. *m*, Extensor carpi radialis longior; and beneath it, the brevior: both are seen at the wrist, inserted into the metacarpal bones of the fore and middle fingers. *n*, Flexor carpi ulnaris. *o*, Part of the radii brevis. *p*, Extensor ossis metacarpi pollicis manus. *q*, Extensor primi internodii pollicis manus. *r*, Extensor secundi internodii pollicis manus. *s*, Indicator, inserted into the root of the first joint of the forefinger. *t*, One of the three external interossei manus: the other two are distinctly seen without letters. *u*, One of the tendons of the extensors of the fingers cut; and the same is seen in each of the other three fingers, joining with the tendons and aponeuroses of the interossei and lumbricales, and spread upon the back of the fingers. On the right hand, part of the flexors of the fingers, the abductor pollicis and minimi digiti, are seen.

INFERIOR EXTREMITY. *a*, Glutæus medius. *b*, Pyrriformis. *c*, The two muscles called *gemi*, between which the tendon and fleshy belly of the obturator internus passes over the tuberosity of the os ischium, are seen within the pelvis, partly covered by the coccygeus and levator ani. *d*, Quadratus femoris. *e*, Vastus externus. *f, f*, Parts of the triceps magnus. *g*, Long head of the triceps flexor cruris, and beneath it part of the short head is seen. *h*, Semi-tendinosus, and beneath it parts of the semi-membranosus are seen on each side of it. *i*, Gracilis. *k*, A small portion of the vastus internus. *l*, Popliteus. *m*, The fleshy belly of the plantaris; and its long slender tendon is seen passing over the inside of the soleus. *n*, Soleus. *o*, The place where the tendon of the gemellus was cut off; but the flesh of the soleus runs farther down. *p*, Tendo Achillis, with the plantaris. *q*, Peronæus longus, passing at the outer ankle to the sole of the foot; beneath it, the peronæus brevis to the root of the metatarsal bone of the little toe; and, between it and the tendo Achillis, a portion of the flexor longus digitorum pedis. *r*, Tendons of the extensor longus digitorum pedis, with the peronæus tertius; and beneath these, the extensor brevis digitorum pedis. *s*, Flexor brevis minimi digiti pedis.

Plate IV. represents a Front and Back View of the THIRD LAYER of the MUSCLES, with some of the Ligaments, Cartilages, and naked Bones.

FRONT VIEW.

MUSCLES on the HEAD and NECK. *a*, Depressor labii superioris alæque nasi. *b*, Orbicularis oris, after most of the muscles, which are fixed to it, and assist to form it, have been taken away. *c*, Buccinator: above *c*, part of the pterygoideus externus is seen passing behind the coronoid process of the lower jaw. *d*, Levator labii inferioris. *e*, Sterno-thyroideus: immediately above, and seemingly the continuation of it, the hyo-thyroideus. *f*, Scalenus anticus: contiguous to it, on the inside, the scalenus medius: above it, a portion of the trachelo-mastoidæus: between the scalenus anticus, and sterno-thyroideus, and hyo-thyroideus, the rectus capitis anterior major, and longus colli.

TRUNK. *a*, Third row of external intercostal muscles: the rest appear in the same manner between the other ribs.

VOL. I. No. 37.

b, Third row of internal intercostal muscles: the rest appear between the other ribs. *c*, Transversalis abdominis. *d*, The place from which the inferior part of the tendon of the transversalis, that passes before the rectus and pyramidalis muscles, is cut off: between these portions of each side, the peritonæum is laid bare, and the ligaments of the bladder which were formerly the umbilical arteries and urachus: between this portion and the os pubis, the spermatic cord is seen cut. *e*, The inferior edge of the upper part of the tendon of the transversalis, which passes behind the rectus, and immediately adheres to the peritonæum. *f*, The anterior lamella of the internal oblique, which joined the tendon of the external to pass over the rectus: between *f* and *g*, the posterior lamella of the internal oblique, joining with the tendon of the transversalis, to pass behind the rectus. *g*, The place at the linea alba, from which the tendon of the external oblique, and anterior lamella of the internal, were cut off: at *g*, Umbilicus.

SUPERIOR EXTREMITY. *a*, Subscapularis. *b*, Teres minor. *c*, Coraco-brachialis: the part from which the short head of the biceps flexor cubiti was cut off from it, is seen at its upper end. *d*, Brachialis internus. *e*, Brachialis externus, or third head of the triceps. *f*, Extensor carpi radialis longior; and with it the extensor carpi radialis brevior; both these are distinctly seen in the right hand: between the tendon of the brachialis internus and extensor radialis, the supinator radii brevis is seen. *g*, Flexor longus pollicis manus, with the fleshy portion of it which arises from the internal condyle of the os humeri. *h*, Flexor profundus perforans, which splits into four tendons, which pass under the ligamentum carpi annulare. *i*, Pronator quadratus. *k*, Adductor minimi digiti manus. *l*, One of the lumbricales: the other three appear in the same manner, along the tendons of the flexor profundus: behind these, the internal interossei are seen.

INFERIOR EXTREMITY. *a*, Glutæus minimus. *b*, Iliacus internus: on the inside of it, between *b* and *c*, the psoas magnus. *c*, Obturator externus. *d*, Adductor brevis femoris. *e*, Adductor magnus femoris. *f*, Gracilis, which is seen inserted into the inside of the head of the tibia. *g*, The short head of the biceps flexor cruris. *h*, Peronæus longus. *i*, Peronæus brevis: between these two peronæi and tibia, the tibialis posticus is seen. *k*, Tendon of the tibialis posticus, covering the tendon of the flexor longus digitorum pedis. *l*, Extensor brevis digitorum pedis.

BACK VIEW.

MUSCLES on the HEAD and NECK. *a*, Part of the buccinator. *b*, Complexus. *c*, Trachelo-mastoidæus; on the outside of it, the transversalis colli. *d*, Scalenus medius. *e*, Scalenus posticus.

TRUNK. *a*, Spinalis dorsi; and beneath it, the multifidus spinæ. *b*, Longissimus dorsi, which sends off a fleshy slip to the trachelo-mastoidæus. *c*, Sacro lumbalis, with the cervicalis descendens sent off from it along the side of the neck, and outside of the transversalis colli. *d*, Semi-spinalis dorsi. *e*, Transversalis abdominis. The spaces between the spinous processes of the vertebræ have muscular fasciculi between them, particularly those of the neck: and are named *interspinales colli, dorsi, and lumborum*; but those of the back seem to be tendinous and ligamentous.

SUPERIOR EXTREMITY. *a*, Teres major. *b*, Part of the coraco-brachialis. *c*, Part of the brachialis internus. *d*, The third head of the triceps extensor cubiti, called *brachialis externus*, after the longus and brevis have been cut off. *e*, Extensor radialis longior. *f*, Extensor radialis brevior. *g*, Part of the flexor profundus perforans. *h*, Supinator radii brevis. *i*, Part of the adductor pollicis manus. *k*, One of the three external interossei; the other two may be easily distinguished without letters. *l*, Tendons of the extensors of the fingers, joining with those of the lumbricales and interossei, which form a tendinous expansion on the back of the four fingers. On the right hand,

part of the flexors of the fingers and thumb, part of the adductor pollicis, and the whole of the adductor minimi digiti, are seen.

INFERIOR EXTREMITY. *a*, Glutæus minimus. *b*, Obturator internus; its fleshy belly is seen within the pelvis: beneath *b*, the tendon of the obturator externus. *c*, Semimembranosus. *d*, The short head of the biceps flexor cruris. *e*, Triceps magnus. *f*, Gracilis: in the ham, the origins of the two heads of the gastrocnemius externus and plantaris are seen. *g*, Popliteus. *h*, Tibialis posticus. *i*, Flexor longus digitorum pedis. *k*, Flexor pollicis longus. *l*, Peronæus longus, running down to be inserted into the metatarsal bone of the little toe: beneath it, the peronæus brevis, passing to the sole of the foot. *m*, Extensor brevis digitorum pedis. *n*, Part of the flexor longus digitorum pedis.

MUSCLES of the EYE.

Fig. 1. represents the right Eye-ball, and the six Muscles which move it, taken out of the orbit, with the Optic Nerve. *a*, The eye-ball. *b*, Optic nerve. *c*, Musculus trochlearis, seu obliquus superior. *d*, The trochlea, or pulley, with a piece of the os frontis, through which the tendon of the muscle passes towards the eye-ball. *e*, Obliquus inferior, with a piece of the superior maxillary bone, from whence it arises. *f*, Levator oculi. *g*, Depressor oculi. *h*, Adductor oculi. *i*, Abductor oculi.

MUSCLES of the FOOT.

Fig. 2. represents the first Layer of Muscles on the Sole of the Foot, after the Aponeurosis Plantaris has been taken away. *a*, Abductor pollicis pedis. *bb*, Abductor minimi digiti pedis. *c*, Flexor brevis digitorum pedis, which splits into four tendons, that are perforated by the tendons of the flexor longus digitorum pedis: between these tendons the lumbricales are seen. *d*, Tendon of the flexor pollicis longus: and beneath it, the flexor pollicis brevis. *e*, Transversalis pedis.

Fig. 3. represents the second Layer of Muscles on the Sole of the Foot, after the Abductor Pollicis Pedis, and Abductor Minimi Digiti Pedis, and the Flexor Brevis Digitorum Pedis, have been taken away. *a*, Tendon of the flexor longus digitorum pedis. *bb*, Flexor accessorius, seu massa carnea Jacobi Sylvii. *cccc*, The four lumbricales arising from the tendons of the flexor longus digitorum. *dd*, Tendon of the flexor pollicis longus; which, in its progress, joins the tendon of the flexor longus digitorum pedis. *e*, Tendon of the tibialis anticus. *f*, Tendon of the peronæus longus. *g*, Tendon of the peronæus brevis. *h*, Flexor pollicis brevis, with a portion of the abductor pollicis, on the inside of the great toe: on the outside of *i*, is the adductor pollicis. *k*, Flexor brevis minimi digiti pedis. *l*, A ligament which supports the bones of the tarsus: before *l*, two of the interossei are seen. *m*, Transversalis pedis.

CARTILAGES and LIGAMENTS of the JOINTS, &c.

The condyloid processes of the os occipitis, the glenoid cavities or articular fossulae of the ossa temporum, the eminences next these cavities, and the condyloid processes of the lower jaw, are all covered over with very white and smooth cartilages; and there is likewise an inter-articular or moveable cartilage in each articulation of the lower jaw with the temporal bones. Besides these there are other cartilages of the bones of the head, viz. the cartilaginous septum, and cartilages of the nose, the small cartilaginous pulley in each orbit, the cartilages of the outer ear, and those which are joined to the os hyoides. The ligaments of the bones of the head are, those of the articulation of the lower jaw with the temporal bones; those between the occipital bone and vertebrae of the neck; and those by which the os hyoides is connected to the styloid process.

LIGAMENTS of the LOWER JAW and TEMPORAL BONES.—*Ligamentum capsulare*, are fixed by one extremity round the glenoid or articular fossula and eminence of each

temporal bone; by their middle round the inter-articular cartilage, and by their other extremity round each condyle of the lower jaw, in such a manner as to allow the intermediate cartilage to follow the motions of the condyles, and to change their situation from the glenoid cavities to the tubercles of the zygomatic processes. *Ligamentum laterale maxilla inferioris*, arises from the inner surface of the angle of the lower jaw, and is fixed to the root of the styloid process, and to the posterior margin of the articular cavity of the temporal bone. It assists in keeping the jaw in its proper place.

LIGAMENTS of the OCCIPITAL BONE and VERTEBRÆ of the NECK.—*Ligamenta capsularia*, arise from the edges of the condyloid process of the os occipitis, and are fixed to the edges of the superior oblique processes of the first vertebra. *Ligamentum latum anterius*, arises from the fore-part of the foramen magnum occipitis, and runs down to the anterior arch of the first vertebra of the neck. *Ligamentum latum posterius*, arises from the posterior margin of the foramen magnum occipitis, and is inserted into the upper part of the posterior arch of the first vertebra. *Ligamentum processus odontoidis seu perpendiculare*, arises from the fore-part of the foramen magnum, and runs down to be fixed to the processus dentatus of the second vertebra. It assists in fixing the head to the spine, but is twisted in the rotation. *Ligamenta lateralia*, are two strong ligaments, which run from each side of the processus dentatus to be fixed to the inner side of the first vertebra, and to the edge of the foramen magnum. *Ligamentum cervicale seu nucha*, arises from the spinous process of the os occipitis, and gives origin to part of the trapezius muscle.

The bones of the head, as well as all the other bones of the body, are covered by a particular membrane: but that which covers the cranium is termed *pericranium*, while that surrounding the other bones are called simply *periosteum*. The internal structure of the bones of the head being for the most part cellular, they contain also distinct portions of marrow included in membranous cells lying in the diploë. The synovial glands of the maxillary and occipital articulations have nothing particular to them; they are proportioned to the joints to which they belong, and lie between the capsular ligaments and circumference of the cartilages.

The cartilages of the vertebrae are of two kinds; one proper to each vertebra, the other common to two vertebrae that lie next each other. The first may be termed *cartilages of articulation*; the others, *cartilages of symphysis*. The proper articular cartilages of each vertebra of the spine, are those four which cover the surfaces of the oblique processes. In the first vertebra of the neck, and vertebrae of the loins, these cartilages are thicker than in the rest. The first vertebra of the neck has a cartilaginous covering on the back-part of the anterior arch, corresponding with another on the fore-side of the processus dentatus of the next vertebra; so that each of those two vertebrae has five articular cartilages. The vertebrae of the back, besides the four cartilages of their oblique processes, have others which do not belong to their articulations with each other, viz. those that cover the lateral fossula in the bodies of these vertebrae, and the fossulae of their transverse processes, by both of which they are articulated with the ribs.

The cartilages of symphysis lie between the bodies of the vertebrae, uniting them closely together; their breadth and circumference answering exactly to that of the surfaces to which they are connected; but their height or thickness is different in each class of the vertebrae. The internal structure of these cartilages is different from that of all the other cartilages of the body. When we view their circumferences only, they seem to be one uniform mass, as the others generally are; but, when they are divided by an incision parallel to that surface of the vertebrae to which they are joined, we see they are composed of many cartilaginous concentric lamellae contained within each other. The most external lamellae are fibrous, thickest, and firmest, and separated by considerable intervals: the

internal

internal approach nearer and nearer together, becoming gradually thinner, and of a softer consistence, till at last they are almost of the form of a glairy liquor in the centre. These rings do not form an entire circumference; being turned inwards on the back-part, answering to the fore-part of the passage for the spinal marrow. They lie horizontally between the vertebræ. The interstices of the rings are filled with a mucilaginous substance, less fluid than that of the joints. Each lamina taken separately is very pliable, according to its length; but, taken together, they are not so easily bent, partly because of their circular figure, and partly because of their vicinity and multiplicity. They yield, however, in the inflections of the spine; and their external surface, which in the ordinary situation of the spine is even with the surface of the vertebræ, becomes prominent, or juts out on that side towards which the inflection is made, the cartilages being then compressed by the vertebræ. They likewise yield on all sides, without any inflection of the spine, to the weight of the upper part of the body; but this is done by very small and imperceptible degrees, and especially at the under part of the true vertebræ, and when the body is loaded with an additional weight. They restore themselves afterwards merely by being freed from compression: so that a man is really taller after lying than after he has walked or carried a burden for a length of time; the most natural and simple reason that can be given for the different height of the same person at different times, first observed in England, and afterwards confirmed by Mr. Morand, a member of the Royal Academy of Sciences, being the different state of the intervertebral cartilages. According to Sabatier, &c. the same person is sometimes more than four or five lines, or twelfths of an inch, higher in the morning than he is in the evening.

LIGAMENTS of the VERTEBRÆ.—The vertebræ are strongly connected to each other by different kinds of ligaments; some of which are proper to a certain number of them; others are common to the whole. *Ligamentum transversum vertebræ colli primæ*, arises from the inner side of the first vertebra, and goes across to the other side behind the processus dentatus, which it prevents from wounding the spinal marrow in the rotation of the head. *Ligamentum anticum commune vertebrarum*. One of the most remarkable is a strong ligamentous band, which embraces their convex surface from the upper to the under end of the spine. It begins at the second vertebra of the neck, and passes down as low as the os sacrum, becoming gradually larger and stronger in its descent. *Ligamenta intervertebralia*, are short but strong ligaments, which cross each other obliquely, and are fixed round the edges of the body of each vertebra. These crucial ligaments cover the circumference of the intervertebral cartilages, and adhere closely to them. *Ligamentum posticum commune vertebrarum*, begins at the second vertebra of the neck; and after having sent a considerable process, which passes behind the transverse ligament of the first vertebra, to be fixed to the anterior part of the foramen magnum, it descends on all the other vertebræ, to end at the lower end of the os sacrum. *Ligamenta interspinosa*, are short and firm ligaments, which run from the whole upper edge of the bony bridge and spinous processes of one vertebra, to the corresponding parts of the vertebra next; and thereby joining the different vertebræ together, and dividing the muscles on the right from those on the left side of the spine. *Ligamenta intertransversalia*, are short small ligaments placed between the extremities of all the transverse processes. *Ligamenta capsularia*, are formed of numerous short strong ligamentous fasciculi, arising from and surrounding the oblique processes of all the vertebræ.

STERNUM and RIBS.

The sternum of an adult has commonly sixteen cartilages; fourteen of which are articular, the other two symphyse. Of the articular cartilages, two belong to the articulations of the clavicles; and twelve to those of the

true ribs, from the second to the seventh inclusive. The two symphyse are those between the sternum and the first rib on each side. The cartilago enfiformis is often bony towards the sternum, and more or less cartilaginous at the other end. In very aged persons it has been found entirely ossified, and sometimes wholly cartilaginous even in adults. All the ribs have cartilaginous portions, which differ from each other in length, breadth, incurvation, adhesion, and in their extremities. The cartilages of the false ribs are naturally more slender and pliable than those of the true ribs; the middle or inner substance acquires the consistence of bones in old age; and their extremities sometimes ossify, and are immoveably fixed to the sternum.

LIGAMENTS of the STERNUM, VERTEBRÆ, and RIBS.—*Membrana sterni propria*, is a firm expansion, composed of many tendinous fibres, covering both the external and internal surface of the sternum. On the fore-part of the sternum the external fibres begin at the articulations of the cartilages of the ribs, and run across in a radiated manner to their fellows on the opposite side, while the internal fibres have a longitudinal direction. *Ligamentum cartilaginis enfiformis*, is composed of tendinous fibres similar to the former, arising from the cartilaginous extremity of the seventh rib and corresponding part of the sternum; and which, after descending obliquely, are fixed to the cartilago enfiformis. *Ligamenta capsularia cartilaginum costarum verarum*, arise round the cartilages of the seven true ribs, to be fixed to the articular pits in the sides of the sternum. *Ligamenta costarum ipsarum propria*, are ligaments by which the ribs are joined to each other. *Ligamenta capsularia capitulorum majorum costarum*, are short ligamentous fasciculi which arise round the cartilaginous surface of the head of each rib, and are fixed to the circumference of the small pits in the sides of the bodies of the vertebræ and intervertebral cartilages. *Ligamenta capsularia capitulorum minorum*, arise from the tubercles of the ten uppermost ribs, and are fixed round the articular pit on the point of the transverse processes of the vertebræ of the back. *Ligamenta interna colli costarum*, arise from the upper part of the neck of the ribs, and are fixed to the inferior surface of the transverse processes. *Ligamenta externa colli costarum*, arise from the outer surface of the superior margin of the neck of all the ribs. *Ligamenta duo specialia*, arise by a broad origin from the inferior margin of the last rib, and are fixed to the transverse process of the first and second lumbar vertebræ. The ligamentous expansions of the vertebræ are in place of a periosteum; at least they are blended together both on the inner and outer side of the spine. The sternum and bony portions of the ribs have a periosteum like the other bones. The cartilaginous portions of the ribs are covered by a membrane of the same kind, termed *perichondrium*.

OF THE SUPERIOR EXTREMITIES.

The scapula in many subjects has a small cartilaginous border along its whole basis; which in children is tolerably distinct, but in adults it disappears. The glenoid cavity of this bone is covered with a cartilage, which is thicker towards the circumference than in the middle, and a little raised above the edge of the bone. The small cartilaginous surface of the acromion, is covered with a very thin cartilaginous lamina; but, being transparent, it does not appear very white. The sternal extremity of the clavicle is crufted over with a cartilage which covers its whole triangular surface; besides which it has another moveable inter-articular cartilage, resembling that at the articulation of the lower jaw. The small cartilaginous surface of the scapular extremity of the clavicle, answering to that of the acromion, is a little convex.

LIGAMENTS of the CLAVICLE and SCAPULA.—*Ligamentum interclaviculare*, is a long narrow ligament which goes behind the furca of the sternum, from the internal angle of one clavicle to that of the other. *Ligamenta capsularia antica claviculæ*, are short and strong ligaments arising

ling round the sternal extremity of the clavicle, and from thence passing over the inter-articular cartilage, are inserted round the clavicular cavity of the sternum. *Ligamentum rhomboideum*, arises from the inferior rough surface at the anterior extremity of the clavicle, and, running obliquely, is fixed to the cartilage of the first rib. *Ligamenta capsularia postica*. The articulation of the scapular end of the clavicle with the acromion, is strengthened quite round by thick strong ligaments which go from one bone to the other. *Ligamentum trapezoideum scapulæ*, arises from the internal surface of the coracoid process of the scapula, and ends at the posterior extremity of the clavicle. *Ligamentum conoideum scapulæ*, arises from the root of the coracoid process, and is inserted into the rough protuberance of the posterior extremity of the scapula. *Ligamentum proprium scapulæ anticum*, arises from the external surface of the coracoid process, and is fixed to the posterior margin of the acromion. *Ligamentum proprium scapulæ posticum*, arises from the middle of the superior margin, and terminates at the root of the coracoid process. Under this ligament the vessels and nerves pass to the shoulder.

LIGAMENTS between the SCAPULA and OS HUMERI.—*Ligamentum capsulare humeri*, arises from the whole margin of the glenoid cavity of the scapula, and is fixed round the under end of the neck of the os humeri, loosely inclosing the head of this bone. The upper part of the ligament sends down a sheath between the two tuberosities of the humerus, over the tendon of the long head of the biceps muscle, which it accompanies as far as the fleshy part, and prevents it from sliding out of the groove in which it is placed. The capsular ligament is strengthened by other ligamentous bands, which adhere firmly to its anterior surface.

LIGAMENTS of the JOINT of the ELBOW.—*Ligamentum capsulare*, arises from the lower end of the os humeri, above the edge of the cartilaginous surface, and is fixed to the top of the ulna round the edge of the great sigmoid cavity, including both the apex of the olecranon and that of the coronoid process. It likewise runs over the head of the radius, and is fixed to the coronary ligament quite round. Near the under end of the body of the os humeri, there are two particular intermuscular ligaments, which are long, narrow, and thin. They increase the surface for the origin of muscles, and thereby supply the place of bones. The lower extremity of the os humeri is also joined to the bones of the fore-arm by the two following fasciculi of ligamentous fibres: viz. *Ligamentum brachio-cubitale seu laterale internum*, arises from the fore-part of the internal condyle of the os humeri, and, running down the capsula, is spread out in a radiated manner to be fixed to the inside of the coronoid process of the ulna. *Ligamentum brachio-radiale seu laterale externum*, is disposed much after the same manner; but it is of a greater extent. Through all its passage, it covers the capsular ligament, and is covered by several tendons, adhering closely to both.

LIGAMENTS joining the HEAD of the RADIUS to the ULNA.—*Ligamentum coronarium seu orbiculare*. The head of the radius is joined to that of the ulna, and the following ligament surrounds the head of the radius, reaching from one side of the small lateral sigmoid cavity of the ulna to the other, in an arch which is about three-quarters of a circle. *Ligamentum obliquum*, arises from the tubercle of the ulna, which gives rise to the brachæus internus muscle, and is inserted into the tubercle of the radius.

LIGAMENTS between the BODIES of the RADIUS and ULNA.—*Ligamentum interosseum*, fills up the space between the two bones of the fore-arm. It is fixed by one edge along the sharp angle of the radius, and by the other along that of the ulna. The greater number of the fibres which compose it descend from the radius to the ulna. Some, however, ascend and cross the former obliquely, so as to make it appear as if composed of two planes. Small spaces are left in different parts of it for the passage of blood-vessels; and a large opening is left above, which is occupied by the oblique ligament, &c. The interosseous liga-

ment ties the two bones together, and gives insertion to muscles. In the supination of the hand, it is stretched; and in the pronation, it is relaxed.

LIGAMENTS of the INFERIOR EXTREMITY of the BONES of the FORE ARM.—*Ligamentum capsulare*, arises round the edge of the glenoid cavity of the lower end of the radius and head of the ulna. It is fixed to the cartilaginous edges of the three first bones of the carpus. *Ligamentum capsulare seu falciforme*, arises from the edges of the semilunar cavity, at the under end of the radius, and surrounds the head of the ulna. *Ligamenta duo transversa*. One of these arises from the styloid process at the under end of the radius, and is inserted into the os naviculare. The other arises from the styloid process at the lower end of the ulna, and is fixed to the os cuneiforme and unciniforme.

LIGAMENTS of the CARPUS.—*Ligamenta ossium carpi brevia*, are small short ligaments, running in various directions, and joining the carpal bones; first of the same row, then of the two rows together. *Ligamentum ossium carpi commune capsulare*, arises from the cartilaginous edges of the first row of carpal bones, and is inserted into those of the second row. *Ligamenta articularia*, short firm ligaments, by which the second series of carpal bones are joined to the posterior extremities of metacarpal bones. *Ligamenta interossea metacarpi*, are small ligaments which join the posterior and anterior extremity of the metacarpal bones together.

LIGAMENTS of the BONES of the FINGERS.—*Ligamenta capsularia phalangum digitorum*, arise from the anterior extremities of the metacarpal bones with the posterior extremities of the first phalanx of the fingers. *Ligamenta lateralia phalangum digitorum*, are strong ligaments which lie between the bones of the first phalanx of the fingers. They are fixed at each end to the capsular ligaments. *Ligamentum capsulare pollicis*, arises from the posterior extremity of the first bone of the thumb, and is fixed round the os trapezium of the carpus.

LIGAMENTS of the HAND and FINGERS in situ.—*Ligamentum carpi transversale externum*, arises from the styloid process of the ulna and os pisiforme of the carpus, and ends in the styloid process of the radius. Between this ligament and the bones, the tendons of the extensor muscles of the carpus and fingers pass. *Ligamenta vaginalia*, adhere to the former ligament and bones, and serve as a kind of sheaths to the tendons. *Ligamenta tendinum extensorum transversa*, are short tendinous ligaments, running transversely on the back of the hand, behind the roots of the fingers. *Ligamenta palmaria transversa*, are fixed to the anterior extremities of the metacarpal bones, from which they run transversely. *Ligamenta vaginalia tendinum flexorum*, arise from the internal transverse ligament of the wrist, and terminate with the tendons of the musculus perforans. *Ligamenta vaginalia seu cruciata phalangum*, run in a circular and crucial direction over the former vaginæ and tendons, and are fixed to the ridges on the concave side of the bones of the fingers. *Ligamentum tendinum flexorum accessoria*, are small but firm tendinous substances, which arise from the first and second phalanx of the fingers. All the bones of the superior extremities are covered with their periosteum, and the quantity of marrow corresponds with the shape of the bone. All the joints have likewise synovial substances; but they are small when compared with those in the inferior extremities. The most considerable are placed in the cavities at the under end of the os humeri, for lodging the coronoid process and olecranon of the ulna, in the flexion and extension of the fore-arm.

OF THE PELVIS, AND INFERIOR EXTREMITIES.

The cartilages of the ossa innominata are not so numerous as one might imagine on examining the skeleton. The true cartilages of the ossa innominata are five in number; three common, and two proper. The first and principal common cartilage is that which makes the symphysis of the

the ossa pubis. The two other common cartilages join the ossa ilium to the os sacrum, but are thinner than that of the ossa pubis. The proper cartilages are those that line the acetabula. The circumference of the acetabulum has a border of a particular kind; the substance of which is neither wholly cartilaginous, nor wholly ligamentous; but it may be rather placed among the ligaments. No part of the os femoris is covered with cartilage, excepting the uniform convexity of its head; and here the cartilage runs as far as the union between the head and neck of the bone. The trochanters have no true cartilage; what looks like it being only the remains of tendinous insertions.

LIGAMENTS of the PELVIS.—*Ligamenta ileo-sacra*, are strong ligaments arising from the posterior part of the spine of the os ilium, and, descending obliquely, are fixed to the first, third, and fourth, spurious transverse processes of the os sacrum. *Ligamenta pelvis transversalia superior et inferior*, are two ligaments arising from the posterior spinous process of the os ilium; the superior is fixed to the transverse process of the last vertebra of the loins; the inferior is fixed to the first transverse process of the os sacrum. *Ligamenta sacro-sciatica*, one broad and external, the other small and internal. The external arises from the anterior and external edge of the false transverse processes of the os sacrum. From thence it descends obliquely towards the tuberosity of the os ischium, and is inserted immediately below the sinus, which lies between the tuberosity and spine of that bone. The internal sacro-sciatic ligament adheres closely to the inside of the posterior portion of the former. It arises internally from the edge of the inferior part of the fourth false transverse process, and from the whole side of the os sacrum, and from the basis of the upper part of the os coccygis. By these two ligaments two openings are formed; a large one, with the superior sciatic sinus, through which the pyriform muscle, the posterior crural vessels, and the sciatic nerve, pass out of the pelvis; and a small one, for the passage of the internal obturator muscle. *Ligamentum obturans foraminis ovalis*. The obturator ligament fills up all the foramen thyroideum, except the oblique notch at its upper part for the passage of the obturator vessels and nerves. This ligament not only assists in supporting the parts contained in the pelvis, but also gives origin to the two obturator muscles. *Ligamentum inguinale, seu Poupartii, seu Fallopii*, the inguinal ligament, is chiefly the under end of the tendon of the external oblique muscle of the abdomen. It is fixed by one end to the anterior superior spinous process of the os ilium, and is stretched over to be fixed by its other end to the spine of the os pubis. Under this ligament the femoral vessels and anterior crural nerve go out of the pelvis. *Ligamentum capsulare coccygis*, arises from the upper end of the os coccygis, and is inserted round the under end of the os sacrum. *Ligamenta longitudinalia coccygis*, small ligaments arising from the inner surface of the os coccygis, and terminating in the os sacrum. They fix the two bones firmly together.

LIGAMENTS between the PELVIS and HEAD of the OS FEMORIS.—The capsular ligament is the most considerable, largest, and strongest, of all the articular ligaments of the human body. It arises quite round the outer edge of a thick strong cartilago-ligamentous border, on the brim of the acetabulum, and from thence largely furrounds the whole head and superior portion of the neck of the os femoris, and is closely inserted to the lower portion of the neck that is between its basis and the middle narrow part. *Ligamentum teres seu rotundum*. This ligament is not round, as the name expresses; it resembles a flat cord, being composed of a bundle of fibres closely interwoven; one end of it is in a manner divided into two flat bands, which are fixed to the inner corners of the notch of the acetabulum. From the insertion it runs obliquely backwards and a little upwards, between the synovial gland within the acetabulum and the cartilaginous convexity at the head of the os femoris, and ends in the upper part of the small femular notch.

VOL. I. No. 37.

LIGAMENTS within the JOINT.—*Ligamenta cruciata*. One of these, called *posterius*, is fixed to the internal superficial impression in the notch between the condyles of the femur; and, running almost straight down, is fixed by its other end to the notch in the head of the tibia. The other, called *anterior*, is fixed by one end to the external impression in the notch of the os femoris; and is fixed by the other end to the head of the tibia. These two ligaments cross each other when we turn the point of the foot inwards, and they separate from each other when the foot is turned outwards. They prevent the leg from being bent forwards on the thigh, and from rolling too much inwards. *Ligamentum alare majus et minus*: are two broad ligaments arising from the inner sides of the capsular ligament, and are fixed to the sides of the patella, and to the fatty substance placed there.

LIGAMENTS at the JOINT of the KNEE.—The internal is fixed to the femur under the tuberosity, the fibres spread out in descending, and terminate at the upper and inner part of the tibia. The external is narrower and shorter. It is fixed above to the external tuberosity of the femur, and descends to embrace the anterior part of the head of the fibula, where it enlarges a little, though its fibres are not radiated like those of the external ligament. *Ligamentum posticum*, has an irregular form. It descends from the posterior, inferior, and external, part, of the outer condyle of the femur; and, having crossed the posterior part of the articulation, it terminates in the posterior, superior, and internal part, of the tibia. The capsular ligament is fixed quite round the inferior extremity of the os femoris, at a small distance above the anterior, lateral, and posterior, parts of the cartilage; internally, it adheres to the femular cartilages, and sends off a very fine vagina over the ligaments within the joint. *Ligamenta cartilaginea*, are two small ligaments which join the femular cartilages to each other, and likewise to the os femoris and tibia. *Ligamentum patellæ*, is a very strong ligament which arises from the point of the patella, and is fixed to the upper and fore part of the tibia.

LIGAMENTS of the FIBULA.—*Ligamentum capsulare extremitatis superioris*, is a very strong ligament, which runs from the head of the fibula to be fixed to the external condyle of the tibia. *Ligamentum interosseum*, fills up the space between the tibia and the fibula. One side of it is fixed to the posterior external angle of the tibia, the other to the internal angle of the fibula. *Ligamentum extremitatis inferioris*, consists of four short strong ligaments, two of which are anterior and two posterior; they arise from the malleolus externus of the fibula, and are inserted into the under and outer part of the tibia.

LIGAMENTS of the INFERIOR EXTREMITY of the LEG.—*Ligamentum fibulæ anticum*, arises from the fore-part of the malleolus externus of the fibula, and is fixed to the upper and outer part of the astragalus. *Ligamentum fibulæ medium*, arises from the point of the malleolus externus, and is fixed to the outside of the os calcis. *Ligamentum fibulæ posticum*, arises from the under and back part of the malleolus externus, and is bent obliquely backwards and fixed to the outer and back part of the astragalus. *Ligamentum tibiæ deltoideum*, arises from the malleolus internus, and is fixed to the astragalus and os naviculare. *Ligamentum capsulare*, arises from the whole edge of the articular cavity of the tibia, and is fixed entirely round the astragalus.

LIGAMENTS of the BASES of the METATARSAL BONES.—*Ligamentum capsulare*, joins the metatarsal bone of the great toe to the os unciniforme internum. *Ligamenta articulatoria*, join the posterior extremities of the metatarsal to the anterior edges of the tarsal bones. On account of their different situations, they have the name of *ligamenta plantaria, pedis dorsalia, lateralia*. *Ligamenta transversa dorso pedis*, are three in number, and are situated on the upper part of the foot, and join the bases of all the metatarsal bones together, excepting that which belongs to the great toe. *Ligamenta transversa plantæ* are likewise three;

but placed in the sole; and lie partly in the interstices of the bones. *Ligamenta interossea metatarsi*, like the former, are also three in number, but run immediately from the side of one bone to that of the bone next it, filling up the interstitial spaces.

LIGAMENTS of the Toes.—*Ligamenta capsularia*, arises from the posterior extremities of the first phalanx of the bones of the toes, and are fixed to the anterior extremities of the metatarsal bones. *Ligamenta lateralia*, lie at the sides of the second and third joint of each of the toes; they arise from the sides of the bases, and are fixed to the sides of the heads of the bones of each of these joints. All these ligaments, in the same manner as in the hand, are covered and strengthened on the dorsum pedis, by an expansion of the tendons of the extensor muscles, and in the sole by the sheaths of the tendons of the flexor muscles.

LIGAMENTS of the Foot and Toes in situ.—*Ligamentum vaginale tibiae*. This strong ligament is part of the tendinous sheath that covers the muscles on the fore-part of the leg; one side of it is fixed to the anterior angle at the lower part of the tibia, the other side is fixed to the outer part of the fibula. *Ligamentum transversum tarfi seu cruciatum*. This is a double ligament; one part arises in the outer part of the foot above the malleolus externus of the fibula, the other from the process of the os calcis. They serve to keep the tendons of the muscles in their places. *Ligamentum tendinum peroneorum*, arises from the fore-part of the os calcis, and is fixed to the outer side of an eminence of this bone. *Ligamentum lacinatum*, arises from the edge of the malleolus internus, and covers the tendons, vessels, and nerves, running in the hollow of the os calcis. *Ligamentum vaginale extensoris pollicis*, surrounds the tendon of this muscle. *Ligamentum vaginale flexoris proprii pollicis*, surrounds the tendon of the flexor longus pollicis in the hollow of the os calcis. *Ligamenta vaginalia tendinum flexorum*, are ligamentous sheaths surrounding the tendons of the flexor muscles of the toes, and are similar to those of the flexors of the fingers. *Ligamenta accessoria tendinum flexorum*, are short, but strong, ligaments, like those on the fingers, arising from the phalanges of the toes. *Ligamentum tendinum extensorum transversa*, are small ligaments running between the tendons of these muscles, and serving to bind them together, and to keep them in their places.

OF THE COMMON INTEGUMENTS.

ALL the parts of the human body are invested by several common and universal coverings, to which anatomists give the name of *integuments*. There have been many disputes about the number of these integuments. The ancients reckoned up five, viz. the *epidermis*, *skin*, *membrana adiposa*, *panniculus carnosus*, and *membrana muscularum communis*. The three first of these coverings are truly common or universal, that is, extended over all parts of the body. The two other coverings are not universal, but confined to particular parts of the body. The moderns divide the integuments into *cuticula*, *rete mucosum cutis vera*, and *corpus adiposum*.

The outside of the skin is covered by a thin transparent insensible pellicle, closely joined to it, which is called *epidermis*, *cuticula*, or *scarf-skin*. The substance of the cuticle appears to be very uniform on the side next the skin, and to be composed on the other side of a great number of very fine small squamous laminae, without any appearance of fibrous or vascular texture, unless we take into account the numerous small vessels by which it is connected to the parts under it. This substance is very solid and compact, but yet capable of being extended and thickened, as we see by steeping it in water, and by the blisters raised on the skin by vesicatories or any other means; and from thence it would seem that it is of a spongy texture. It yields very much in swellings, but not so much as the skin without breaking or cracking. It is not readily destroyed by putrefaction. Hard and reiterated frictions loosen it

insensibly, and presently afterwards a new stratum arises, which thrusts the first outward, and may itself be loosened and thrust outward by other strata.

The cuticle adheres very closely to the cutaneous papillae under it; but it may be separated by boiling, or steeping for a long time in cold water. It is not impossible to separate it with the knife; but this management teaches us nothing of its structure. It adheres still closer to the corpus mucosum, which is easily raised along with it; and they seem to be true portions or continuations of each other. The colour of the cuticle is naturally white; and its apparent colour is owing to that of the corpus mucosum. For, if we examine the European and African, we find the cuticle to be nearly of the same colour in both, whereas their corpus mucosum is very different. The cuticle covers the skin through its whole extent, excepting at the nails. It is marked with the same furrows and lozenges as the skin, and has the same openings and pores, and may be said to cover not only the whole external part of the body, but to line many of the large passages, as the alimentary canal, the lungs, vagina, urethra, &c. In these passages, however, it is somewhat different. The cuticle on the external parts of the body gives passages to the ducts of the sebaceous glands, while that lining the cavities already mentioned is pierced with the ducts of the mucous follicles.

When we examine narrowly the small passages through which the sebaceous matter of the skin passes, the cuticle seems to enter these, in order to complete the secretory tubes. The follicles of the hairs have likewise the same productions of the cuticle, and it seems to give a kind of covering to the hairs themselves. Lastly, the almost imperceptible ducts of the cutaneous pores are lined by it. If the skin be macerated for a long while in water, the cuticle, with its elongations, may be separated from it. By this observation we may explain how blisters may remain for a long time on the skin without giving passage through these holes to the matter which they contain; which holes one would think ought to be increased by this dilatation and tension of the cuticle. But, when the cuticle is separated from the skin, it carries along with it part of these cutaneous fibres; which, being compressed by the matter contained in the blister, shut the pores of the separated cuticle like so many valves; and it is probable, that some of these small portions, being detached, are the substances which have been taken for valves of the cutaneous tubes.

With respect to its origin, some authors have supposed it to be formed by a moisture exhaled from the whole surface of the body, which gradually hardens when it is exposed to the air; but the foetus in utero, where no air is admitted, is a proof against this opinion; and it grows readily under plasters applied to any part of the body. Leuwenhoeck supposed its formation to be owing to the expansion of the extremities of the excretory vessels, which are found every where upon the surface of the true skin. Ruyfch attributed its origin to the nervous papillae of the skin; and Heister thinks it probable that it may be owing both to the papillae and the excretory vessels. Morgagni, on the other hand, contends, that it is nothing more than the surface of the cutis, hardened and rendered insensible by the liquor amnii in the uterus, or by the pressure of the air. In fact, we know little about its origin; but the regeneration of it is very evident, sudden, and surprising; for, let it be destroyed ever so often, it still grows again.

Under the cuticle, we meet with a substance of a greyish colour, which has been thought to represent a net-work; hence it has the name of *corpus reticulare*, or *mucosum*. It is of a soft, mucilaginous, and viscid, nature; and fills up the interstices of the fibres running between the cutis vera and cuticula. After raising the cuticle in a negro, where it is thickest and most distinct, this substance appears of a black colour, and is composed of two layers. It is this that chiefly gives the colour to the skin; for it is black in the African; white, brown, or yellowish, in the European.

The origin of this mucous substance has not hitherto been sufficiently explained; nor has it been fully determined what purposes it serves in the human body. Haller thinks it probable, that it is composed of a humour transuding from the surface of the cutis vera. The reason why it is black in the negro has been supposed to be for serving as a defence against the external heat, by preventing the rays of the sun from penetrating his body; but the matter still lies hid in obscurity.

The *cutis vera*, or *skin* properly so called, is a substance of very large extent, made up of several kinds of fibres, closely connected together, and running in various directions, being composed of the extremities of numerous vessels and nerves. This texture is what we commonly call *leather*; and it makes, as it were, the body of the skin. It is not easily torn; may be elongated in all directions, and afterwards recovers itself, as we see in fat persons, in women with child, and in swellings; and it is thicker and more compact in some places than in others. Its thickness and compactness are not, however, always proportional: for, on the posterior parts of the body it is thicker and more lax than on the fore-parts; and on the palms of the hands, and soles of the feet, it is both very thick and very solid. It is generally more difficult to be pierced by pointed instruments in the belly than in the back. The outer surface of this substance is furnished with small eminences, which anatomists have thought fit to call *papillæ*. They appear through its whole surface like small granulations; and seem to be calculated to receive the impressions of touch, being the most easily observed where the sense of feeling is the most delicate, as in the points of the fingers and palms of the hands; and are supposed by many to be the capillary filaments of the cutaneous nerves, which terminate by small radiated pencils: but they must be allowed to be formed like the other parts of the cutis; only the nervous fibrillæ will be found to be more numerous in them than in other parts. These *papillæ* differ very much in figure and disposition; and they may be distinguished into several kinds. The greatest part of them is flat, of different breadths; and separated by sulci, which form a kind of irregular lozenges. The pyramidal figure ascribed to them is not natural; and appears only when they are contracted by cold, by diseases, by boiling, or by some other artificial preparation, which alters their ordinary structure.

The *papillæ* of the palm of the hand, of the sole of the foot, and of the fingers and toes, are higher than on the other parts of the body; but they are likewise smaller, closely united together, and placed as it were end-wise with respect to each other, in particular rows, which represent on the skin all kinds of lines, straight, crooked, waving, spiral, &c. These several lines are often distinctly visible in those parts of the palm of the hand which are next the first phalanges of the fingers. The red part of the lips is made up of *papillæ*, representing very fine hairs or villi closely united together. There is another particular kind under the nails; the *papillæ* being there more pointed, or in a manner conical, and turned obliquely toward the ends of the fingers. Those which are found in the hairy scalp, scrotum, &c. are still of other kinds.

In inflammations, we observe a reticular texture of capillary vessels, more or less extended on the surface of the skin; and curious anatomists demonstrate the same thing by fine injections, which may be looked upon as artificial inflammations. Something similar to this has been injected lately by Mr. Baynham of London, who thought it *rete mucosum*; and afterwards by Mr. Cruikshank, who calls it *cuticula quarta*. But neither of these methods prove, that, in the natural state, these vessels are blood-vessels; that is, that they contain the red portion of the blood. It is more probable that this vascular texture is only a continuation or production of the very small capillaries of the arteries and veins; which, in the natural state, transmit only the serous part of the blood, while the red part continues its course through wider ramifications, which more

properly retain the name of *blood-vessels*. This vascular texture is of various forms and figures in the different parts of the body. It is not the same in the face as it is elsewhere; neither is it alike on all the parts of the face, as may be discovered by the most ordinary microscopes; and from hence we might perhaps be enabled to give a reason why one part of the body turns red more easily than another. The skin has several considerable openings, some of which have particular names; such as, the fissure of the palpebræ, the nares, the mouth, the external foramen of the ears, the anus, and openings of the parts of generation.

Besides these, it is perforated by an infinite number of small holes, called *pores*, which are of two kinds. Some are more or less perceivable by the naked eye; such as the orifices of the milky ducts of the mammae, the orifices of the excretory canals of the cutaneous glands, and the passage of the hairs. The other pores are imperceptible to the naked eye, but visible through a microscope; and their existence is likewise proved by the cutaneous transpiration, and by the effects of topical applications; and from these two phenomena, they have been divided into arterial and venal pores. We ought likewise to observe the adhesions and folds of the skin. It is every where united to the corpus adiposum; but it adheres to it much more closely in some parts than in others, as in the palm of the hand, sole of the foot, elbow, and knee. Some plicæ or folds in the skin depend on the structure of the membrana adiposa or cellularis, as those in the neck and buttocks: others do not depend on that membrane, such as the rugæ in the forehead, palpebræ, &c. which are formed by cutaneous muscles, and disposed more or less in a contrary direction to these muscles. These folds increase with age. There is, besides, a particular kind of folds in the skin of the elbow, knee, and condyles of the fingers and toes; which are owing neither to the conformation of the membrana adiposa, nor to any muscle. Lastly, there is a kind of plicæ, or rather lines, which cross the palm of the hand, sole of the foot, and corresponding sides of the fingers and toes, in different directions. These serve for employment to fortune-tellers; whose pretended art is contrary to religion, and despised by all men of sense.

In different parts of the body, we meet with small glands or follicles of an oval form, and seated chiefly under the skin in the corpus adiposum. They are composed of convoluted vessels; but in some parts of the body they appear to be formed of small cylindrical tubes, or simple follicles, continued from the ends of the arteries, and discharging, by small excretory ducts, a fat and oily matter, that serves to lubricate and moisten the surface of the skin. When the fluid they secrete has acquired a certain degree of thickness, it approaches to the colour and consistence of suet: and from this appearance they have derived the name of *sebaceous glands*. They are found chiefly on the nose, ears, axillæ, likewise round the nipple, and about the external parts of generation in both sexes. Besides the sebaceous glands, anatomical writers mention other small spherical bodies placed every where over the surface of the body, in much greater abundance than those just mentioned, and named *miliary*. They are said to have excretory ducts that open on the surface of the cuticle, and distil the sweat and matter of insensible perspiration; but, after all that has been said about them, it is certain there are no distinct glands that can be traced by the knife.

It is chiefly and properly the filamentary substance, called the *body of the skin*, which is the universal integument of the body, and the basis of all the other cutaneous parts; each of which has its particular uses. The skin is able to resist external injuries to a certain degree and such impressions, frictions, strokes, &c. to which the human body is often liable, as would hurt, wound, and disorder, the parts of which it is composed, if they were not defended by the skin. The *papillæ* are the organs of feeling, and contribute to an universal evacuation, called *insensible transpiration*. They likewise serve to transmit from without in-

wards,

wards, the subtle particles or impressions of some things applied to the skin. The first of these three uses depends on the extremities of the nerves; the second, on the arterial productions; and the third, on the origin of the absorbent system. The cutaneous glands secrete an oily humour of different consistences. But, without the epidermis, both papillæ and glands would be disturbed in their functions; on which great disorders must ensue. The epidermis serves to keep the pencils or nervous filaments of the papillæ in an even situation, and without confusion; and it likewise moderates the impressions of external objects. Particular as well as general feeling is more or less perfect in proportion to the thinness of the epidermis; callosities in which weaken, and sometimes destroy, both. Another use of the epidermis is, to regulate the cutaneous evacuations already mentioned; the most considerable of which is insensible transpiration.

The last universal integument of the human body, is the *membrana adiposa* or *corpus adiposum*. This is not, however, a single membrane, but a congeries of a great number of membranous laminae, joined irregularly to each other at different distances, so as to form numerous interstices of different capacities, which communicate with each other. These interstices have been named *cellulae*, and the substance they compose the *cellular substance*. The thickness of the cellular substance is not the same all over the body, and depends on the number of laminae of which it consists. It adheres very closely to the skin; runs in between the muscles in general, and between their several fibres in particular; and communicates with the membranes which line the inside of the thorax and abdomen. This structure is demonstrated every day by butchers, in blowing up their meat when newly killed; in doing which, they not only swell the *membrana adiposa*, but the air insinuates itself likewise in the interstices of the muscles, and penetrates even to the viscera, producing a kind of artificial emphysema. These cellular interstices are so many little bags or satchels, filled with an unctuous or oily juice, more or less liquid, which is called fat; the different consistence of which depends not only on that of the oily substance, but on the size, extent, and sub-division, of the cells. It is generally known, that the illustrious Malpighi took a great deal of pains about this substance; that in birds and frogs, the viscera and vessels of which are transparent, he thought he saw a kind of ductus adiposi; and that, by pressing these ducts, he observed oily drops to run distinctly into the small ramifications of the mesenteric veins; such ducts, however, have not been seen by later anatomists.

The manufacture of soap, the composition of some of the ointments, and the different mixtures of oils with saline and acid liquors, give us some idea, at least, of the formation of the fat in the human body; but the organ which separates it from the mass of blood, which ought to be the subject of our present enquiry, is not yet sufficiently known. Fat is more fluid in living than in dead bodies. It melts with the heat of the fingers in handling it; and its fluidity is in part obstructed by the sacculi which contain it. The method to take it entirely out of these bags is, to set the whole over a fire in a proper vessel; for then the bags burst, and swim in clusters in a true oily fluid. This substance increases in quantity by rest and good living; and, on the contrary, diminishes by hard labour and a spare diet. Why nourishment should have this effect, is easily conceived; and it is likewise easy to see, that an idle sedentary life must render the fat less fluid, and consequently more liable to block the passages of insensible transpiration, through which it would otherwise run off. Hard labour dissolves it, and consequently fits it for passing out of the body, with the other matter of insensible transpiration. Some authors are of opinion, that it returns into the mass of blood by the lymphatics; and that it can, for some certain time, supply the want of nourishment. By this, they think, the long abstinence of some animals may be explained; but it would appear, that the

mere decrease of cutaneous transpiration, occasioned by the continual rest and inaction of these animals, has a great share in this effect.

The proportional differences, in the thickness of this *membrana adiposa*, are determined, and may be observed, to be regular in some parts of the body, where either beauty or use require it. Thus we find it in great quantities where the interstices of the muscles would otherwise have left disagreeable hollow or void places; but the skin being filled, and as it were stuffed with fat, is raised, and an agreeable form given to the whole body. In some parts of the body the fat serves for a cushion, pillow, or mattress; as on the buttocks, where the laminae and cells are very numerous. In other parts, this membrane has few or no laminae, and consequently little or no fat; as on the forehead, elbows, &c. In some places it seems to be braced down by a kind of natural contraction in form of a fold; as in that fold which separates the basis of the chin from the neck, and in that which distinguishes the buttocks from the rest of the thigh. We observe it likewise to be entirely sunk, or as it were perforated by a kind of dimple or fossula, as in the navel of fat persons. These depressions and folds are never obliterated, let the person be ever so fat; because they are natural, and depend on the particular conformation of the *membrana adiposa*, the laminae of which are wanting at these places. The fat is likewise of great use to the muscles in preserving the flexibility necessary for their actions, and in preventing or lessening their mutual frictions. Lastly, the fat, as a fine oily substance in its natural state, may be some defence against the cold, which we find makes more impression on lean than on fat persons. It is for this reason, that, to guard themselves against the excessive colds of hard winters, and to prevent chilblains, travellers rub the extremities of their bodies, and especially their feet, with spirituous oils, &c. This mass of fat, which makes an universal integument of the body, is different from that which is found in the abdomen, thorax, canal of the spina dorsa, articulations of the bones, and in the bones themselves. But the difference of all these particular masses of fat consists chiefly in the thickness or fineness of the pellicles, in the largeness or smallness of the cells, and in the consistence, fluidity, and subtilty, of the oily matter.

Some authors think the *nails* are productions of the cutaneous papillæ; and others, that they are a continuation of the epidermis. This last opinion agrees with experiments made by maceration; by means of which the epidermis may be separated entire from the hands and feet, like a glove or sock. In this experiment we see the nails part from the papillæ, and go along with the epidermis, to which they remain united like a kind of appendix; and yet their substance and structure appears to be very different from that of the epidermis: but like it, they are also insensible, and renewable after having been cut, or after having fallen off. Their substance is like that of horn, and they are composed of several planes of longitudinal fibres folded together. These strata begin with a square root intermixed with the periosteum a little before the last joints, and end at the extremity of each finger; they are nearly all of an equal thickness, but of different lengths. The external plane or stratum is the longest, and the rest decrease gradually, the innermost being the shortest; so that the nail increases in thickness from its union with the epidermis where it is thinnest, to the end of the finger where it is thickest. The graduated extremities or roots of all the fibres of which these planes consist, are hollowed for the reception of the same number of very small oblique papillæ, which are continuations of the true skin: which, having reached the root of the nail, forms a semilunar fold in which the root is lodged. After this semilunar fold, the skin is continued on the whole inner surface of the nail, the papillæ insinuating themselves in the manner already said. The fold of the skin is accompanied by the epidermis to the root of the nail exteriorly, to which it adheres very closely. Three parts are generally

generally distinguished in the nail; the root, body, and extremity. The root is white, and in form of a crescent; and the greatest part of it is hid under the semilunar fold already mentioned. The crescent and the fold lie in contrary directions to each other. The body of the nail is naturally arched, transparent, and appears of the colour of the cutaneous papillæ which lie under it. The extremity of the nail does not adhere to any thing, and still continues to grow as often as it is cut. The principal use of the nails is to strengthen the ends of the fingers and toes, and to hinder them from being inverted towards the convex side of the hand or foot, when we handle or press any thing hard. For, in the hand, the strongest and most frequent impressions are made on the side of the palm; and, in the foot, on the sole; and therefore the nails serve rather for buttresses than for shields.

The hairs belong as much to the integuments as the nails. The roots or bulbs lie toward that side of the skin which is next the membrana adiposa. The trunk or beginning of the stem perforates the skin, and the rest of the stem advances beyond the outer surface of the skin, to a certain distance, which is very various in different parts of the body. When the different hairs are examined by a microscope, we find the roots more or less oval, the largest extremity either being turned towards, or fixed in, the corpus adiposum. This oval root is covered by a whitish strong membrane, in some measure elastic; and it is connected either to the skin, to the corpus adiposum, or to both, by a great number of very fine vessels and nervous filaments. Within the root, we observe a kind of glue, some very fine filaments of which advance toward the small extremity, where they unite and form the stem, which passes through this small extremity to the skin. As the stem passes through the root, the outer membrane is elongated in form of a tube, which closely invests the stem, and is entirely united to it. The stem having reached the surface of the skin, pierces the bottom of a small fossula between the papillæ, or sometimes a particular papilla; and there it meets the epidermis, which seems to be inverted round it, and to unite with it entirely. A sort of unctuous matter transudes through the sides of the fossula, which is bestowed on the stem, and accompanies it more or less, as it runs out from the skin.

Hairs are scattered almost over the whole surface of the body, the palms of the hand and soles of the feet excepted. They differ in length, thickness, and solidity, in the different parts of the body. Those on the head, are called in English by the general name of *hairs*; those which are disposed archwise above the eyes, *supercilia* or the *eyebrows*; those on the edges of the palpebræ, *cilia* or the *eye-lashes*; and those which surround the mouth, and cover the chin, the *beard*. In other parts of the body, they have no particular names; and their different lengths, thicknesses, &c. in all these parts, are sufficiently known. Their natural figure seems to be rather cylindrical than angular, which is chiefly accidental. Their colour is probably the same with that of the glue, or medullary matter of the root, the different consistence of which makes the hairs more or less hard, flexible, &c. Their straight or crooked direction must depend on that of the holes through which the stems pass. The hairs grow continually, and are renewed again after being cut, by a protrusion of their medullary substance from the skin outwards under a production of the cuticle. When they are destitute of this medulla in old people, they dry up, split, and fall off. They seem to perspire through their extremities, and possibly through their whole surface; as we may conclude from the constant force of protrusion in their medulla, which in the plica polonica wants a boundary to terminate it.

Besides the integuments which have been already described, the ancients reckoned the panniculus carnosus, and membrana communis musculorum. The panniculus carnosus is found in quadrupeds, but not in men, whose cutaneous muscles are of a very small extent, except that which is called *platysma myoides* in particular; but even

that muscle cannot in any tolerable sense be reckoned a common integument. There is no common membrane of the muscles, which covers the body like an integument; it being no more than particular expansions of the membranes of some muscles, or aponeurotic expansions from others. The elongations from the lamina of the membrana adiposa or cellularis, may likewise have given rise to this mistake, especially in such places where this membrane is closely united to the proper membrane of the muscles.

The sense of *feeling* is to be understood in a two-fold manner. Every change of the nerves, produced by the heat, cold, roughness, smoothness, weight, moisture, or dryness, of external substances applied to any part of the body, is commonly called feeling. In this sense, feeling is ascribed to almost all parts of the human body; to some more, to others less, as in different places of the body the nerves are more numerous and bare, or covered with more tender membranes; and thus even pain, pleasure, hunger, thirst, anguish, itching, and the other sensations, belong to the sense of feeling. In a more peculiar sense, feeling is said to be the change arising in the mind from external bodies applied to the skin, more especially at the ends of the fingers. For, by the fingers, we more accurately distinguish the qualities of tangible substances than by other parts of our body.

The papillæ, regularly disposed in the spiral folds at the ends of the fingers, on the inside of the hand, may, by the attention of the mind, become erect or elevated; and, being in this state gently pressed or rubbed against a tangible substance, they receive an impression from that substance into their nervous fabric, which is thence conveyed, by the trunks of the nerves, to the brain. This is what we call the *touch*, whereby we become sensible chiefly of the roughness of objects. Some persons have this sense so acute as to be able to distinguish colours by touching the surface only. By this sense we perceive heat in those bodies which exceed the heat of our fingers; and weight, when the body presses more than is usual. Humidity we judge of by the presence of water; softness, by a yielding of the object; hardness, from a yielding of the finger; figure, from the limits, or rough circumscribed surface; distance, from a rude calculation or estimate made by experience, to which the length of the arm serves as a measure. The touch serves to correct the mistakes of our other senses; but yet it sometimes errs itself, and then the other senses shew themselves to be true guides to the animal without touch.

The corpus mucosum moderates the action of the object touched, and preserves the softness and sound state of the papillæ. The cuticle excludes the air from withering and destroying the skin; qualifies the impressions of bodies, so that they may be only sufficient to affect the touch, without causing pain. When, therefore, the cuticle is become too thick by use, the sense of feeling is either lost or lessened; and, if it be too thin and soft, the touch becomes painful. The hairs serve to defend the cuticle from abrasion; to preserve and increase the heat; to cover what ought to be concealed; to render more irritable the membranes of those parts, which ought to be defended against the injuries of insects; and perhaps to exhale some useless vapours or oil. The nails serve to guard the organs of feeling, that the papillæ and ends of the fingers may not be bent back by the resistance of tangible objects: at the same time they increase our power of grasping large objects, and assist in handling minute objects. In brute animals, they generally serve as weapons of offence, and might be of the same use to man, if they were not cut off.

One most important office of the skin is, to exhale from the body a large quantity of humours, and to reſorb vapours from the air. The skin is replete with an infinite number of small arteries, either coiled up into papillæ, or passing directly through it, which afford a passage to the exhaling vapour; and, lest this vapour should be collected, as it is in some diseases, between the skin and the cuticle, there are pores in the cuticle corresponding with the exha-

ling arteries of the skin, through which it freely passes. These exhaling vessels or arteries, are easily demonstrated by an injection of water or isinglass into the arteries, which sweat out from all parts of the skin, in an infinite number of small drops; and these substances being transfused under the cuticle, rendered impervious by death, raise it up into a blister. In a living person, this exhalation is many ways demonstrable. A clean looking-glass placed against the warm and naked skin, is quickly obscured by the moist vapour. In subterraneous caverns, where the air is more dense, it is evidently seen to fly off from the whole surface of the body, like a thick cloud.

Whenever the motion of the blood is increased, while at the same time the skin is hot and relaxed, the small cutaneous pores, instead of an invisible vapour, discharge sweat, consisting of minute but visible drops, which run together into larger drops by joining with others of the same kind. The hottest parts are most subject to sweat, as the head, breast, and foldings of the skin. The experiment before-mentioned, of injecting the arteries, the simplicity of nature, and the apparent cutaneous and pulmonary exhalation, sufficiently persuade us, that the perspirable matter and sweat are discharged through one and the same kind of vessels, and that they differ only by the quantity and celerity of the matter. The humour of the sebaceous glands and the subcutaneous oil, which being more plentifully secreted, and diluted with the arterial juice discharged with the sweat, are of an oily and yellow consistence, and chiefly give smell and colour to the sweat. Hence we find the sweat more fetid in the armpits, groins, and other parts, where those glandules are most numerous or abundant. Both blood and small sand have been known to proceed from the skin along with the sweat.

The nature and quantity of the perspirable matter may be investigated by experiments, and by considering its analogy to the pulmonary exhalation. What flies off from the lungs in this exhalation is chiefly water, as appears from experiments, by which the breath, being condensed in large vessels, forms into watery drops. That the perspirable matter is also chiefly water, is demonstrated by its obscuring a glass on which it is received; by obstructed perspiration producing a diuresis or diarrhoea; by the speedy passage of liquors, drunk warm, through the skin if the body be kept warm, or through the kidneys if the body be cold; and by several other phenomena. The water of these vapours is chiefly from what we drink, but is in part supplied from what is inhaled by the skin. The particular smell of the aliments may be sometimes plainly perceived in the perspiration. That there are, besides water, some volatile alkaline particles, is evident, as well from the nature of our blood, as from the considerable mischiefs which follow an obstructed perspiration. This volatile alkaline matter arises from the finer particles of blood, attenuated by perpetual heat and triture, and changed into an acrimonious nature. These afford the scent which is closely followed by dogs, who would not know their masters unless something of a peculiar nature perspired from each person.

The quantity of our perspiring moisture is very large, whether we consider the extent of the organ by which it is separated; the abundance of vapours derived from the lungs only; or barely take a review of the experiments made by Sanctorius. This indetigable man concluded, that five pounds out of eight of the aliment was discharged in a healthy person by the insensible perspiration alone, independent of the visible sweat, and other excretions. In colder climates, the quantity perspired was found to be $\frac{4}{5}$ out of 8. But the cutaneous exhalation is even much larger than this; since it not only throws off a quantity of the aliment, but likewise what is added to the blood by inhalation, which entering, often in a very considerable quantity, is thus again expelled. But different dispositions of the air, and of the human body, cause great variations in these proportions. In warm countries, in the summer

months, and in young persons using much exercise, more goes off from the body by perspiration, and less by the urine; while in cold climates, during the temperate or winter seasons, in aged or inactive persons, more goes off by the urine than by the insensible discharge. In temperate countries, making a computation throughout the whole year, something more is perspired than what passes off by urine; and, joining together all the experiments made in different countries, both excretions are almost alike. The difference of time after feeding also in some measure varies the quantity perspired; but in general it is most copious when the greater part of the digested nourishment is conveyed into the blood, and there attenuated so as to be fit for exhalation. It is naturally diminished in sleep, even in the warmer climates; but it is increased by the heat of bed-clothes.

In general, a plentiful and uniform perspiration, with strength of body, are good signs of health. According to writers on this subject, if the perspiration be increased by the weakness of the body, it is more hurtful than if it were altogether obstructed. It is a sign of health, because it denotes a free pervious disposition of the vessels throughout the whole body, together with a complete digestion of the nourishment, the greater part of which is perfectly attenuated into a vapour. When it is diminished, it indicates either a constriction of the skin, a weakness of the heart, or an imperfect digestion of the aliments. Perhaps in too great a perspiration the nervous spirits themselves are evaporated. This discharge is, by moderate exercise, increased to six times that of an idle person, even to an half or whole pound in an hour. It is likewise increased by the vessels being strong and pervious; by warm, watery, and vinous, drinks; by animal food of an easy digestion; by a heavy, temperate, or moderately-warm, air; and lastly by joy and a tranquil state of mind. The contrary of these either lessen or suppress the perspiration; as a thick skin, a moist air, or a cold and dry one; rest; more frequent bathing than usual; a supervening diarrhoea; and, lastly, a disagreeable nervous affection of the mind. The continuance of life, however, does not depend on a scrupulous exactness in the quantity of this discharge, which is so easily increased or diminished by slight causes. It is shut up by pains in many Indian nations; and it is inconsiderable in many animals without any sensible injury. When suppressed, it is extremely hurtful, producing fevers of the worst kind. The mischiefs arising from its suppression, depend on the putrescent quality of the particles which are retained along with it.

The sweat is evidently of a saline nature; as appears from the taste; from the minute crystallizations on the clothes of people who work in glass-houses; and from distillation, which shews the sweat to be of an alkaline nature. Hence it is, that by this discharge the most malignant matter of many diseases is thrown off from the body. But, in reality, sweat is always a preternatural or morbid discharge, from which a person ought always to be free; unless by violent exercise, or other accidents, his constitution is for a short time thrown into a diseased state. Nor is it unfrequent for sweats to do considerable mischief in acute diseases, by wasting the watery parts, thickening the rest of the blood, and at the same time rendering the salts more acrimonious. By a too violent motion of the blood, the sweat is rendered extremely fetid; and is sometimes even red, or mixed with blood itself; and, being electrified, it is sometimes lucid. The uses of perspiration are, to free the blood from its redundant water, and throw out those particles, which, by repeated circulations, have become alkaline or otherwise acrimonious; and possibly to exhale therewith an extremely volatile oil, prepared from the same blood. Perspiration likewise qualifies and softens the cuticle, which is a necessary medium extended before the tender sensible papillæ.

Besides the exhalent vessels before-mentioned, the skin is full of small vessels, which inhale or absorb thin vapours from the air, either perpetually, or at least when it is not
very

very cold; more especially when the air is damp, the body unexercised, the mind oppressed with grief, or both under conditions contrary to those which increase perspiration before-mentioned. These veins, says Haller, are demonstrated by anatomical injections, which, if thin or watery, sweat through them as through the arteries: but, according to later physiologists, absorption is performed solely by the lymphatic vessels. That absorption takes place, is sufficiently proved by the manifest operation of medicines, pervading the air, or applied to the skin; such as the vapours of mercury, turpentine, saffron, waters of baths, mercurial plasters, tobacco, coloquintida, opium, cantharides, arsenic, with the fatal effects of contagious or other poisons entering through the skin; as in the venereal infection. Another proof of absorption by the skin is, that animals live in hot moist climates without drink, and yet discharge a considerable quantity of humours both by perspiration and urine. Lastly, absorption has been proved in some diseases where a much greater quantity of urine has been discharged than the quantity of drink taken in. It is difficult to ascertain the quantity of this inhaled matter in animals; in plants it appears, from well-authenticated experiments, to be very considerable, especially during the night. These cutaneous vessels, both exhaling and inhaling, are capable of contraction and relaxation by the power of the nerves. The truth of this appears from the effects of the passions of the mind; which, if joyful, increase the circulation, and relax the exhaling vessels, so as to yield easier to the impulse of the blood; from whence, with a shortening of the nerves, there follows a redness, moisture, and turgescence, of the skin. Those passions, on the contrary, which are sorrowful, and retard the circulation, contract the exhaling vessels; as appears from the dryness and corrugation of the skin, like a *goose-skin*, after-frights; and from a diarrhoea being caused by fear. And the same affections seem to open and increase the power of the inhaling vessels, whence the venereal or pestilential contagions are easily contracted by fear.

Of the DIFFERENT VISCERA and ORGANS.

Of the HEAD.

THE *head* is generally considered as one of the three principal cavities of the human body. On its outside are situated the seats and bases of several very complex particular organs; whereas on the inside it contains only one, namely the *brain*, which is indeed the primum mobile of the whole animal economy. The mechanism of this organ is very little known; and the structure of its different parts, even of those with which we are supposed to be most acquainted, is very difficult to be demonstrated.

The *brain* is that mass which fills the cavity of the cranium, and which is immediately surrounded by two membranes, called *meninges* by the Greeks, and *matres* by other ancients, because they were commonly of opinion, that these membranes were the origin, and, as it were, the mother, of all the other membranes of the body. This general mass is divided into three particular portions; the cerebrum or *brain* properly so called, the cerebellum, and medulla oblongata. To these three parts contained within the cranium, a fourth is added, which fills the great canal of the *spina dorsalis*, and is known by the name of *medulla spinalis*, being a continuation of the medulla oblongata. The meninges, or membranes, are two in number; one of which is very strong, and lies contiguous to the cranium; the other is very thin, and immediately touches the brain. The first is named *dura mater*, the second *pia mater*. This last is again divided into two; the external lamina being termed *arachnoides*, the internal retaining the common name of *pia mater*.

The *dura mater* incloses the brain and all its appendages. It lines the inside of the cranium, and supplies the place of an internal periosteum, being spread in holes and depressions, and covering all the eminences in such a manner, as to prevent their being hurtful to the brain. It sends off several processes; three of which form particular

septa, that divide the brain into certain parts. One of them is superior, representing a kind of mediastinum between the two great lobes of the brain. The second is in a middle situation like a diaphragm, between the cerebrum and cerebellum. The third is inferior between the lobes of the cerebellum. The superior septum is longitudinal, in form of a scythe, whence it is termed the *fals of the dura mater*; and it may likewise be called *septum sagittale*, *verticale*, or *mediastinum cerebri*. The middle septum is transverse, and might be called the *floor of the cerebrum*, the *diaphragm of the brain*, *tentorium cerebelli*. The inferior septum is very small, and runs down between the lobes of the cerebellum; on which account it may be termed either simply *septum cerebelli*, or *septum occipitale minus*, the middle partition being looked upon as the *septum occipitale majus*. The *dura mater* contains in its duplicature several particular canals, into which the venous blood, not only of that membrane, but of the whole brain, is carried. These canals are termed *sinuses*; and some of them are disposed in pairs, others in uneven numbers; that is, some of them are placed alone in a middle situation; others are disposed laterally on each side of the brain. All these sinuses communicate with each other, and with the great lateral sinuses, by which they discharge themselves into the internal jugular veins, which are only continuations of these lateral sinuses. They likewise unload themselves, partly into the vertebral veins, which communicate with the small lateral or inferior occipital sinuses; and partly into the external jugular veins, by the orbital sinuses, which communicate with the *venae angulares*, *frontales*, *nasales*, *maxillares*, &c. as the lateral sinuses likewise communicate with the *venae occipitales*, &c. Thus the blood, which is carried to the *dura mater*, &c. by the external and internal carotid, and by the vertebral arteries, is returned to the heart by the external and internal jugular and vertebral veins; so that the blood, if obstructed in one place, finds, in consequence of these communications, a passage at another, though perhaps not with the same ease. This observation is of consequence, in relation not only to obstructions, but to the different situations of the head.

It has been thought, that the arteries of the *dura mater* discharged themselves immediately into the sinuses; because injections made by the arteries, or a hog's bristle thrust into them, have been found to pass into these sinuses. But, on a more close examination, it has been discovered, that the injections passed from the arteries into the veins, and from thence into the sinuses; and that the hog's bristle pierced the sides of the artery, which are very thin near the sinuses. This mistake gave rise to another, namely, that the *dura mater* had no veins; and what confirmed it was, that the arteries of the *dura mater* cover the veins so entirely, that the edges of the veins are hardly perceivable on either side of the arteries. There are, however, some places where the veins, being broader than the arteries, their two edges are seen on each side of the arteries like capillary vessels. These veins are, for the most part, branches of these sinuses, and the small trunks of some of them open into the head of the *vena jugularis interna*. The prominent fibres which appear intersecting each other in different manners on the inside of the *dura mater*, especially near the *fals* and transverse septum, and which have been taken for a kind of fleshy fibres, seem to be only ligamentary and elastic. The universal adhesion of this membrane to the cranium, proves that it can have no particular motion, and consequently, that such fleshy or muscular fibres would be altogether useless. This adhesion was plainly demonstrated by Vesalius, Riolan, &c. long before Roonhuyzen.

The *pia mater* is a much softer and finer membrane than the former, being exceedingly delicate, transparent, and vascular; and is connected to the *dura mater* only by the veins which open into the sinuses. It is composed of two laminae, of which the external one is named *tunica arachnoides*, from its resemblance to a cobweb. They adhere closely to each other at the upper part of the brain; but

are easily separable at the basis, and through the whole length of the spinal marrow.

The *cerebrum* is a kind of medullary mass, of a moderate consistence, and of a greyish colour on the outer surface, filling all the superior portion of the cavity of the cranium, or that portion which lies above the transverse septum. The upper part of the cerebrum is of an oval figure, like half an egg cut lengthwise, or rather like two quarters of an egg cut lengthwise, and parted a little from each other. It is flatter on the lower part, each lateral half of which is divided into three eminences, which correspond with the cavities at the base of the cranium. The cerebrum is divided into two lateral portions, separated by the falx, or great longitudinal septum, of the dura mater. They are generally termed *hemispheres*, but they are more like quarters of an oblong spheroid. Each of these portions is divided into two extremities, one anterior and one posterior, which are termed the *lobes of the cerebrum*, between which there is a large inferior protuberance which goes by the same name; so that in each hemisphere there are three lobes, one anterior, one middle, and one posterior. The substance of the cerebrum is of two kinds, distinguished by two different colours; one part of it being of a greyish or ash colour; the other, which is somewhat firmer than the former, is remarkably white, but redder in the fœtus. The ash-coloured substance lies chiefly on the outer part of the cerebrum like a kind of cortex, from whence it has been named *substantia corticalis*, or *cineæ*. The white substance occupies the inner part, and is named *substantia medullaris*, or simply *substantia alba*. This abounds in greater quantity than the other, and in many places is perforated with red arteries. If we separate gently the two lateral parts or hemispheres of the cerebrum, we see a longitudinal portion of a white convex body, which is named *corpus callosum*. The surface of it is covered by the pia mater, which runs in between the lateral portions of this body and the lower edge of each hemisphere. Along the middle of its surface, from one end to the other, a kind of raphe is formed, by a particular intertexture of fibres crossing each other. This raphe is made more perceivable by two small medullary cords, which accompany it on each side, and adhere closely to the transverse fibres. The corpus callosum becomes afterwards continuous on each side with the medullary substance; which, through all the remaining parts of its extent, is entirely united with the cortical substance, and, together with the corpus callosum, forms a medullary arch or vault of an oblong or oval figure. Under this arch are two lateral cavities, separated by a transparent medullary septum. These cavities are generally named the *anterior superior ventricles of the cerebrum*, to distinguish them from two other smaller cavities which are situated more backward; but the name of *lateral or great ventricles*, given them by Steno, is more proper than either of the other two. The transparent partition, or *septum lucidum*, as it is commonly called, lies directly under the raphe or suture of the corpus callosum, of which it is a continuation and a kind of duplicature. It is united, by its lower part, to the anterior portion of that particular medullary body, improperly called the *fornix*, with three pillars, because of some resemblance it is thought to bear to the arches of ancient vaults. It is, in reality, nothing but the corpus callosum; the lower side of which is like a hollow ceiling with three angles, one anterior, and two posterior; and three edges, two lateral, and one posterior. The lateral edges are each terminated by a large semicylindrical border, like two arches, which, uniting at the anterior angle, form by their union what is called the *anterior pillar of the fornix*; and, as they run backward separately toward the two posterior angles, they have then the name of the *posterior pillars*. The anterior pillar being double, is larger than either of the posterior; and the marks of this duplicity always remain. Immediately below the basis of this pillar, we observe a large, white, short, medullary, rope, stretched transversely between the

two hemispheres, and commonly called the *anterior commissure of the cerebrum*. The posterior pillars are bent downward; and at their outsides they have each a small, thin, flat, collateral, border, to which the name of *corpora fimbriata* is applied. The posterior pillars also unite with two medullary protuberances, called *pedes hippocampi*. The inferior surface of the triangular ceiling, which lies between these arches, is full of transverse prominent medullary lines; for which reason the ancients called it *psaloides* and *lyra*, comparing it to a stringed instrument, something like what is now called a dulcimer. Under the fornix, and immediately behind its anterior crura, there is a hole of considerable size, by which the two lateral ventricles communicate; and another passage leads down from this, under the different appellations of *foramen commune arterius*, *vulva*, *iter ad infundibulum*, but more properly *iter ad tertium ventriculum*. The fornix being cut off and inverted, we see first of all a vascular web, called *plexus chorooides*, and several eminences more or less covered by the expansion of that plexus. There are four pairs of eminences which follow each other very regularly, two large and two small. The first two great eminences are named *corpora striata*; and the second, *thalami nervorum optico-rum*. The four small eminences are closely united together, the anterior being called *nates*, and the posterior *testes*; but it would be better to call them simply *anterior* and *posterior tubercles*. Immediately before these tubercles there is a single eminence, called *glandula pinealis*. Immediately under the union or beginning of the thalami nervorum optico-rum, lies a particular cavity called the *third ventricle* of the cerebrum. It opens backwards into the passage called *iter ad quartum ventriculum*. Between the basis of the anterior pillar of the fornix, and the anterior part of the union of the optic thalami, lies a small medullary canal, named *infundibulum*. It runs down towards the basis of the cerebrum, gradually contracting, and terminates by a small membranous and straight canal, in a softish body situated in the sella turcica, named *glandula pituitaria*. This pituitary gland is a small spongy body lodged in the sella turcica, between the sphenoidal folds of the dura mater. It is a singular kind of substance, and seems to be neither medullary nor glandular. On the outside it is partly greyish and partly reddish, but white within. The tubercles are four in number, two anterior and two posterior. They are transversely oblong, the anterior being a little more rounded, and broader or larger from before backward, than the posterior; their surface is white, and their inner substance greyish. The names of *nates* and *testes*, given by the ancients to these tubercles, are not very proper, there being little resemblance between them and the things from which the names are taken. Some of the moderns, with perhaps still less propriety, have called them *tubercula quadrigemina*. Directly under the place where the tubercles of one side are united to the tubercles of the other side, lies the *iter ad quartum ventriculum*, which communicates, by its anterior opening, with the third ventricle, under the thalami nervorum optico-rum, and, by its posterior opening, with the fourth ventricle, which belongs to the cerebellum. Where the convex parts of the two anterior tubercles join these posterior convex parts of the thalami nervorum optico-rum, an interstice or opening is left between these four convexities; but it does not communicate with the third ventricle, for the bottom of it is shut up by the pia mater. The name of *anus* is applied to it. The *glandula pinealis* is a small soft greyish body, about the size of an ordinary pea, irregularly round, and sometimes of the figure of a pine-apple, situated behind the thalami nervorum optico-rum above the tubercula quadrigemina. It is fixed like a small button to the lower part of the thalami, by two very white medullary pedunculi, which, at the gland, are very near each other, but separate almost transversely toward the thalami. It seems to be mostly of a cortical substance, except near the footstalks, where it is somewhat medullary. This gland

gland has been often found to contain gravel. Below the glandula pinealis there is a medullary transverse cord, called the *posterior commissure of the hemispheres of the cerebrum*.

The *cerebellum* is contained under the transverse septum of the dura mater, in the under and back part of the cranium. It consists, like the cerebrum, of two substances. It has no circumsolutions on its surface; but, instead of them, numerous sulci, which are deep, and disposed in such a manner as to form thin flat strata, more or less horizontal, between which the internal lamina of the pia mater infinuates itself by a number of septa equal to that of the strata. Under the transverse septum, it is covered by a vascular texture, which communicates with the plexus choroides. It has two middle eminences, called *appendices vermiformes*, from their resemblance to the rings of an earth-worm. Besides the division of the cerebellum into lateral portions, or into two lobes, each of these lobes seems to be likewise sub-divided into three protuberances; one anterior, one middle or lateral, and one posterior. When we separate the two lateral lobes, we discover the posterior portion of the medulla oblongata; and, in the posterior surface of this portion, from the tubercula quadrigenina, we observe an oblong cavity, which is called the *fourth ventricle*; this terminates backward, like the point of a writing pen. Hence the under end of it is called *calamus scriptorius*. At the beginning of this cavity we meet with a thin medullary lamina, which constitutes a valve between that canal and the fourth ventricle. It is lined by a thin membrane, and seems often to be distinguished into two lateral parts, by a kind of small groove, from the valvular lamina to the point of the calamus scriptorius. This membrane is a continuation of that part of the pia mater which lines the small canal, the third ventricle, infundibulum, and the two great ventricles. To be able to see the fourth ventricle in its natural state, in which it is narrowest, it must be laid open while the cerebellum remains in the cranium. On each side of this ventricle, the medullary substance forms a trunk which expands itself in form of laminae through the cortical strata. But here we find the medullary bearing a less proportion to the cortical than it does in the cerebrum. We discover these medullary laminae according to their breadth, by cutting the cerebellum in slices almost parallel to the basis of the cerebrum; but, if we cut one lobe of the cerebellum vertically, the medullary substance will appear to be dispersed in ramifications through the cortical substance. These ramifications have been named *arbor vitæ*; and the two trunks, from whence these different laminae arise, are called *pedunculi cerebelli*.

The *medulla oblongata* is a medullary substance, situated in the middle part of the bases of the cerebrum and cerebellum, without any discontinuation, between the lateral parts of both these bases; and is justly esteemed to be a third general part of the whole mass of the brain, or as the common production, or united elongation, of the whole medullary substance of the cerebrum and cerebellum. The lower side of the medulla oblongata, in an inverted situation, presents to our view several parts, which are in general either medullary productions, trunks of nerves, or trunks of blood-vessels. The chief medullary productions are these; the large or anterior branches of the medulla oblongata, which have likewise been named *crura anteriora*, *femora*, and *brachia medullæ oblongatæ*, and *pedunculi cerebri*. The transverse protuberance, called likewise *processus annularis* or *pons Varolii*. The small or posterior branches, called *pedunculi cerebelli*, or *crura posteriora medullæ oblongatæ*. The extremity or cauda of the medulla oblongata, with two pairs of tubercles; one of which is named *corpora olivaria*, the other *corpora pyramidalia*; and to all these productions we must add a production of the infundibulum and two medullary papillæ. The great branches of the medulla oblongata are two very considerable medullary fasciculi. These fasciculi are flat, much broader before than behind; their surfaces being composed of several longitudinal and distinctly prominent medullary fibres.

Their anterior extremities seem to be lost at the lower part of the corpora striata; and, it is for that reason, that they are esteemed the pedunculi of the cerebrum. The transverse annular protuberance is a medullary production, which seems at first sight to surround the posterior extremities of the great branches; but the medullary substance of the protuberance is in reality intimately mixed with that of the two former. Variolus, an ancient Italian author, viewing these parts in an inverted situation, compared the two branches to two rivers, and the protuberance to a bridge over them both; and from thence it has the name of *pons Varolii*. When we cut into the substance of the pons, we find much cortical substance within it, and this formed into striæ, which run in various directions. The small branches of the medulla oblongata are lateral productions of the transverse protuberance, which by their roots seem to encompass that medullary portion in which the fourth ventricle or calamus scriptorius is formed. They form in the lobes of the cerebellum, on each side, those medullary expansions, a vertical section of which shews the white ramifications commonly called *arbor vitæ*; and they may be justly styled *pedunculi cerebelli*. The extremity is no more than the medulla oblongata contracted in its passage backward to the anterior edge of the foramen magnum of the os occipitis, where it terminates in the medulla spinalis; and, in this part of it, several things are to be taken notice of. We see, first of all, four eminences, two named *corpora olivaria*, and the other two *corpora pyramidalia*. Immediately afterwards, it is divided into two lateral portions by two narrow grooves, one on the upper side, the other on the lower. They both run into the substance of the medulla, as between two cylinders, flattened on that side by which they are joined together. When we separate these ridges with the fingers, we observe a crucial intertexture of several small medullary cords, which go obliquely from the substance of one lateral portion into the substance of the other. M. Petit, member of the Royal Academy of Sciences, and doctor of physic, is the author of this discovery, by which we are enabled to explain several phenomena, both in physiology and pathology. The corpora olivaria and pyramidalia are whitish eminences, situated longitudinally near each other, on the lower side of the extremity or cauda, immediately behind the transverse or annular protuberances. The corpora pyramidalia are in the middle; so that the interspace between them, which is only a kind of superficial groove, answers to the inferior groove of the following portion. The corpora olivaria are two lateral eminences situated at the outside of the former, and are thus termed by Willis, Duverney, Haller, &c. but Winslow reverses the names. These four eminences are situated on the lower half of the medulla; which observation we here repeat, to make it be remembered, that, in all the figures and demonstrations, these parts are represented as superior, which, in their natural situation, are inferior. Thus these eminences are under the fourth ventricle, and under the pedunculi cerebelli. The tubercula mammillaria, which are situated very near the production of the infundibulum, have been taken for glands; probably because of their greyish inner substance, which, however, does not seem to be different from that of several other eminences of the medulla oblongata. And, for that reason, we choose rather to call them, from their figure, *tubercula mammillaria*, than *papillæ medullares*. These tubercles seem to have some immediate relation to the roots or bases of the anterior pillar of the fornix; so that we might call them, as M. Santorini has done, *the bulbs of these roots*, though they appear to be likewise a part of a continuation of other portions of the cortical and medullary substance, of a particular texture. The beak or tube of the infundibulum is a very thin production from the sides of that cavity; and it is strengthened by a particular coat given to it by the pia mater. It is bent a little from behind forward, toward the glandula pituitaria, and afterwards expands again round this gland. The membrana arachnoides, or external lamina of the pia mater, appears

to be very distinctly separated from the internal lamina, in the interstices between all these eminences on the lower side of the medulla oblongata. From this common portion of the cerebrum and cerebellum, arise almost all the nerves which go out of the cranium, through the different foramina perforating its base. It likewise produces the medulla spinalis; and may justly be said to be the first origin or primitive source of all the nerves which go out through the spina dors, and consequently of all the nerves of the human body.

The *medulla spinalis* is only an elongation of the extremity of the medulla oblongata; and it has its name from its being contained in the bony canal of the spina dors. It is consequently a continuation or common appendix of the cerebrum and cerebellum, as well because of the two substances of which it is composed, as because of the membranes by which it is invested. The spinal marrow consists of a cortical and medullary substance, as the cerebrum and cerebellum; but with this difference, that the ash-coloured substance lies within the other; and, in a transverse section of this medulla, the inner substance appears to be of the form of a horse-shoe, the convex side being turned forward and the extremities backward. The body of the medulla spinalis runs down to the bottom of the first vertebra of the loins, where it terminates in a point. The size of it is proportionable to that of the bony canal, so that it is larger in the vertebræ of the neck than in those of the back.

From a general view of the nerves and blood-vessels belonging to the brain, it appears that a very great quantity of blood, derived from trunks that are near the heart, is, at every pulsation, sent to this organ: Dr. Haller says a sixth part, Dr. Monro, a tenth part of the whole circulating mass. Hence it is probable, that the strongest parts of the blood, and such as are most retentive of motion, go to the head. Is not this evident from the effects of mercurials exerting themselves almost in the head only? from the sudden force and action of inebriating spirits upon the head? from the short stupor which camphor excites? from the heat, redness, and sweat, which happen oftener in the face than other parts of the body? to which add, the more easy eruption of volatile and contagious pustules in the face? Dr. Wrisberg, however, observes, that all these arguments are not of the same force; for mercury, applied in different ways to the body, produces its effects not in the head alone; since it occasions in some patients a diaphoresis, in others a diarrhœa, and in others it acts as a diuretic.

The *veins* of the brain are not disposed in the same manner with those in other parts of the body. For they have no valves, nor do they run together in company with the arteries, nor have their trunks the structure which is commonly observed in the other veins. The great quantity of blood which goes to the brain, the greater impulse with which it is sent into the carotid arteries, the security of this part from every kind of pressure by a strong bony fence, the slower motion of the blood through the abdominal viscera and lower extremities, and the perpetual exercise of the brain and senses, all determine a copious flux of blood to these parts; some other causes also serve to fill the head largely with blood. Hence it is that a redness of the face, a turgescence, a sparkling of the eyes, with a pain of the head, a pulsation or throbbing of the arteries, and a bleeding at the nose, are produced by violent exercises or motions of the body. Hence, therefore, it is evident, that if the veins were of a thin structure, and round shape, in the brain, they would unavoidably be in greater danger in rupturing, (to which, even in their present state, they are often liable,) and consequently apoplexies would be much more frequent. To avoid this inconvenience, therefore, nature has given a different figure to the veins carrying the blood from the brain, by which they are more easily and largely dilatable, because they make an unequal resistance: their texture is likewise very firm, and more difficultly ruptured, especially in the larger

sinuses, which perform the office of trunks; but, as to the sinuses of the lesser sort, they are either round, half cylindrical, or of an irregular figure. Besides this, nature has guarded the sinuses by cross beams, or fræna, internally, made of strong membranes, and detached from the right to the left side of the bottom of the sinus, which, in greater distensions, they draw towards a more acute angle, strengthening and guarding it from a rupture. She has likewise furnished these veins with numerous anastomoses, by which they communicate with one another, with the external veins of the head, and with those of the spinal marrow; and by this contrivance, they are capable of evacuating themselves more easily whenever they are overcharged with blood.

Some writers have doubted, Whether a part of the arterial blood is not poured into the sinuses of the brain; and whether the sinuses have not a pulsation excited from that blood? That they have no pulsation, Dr. Haller says, is past a doubt; because the dura mater every where adheres firmly to the skull, but much more firmly in those parts which are the seats of the sinuses. But Dr. Monro observes, that whilst the heart is performing its systole, the arteries here, as elsewhere, may be dilating; and, in the mean time, a quantity of blood, equal to that which is dilating them, is passing out of the head by the veins. Indeed the sinuses receive liquors injected by the arteries; but whether they transude through the small exhaling arterial vessels, or whether they first make a complete circle through the veins, as indeed is much more probable, we are not yet furnished with experiments enough to determine. The veins form innumerable anastomoses with one another, that the blood may return with the greatest ease from the head, the repletion of which is very dangerous. The brain is also more easily evacuated in the time of inspiration, for it then subsides, as we see when the skull is opened, but swells during the time of expiration. Hence, blowing the nose, sneezing, and coughing, are dangerous to those whose brain is swelled by retained blood.

Whether lymphatic vessels are to be seen in the brain, is questioned by some writers. Dr. Haller thought it probable that no lymphatic vessels are in the brain, because no conglobate glands are found there; and that the superfluous moisture is absorbed by the red veins. But, according to most of the present physiologists, lymphatic vessels take up the superfluous fluids of the brain, as well as of the other parts of the body, although they cannot be distinctly shewn. "Scarcely in any viscus," says Dr. Wrisberg, "has the existence of lymphatic vessels been oftener asserted, and again denied, than in the brain. Although, indeed, I am fully certain, that a group of lymphatic glands is no where found without lymphatic vessels, I could not, however, assert that, where glands do not appear, lymphatic vessels are wanting. By analogy drawn from the whole body, and all the viscera, I am led to think that the brain is not destitute of its aqueous vessels, and that they run in particular upon the surface, not in the middle of its substance, although I myself have never seen any other than those going on the choroid plexus towards the sensorium, and on the inner surface of the dura mater, in the course of the superior longitudinal sinus. The industrious and celebrated Sommering confirms the observations of King, Collins, and Pacchioni, who saw lymphatics upon the pia mater. I would ask, May they be joined with the glands of Pacchioni? May these corpuscles supply the place of lymphatic glands?"

It now remains for us to speak of the encephalon itself. Upon the surface of the brain lies the cortex, the fabric of which has been a long time controverted; but it is now sufficiently evident, from anatomical injections, that the greater part of it consists of mere vessels, which are every way inserted from the small branches of the pia mater, detached like little roots into the cortical substance. These vessels, in their natural state, convey a juice much thinner than blood; although, in some diseases, and by strangling, they often, especially in brutes and birds, receive even the red

red parts of the blood. The remaining part of the cortex, which is not filled by any injection, is probably either an assemblage of veins, or of yet more tender vessels; for no dissimilar parts are apparent in the cortex, whilst it is in an entire or natural state; and hence we are not permitted to conclude that part of it is tubular, and part solid. As to glandules making the fabric of the brain, that notion has been discarded by universal consent, as not being founded on the least probability.

The nerves of the brain, as well as of the spinal marrow, divide into branches like the blood-vessels, but in acute angles, and often in a course manifestly retrograde, they generally, but not always, gradually become softer, and less bulky, as they recede from the brain, till at length their ultimate extremities, which are seldom visible, seem to terminate in a pulp, by depositing the firm integuments with which they were covered, as we observe in the optic nerve. The recti-linear course of the fibres, continued from the brain itself, is never broken off by the division or splitting of a nerve into smaller threads; but the fibres themselves recede from each other by an opening of the cellular substance that tied them together. This appears from the disorders which are determined not to all, but only to some single parts of the body, by injuries of the brain; as a loss of the voice, deafness, dumbness, and palsies of particular muscles. The nerves are connected in their course by the cellular substance to the adjacent parts, but have hardly any elasticity; whence they do not fly back after being cut, but only expel, by the contraction of their integuments, the soft medulla which they include. Though they be ever so much irritated, they are neither contracted, nor rendered shorter during the muscular motion which they produce. A great many nerves, says Haller, are sent into the muscles; many of them go to the skin; fewer to the viscera, and very few to the lungs. Wrisberg, however, observes, that more nerves manifestly enter the organs of sense than the muscles; and that the lungs are supplied with more nerves than the spleen, uterus, and other viscera. Haller also asserts, that no nerves go to the dura and pia mater, arachnoides, tendons, capsules, and ligaments. That these parts have few nerves is certain; but that nerves can be traced into some of them, especially into ligaments, cannot now be denied.

Thus much we are taught by anatomy concerning the brain and nerves; it now remains that we explain the physiological uses of these parts. Every nerve that is irritated by any cause produces a sharp sense of pain. To feel or perceive is to have the mind changed or affected by a change or affection of the body. It is the medullary part of the nerve that feels. If the nerve was endowed with any peculiar sense, that sense perishes when the nerve is compressed or cut through; the senses of the whole body are lost by a compression of the brain, and a pressure of the spinal marrow deprives only those parts which are below it of sensation. If a pressure be made on the brain where particular nerves arise, then only those senses depending on these nerves are lost. Those parts of the body that are furnished with nerves, are the only parts endued with sensation, which is greater in proportion to the quantity of nerves sent to the parts, of which we have examples in the eye and the penis; those have less sensibility which receive few nerves, as the viscera; and those which have fewest nerves, as the dura mater, tendons, ligaments, secundines, bones, and cartilages, have little or no sensation in the sound state. It is therefore evident, that all sensation arises from the impression of an active substance on some nerve of the human body; and that the same is then represented to the mind by means of that nerve's connection with the brain. It seems to be false, that the mind perceives immediately by means of the sensoria and branches of the nerves. For this opinion is refuted by the pains felt after amputation, by the cessation of all pain when the nerve is compressed, and by defects or faults of the senses in consequence of diseases of the brain. And that the effect of the senses is preserved in the brain, is

evident from the loss of memory which follows an injury or compression of the brain; and also from the delirium which happens in some diseases, and the stupor and sleepiness which happen in others.

Another office of the nerves is to excite motions, even the most violent, in the muscles. When a nerve is irritated, every muscle to which it goes is immediately convulsed; or, if it sends branches to several muscles, they are all convulsed at the same time. This happens both during the life of the animal, and a little after its death, while all the parts remain moist. By a great irritation other muscles, besides those to which it sends branches, are thrown into convulsions, and afterwards the whole body. Nor is it necessary that the nerve should be whole; for even when it is cut, an irritation of it will excite similar motions in the muscles. On the other hand, when a nerve is compressed or tied, a palsy follows; that is, the muscles which have their nerves from it lie unmoved, when they are commanded by the will to act; but they recover their motion when the compression is removed, provided the nerve has received no hurt.

But the medulla of the brain being vellicated, or irritated deeply in its crura, dreadful convulsions ensue throughout the whole body; and this effect is universally produced, what part of the brain soever be irritated; whether it be the brain itself, the cerebellum, or the corpus callosum. The same consequences also follow, if the spinal marrow be irritated. But if the encephalon itself be compressed in any part whatever, there follows thence a loss of sense and motion in that part of the body whose nerves come from the affected or compressed quarter of the brain. This fact is proved by experiments made in diseases of the brain, where the origin of particular nerves have been compressed; thus the voice, the power of deglutition, the motion of an arm or a leg, are lost, if the origin of the nerves, on which these faculties and motions depend, be compressed. This is still more evident in irritations or compressions of the spinal marrow, which produce respectively convulsions or palsies of those parts that receive nerves from or below the place injured. If any large portion of the brain be compressed by an extravasation of blood, by a collection of water, by a schirrus, or by an impacted bone, or by any mechanical cause whatever, then, in proportion to the violence of the compression, there will follow either a partial or a total loss of the power of motion, those organs obedient to the will being affected in consequence of a slighter compression; but all the organs, if the pressure be great. The effects above recited cease when the cause is removed. It may be proper to add, that, if the spinal marrow be hurt in the neck, death immediately follows, probably because the nerves of the heart chiefly arise from that part.

From these considerations, we cannot doubt that the cause of all motion in the human body arises from the brain, and its annexed cerebellum and spinal marrow; and that it thence proceeds through the nerves to all the muscular parts of the body. Besides, the cause of this motion cannot reside in the parts themselves, because otherwise the moving cause would continue to act after being separated from the brain; nor would it be increased by irritating the brain, or weakened by a compression of it. Is there in the brain any principal part, in which the origin of all motion and the end of all the sensations reside, and where the soul has its seat? Is this opinion proved by the frequent observation, that the senses are sometimes entire, and that motion likewise remains, though the brain be materially injured? Is the seat of the soul in the corpus callosum? Is this opinion shewn by the greater fatality of wounds or diseases in the corpus callosum? Is this body sufficiently connected with the nerves? Are there any experiments which prove that from thence the fifth, seventh, and other, nerves arise? Doth not the same, or even greater, mortality of wounds in the medulla spinalis, prove the same thing? Yet this is not the seat of the soul, since though it is compressed, or even destroyed, the person will survive

survive a long time with the perfect use of all his mental faculties. Lastly, this opinion is opposed by numerous facts: birds have no corpus callosum, and wounds in that body are not more mortal than those in other parts of the brain, as appears from undoubted experiments.

The prerogative of exciting vital motions, is not more peculiar to the cerebellum than to the other parts of the encephalon; nor does it sufficiently appear, that the vital and animal functions are distinct: for the cerebellum does not produce the nerves of the heart and of the other vital organs, and the brain those which go to the organs of sense and voluntary motion. From the cerebellum the fifth nerve is most evidently produced; but that goes to the tongue, pterygoid, buccinator, temporal and frontal muscles, to the ear, the eye, the nostrils; parts which are either moved by the will, or destined for sense. Again, the same nerve, like the eighth, sends vital branches to the heart and lungs, animal and voluntary ones to the larynx, and sensitive ones to the stomach. Again, it is not even true that disorders of the cerebellum bring on so certain and speedy death as is generally imagined; for some experiments, even of our own making, shew that it has born wounds and schirrh, without taking away life. Lastly, it is not much different from the brain, only that it is softer and more tender; and we have often known wounds of the cerebellum cured. The power, however, of this part, in exciting convulsions, is somewhat greater than that of the brain.

We must inquire experimentally concerning the seat of the soul. In the first place it must be in the head, and not in the spinal marrow: for, though this is obstructed, the constancy of the mind remains the same. Again, from the experiment of convulsions arising when the inmost parts of the brain are irritated, it appears to be seated, not in the cortex, but in the medulla; and, by a probable conjecture, in the crura of the medulla, the corpora striata, thalami, pons, medulla oblongata, and cerebellum. And again, by another not absurd conjecture, it is perhaps seated at the origin of every nerve, as the first origin of all the nerves taken together make up the sensorium commune. Are the sensations of the mind represented there, or do the voluntary and necessary motions arise in that place? This seems very probable; for it is scarcely possible, that the origin of motion can lie below that of the nerve, since the nerve is similar throughout its whole length. The origin of motion cannot be in the arteries, which have neither the faculty of sensation nor that of voluntary motion. It therefore follows, that the seat of the soul must be where the nerve first begins its formation or origin.

We come now to explain the manner in which the nerves become the organs of sense or motion, which, lying hid in the ultimate elementary fabric of the medullary fibres, seem to be placed above the reach both of sense and reason. We shall nevertheless endeavour to make this as plain as experiments will enable us. And first, it is demonstrated, that the sensation does not come through the membranes from the sentient organ to the brain, nor that motion is sent through the coverings from the brain into the muscle; for the brain itself lies deeper than these membranes, and receives the impressions of sense, and, when hurt, throws the muscles into convulsions. Moreover it is certain, that the nerves arise from the medulla of the brain; for, by ocular inspection, we see that to be the case in all the nerves of the brain, more especially in the olfactory, optic, fourth, and seventh, pair of nerves, which continue their medullary fabric a long way before they put on the covering of the pia mater.

We must therefore next inquire what this medulla is. It is a very soft substance; its composition is fibrous, as appears from innumerable arguments: its fibres are visible in the corpus callosum, in the striatum, in the thalami of the optic nerves, and spinal marrow; and still more evidently in the brains of fish, and especially in their thalami optici; but in no part of the human brain does the fibrous nature of the medulla more evidently appear than in the

fornix, especially when immersed in some of the acids. Again, that the fibres of the brain are continuous with those of the nerves, so as to form one extended and open continuation, appears very evidently in the seventh, fourth, and fifth, pair of nerves. There is a great deal of oil in the medulla, upwards of a tenth part of its whole weight. But here a controversy begins concerning the nature of these fibres, a congeries of which composes the substance of the medulla and of the nerves. That this is a mere solid thread, and only watered by a vapour exhalant into the cellular fabric which surrounds the nervous fibres, has been asserted by many of the moderns; but that, when it is struck by a sensible body, a vibration is excited, which is then conveyed to the brain. But the phenomena of wounded nerves will not allow us to imagine the nervous fibres to be solid: for, if irritation causes a nerve to shake, (in a manner somewhat similar to an elastic cord, which trembles when it is taken hold of,) the nerve ought to be made of hard fibres, and tied by their extremities to hard bodies: they ought also to be tense; for neither soft cords, nor such as are not tense, or such as are not well fastened, are ever observed to tremulate. But all the nerves at their origin, are medullary, and very soft, and exceedingly far from any kind of tension. Where they pass through channels, and are well guarded, they retain the same soft texture, and are not covered with membranes; as the intercostal nerves, and the second nerves of the fifth pair. Some also are soft throughout their whole length, whatever their size be. For example, the soft olfactory and acoustic nerves, from which last we would most readily expect a tremor produced by sound. Again, though the nerves are hard, they are softened in the viscera, muscles, and sensoria, before they exert their operations. The nervous fibres, being neither firmly fixed at each end, nor tense, cannot therefore tremulate like a tight stretched cord. Another argument against their tremulation is, that, through their whole length, the nerves are firmly attached to the solid parts by the cellular fabric. An example of this fact is seen in those very material nerves, the nerves of the heart, which are tied to the great arteries and pericardium. Finally, that the nerves are destitute of all elasticity, is demonstrated by experiments, in which the nerves cut across neither shorten, nor draw back their divided ends to the solid parts; but are rather more elongated by their laxity, and expel their medulla in form of a protuberance. Again, the extreme softness of the medulla in the brain, with all the phenomena of pain and convulsion, leave no room to suspect any sort of tension concerned in the effects or operations produced by the nerves. Add to this, that the force of an irritated nerve is never propagated upward, so as to convulse the muscles that are seated above the place of irritation. This is a consequence altogether disagreeing with elasticity; for an elastic cord propagates its tremors every way, from the point of percussion to both extremities. But, if neither phenomena of sense nor motion can be explained from the nature of elasticity, the most probable supposition that remains is, that there is a liquor sent from the brain, which, descending through the nerves, flows out at their extremities; the motion of which liquor, quickened by irritation, operates only according to the direction in which it flows through the nerve; so that convulsions cannot thereby ascend upwards, because of the resistance made by the fresh afflux of the fluid from the brain. But the same liquid, being put in motion in an organ of sense, can carry that sensation upwards to the brain; since it is resisted by no sensitive torrent coming from the brain in a contrary direction. It is therefore probable, that the nervous fibres, and those of the medulla of the brain, which are of the same nature, are hollow. The objections against this doctrine are so few, and at the same time so frivolous, that they need not be mentioned. If they are tubes, it is very probable that they have their humours from the arteries of the brain.

There are many doubts concerning the nature of this nervous liquid. Several of the moderns will have it to be

be extremely elastic, of an ethereal or of an electrical nature; the ancients supposed it to be incompressible and watery, but of a lymphatic or albuminous nature. Indeed, it is not to be denied that we have many arguments against admitting either of these opinions. An electrical matter is doubtless very powerful, and fit for motion; but then it is not confinable within the nerves, since it penetrates throughout the whole animal to which it is communicated, exerting its force upon the flesh and fat, as well upon the nerves. In a living animal, the nerves only, or such parts as have nerves running through them, are affected by irritation; and therefore this liquid must be of a nature that will make it flow through, and be contained within, the narrow tubes of the nerves. And a ligature on the nerve takes away sense and motion, but cannot stop the motion of a torrent of electrical matter.

A watery and albuminous matter is common to most of the juices in the human body, and may therefore be readily granted to the juice of the nerves. The nervous fluid may probably be similar to the water exhaled into the ventricles of the brain; and this opinion is strengthened by the flux of a gelatinous or lymphatic juice from the brain of fishes, and nerves of large animals, when cut. But, are these properties sufficient to explain the wonderful force of convulsed nerves, observable in the dissections of living animals, even of the smallest insects? or to account for the great strength of mad and hysterical people? Is not this difficulty somewhat lessened from the hydrostatical experiments of attraction in small tubes; which, although it may explain the strength and motion, is nevertheless inconsistent with the celerity?

The nervous liquor, then, which is the instrument of sense and motion, must be exceedingly moveable, in order to carry the impressions of sense, or the commands of the will, to the places of their destination, without any remarkable delay; nor can it receive its motions only from the heart. Moreover, it is very thin and invisible, and destitute of all taste and smell; yet separable from the aliments. It is carefully to be distinguished from that visible viscid liquor, exhaling from the vessels in the intervals between the nervous cords. That this liquor moves through tubes rather than through a spongy solid, we are persuaded, from its celerity, and from the analogy of all the fluids of the body, fat only excepted, running through their proper vessels.

On the whole, therefore, it certainly appears, that, by the vessels of the cortex, some kind of fluid is infused into the tubes of the medulla; which fluid is continued through the extremely small tubes of the nerves to their extremities, and is the cause both of sense and motion. But there will be a twofold motion in that humour; the one slow and constant, from the heart; the other not continual, but exceedingly swift, which is excited either by sense, or any other cause of motion arising in the brain. The same nerves most evidently preside over both sense and motion; as we cannot admit a distinction between the two systems of motory and sensitive nerves. If sense sometimes remain after motion is destroyed, this seems to be because much more strength is required for the latter. Dying people hear and see when they are incapable of motion.

OF THE EYE.

The eyes consist of hard and soft parts. The hard parts are the bones which form the *orbis*. The soft parts are of several kinds; the most essential of which is the globe or ball of the eye; the others are partly external and partly internal. The external parts are the supercilia or eye-brows, the palpebræ or eye-lids, the caruncula lachrymalis, and the puncta lachrymalia; and the internal parts are the muscles, fat, lachrymal gland, nerves, and blood-vessels. The coats of the globe of the eye are of three kinds. Some of them form chiefly the shell of the globe; others are additional, being fixed only to a part of the globe; and others are capsular, which contain the humours. The coats which form the globe of the eye

are, the *sclerotica* or *cornea*, the *choroides*, and the *retina*. The additional coats are two; one called *tendinosa* or *albuginea*, which forms the white of the eye; and the other *conjunctiva*. The capsular tunics are likewise two, the *vitreæ* and the *crystallina*. The humours are three; the aqueous, vitreous, and crystalline. The first may properly enough be called a *humour*, and is contained in a space formed in the interstices of the anterior portion of the coats. The second, or vitreous humour, is contained in a particular membranous capsula, and fills above three-fourths of the shell or cavity of the globe of the eye. It has been named *vitreous*, from its supposed resemblance to melted glass; but it is really more like the white of a new-laid egg. The crystalline humour is so called from its resemblance to crystal, and is often named simply the *crystalline*. It is rather a gummy mass than a humour, of a lenticular form, more convex on the back than on the fore-side, and contained in a fine membrane called *membrana* or *capsula crystallina*.

The most external, the thickest, and strongest, coat of the eye, is the *sclerotica* or *cornea*, and it invests all the other parts of which the globe is composed. It is divided into two portions, one called *cornea opaca* or *sclerotica*, the other *cornea lucida*, which is only a small segment of the sphere situated anteriorly. The next coat of the globe of the eye is the *choroides*, which is of a blackish colour, more or less inclined to red, and adheres, by means of a great number of small vessels to the *sclerotica*, from the insertion of the optic nerve all the way to the cornea, where it leaves the circumference of the globe, and turns inward, to form a number of little processes termed *ciliary*, which are situated at the edge of the crystalline lens. At the interior edge of the *choroides* we find the *iris* composed of two laminae; the posterior of which, being of the colour of a grape, was called *uvea* by the ancients. In the middle of the iris there is a hole termed *pupil*; this, in a fœtus, is covered with a membrane called *pupillaris*, which generally disappears about the seventh month; or between the seventh and ninth month, according to Wrisberg.

The last coat proper to the eye is of a very different texture from that of the other two. It is white, soft, and tender, and, in a manner, medullary, or like a kind of paste spread upon a fine reticular web; it lines the bottom of the eye, and is a continuation of the optic nerve. Some authors, as Zinn, affirm, that it terminates at the ciliary circle; others, as Dr. Haller, represent the whole, or a part of it, as extended to the lens, and even as giving a covering to that humour; but Dr. Monro observes, that it ends some way behind the ciliary circle.

The vitreous humour is a clear and very liquid gelatinous fluid, contained in a fine transparent capsula, called *tunica vitrea*. It fills the greatest part of the globe of the eye, that is, almost all that space which answers to the extent of the retina, except a small portion behind the *uvea*, where it forms a fossula, in which the crystalline lens is lodged. The crystalline is a small lenticular body, of a firm consistence, and transparent like crystal. It is contained in a transparent membranous capsula, and lodged in the anterior fossula of the vitreous humour. It is very improperly called a *humour*, because it may be handled and moulded into different shapes by the fingers, and sometimes almost dissolved by different reiterated compressions, especially when taken out of the capsula. The aqueous humour is a very limpid fluid, resembling a kind of lymph or serum, with a very small degree of viscosity; but, in the fœtus, and a short time after birth, it is of a reddish colour. It fills the space between the cornea and iris, that between the iris and the crystalline, and the hole of the pupilla. These two spaces are called the *chambers of the aqueous humour*, and they are distinguished into the anterior and posterior.

The *tunica albuginea*, commonly called the *white of the eye*, and which appears on all the anterior convex side of the globe, from the cornea to the beginning of the posterior side, is formed chiefly by the tendinous expansion of the

the four recti muscles. This expansion adheres very close to the sclerotica, and makes it appear very white and shining; whereas the rest of it is of a dull whitish colour. It is very thin near the edge of the cornea; in which it seems to be lost, terminating very uniformly.

The supercilia, or eye-brows, peculiar to the human species, are the two hairy arches situated at the lower part of the forehead, between the top of the nose and temples, in the same direction with the bony arches which form the superior edges of the orbits. The skin in which they are fixed does not seem to be much thicker than that of the rest of the forehead; but the membrana adiposa is thicker than on the neighbouring parts. The supercilia have motions common to them with those of the skin of the forehead, and of the hairy scalp. By these motions the eye-brows are lifted up; the skin of the forehead is wrinkled more or less regularly and transversely; and the hair and almost the whole scalp is moved, but not in the same degree in all persons; for some people by this motion alone can move their hat, and even throw it off their head. The eye-brows have likewise particular motions which contract the skin above the nose; and all these different motions are performed by the occipital, frontal, and superciliary, muscles.

The palpebræ are a kind of veils or curtains placed transversely above and below the anterior portion of the globe of the eye, and accordingly there are two eye-lids to each eye, the one superior and the other inferior. They both unite at each side of the globe, and the places of their union are termed *angles*, one large and internal, which is next the nose, the other small and external, which is next the temples. The palpebræ are made up of common and proper parts. The common parts are the skin, epidermis, and membrana adiposa. The proper parts are the muscles, the tarsi, the puncta or foramina lachrymalis, the membrana conjunctiva, the glandula lachrymalis, and the particular ligaments which sustain the tarsi. The tarsi and their ligaments are in some measure the basis of all these parts. They consist of thin cartilages, forming the principal part of the edge of each palpebra, and they are broader at the middle than at the extremities. Those of the superior palpebræ are a little more than a quarter of an inch in breadth; but in the lower palpebræ they are not above the sixth part of an inch, and their extremities next the temples are more slender than those next the nose.

The membrana conjunctiva is a thin membrane, one portion of which lines the inner surface of the palpebræ, that is, of the tarsi and their broad ligaments. At the edge of the orbit it has a fold, and is continued from thence on the anterior half of the globe of the eye, adhering to the tunica albuginea; so that the palpebræ and the fore-part of the globe of the eye are covered by one and the same membrane, which does not appear to be a continuation of the pericranium, but has some connection with the broad ligaments of the tarsi. The name of *conjunctiva* is commonly given only to that part which covers the globe, the other being called simply the *internal membrane of the palpebræ*; but we may very well name the one *membra oculi conjunctiva*, and the other *membrana palpebrarum conjunctiva*.

The lachrymal gland, the use of which, till of late years, was not known, is yellowish, and of the number of those called *conglomerate glands*. It lies under that depression observable in the arch of the orbit near the temples, and laterally above the globe of the eye. It is a little flattened, and divided, as it were, into two lobes; one of which lies towards the insertion of the musculus levator, the other towards the abductor. It adheres very closely to the fat which surrounds the muscles and posterior convexity of the eye, and it was formerly named *glandula innominata*.

The flat edge of each palpebra is adorned with a row of hairs called *cilia*, or the *eye-lashes*. Those belonging to the superior palpebra are bent upward, and are longer than those of the lower palpebra which are bent downward. These rows are placed next the skin, and are not single, but irregularly double or triple. The hairs are

longer near the middle of the palpebræ than toward the extremities; and, for about a quarter of an inch from the inner angle, they are quite wanting. Along the same border of the palpebræ, we see a row of small holes, which may be named *foramina* or *puncta ciliaria*. They are the orifices of the same number of small oblong glands which lie in the sulci, channels, or grooves, on the inner surface of the tarsus. These little glands are of a whitish colour; and, when examined through a single microscope, they appear like bunches of grapes, those of each bunch communicating together; and, when they are squeezed between two nails, a sebaceous matter, like soft wax, is discharged through the puncta ciliaria.

The puncta lachrymalia are two small holes in the edge of each palpebra, opposite to each other, so that they meet when the eye is shut. Round the orifice of these points, we observe a whitish circle, which seems to be a cartilaginous appendix of the tarsus, and which keeps the orifice always open. These two oblique circles are so disposed, that, when the eye is but slightly shut, they touch each other only toward the skin, and not toward the globe of the eye.

The caruncula lachrymalis is a small reddish granulated oblong body, situated precisely between the internal angle of the palpebræ and globe of the eye, but it is not fleshy, as its name would insinuate. The substance of it seems to be wholly glandular; and it appears through a single microscope in the same manner as the other conglomerate glands. We discover on the globe of the eye, near this glandular body, a semilunar fold formed by the conjunctiva, the concave side of which is turned to the uvea, and the convex side to the nose. This fold, which has the name of *membrana semilunaris*, appears most when the eye is turned toward the nose; it is shaped like a crescent, the two points of which answer to the puncta lachrymalia, and conduct the tears into the puncta.

The muscles which move the palpebræ are commonly reckoned to be two. In man, the superior palpebra has much more motion than the inferior. The small simple motions, called *twinkling*, which frequently happen, tho' not equally often in all subjects, are performed by the alternate contraction of the levator palpebræ and orbicularis.

The external carotid artery, and the temporal and frontal arteries, give several ramifications to the integuments which surround the eye; the internal carotid, having entered the cranium, sends off a considerable branch called the *ocular*, which accompanies the optic nerve, to be distributed to the muscles and globe of the eye, to the levator palpebræ, to the fat, glandula lachrymalis, membrana conjunctiva, caruncula lachrymalis, &c. The veins of all these parts answer nearly to the arteries; those of the globe of the eye are called *vasa vorticosa*. The internal veins unload themselves, partly into the internal jugular vein, by the sinus cavernosi; and partly into the external jugular vein, by the vena angularis, or maxillaris externa, the maxillaris interna, temporalis, &c.

Besides the optic nerve, the globe of the eye receives several small ones, which run on each side along and about the optic nerve, from its entry into the orbit to its insertion in the globe. These small nerves, which run from behind forward, between the sclerotica and the choroides, have formerly been taken for particular ligaments by anatomists of considerable eminence, but are now known under the name of *ciliary nerves*.

The eye being the organ of vision, the greater part of it is composed of pellucid humours capable of refracting the rays of light. The complexity of this organ is necessary for the defence of its tender parts; and the diversity of the several humours, together with the various offices which this curious machine performs, necessarily required a very compound instrument. The perpetual attrition of the eye-lids ascending and descending against the globe of the eye, is prevented by the *tears*; which preserve also the tenderness of the membranes and of the cornea, and serve to wash out any insects or other sharp corpuscles.

corpuscles. These form a saline pellucid liquor that may be evaporated, and never ceases to be poured over the anterior surface of the eye; but never runs over the cheeks, unless collected, by a foreign cause, in larger than usual quantity. This liquor is exhaled partly from the arteries of the conjunctiva, and partly proceeds from the lachrymal gland. The separation of the tears is increased by the more frequent contraction of the orbicular muscle, either from irritation, or some sorrowful passion; by which means the tears are urged over, and wash the whole surface of the eye and conjunctiva.

Among the coats of the eye, the iris is the only one possessing motion. Though it has little sensation, and is not endowed with any mechanical irritability; yet, in a living man, quadruped, or bird, it is contracted on every greater degree of light, and is dilated on every smaller one; hence it is rendered broader for viewing distant objects, and narrower for viewing such as are near. The cause of this dilatation seems to be a remission of the powers resisting the aqueous humour; an argument of which is the dilatation of the pupil, occasioned by debility, or succeeding syncope and death.

Before we can attain any satisfactory knowledge of the properties of the eye, it will be necessary to say something of the nature of light. Light is an extremely subtle fluid, penetrating with facility bodies of the closest texture, and greatest density, in a rectilinear direction, with the amazing velocity of ten millions of miles in a minute. Every luminous body has the peculiar property of sending forth rays of light in every possible direction, which, falling on the surfaces of surrounding objects, are reflected thence to our eyes. Rays of light falling perpendicularly on the surface of a transparent body, pass through the body without changing their direction; but rays falling obliquely on the surface pass through the body with a change of their direction nearer to the perpendicular; and this change of direction is called *refraction*.

The rays of light, whether direct or reflected, fall upon the tunica cornea of the eye, so as to form a very sharp cone between the lucid point and the membrane upon which they are spread; the basis of which cone will be the surface of the cornea, and the apex the radiant point; yet so that all rays may, without any sensible error, be reckoned parallel with each other. Among these, there are some rays reflected back from the cornea, without ever penetrating the surface; namely, all such as fall upon that membrane in a greater angle than that of forty degrees. Others, which enter the cornea at very large angles, but less than the former, and fall in betwixt the iris and the sides of the crystalline lens, are focussed or lost in the black paint that lines the iris and the ciliary processes; but those rays only fall upon the surface of the lens which enter the cornea at small angles, not much distant from the perpendicular, or, at most, not exceeding twenty-eight degrees. By this means, all those rays are excluded which the refracting power of the humours of the eye could not be able to concentrate or bring together upon the retina; without which they would paint the object too large and confusedly. The rays falling on the cornea are therefore refracted, and pass through the aqueous humour in a more parallel, or perhaps converging, direction, by which contrivance a greater number of rays fall on the crystalline than if they had not previously passed through the cornea and the aqueous humour. But since the necessary offices of human life require a distinct object to be painted upon the retina, not only by the rays which come from one certain distance, but likewise by rays which come from very different parts more or less distant; it has therefore been thought that a necessary change, produced by its own causes, is made on the eye. Others have supposed the lens moveable by the powers before-mentioned. This art of seeing distinctly at different distances is said to be learned by experience, it being unknown to those who have been lately couched. It is also said, that, in an artificial eye, the use and necessity of this motion may be

plainly perceived. The point of distinct vision is in that part of the retina where the given object is painted in the least compass possible. The powers causing the visual rays to unite on the retina, are often very different in the two eyes of the same person, the one being long-sighted and the other short-sighted.

These, and other commonly received opinions, are taught by mathematicians, who more readily perceive the necessity of these changes. But yet there is no power in the human eye which can either move the crystalline humour out of its place, or compress it. Besides, we do not perceive this faculty in ourselves; for we move a book nearer to our eyes when it is too far off, so as to appear confused, which we should have no occasion to do, if by changing the internal figure of the eye we could correct the fault of the distance. And, through a small hole, we perceive an object single only in the point of distinct vision, but double in every other. Perhaps the contraction of the pupil may enable to see near objects more distinctly. This contraction, however, is not in all people sufficient for the purpose. There are several people, especially such as lead a sedentary life, and such as are employed in examining minute objects, whose cornea is too convex and dense, whose crystalline lens is too gibbous and solid, and whose eye is lengthened by the incumbent weight of the humours, and perhaps the humours themselves are too dense; and in the same person the eye may probably have all these defects joined together. People labouring under one or more of these inconveniences have an iris that is sensible in a very small degree of light, which circumstance makes them twinkle with the eye-lids when they are in a strong light, and they are called *myopes* or short-sighted. In these, the point of distinct vision is very near to the eye, commonly from one to seven inches from the cornea; but they see remoter objects more obscurely, without being able to distinguish their parts. The reason of this is evident; since, from the fore-mentioned causes, there is a greater refracting power of the humours, by which the distant, and consequently parallel, rays are obliged to meet in their focus before the retina, from whence spreading again, they fall upon the retina in many points. The remedy for this fault in the sight is to correct it in its beginning, by looking at distant rather than near and minute objects; by the use of concave glasses, or by viewing things through a small hole, by which the light is weakened. When the disorder is confirmed, the remedy is a concave lens, which takes off a degree of the refracting power in the humours, cornea, and crystalline lens, in proportion as it is more concave; by which means the focus of rays from remote objects is removed farther behind the cornea, so as to fall upon the retina.

The other disorder of the sight, contrary to the former, troubles people who often look at very distant objects, and is more especially familiar and incurable in old people. In such, the cornea and crystalline lens are flatter, and the humours of the eye have a less refracting power. Hence near objects, whose rays fall very diverging upon the cornea, appear confused; because the converging or refracting powers of the eye are not sufficient to bring the rays together in a focus upon the retina; but the rays go on scattered beyond the retina, and throw the point of their pencil behind the eye, from whence vision is confused. The point of distinct vision among *presbyopi*, or old or long-sighted people, is from the distance of fifteen inches to three feet. Such persons are relieved by looking through a black tube held before the eye; by the use of which the retina grows tenderer, and the rays come to the eye in a parallel direction. The remedy here is a convex lens, which causes the rays to converge and unite together sooner in a focus, that it may not fall behind the eye, but upon the retina. The medium between the short and long sighted eye is the best, by which a person can see distinctly enough objects that are both near and remote; and of this kind we reckon an eye that is able to read distinctly at the distance of one foot. But a good eye requires other necessary

cessary conditions, such as a perfect clearness of the humours; a due mobility of the eye itself, and its parts; a sensibility of the pupil; and a retina neither too prurient nor too callous.

The mind only receives a representation of the image of the object by the eye, impressed on the retina, and transferred to the common sensory or seat of the soul. Several circumstances relative to vision are not determined by the instrumentality of the eye, but are perceived by the mind from mere experience; and sometimes the mind interprets the representation to be very different from that which the eye gives to her. The magnitude of an object, for instance, is not determined by the eye, but by the optical angle, which is formed by lines supposed to be drawn from the extremities of the object to the cornea. Hence near objects seem large, and those at a distance small. On this circumstance also the power of microscopes depends, which magnify in proportion to the difference between the focal length of the magnifier and the distance of distinct vision. Objects, by the means of this instrument, not only appear larger, but brighter and more distinct, and hence the mind thinks them nearer.

Distance we cannot perceive; and if a blind man, who never saw, should by any means be restored to sight, he would imagine every thing he saw to touch his eyes. Even we, who are accustomed to judge by sight, make many fallacious conjectures concerning the distance of objects. We judge of the distance of an object from the diminution of its known bulk; from its diminished brightness; from the faintness of its image, by which we are less capable of distinguishing its parts; and, lastly, from the number of bodies, whose distance is known, that are interposed between us and the object. The visible situation of the parts of an object, is judged by the mind to be the same with that which these parts naturally have in the object, and not the inverted position in which they are painted upon the retina. The faculty of correcting this inversion seems to be innate; for new-born animals always see objects upright; and men who have been born with cataracts are observed, upon couching the cataracts, to see every thing in its natural situation, without the use of any feeling, or previous experiences. The mind is often imposed on by the continuance of the sensation after it has been conveyed to the mind, by which means objects, although instantly removed, continue to be seen for about a second. Hence proceeds the idea of a fiery circle from the circumrotation of a lucid body; and hence also proceeds the continuance of the shining image of the sun, and sometimes of other bodies, after they have been viewed by the eye.

Why do we see only one object with two eyes? because, when the impressions of two objects are similar, the sensation becomes single. Even without the concurrence of optic nerves, insects who have numerous eyes perceive objects single. Hence the images of two objects excite only one sensation, when they fall upon the same point of the retina; but two sensations arise from one object, when the images fall upon different parts of the retina. Whence proceed diurnal and nocturnal blindness? The former is common to many nations living in the warmest climates, under the brightest sun, and to old men. The other happens in inflamed eyes, and to young men of a hot temperament, who are endowed with eyes vastly sensible. Whence do animals see in the dark? From a large dilatable pupil, and tender retina; and a shining choroides, which reflects the light very strongly. Why are we blind when brought out of a strong light into a weak one? Because the optic nerve, having suffered the action of stronger rays of light, is incapable of being moved by those that are weaker. Whence have we a pain, by passing suddenly from a dark place into the light? Because the pupil, being widely dilated in the dark, suddenly admits too great a quantity of light before it can contract; whereby the tender retina, which is easily affected by a small light, feels, for a time, an impression too sharp and strong. Whether do we see

with one eye, or with both? Most frequently with one, and more especially the right eye. But, when both are employed together, we see more objects, and more plainly; and we also distinguish more points of the same object, and judge better of their distances.

OF THE NOSE.

The parts of which the nose is composed, may be divided in two different ways, viz. from their situation, into external and internal parts; and, from their structure, into hard and soft parts. The external parts are the root of the nose, the arch, the back or spine of the nose, the sides, the tip of the nose, the alæ, the external nares, and the part under the septum. The internal parts are the internal nares, the septum narium, the circumvolutions, the conchæ superiores, or ossa spongiosa superiora, conchæ inferiores, the posterior openings of the internal nares, the sinus frontales, sinus maxillares, sinus sphenoidales, the ductus lachrymales, and ductus palatini. The firm or hard parts are mostly bony, and the rest cartilaginous. The soft parts are the integuments, muscles, sacculus lachrymalis, membrana pituitaria, vessels, nerves, &c. The internal nares, or the two cavities of the nose, comprehend the whole space between the external nares and posterior openings, immediately above the arch of the palate, from whence these cavities reach upward as far as the lamina cribrosa of the os ethmoides, where they communicate forward with the sinus frontales, and backward with the sinus sphenoidales. Laterally, these cavities are bounded on the inside by the septum narium; and, on the outside, or that next the cheek, by the conchæ or ossa spongiosa, between which they communicate with the sinus maxillaris. The external nose is covered by the common integuments, the skin, epidermis, and fat. The parts which cover the tip of the nose and alæ narium, are pierced with the ducts of a great number of glandulæ sebaceæ. All these bony and cartilaginous parts have likewise the common periosteum or perichondrium.

The membrana pituitaria is that which lines the whole internal nares, the ossa spongiosa, the sides of the septum narium, and, by an uninterrupted continuation, the inner surface of the sinus frontales and maxillares, and of the ductus lachrymales, palatini, and sphenoidales. It is termed *pituitaria*, because, through the greatest part of its large extent, it serves to separate from the arterial blood a mucilaginous lymph, called *pituita* by the ancients, which, in its natural state, is nearly liquid; but it is subject to very great changes, becoming sometimes glutinous, sometimes limpid, &c. neither is it separated in equal quantities thro' the whole membrane. The lachrymal sacculus is an oblong membranous bag, into which the serous fluid is discharged from the eye, through the puncta lachrymalia, and from which the same fluid passes to the lower part of the internal nares. The ductus incisorii, or naso-palatini of Steno, are two canals which go from the bottom of the internal nares, cross the arch of the palate, and open behind the first or largest dentes incisorii. In fresh subjects they are not so apparent, especially in human subjects; but in sheep and oxen they are easily discoverable.

In animals which smell acutely, the parts of the nose are remarkably large; but the formation of the human head into a roundish figure, has given to the organ of smelling only a small extent of surface; but nature has made the internal parts of the nose hollow, and variously complicated in a surprising manner, to enlarge the faculty of smelling, because tasting noxious food might in many instances be highly dangerous. We can by this sense, independent of taste, discover the noxious quality of aliments, especially such as are putrid, and consequently peculiarly hurtful to the human frame; and at the same time that it directs us to avoid what is dangerous, it enables us to discern what is grateful and wholesome. This use of smelling in choosing food, is more observable in brutes than in men; yet men left to themselves, and who are undebauched by a variety of scents; possess this fagacious

cious faculty in a very eminent degree. The powers and virtues of medicinal plants are hardly to be better known than by the testimony of tasting and smelling. Hence it is, that in all animals those organs are placed together; and hence the smelling is stronger, and the organs larger, in those animals which seek their prey at a considerable distance, or are to reject malignant plants from among those fit for food.

The sense of smelling is performed by means of a soft pulpy membrane, full of pores and small vessels, which lines the whole internal cavity of the nostrils; it is thicker upon the septum and principal convolutions, but thinner in the sinuses. The nerves of the nose, being almost naked, require a defence from the air, which is continually drawn through the nostrils, and blown out again by respiration. Nature has therefore supplied this part, which is the organ of smelling, with a thick insipid mucus, very fluid in its first separation, but, by the air, condensing into a thick, dry, and more consistent, crust. By this mucus the nerves are defended from drying and from pain. It is poured out from many small arteries, and deposited partly into numerous cylindrical ducts, and partly into round visible cryptæ or cells, scattered all over the nostrils. It flows out all over the surface of the olfactory membrane, which is anointed with it on all sides. This mucus is accumulated in the night-time; but, in the day, it either flows spontaneously, or may be more powerfully expelled by blowing the nose. By becoming dry and harsh, it irritates the very sensible nerves of the membrane, whence a sneezing is excited for its removal. The tears descend, by a channel proper to themselves, into the cavity of the nose, by which they moisten and dilute the mucus.

The air, filled with the subtle and invisible effluvia of bodies, consisting of their volatile, oily, and saline, particles, is, by the powers of respiration, urged through the nose, and applied to the almost naked, and constantly soft, olfactory nerves, in which a kind of feeling is excited, which we call *smelling*; and by this sense we distinguish several kinds of oils and salts, by different scents or odours, which are difficultly redneible to classes, and difficultly recalled to memory. This scent serves to admonish us of pernicious putrefaction; of violent acrimony; or of a mild and soapy quality in bodies. As salt, joined with an oil, is the object of taste; and a volatile oil, added to salts, serves to excite smells, we may perceive the affinity of these two senses, which affinity seemed to be the more necessary on account of these senses mutually and jointly assisting each other in performing their offices. Volatile particles are chiefly distinguished by smell, and fixed ones by taste; perhaps because the thick mucous cuticle, spread over the tongue, intercepts the action of the more subtle saline effluvia from acting upon the taste, which yet easily affect the softer and less covered nerves of the internal nose.

The power of odours is strong and quick, because minute particles of matter are immediately applied to naked nerves situated very near the brain. Hence the force of poisonous vapours, and hence also the quality certain odours possess, of recovering people from faintings, or after drowning. Hence also that violent sneezing which often arises from acrid particles, and a diarrhoea from the smell of some medicines; hence the power of particular antipathies. Hence also the pernicious effects of excessive sneezing, more especially in producing blindness, which may, in some measure, also be more easily brought on by the consent of the nerves that are exceedingly numerous in the neighbouring organs. Among the various parts of the nose, the septum, and more especially the os turbinatum, have a considerable share in the organ of smelling, since these parts are multiplied in quick-scented animals. In dogs, and other quadrupeds, they are prodigiously lengthened, and beautifully formed into spiral laminæ; in fishes they are elegantly formed, like the teeth of a comb.

OF THE EAR.

Anatomists commonly divide or distinguish the ear into external and internal. The greatest part of the external

ear consists of a large cartilage, very artificially framed, which is the basis of all the other parts of which this portion of the ear is composed. The internal ear consists chiefly of several bony pieces, partly formed in the substance of the os temporis, and especially in that portion of it called *apophysis petrosa*; and partly separated from, but contained in, a particular cavity of that bone. Two portions are distinguished in the external ear; one large and solid, called *pinnæ*, which is the superior, and by much the greater, part; the other small and soft, called the *lobe*, which makes the lower part. The fore-side of the ear is divided into eminences and cavities. The eminences are four in number, called *helix*, *antihelix*, *tragus*, and *antitragus*. The helix is the large folded border or circumference of the great portion of the ear. The antihelix is the large oblong eminence, surrounded by the helix. The tragus is the small anterior protuberance below the anterior extremity of the helix. The antitragus is the posterior tubercle, below the inferior extremity of the antihelix. The cavities on the fore-side are four in number: the hollow of the helix; the depression at the superior extremity of the antihelix, called *fossa navicularis*; the concha, or great double cavity; and the meatus, situated at the lower part of the bottom of the concha. The lobe of the ear, or that soft portion which lies under the tragus, antitragus, and meatus auditorius, is made up of nothing but skin and cellular substance. The meatus auditorius is partly bony and partly cartilaginous. The skin which covers the cartilage contains a great number of small glands, which continually discharge an oily whitish humour, collected chiefly near the adhesions of the ear to the head, and under the fold of the helix; and these glands are of the sebaceous kind. The skin, which lines the meatus auditorius, contains another kind of glands, of a yellowish colour. These glands are disposed in such a manner as to leave reticular spaces between them, and they penetrate a little way into the substance of the skin. They are called *glandulæ ceruminosæ*, because they discharge that matter which is named *cerumen*, or the *wax* of the ear.

The bony part of the organ of hearing may be divided into four general parts: 1. The meatus auditorius externus; 2. The tympanum; 3. The labyrinth; 4. The meatus auditorius internus. It may likewise be divided into immoveable or containing parts, which take in all the four already mentioned; and moveable or contained parts, which are four little bones lodged in the tympanum, called *incus*, *malleus*, *stapes*, and *os orbiculare* or *lenticulare*. The external auditory passage begins by the external auditory hole, the edge of which is rough and prominent; but, backward toward the mastoid process, it appears very much sloped.

The tympanum, or drum of the ear, is a cavity somewhat spherical, or rather hemispherical, the bottom of it being turned inward. The tympanum contains several little bones, called the *bones of the ear*. They are generally four in number, denominated from something to which they are thought to bear a resemblance, viz. *incus*, *malleus*, *stapes*, and *os orbiculare* or *lenticulare*. The *incus*, or anvil, resembles, in some measure, one of the anterior dentes molares, with its roots at a great distance from each other. It may be divided into a body, and two branches or legs; one of the legs is long, the other short. The *malleus*, or hammer, is a long bone, with a large head, a small neck, a handle, and two processes; one in the neck, the other in the handle. The *stapes* is a small bone, very well denominated from the resemblance it bears to a stirrup. It is divided into the head, legs, and basis. The head is placed upon a short flatted neck. The two legs form an arch like that of a stirrup; in the concave side of which is a groove that runs through their whole length. The basis resembles that of a stirrup, both in its oval shape and union with the legs, but it is not perforated. The *os orbiculare*, or lenticular bone, is the smallest bone in the body. It lies between the head of the *stapes* and extremity of the long leg of the *incus*, being articulated

with each of these. These four little bones appear to have been unknown to the Greek anatomists.

The labyrinth is divided into three parts; the anterior, middle, and posterior. The middle portion is termed *vestibulum*, the anterior *cochlea*, and the posterior *labyrinth in particular*; which comprehends the three femicircular canals. The cochlea lies forward and inward toward the extremity of the pars petrosa; the femicircular canals backward and outward toward the basis of the process; and the vestibulum between the other two.

The soft parts of the internal ear are chiefly the membrana tympani, the periosteum of the tympanum, and of the ossicula auditus, labyrinth, and of all its cavities, the membrana mastoidea interna, the muscles of the ossicula, the parts which complete the formation of the Eustachian tube, the arteries, veins, and nerves.

The periosteum of the tympanum, or barrel of the ear, produces that of the small bones; and it may be made visible by means of anatomical injections, which discover capillary vessels very distinctly ramified on the surface of the ossicula. It is likewise continued over the two fenestrae, and enters the Eustachian tube, where it is lost in the inner membrane of that duct.

As the sense of hearing perceives the elastic tremors or impulses of the air, so we observe the sensitive organ of the ear to be composed in a different manner from that of any of the other senses. The sonorous waves of the elastic air, being driven into the cartilaginous funnel of our ear, are repelled and collected together, by alternate reflections from its elastic sides, into the cavity of the concha, whence they proceed through the auditory passage; where their force is increased by being contracted into so narrow a compass. They are likewise increased by new sounds from the percussion of the elastic cartilages and hard bones, which mix imperceptibly with the primitive sounds. The bottom or end of the auditory passage is terminated internally by the *membrana tympani*; which Dr. Haller says is not naturally perforated, as far as he has been able to discover; and that the transmission of tobacco-smoke from the mouth through the ear is fabulous. Authors in general agree with him now in the former of these opinions; but that an accidental opening has sometimes happened, and that the smoke of tobacco has been blown through it during life, is certain. Upon the surface of this membrane, and more especially upon its conical cavity pointing inward, the sonorous waves strike, after they have received their last reflections from the auditory passage, by which the elastic fabric of this membrane is forced into oscillation. The membrane is stretched over the *tympanum*, containing the little bones to which the small muscles of the internal ear are fixed. By means of the tensor of the malleus, the membrane of the tympanum is the better disposed to hear weak sounds; and the other muscle serves to moderate those that are too violent, by drawing the malleus from the incus; by which means the propagation of the sonorous tremors is interrupted. If the membrane of the tympanum be broken, or the bones of hearing dislocated, the person becomes at first hard of hearing, and afterwards perfectly deaf. There have been instances, however, where the membrana tympani has been partly destroyed, and yet the person has retained the sense of hearing, though less distinctly than before. The malleus returns the tremors impressed upon the membrane of the tympanum to the incus, which sends it inwards to the next bones. The *stapes*, aptly enough so called from its figure, lies inclined, and is covered by its own muscle, which seems to draw the stapes, that it may lie higher up, under the back-part of the fenestra ovalis, and pass out of it before. Thus the nervous pulp of the vestibulum is pressed by the basis of the stapes, and by the air of the tympanum; and the *Eustachian tube*, by the action of the circumjacent muscles, may be compressed and closed, and probably a little relaxed and opened again, by the circumflex muscle of the moveable palate. By this canal the inspired air enters into the tympanum,

to be changed or renewed; and it also serves to convey the mucus that covers the little bones and the tympanum. Nor is it at all improbable that the air enters by this tube, to support the tympanum when it is pressed inward by the more violent sounds; for sounds themselves, received into the mouth, are this way conveyed to the organ of hearing. In inspiration, the air presses the membrane of the tympanum outward; and thence proceeds that clashing or whispering noise, by which the hearing is obscured, in yawning; for then the air entering more abundantly through the cavity of the tube, to the tympanum, resists the tremors of the external air.

From what has been said, it appears that the elastic waves or tremors of the air come through the outer ear and auditory passage, to the membrane of the tympanum; which being injured, and not repaired, the hearing is in a great measure destroyed. This seems to be stretched, for hearing weak sounds, by the muscles of the malleus. From this membrane the sound is conveyed through the small bones to the vestibulum; for, these bones being destroyed, the hearing is again abolished. The bony sides of the vestibulum, by their tremulation, agitate the small quantity of aqueous fluid surrounding the nervous pulp. It seems to be struck by the nervous pulp suspended in the vestibulum, and that tremor seems to be continued through the continuous pulp of the cochlea and femicircular canals. Of more than this we are not certain; but, by undoubted experiments, tremors, and even elastic sounds, communicate themselves by the internal Eustachian tube, and thro' all the bones of the skull, so as to impress their force upon the auditory nerve.

The distinction of sounds proceeds from the celerity of the tremors excited in the hearing nerve, according as they succeed each other more swiftly or slowly. It is not necessary that the mind should number them; it is sufficient that the perceive their numbers to be different, and that this difference excites a variation in the thoughts and ideas thence arising. Does the harmony or agreeableness of sounds arise from the number of parts sounding together in unison? and does the mind number the degrees of consonance, so as to please herself in the majority of them? These are questions denied by the most expert musicians, who make it appear that there is an agreeableness, and that very considerable, in sounds approaching the least to a consonance, and which are in a proportion very difficult to determine. Why do sounds often become too sharp for the ear? Because our auditory nerves seem to be so strained upon the spiral plates, as to be in danger of breaking. Thus, drinking-glasses are broken by sharp sounds; and the hearing is sometimes almost lost for a while by the violently-thrill whistlings of the inhabitants of the Canaries.

OF THE MOUTH.

The cheeks and lips form the sides and entry of the cavity of the mouth. The substance which forms the red border of the lips is very different from the rest of the skin, being a collection of very fine, long, villous, papillae, closely connected together, and covered by a fine membrane, which seems to be both a continuation of the epidermis, and of that pellicle which covers the glandular membrane of the cavity of the mouth. This substance is extremely sensible, and very painful when the outer membrane is by any accident destroyed. The substance of the gums is also of a very singular structure, resembling, in some measure, the texture of a hat, supposed to be very compact and elastic. It is not immediately fixed to the bones of the jaws, but by the intervention of the periosteum, with which it is perfectly united; and it is covered by a fine strong even membrane, which sticks very close to the substance of the gums; and seems to be a continuation of that thin membrane which goes to the lips and cheeks, and of that which goes to the tongue.

The *palate* is that arch or cavity of the mouth surrounded anteriorly by the alveolar edge and teeth of the upper jaw, and reaching from thence to the great opening of the

the

the pharynx. The arch is partly solid and immoveable, and partly soft and moveable. The solid portion is that which is bounded by the teeth, being formed by the two ossa maxillaria and two ossa palati. The soft portion lies behind the other, and runs backward like a veil fixed to the edge of the ossa palati, being formed partly by the common membrane of the whole arch, and partly by several muscular fasciculi, &c. The membrane that covers all this cavity, is continued with the membrane of the nares, upon the inner surface of the pharynx. It is very thick set with small glands, known under the name of *palatine*, the orifices of which are not so sensible as in the pharynx, and especially in the rugæ of its superior portion. This membrane, together with that of the posterior nares, forms, by an uninterrupted continuation, the anterior and posterior surface of the soft portion of the palate, or velum palati, so that the muscular fasciculi of this portion lie in the duplicature of a glandular membrane. The velum or valvula palati, terminates below by a loose floating edge, representing an arch situated transversely above the basis or root of the tongue. The highest portion or top of this arch sustains a small, soft, and irregularly-conical, glandular body, fixed by its basis to the arch, and its apex, which hangs down without adhering to any thing, is called *uvula*; on each side of which there are two muscular half-arches, called *columnæ septi palati*. The septum palati serves to conduct the lachrymal lymph, and that which is continually collected on the arch of the palate, into the pharynx. It serves for a valve to hinder what we swallow, and especially what we drink, from returning by the nose.

The tongue is a soft fleshy body, which fills all that part of the cavity of the mouth that is surrounded by the alveolar border and teeth of the lower jaw, and extends still farther back. The tongue is divided into the basis and point; the upper and under sides; and the lateral portions or edges. The basis is the posterior and thickest part; the point, the anterior and thinnest part. The upper side is not quite flat, but a little convex, and divided into two lateral halves, by a shallow depressed line, called *linca linguae mediana*.

All the upper side of the tongue is covered by a thick membrane of a papillary texture, upon which lies another very fine membrane like a kind of epidermis, which is likewise continued over the lower side, but without papillæ. Under the epidermis, on the surface of the tongue, we find the corpus mucosum thicker but more moist than in other parts of the body. Three sorts of papillæ may be distinguished in the upper side of the tongue; capitate, semi-lenticulares, and villosæ. Those of the first kind are the largest, and are of a lenticular form, having round heads with short stems. They lie on the basis of the tongue in small superficial fossule.

The tongue is the organ of that sense called the *taste*; and, by certain experiments, it appears that the power of taste is exercised by the tongue chiefly, although it is not confined to the tongue alone. For, on whatever part of the mouth, palate, or cheek, we apply a sapid body, we do not perceive the sense of pain, but of taste; and from some bodies, as arum, pepper, &c. the sensation produced will be stronger and more distinct in these parts than any where else. The sensation which is sometimes excited in the stomach, œsophagus, and fauces, by the regurgitation of the aliments, seems also to belong to the tongue, to which the sapid vapours are sent back, uncommonly acrid and penetrating; and even that sense which is sometimes occasioned in the stomach, œsophagus, and fauces, from a rising of the aliments, seems also to be owing to the tongue, to which the tasteable vapours are conveyed.

The *papillæ* of the tongue, which are larger and softer than those of the skin, and perpetually moist, perform the office of touch more exquisitely than the small and dry cutaneous papillæ. The papillæ of the tongue being raised a little protuberant to perform the office of taste, are affected in a particular manner by salts dissolved in water,

or saliva, and applied against their tips or summits; which being distinguished by the mind, and referred to certain classes, are called *tastes*, either sour, sweet, acerb, bitter, saline, urinous, spirituous, aromatic, or pungent and acrid, insipid, putrid, and others resulting partly from pure salts, and in part from an intermixture of the subtile, animal, or vegetable, oils, variously compounding and changing each other.

Does the diversity of tastes arise from the different figures which are natural to salts? Is the cubical figure of sea-salt the reason of its having a different taste from nitre that is prismatical, or from other salts of a different form? We answer, that this does not seem probable; for, even tasteless crystals have their particular configurations; and the taste arising from very different salts, and differently qualified objects of this sense, are too much alike each other, and at the same time too inconstant or changeable, to allow such a theory; as, for example, in nitre. The mechanical reason, therefore, of the diversity of tastes, seems to reside in the intrinsic fabric of the elements of sapid bodies, which do not fall under the scrutiny of our senses. But the nature or disposition of the covering with which the papillæ are clothed, together with that of the juices, and of the aliments lodged in the stomach, have a considerable share in determining the sense of taste; inasmuch, that the same flavour does not equally please or affect the organs in all ages alike, nor in persons of all temperaments; nor even in the same person at different times, and in different states of health or disease. In general, whatever contains less salt than the saliva itself, seems insipid.

Nature designed the difference of tastes to be felt by the tongue, that we might know and distinguish such foods as are most salutary; for, in general, there is not any one kind of wholesome aliment that is of a disagreeable taste; nor are there any ill-tasted substances that are fit for our nourishment. By excess, indeed, the most wholesome food becomes prejudicial. Nature has invited us to take necessary food, as well by the pain called hunger, as by the pleasure arising from the sense of taste. But brute animals, who have not like us, the advantage of learning from each other by instruction, have the faculty of distinguishing flavours more accurately, by which they are admonished cautiously to avoid poisonous or unwholesome food; and therefore it is that, in herbivorous cattle, to which a great diversity of noxious plants is offered among their food, the tongue is of a more exquisite texture, and furnished with larger and longer papillæ, than in man, to whom they are less necessary.

The *larynx* forms the protuberance in the upper and anterior part of the neck, called commonly *pomum Adami*. This is larger and more prominent in men than in women. It consists chiefly of five cartilages; the names of which are these: Cartilago-thyroides, which is the anterior and largest; cricoides the inferior, and basis of the rest; two arytenoides, the posterior and smallest; and the epiglottis, which is above all the rest. These cartilages are connected together by ligaments, and they have likewise muscles, glands, membranes, &c. The larynx serves particularly to admit and let out the air in respiration; and the solidity of the pieces of which it is composed, hinders not only external objects, but also any hard thing which we swallow, from disordering this passage. The glottis, being a narrow slit, modifies the air which we breathe; and, as it is very easily dilated and contracted, it forms the different tones of the voice, chiefly by means of the different muscles inserted in the cartilaginous arytenoides, to which the other muscles of the larynx, both proper and common, are assistants. The facility of varying and changing the tone of the voice depends on the flexibility of the cartilages of the larynx, and decreases in proportion as we advance in age; because these cartilages gradually harden and ossify, though not equally soon in all persons. Hence the larynx is the principal organ of the voice; for, that being injured, the air passes through the wind-pipe without yielding any sound; but when it is driven from the lungs.

lungs in expiration through the trachea into the larynx, and through the glottis into the mouth, it produces voice, speech, and singing. The strength of the voice is proportional to the quantity of air blown out, together with the narrowness of the glottis; and, therefore, a large pair of lungs easily dilatable, an ample cartilaginous and elastic larynx and wind-pipe, a free echo of the nostrils, and a powerful expiration, all conduce to this effect. *Singing* is when the voice, modulated through various degrees of acuteness and gravity, is expelled through the larynx, while it is trembling and suspended between two contrary powers; and herein lies the principal difference between the chanting of simple notes and the expression of words. *Speech* is performed by the larynx at rest, or held in the same place, with tones of voice differing but little in acuteness and gravity; but then the voice is variously changed or modulated by the organs of the mouth. *Singing* has a variation in the tone or cadence of the voice, together with a modulation of it by the organs of the mouth at the same time.

The *pharynx* is a muscular and glandular bag; the outer surface of which is closely joined to the inner surface of all the space which is at the bottom of the mouth, behind the posterior nares, uvula, and larynx, and which reaches from the cuneiform process of the os occipitis all the way to the œsophagus, which is a continuation of the pharynx.

The *salivary glands* furnish that fluid by which the mouth and tongue are continually moistened in their natural state; and they may be enumerated in the following manner: glandulæ parotides, glandulæ maxillares, glandulæ sublinguales, glandulæ molares, glandulæ buccales, glandulæ labiales, glandulæ linguales, amygdalæ, glandulæ palatinæ, glandulæ uvulæ, glandulæ arytenoidæ, glandulæ thyroidæ. All the inside of the cheeks, near the mouth, is entirely full of small glandulous bodies, called *glandulæ buccales*, which open by small holes or orifices through the inner membrane of the mouth. The membrane which covers the inside of the lips, which is a continuation of that on the cheeks, is likewise perforated by a great number of small holes, which answer to the same number of small glands, called *glandulæ labiales*. We might likewise reckon among the salivary glands those of the superior portion of the pharynx, and also the follicles of the membrana pituitaria of the nares, and of the sinuses which communicate with them.

Such hard and tough foods as consist of long parallel fibres, or are covered with a bony shell or cartilaginous skin, generally require mastication to divide them into less cohering parts, that they may more easily yield their nourishment to the dissolving powers of the stomach. The more diligently they are subdivided in the mouth, the more relishing and agreeable they become to the stomach; and the nearer they approach to the nature of a fluid, the more easily are they digested or assimilated. Most animals, therefore, are provided with teeth extremely hard; and, as the materials of our food are various in their texture and firmness, nature has accordingly furnished us with teeth variously figured. The office of the incisores is only, in the softer foods, to cut those which are tougher than the rest into smaller portions; such as the fibres and membranes of animals and vegetables, with the brittle seeds and kernels of fruits. The canine teeth lacerate tough aliments, and hold fast such as require long trituration by the grinders. By the motion of the jaw in mastication, the salivary glands are compressed, so as to discharge their juices into the mouth in great plenty; and the food being ground between the teeth, and intermixed with the watery saliva and air, is broken down into a soft juicy pulp, replete with elastic air; the food afterwards undergoes a farther dissolution from the warmth of the parts causing the air to expand, and, by its elasticity, burst asunder the particles of the food, between which it is included and confined. In this act of mastication, the oily, aqueous, and saline, parts of the food are intermixed the one with the other; the

smell and taste of different ingredients are lost in one, which, by the dilution of the saline parts with saliva, renders the food flavourable; but such particles as are more volatile and penetrating, being directly absorbed by the bibulous vessels of the tongue and cheeks, enter straight into the blood-vessels and nerves, so as to cause an immediate recruit of the whole faculties.

OF THE THORAX.

By the thorax we commonly understand all that part of the body which answers to the extent of the sternum, ribs, and vertebrae of the back, both outwardly and inwardly. It is divided into the anterior part, called commonly the *breast*; the posterior part, called the *back*; and the lateral parts, called the *right and left sides*. The external parts of the thorax, besides the skin and membrana adiposa, are principally the mammae; and the muscles which cover the ribs, and fill the spaces between them. The internal parts are contained in the large cavity of that portion of the trunk which the ancients called the *middle venter*, but the moderns name it simply the *cavity of the breast*. This cavity is lined by a membrane named *pleura*, which forms the mediastinum; and contains the heart and lungs, with the vessels, &c. which go in or from them: through it, likewise, the œsophagus passes to the stomach; and part of the nerves are contained in it which go the contents of the abdomen.

The name of *mamma*, or *breasts*, is given to two eminences, more or less round, situated in the anterior, and a little towards the lateral parts of the thorax. Their size and figure vary in the different sexes and different ages. The body of the mamma is partly glandular, and partly consists of fat; or it is a gland of the conglomerate kind, surrounded on all sides with cellular substance and fat. The glandular part is divided into little masses, separated also by fat, and again subdivided into small granules, from which the lactiferous ducts arise. The cellular pellucula support a great many blood-vessels, lymphatics, and serous or lactiferous ducts, together with small glandular molecules.

The *areola*, or coloured circle or disk round the papilla or nipple, is formed by the skin; the inner surface of which sustains a great number of small glandular molecules, of that kind which Morgagni calls *glandulæ sebaceæ*. These tubercles are perforated by small holes, through which a kind of sebaceous matter, more or less liquid, is poured out, to defend the areola and nipple. The texture of the nipple is spongy, elastic, and liable to divers changes of consistence, being sometimes harder, sometimes more flaccid. It seems to consist chiefly of ligamentary fasciculi, gently folded, or curled; among which, those near the circumference of the nipple seem to have a transverse or annular disposition, which, however, is not uniform. This disposition or direction seems to be owing to the elastic folds; and, from this simple structure, it is easy to explain how infants, in sucking, and women in drawing the teats of cows, bring out the milk. For the excretory tubes, being wrinkled in the same manner as the fasciculi, do, by these wrinkles or folds, as by so many valves, hinder the milk contained in the ducts from flowing out; but, when the nipple is drawn and elongated, the tubes lose their folds, and the passage becomes straight. Those who understand the principles of the air-pump, will more readily conceive the manner in which the child draws out the milk.

The *pleura* is a membrane which adheres to the inner surface of the ribs, sternum, and convex side of the diaphragm. It is of a very firm texture, and is supplied with blood-vessels and nerves, in all which it resembles the peritonæum. Each side of the thorax has its particular pleura, entirely distinct from the other, and making, as it were, two great bladders, situated laterally with respect to each other in the great cavity of the breast, in such a manner as to form a double septum or partition, running between the vertebrae and the sternum. This particular duplicature is termed *mediastinum*; the two laminae of which are closely united together; but, in the middle, and towards the lower part

of the fore-side, they are separated by the pericardium and heart. A little more backward, they are parted in a tubular form by the œsophagus, to which they serve as a covering; and, in the most posterior part, a triangular space is left between the vertebræ and the two pleuræ from above downward, which is filled chiefly by the aorta. The pleura is connected to the membranous portion of the sternum, ribs, and muscles; to the diaphragm, pericardium, thymus, and vessels; and, in a word, to whatever lies near its convex side. The pleura serves in general for an inner integument to the cavity of the thorax. The mediastinum cuts off all communication between the two cavities, and hinders one lung from pressing on the other when we lie on one side. It likewise forms receptacles for the heart, pericardium, œsophagus, &c.

The œsophagus is a canal partly muscular and partly membranous; which commences at the inferior part of the pharynx, and descends along the neck and back-part of the thorax, into the abdomen. While it lies in the neck, it is placed between the middle and left part of the cervical vertebræ behind the left part of the trachea; in the thorax it is situated between the layers of the posterior mediastinum, and descends to the fourth or fifth vertebræ of the back, in the same direction which it had above; there it inclines a little from left to right, till it reaches the ninth rib, to make way for the aorta; afterwards it inclines from right to left, and from behind forward, to get through the diaphragm into the upper orifice of the stomach. It is made up of several coats, almost in the same manner as the stomach, of which it is the continuation. The first coat, while in the thorax, is formed only by the duplicature of the posterior part of the mediastinum, and is wanting above the thorax and in the neck, where the outer coat of the œsophagus is only a continuation of the cellular substance belonging to the neighbouring parts. The second coat is muscular, being made up of several strata of fleshy fibres. The outermost are mostly longitudinal, and their quantity is much greater than that on the rest of the alimentary canal; but they are not all continued from one end of the œsophagus to the other. The third is termed the *nervous coat*, and is like that of the stomach and intestines. It is differently folded or plaited, according to its length, being much wider than the muscular coat; and it is surrounded by a whitish, soft, fine, filamentary substance, like a kind of cotton, which, when steeped in water, swells and grows thicker. The fourth or innermost coat resembles, in some measure, that of the intestines; except that, instead of the villi, it has small and very short papillæ. It is folded lengthwise like the third coat; so that the œsophagus, when cut across, represents one tube within another. Through the pores of this coat a viscid lymph is continually discharged.

The *thymus* is an oblong, soft, glandular, body, round on the upper part, and divided below into two or three great lobes, of which that towards the left side is the longest. It lies between the duplicature of the superior and anterior portion of the mediastinum, and the great vessels of the heart. Among the various opinions about the use of this substance, some have thought it served only to fill a part of the thorax of the fœtus in the collapsed state of the lungs, because its size decreases after the lungs are dilated. Its particular inward structure and secretions are not as yet sufficiently known, so as to enable us to determine its uses; which, however, seem to be designed more for the fœtus than for adults.

The *pericardium* is made up of three laminæ, the middle and chief of which is composed of very fine tendinous filaments, which are best seen in old persons; they are closely interwoven, and cross each other in different directions. The internal lamina seems to be a continuation of the outer coat of the heart, auricles, and great vessels. It is perforated by an infinite number of very small holes, through which a serous fluid continually transudes, in the same manner as in the peritoneum; there being no glands for this purpose, as some have supposed. This fluid, being

gradually collected after death, makes what is called *aqua pericardii*, which is found in considerable quantities in opening dead bodies while they remain fresh.

OF THE HEART.

The heart is a muscular body, situated in the cavity of the thorax, on the anterior part of the diaphragm, between the two laminæ of the mediastinum. It is nearly of a conical figure, flattened on the sides, round at the top, and oval at the basis. Accordingly we consider in the heart, the basis; apex; two edges, the one right and the other left; and two sides, one of which is generally flat and inferior, the other more convex and superior. The heart is hollow within, and divided by a septum which runs between the edges into two cavities, called *ventriculi*; one of which is thick and solid; the other thin and soft. The latter is termed the *right ventricle*, the other the *left*. The right ventricle opens into the right auricle, and into the trunk of the pulmonary artery; the left into the left auricle, and into the great trunk of the aorta. At the edges of these orifices are several moveable pelliculæ, called *valves*; of which some are turned inward towards the cavity of the ventricles, called *triglochinæ*, or *tricuspidæ*; others are turned towards the great vessels, called *femilunares*, or *sigmoidales*. The valvulæ tricuspidæ of the left ventricle are likewise termed *mitrales*.

The fleshy or muscular fibres, of which the heart is made up, are disposed in a very singular manner, especially those of the right or anterior ventricle; being either bent into arches, or folded into angles. The fibres which are folded into angles are longer than those which are only bent into arches. The middle of these arches, and the angles of the folds, are turned towards the apex of the heart, and the extremities of the fibres towards the basis. These fibres differ not only in length, but in their directions, which are very oblique in all, but much more so in the long or folded fibres than in the short ones, which are simply bent. The tubes which cross each other transversely are much more numerous than those which cross longitudinally; which ought to be taken notice of, that we may rectify the false notions that have been entertained concerning the motion of the heart, namely, that it is performed by a contortion or twisting like that of a screw, or that the heart is shortened in the time of contraction, and lengthened in dilatation.

The valves at the orifices of the ventricles are of two kinds: one kind allows the blood to enter the heart, and hinders it from going out the same way; the other kind allows the blood to go out of the heart, but hinders it from returning. The valves of the first kind terminate the auriculæ; and those of the second lie in the openings of the great arteries. The first are termed *femilunar* or *sigmoidal valves*; the others, *triglochinæ*, *tricuspidal*, or *mitral*. The femilunar valves are six in number, three belonging to each ventricle, situated at the mouths of the great arteries; and they may be properly enough named *valvulæ arteriales*. Their concave sides are turned towards the cavity of the arteries, and their convex sides approach each other. In examining them with a microscope, we find fleshy fibres lying in the duplicature of the membranes of which they are composed. The great artery that goes out from the left ventricle, is termed *aorta*. As it goes out, it turns a little towards the right, and then bends obliquely backward, to form what is called *aorta descendens*. The trunk of the artery which goes out from the right ventricle is called *arteria pulmonaris*. This trunk, as it is naturally situated in the thorax, runs first of all directly upward for a small space; then divides laterally into two principal branches, which are attached to the lungs.

The auricles are muscular bags situated at the basis of the heart, and their capacities are in proportion to those of their respective ventricles; one towards the right ventricle, the other towards the left, and joined together by an inner septum and external communicating fibres, much in the same manner with the ventricles; one of them being

named the *right auricle*, the other the *left*. They open into the orifices of each ventricle, called *auricular orifices*; and they are tendinous at their opening, in the same manner as the ventricles. The right auricle is larger than the left; and it has two other openings united into one, and formed by two large veins which meet and terminate there, almost in a direct line, called *vena cava superior* and *inferior*. At the mouth of the inferior cava we find a membrane in form of a crescent, described by Eustachius, and named from him. The left auricle is a kind of muscular bag or reservoir, of a considerable thickness, and unequally square, into which the four *venæ pulmonares* open, and which has a distinct appendix belonging to it, like a third small auricle. This bag is very even on both surfaces, and is therefore called *sinus venosus*; but, to distinguish it from the one on the right side, it is called *sinus venosus sinister*.

Besides the great common vessels, the heart has vessels peculiar to itself, called the *coronary arteries* and *veins*, because they in some measure crown the basis of the heart. The coronary arteries, which are two in number, go out from the beginning of the aorta, and afterwards spread themselves round the basis of the heart, to the substance of which they send numerous ramifications. The coronary veins are distributed exteriorly, much in the same manner. The largest opens into the posterior inferior part of the right auricle, by an orifice which is furnished with a valve, first described by Eustachius. Besides the coronary veins, the heart has other anterior veins, called *venæ innominate*. Some of them go into the right auricle, others end in the right ventricle; and there are other veins still smaller, which are found in the substance of the heart, and which terminate in the right sinus and auricle. The nerves of the heart, are from the par vagum and great sympathetics: these form the cardiac plexus, which sends off branches to the pericardium, to the roots of the great vessels, and are spent at last on the different parts of the heart.

The heart lies almost transversely on the diaphragm, the greatest part of it being in the left cavity of the thorax, and the apex being turned towards the bony extremity of the sixth true rib. The basis is towards the right cavity; and both auricles, especially the right, rest on the diaphragm; but the situation of the heart during life changes a little, according to the state of respiration, and to the position of the body.

The heart, and the parts belonging to it, are the principal instruments of the circulation of the blood. The two ventricles ought to be considered as two syringes, so closely joined together as to make but one body, and furnished with suckers placed in contrary directions to each other, so that by drawing one of them a fluid is let in, and forced out again by the other. When the fleshy fibres of the ventricles are contracted, the two cavities are lessened in an equal and direct manner; and the fleshy fibres do the office of suckers, by pressing upon the blood contained in the ventricles; which blood being thus forced towards the basis of the heart, presses the tricuspidal valves against each other, opens the semilunares, and rushes with impetuosity through the arteries and their ramifications, as through so many elastic tubes. The blood, thus pushed out, enters the capillary vessels, and is from thence forced to return by the veins to the auricles, which, like retirements, or antichambers, receive and lodge the blood returned by the veins during the time of a new contraction. This contraction of the heart is termed *systole*. The contraction or systole of the ventricles ceases immediately, by the relaxation of their fleshy fibres; and, in that time, the auricles which contain the venal blood, being contracted, force the blood through the tricuspidal valves into the ventricles, the sides of which are thereby dilated, and their cavities enlarged. This dilatation is termed *diastole*. In this manner does the heart, by the alternate systole and diastole of its ventricles and auricles, push the blood thro' the arteries to all the parts of the body, and receive it again by the veins. This is called the *circulation of the blood*, which is carried on in three different manners. The first

and most universal kind of circulation is that by which almost all the arteries of the body are filled by the systole of the heart, and the greatest part of the veins evacuated by the diastole. The second kind of circulation is through the coronary vessels of the heart, the arteries of which are filled with blood during the diastole of the ventricles, and the veins emptied during the systole. The third kind of circulation is that of the left ventricle of the heart; thro' the venal ducts of which a small quantity of blood passes, without going through the lungs, which is the course of all the remaining mass of blood.

There resides in the heart a kind of desire to be stimulated, so that, even when it is almost dead, wrinkles radiating from a point appear in many places, and trembling motions are propagated through different parts of its surface. Again, the heart, when torn out and cold, on being pricked, inflated, or irritated, contracts itself; and its fibres, when dissected, corrugate themselves orbicularly, when there is neither nerve nor artery to bring it supplies of any kind. This irritability is greater, and remains longer in the heart, than in any other part of the body; for, by stimulating the heart, its motion may be renewed at a time when that of no other muscle can. The heart of the fœtus is most irritable, as well as larger in proportion, than in adults, and most tenacious of its motion, even in the cold. The motion of the heart appears to be innate, coming neither from the brain nor the soul; it remains even when the heart is removed from the body, and it can neither be increased nor retarded by the will. It is, therefore, evident, that the stimulus occasioned by the venous blood driven into the heart, causes it to contract. This contraction is convulsive, made with great celerity, and a manifest corrugation of the fibres. The blood, thus impelled from the sides towards the axis of the contracting heart, endeavours to escape in that direction, and, by rushing like a wedge between the valves, presses their loose edges against the sides of the pulmonary artery, so as to run freely out of the heart. The blood now received into the pulmonary artery circulates through the lungs; for, when it has once entered the pulmonary artery, it cannot return to the heart; because its valves are of such dimensions, that, when distended, they perfectly shut up the opening at the heart; and they are so strong that they resist a much greater force than the contraction of the pulmonary artery. The *pulmonary veins* run into larger branches, which at last terminate in four trunks; to which it has been customary to affix a name in the singular, by calling them the *pulmonary vein*. These enter the cavity of the pericardium, from whence they receive an external covering, and are then inserted into the corners of the left or posterior sinus, which is called the *pulmonary sinus*. In this course the upper veins descend, and the lower ones ascend. In this left sinus the blood waits for the heart's relaxation, when it is driven into the left ventricle, in the same manner as the right auricle impelled its blood into the right ventricle. Thus the same blood is now arrived into the left ventricle, which was a little before sent from the *venæ cavæ* into the right auricle. This course of the blood, from one side of the heart to the other, through the lungs, is called the *pulmonary* or *lesser circulation*, and was known to many of the ancients. Again, this left ventricle being excited to motion by the impelled blood, from the same irritable nature already mentioned, contracts, and drives its contained blood with a violent motion in the direction of its axis, the tip or cone of the heart being at the same time drawn nearer to its basis. And since the apparatus of the mitral valves is here the same as in the tricuspid, the blood now expanding the ring from whence they arise removes that valve which lay against the mouth of the aorta, and opens a way for itself into the artery. After the contraction of the heart, follows its relaxation or diastole, in which it becomes empty, lax, and soft, recovers its former length, the ventricles recede from the septum, and the basis from the apex. But, while it is in this state, the blood in the auricles, having been, as it were, in a state of expectation, rushes

rushes through the openings of the valves of the veins, dilates the opposite sides of the heart, and increases all its dimensions. After the auricles have freed themselves of the blood they contained, they are in like manner relaxed, and their opposite sides remove from each other. The blood then collected in the *venæ cavæ* and pulmonary veins fills the auricles by the contraction of the veins; renders them long, broad, and thick, like the ventricles; and even distends and fills the dentated processes of the crested margin. These motions of the right and left auricle, with the right and left ventricle, are not performed in that succession in which, for the sake of method, we have here described them; for both the auricles are contracted, while both the ventricles are relaxed: so that the contraction of the auricles precedes the contraction of the ventricles. This fact is ascertained by experiments on dying animals, and on animals with cold blood. Those who have inadvertently taught otherwise, have not taken the advantage of making a sufficient number of experiments on living animals. That the auricle, near death, makes frequent palpitations before the ventricle of the heart performs one contraction, is certainly true. The auricle, with its sinus, forms one cavity; and both are filled and both emptied in the same instant.

It may be asked, Why the heart is not wearied, or becomes painful, by so rapid, long continued, uninterrupted, and violent, a motion? The heart contracts, in a healthy person, about 5000 times in an hour, and never ceases its alternate contractions and dilatations from the first beginning of its existence till death? Why, then, does it not, like other muscles, become tired, in a very few hours, by such violent motions? How is its strength preserved? Different answers have been given to these questions by different professors, founded either on a compression of the cardiac nerves between the large arteries, or on an alternate repletion of the coronary arteries and cavities of the heart, &c. But to Dr. Haller the simplicity of nature in this matter is very conspicuous. When the auricle is relaxed, it is directly filled by the muscular force of the continuous great vein; and the heart contracts when it is irritated by the blood being driven into it from the auricle, and thus empties itself of the blood. Being freed from the stimulus, it immediately relaxes or relaxes itself. The heart being now relaxed, the auricle is, in like manner, irritated by its contained blood, and, by contracting, fills the heart again; while the incessant actions of the heart and arteries continually urge new blood into the right sinus and auricle. That this is the true cause of the heart's motions is proved from actual experiment and observation. The successive repletions and contractions made in the great vein, auricle, ventricle, and artery, are plainly and easily seen in a weak or expiring animal; but, more especially, and more evidently, in those animals which have but one ventricle in the heart, as the tortoise, frog, snake, fishes; and in the chick hatching in the egg, which, instead of a heart, has only one crooked canal. Besides, it is confirmed from the inertia of the heart, produced by tying the veins; and, from the return of its motion, when the ligatures are unloosed; provided these phenomena are sufficiently valid; but it is more unequivocally corroborated by injection, and by the experiment of inflating a frog's heart with a small bubble of air, which we see alternately pass from the ventricle to the auricle and back again for many hours. The left ventricle first ceases its motion; then the auricle of that side; then the right ventricle; after that the right auricle; and, last of all, the pulmonary veins and *venæ cavæ*. Whatever motion is in the *venæ cavæ*, ought to be attributed to the auricle repelling the blood into both these veins, and which the heart, when dead, is not capable of receiving. Dr. Haller believes that nothing more is requisite to produce the heart's motion than a continual stimulus applied to a very irritable part. For, on the approach of death, the coldness of the limbs contracts the veins, and drives the blood to the heart; the lungs, being impermeable for want of respiration, transmit no blood to the cavities of the left side; and

the heart, after it is thoroughly emptied, remains at rest. The velocity of the blood, at its entrance into the aorta, and the force with which it is expelled from the heart, have been subjects of much controversy; and different anatomists have computed them differently. To determine the velocity, modern writers proceed on the following data. They suppose that two ounces are expelled by each systole, that each systole is the third part of the whole pulsation, and is performed in healthy persons in $\frac{1}{25}$ part of a minute, that the area of the aorta is 0.4187 of an inch, and that two ounces of blood occupy a space of 3.318 cubic inches; or, in other words, that a cylinder of blood, whose solidity is 3.318 inches, and base 0.4187, is expelled by the heart in $\frac{1}{25}$ part of a minute. Since the solidity of a cylinder is the product of the area of its base into the length, its length will be equal to the solidity divided by the base; therefore, in this case, 3.318 divided by 0.4187 gives 7.9245 for the length which the blood runs in $\frac{1}{25}$ part of a minute; that is, 148 feet 7 inches in a minute. To determine the force, they suppose that the perpendicular jet from the heart is 7 feet 6 inches, and the area of the surface of the ventricle is 15 inches; these two numbers multiplied give 1350 cubical inches, or 51 pounds of blood against which the heart acts. The heart, therefore, sends a weight of 51 pounds, with the velocity of 149 feet in a minute.

The above computation may perhaps be inaccurate, both from the omission of some circumstances that ought to have been taken into the account, and from the inaccuracy of the data; but that the heart appears to be a very powerful machine, is evident from the great difficulty we have in filling all the red blood-vessels by anatomical injections, and the utter impossibility of filling all the smaller ones; yet the heart, we see, not only gradually distends all the larger, the smaller, and even the least, vessels, with blood, but also drives it forward through them with a considerable velocity. Even in the least arteries, the blood is urged forward by the heart with such a force as to make the alternate motions of that powerful muscle perceptible; even in such animals as are scarcely visible to the naked eye, and in the small embryos of insects.

Moreover, that we may make a just estimate of the heart's force in living animals, we must consider what great resistances that complex muscle overcomes: we must compute the enormous weight of the whole mass of blood; a mass perhaps of fifty pounds and upwards: for all the quantity of fluids, once stagnant in a person lately drowned or fainting away, are easily put into their former motion by the heart alone. We must also consider the great decrease of the blood's velocity, arising from the greater capacity of the dividing branches; and yet, even in the least vessels, its velocity is very considerable, as appears by the Sanctorian perspiration seen to fly rapidly off like smoke, and by the quick motion of the blood seen, by the help of microscopes, in fishes tails. Frictions in every machine always consume the greatest part of the moving forces; and these frictions will doubtless be very large in the human body, whose blood and juices are extremely viscid, and whose vessels are so small as scarcely to allow more than a single globule to pass at a time, and even that not without changing its figure. All these resistances being considered, we may without doubt conclude that the force of the heart must be extremely great, in order to preserve the motion so strong as we perceive it in the least arteries. Another argument of the heart's force is, that aneurisms and arteries are burst, and very great weights, as well as the body itself, raised by the force of the heart's systole.

The liquor which is contained in the arteries and their corresponding veins, is known by the general name of *blood*. It appears homogeneous, is coagulable, and of a red colour; it is redder in strong and well-fed animals, and generally yellow in such as are weak and starved. White streaks sometimes appear in it, in consequence of the chyle. But from various experiments it is certain, that this animal liquor contains very different ingredients. That fire

is contained in the blood may be proved from its heat, which, in human blood, and that of some other animals, is from 92 to 100 degrees of Fahrenheit's thermometer, which is more than the mean degree of atmospheric heat, but less than the greatest. Dr. Wrisberg says, that it differs in man, according to age, temperament, state of mind, motion or rest of body, climate, weather, kind of life, meat and drink, health, and the various species and violence of disease. It is also certain that the degree of heat in the body increases a little from an augmentation of heat in the atmosphere; but it does not rise to the greatest pitch of summer heat. We can live in a much greater heat than the heat of the warmest summer, as is proved by persons employed in sugar-houses, melting-furnaces, by mowers, and the use of baths and stoves in Finland and Russia; and also by the late experiments of Fordyce, Blagden, Hunter, and Dobson. The heat of the blood is sometimes so diminished in an intense cold, that in a person frost-bitten, but not dead, a thermometer applied to the mouth, armpits, groins, and even the vagina, would not rise above 76° of Fahrenheit. Is the matter of heat in the blood alone? This is sufficiently probable from phenomena; for the heat of the body is diminished by hæmorrhage, or when the blood is intercepted by ligature and compression from reaching the joints, and is restored when the blood returns. Again, a kind of volatile vapour or exhalation continually flies off from the warm blood, which has a sort of foetid smell, intermediate between that of the sweat and urine. After this vapour has dissipated, the blood of a healthy person spontaneously congeals into a scissile trembling mass, especially in a heat of about 130 degrees, and sooner in feverish persons than in such as are in health. It sometimes coagulates in the veins of a living person, and is found clotted in wounds of the arteries. The principal part of this coagulated mass is the *crassamentum* or *crur*, which has the red colour peculiar to itself, and gives it to the other parts of the blood. This, if it be not kept fluid by the attrition of a vital circulation, or some similar concussion, runs into a confused compact, but soft, mass, like liver, merely by rest and a moderate degree of cold; as it also does by the addition of alcohol, by mineral acids, or by a heat of 150 degrees. It is, either as a fluid or a solid, specifically heavier than water by near an eleventh part; and, when freed from its water, it is inflammable. In a mass of healthy blood, one half or upwards is red cruor; and, in strong laborious people, the serum makes only a third part; and is still more diminished in fevers, often to a fourth or fifth part of the mass.

The white yellowish watery part of the blood, commonly called serum, which separates from this coagulum, transuding, as it were, through its pores, forms a fluid in which the coagulum sinks; this again seems, though it really is not so, a homogeneous liquor; it is, in general, one thirty-eighth part heavier than water, and almost a twelfth part lighter than the red globular mass of crassamentum. By a heat of 150 degrees, or by mixture of mineral acids or alcohol, and by a concussive motion, it is coagulable into a much harder mass than the red cruor, and forms first an indissoluble glue, then a flesh-like membrane, and at length shrinks up to a horn-like substance or friable gum. The pleuritic crusts or skins, polypuses, and artificial membranes, are formed from this part of the blood. By putrefaction alone, or the dissolving power of the air, in a heat equal to 96 degrees, the whole mass, but especially the serum, dissolves or melts into a foetid liquor; first the serum, and then the cruor more slowly, till at length the whole mass, both of serum and cruor, is turned into a volatile and foetid exhalation, leaving very few feces behind.

The exact mass or quantity of blood contained in the whole body cannot be certainly computed. The weight of the mass of humours, however, is much greater than that of the solids; but many of them, as the gluten and fat of particular parts, do not flow in the circulation. But, if we may be allowed to form a judgment from those pro-

fuse hæmorrhages that have been sustained without destroying the life of the patient, and from experiments made on living animals by drawing out all their blood, the mass of circulating humours will be at least fifty pounds; of which, about twenty-eight will be true red blood, running in the arteries and veins; of which the arteries contain only four parts, and the veins nine. The blood does not always contain the same proportion of the principles above-mentioned. For an increased celerity, whether by laborious and strong exercises, a full age, fever, or otherwise, augments the crassamentum, the redness, the congealing force, and the cohesion of the particles; and the hardness and weight of the concreted serum with the alkaline principles are increased by the same means. On the other hand, the younger and less active animal, and the more watery or vegetable the diet on which it is fed, the crassamentum of the blood is proportionably lessened, and its serum and mucus increased. Old age, again, lessens the crassamentum, and the gelatinous part likewise.

From these principles, and a due consideration of the solid fibres and vessels, the different temperaments are derived. For a *plethoric* or *sanguine* habit arises from an abundance of the red globules; a *phlegmatic* temperature from a redundancy of the watery parts of the blood; a *choleric* disposition of the humours seems to arise from a more acrid and alkalescent property of the blood; as appears from those, who live on flesh and on the human species, being so much fiercer and more passionate than those who live on vegetable food. A great firmness in the solid parts, joined with an exquisite sensibility, or nervous irritability, disposes to a choleric habit; a less irritability, with a moderate density, to a sanguine habit; and a less degree, both of density and irritability, are to be referred to a phlegmatic temperament. There is also a kind of dull heavy temperament, in which there is the greatest strength of body, joined with no great degree of irritability. In the melancholic, again, a weakness of the solids is joined with the highest degree of nervous irritation or sensibility. But we must not describe the temperaments too systematically; for they are found to be not only four or eight, but almost infinitely varied.

The red part of the blood seems chiefly of use to generate heat, since its quantity is always in proportion to the heat of the blood. The globular figure of its parts, together with their density, makes it easily pervade the vessels; and the quantity of iron it contains, as well as of oil, perhaps increases its power of generating heat. And hence it is, that the red part of the blood being too much diminished by profuse bleedings, there follows a stagnation or lessened motion of the humours in the smaller vessels; whence fatness and dropsy. By the same rule also a due proportion of cruor is necessary within the habit, to generate new blood. For, by large hæmorrhages, we see the blood loses its red and dense nature, and degenerates into a pale, serous, or watery, state. Health, therefore, cannot subsist without a dense and red blood; and, if its quantity be too much diminished, a stagnation of juices takes place, whence the whole body becomes pale, cold, and weak. Nor can life or health subsist without a sufficiency of thinner juices intermixed with the red blood; since the cruor, deprived of its watery part, congeals and obstructs the smallest passages of the vessels, and causes too great a heat.

"The theory of the temperaments of the human body (says Dr. Wrisberg), in the sense commonly received by physicians, and taught in the schools, the received division of them into four species, and their repeated production from the different nature and mixture of the blood, favours too much of the ancient and particularly of the Galenical doctrine. I think there can be no doubt that there are temperaments; and that the manner and rule which nature follows in man, and likewise in perfect animals, may be observed in the performance of the corporeal and mental functions, in either preserving or endangering health, in the exercise of most of the duties and affairs

affairs of life, and in the actions of the internal and external parts, which are more or less connected with the health of the animal.

"The causes of diversity of temperament seem to be, 1. The various quantity, firmness, and sentient faculty, of the nervous system, from the brain communicated to each nerve. I have always observed a choleric disposition in all persons having a large brain and thick strong nerves, along with a great sensibility as well of the whole body, as of the organs of sense. Hence arises a ready apprehension of objects, and an increase of understanding and knowledge, and, owing to the comparison of many ideas, an acute and entire judgment, which choleric persons possess in so eminent a degree. But, along with this condition of the nerves, these people are excessively liable to grief and anger, when the body or mind is but slightly affected; and on this account medicines should be cautiously given, and less doses prescribed to them. With a small brain, and slender nerves, I have observed the senses more dull. These people therefore require from external objects stronger impressions upon the organs of sense, and these impressions longer applied, if they are meant to leave lasting effects. Hence their judgment is frequently weak on account of the defect of ideas; and they seldom acquire any extensive knowledge. But nature has compensated these disadvantages, by making them more able to undergo hardships, from change of climate, life, or labour; they demand more powerful medicines, and larger doses. 2. The various degrees of irritability in the muscular parts. For, wherever you find a very delicate irritability, affected by almost every stimulus, and retaining lasting impressions, and at the same time acting with a certain celerity; in that case you cannot doubt of a choleric disposition. Hence that remarkable strength in the muscles of some persons, which act with incredible quickness, dispatch, and constancy. On the contrary, if you examine a phlegmatic person, you observe the contractile power of the muscles languid, and long of being determined to motion, although strongly excited. 3. Even a certain softness is observable in all fibres and membranes, if you touch the body of a phlegmatic person; or a seeming hardness and dryness in melancholic habits. Along with which particularities the phlegmatics join less elasticity, whilst, in the melancholic, there is a greater tone and contractile power. 4. There is in the air, undoubtedly, a certain electrical principle, which being by respiration communicated in different ways with the body, imparts a natural tone to the fibres, occasions a quicker motion in the vessels, and increases and diminishes by turns the alacrity of the mind. But, as this principle of atmospheric air does not prevail in equal quantity every hour of the day, all times of the year, and in every climate; so sometimes we feel an universal lassitude, which suddenly ceases, the strength of the body and mind being restored with a serene and elastic air; so, in like manner, all men do not equally absorb this electric matter, which thus forms a remarkable diversity of temperament. 5. We ought, too, to combine with these the various nature of the blood from the proportion of its elements. And, in fact, as greater stimuli in the blood excite the heart to brisker contractions, so a more acrid and copious bile may effectually promote the peristaltic motion, and the abundance of mucus occasion a tendency to lentor and frequent catarrhs.

"There are then sufficient causes, which, from our birth, may bring on, in the first growth of the parts of the body, an irrevocable determination to this or that habit or temperament. I therefore can scarcely admit a complete transmutation of temperament, which, during the exercise of these natural laws, could render a purely choleric person phlegmatic. But, that some change may take place in temperaments, that violent attacks may be mitigated, that lentor, torpor, and listlessness, may be increased, I readily agree; and, from the remedies by which such a change may be produced, I form a second class of the causes of temperaments. The chief are, 1. A different kind

Vol. I. No. 39.

of meat and drink. An animal diet adds a great stimulus to our strength, invigorates our senses, and sometimes induces ferocity; as is evident from the Anthropophagi, carnivorous animals, wild beasts and their whelps, and hunters, particularly if the abuse of aromatics, wines, and medicines, has supervened. Vegetables, on the contrary, increase the lentor of the fibres, weaken the strength, diminish sensibility and irritability; in a word, induce a phlegmatic disposition; in which potatoes have a wonderful effect. It would be of great consequence to pay regard to this in the bringing up of children, viz. to invigorate the inertia of the mental and corporeal faculties by the use of animal food, but to temper the vehement passions peculiar to choleric persons, by using a vegetable diet. 2. The particular mode of education and examples. It need scarcely be insisted on that these possess great influence, particularly in infancy. Hence it happens that whole nations are of one temperament. 3. Climate, weather, native country. Rarely in an unsettled climate or country, in hot climates, or in moist countries, will you find in choleric persons that alacrity of temper, agility of body, and quickness of understanding, which is so common in a serene and temperate climate, and high hilly countries. 4. The increase of knowledge. I have often admired that change which a strenuous industry produces in some of the most dull men; so that, with the increase of knowledge, they became of a more cheerful temperament. 5. Abundance and want of necessities, both in life, and for the purpose of forwarding improvement. For this reason, it may happen that, according to the diversity of the form of government, whether under mild or more severe and tyrannical laws, the temperament of the subject may be either lively or languid. 6. The sort of life itself, intercourse with men, and public employment, may have a great share in changing temperaments; since rarely, after the thirty-sixth year of a man's life, do you find the blood still pure; and a choleric person scarcely preserves his former alacrity after his fiftieth. It is therefore difficult to say, into how many species temperaments might be divided, and what kind of character should be assigned to each, according to nature, and not conjecture."

Of the CIRCULATION or MOTION of the BLOOD.

The arteries and veins contain either blood or lymph. The red blood fills those arteries and veins which we call *red*, or of the first order, and which have their origin in the heart. Sometimes they are very loosely and imperfectly distended by the blood, and at other times they are rendered very full and turgid. This distending blood is rapidly moved through all the vessels of the body, as is demonstrated to us from wounds; and the patient sooner or later expires from the loss of so much blood as was necessary for the maintenance of life; this loss of blood happens almost instantly from the larger arteries, and sometimes very suddenly from the smaller ones. But from the veins, unless they are some of the largest, it is generally slow; yet there are not wanting instances of fatal hæmorrhages from wounds of the veins, in the inner corners of the eyes, and those under the tongue. The motion of the blood through the veins is uniform and equable; but, in the arteries, it is alternately greater when the vessel is more dilated, and less when it is contracted. This is proved by ocular inspection in living animals.

That the motion of the blood is a continued course through the sanguineous arteries into the veins is discovered from experience. For, first, it is certain, that all the arteries and veins communicate or open the one into the other; because often, from even a small artery, all the blood of the whole body may be evacuated. We have numerous examples of fatal hæmorrhages from an inner artery of the nose, from the gums, from a finger, from a tooth, from a cutaneous pore enlarged, from the punctum lachrymale, from the wound of cupping, and even from the bite of a leech. There are, therefore, of course, open ways, by which the blood speedily flows from the venous into the arterial

terial system. That the blood, again, in the arteries, flows from the heart towards the extreme parts of the body, is proved by the microscope, and by a ligature on the artery of a living animal, and likewise by the fabric, mechanism, and proportion, of the femilunar valves between the arteries and their corresponding ventricles. Whatever artery is stopped by a ligature, the swelling ensues in that part between the heart and the ligature, whilst the other part beyond the ligature, which is more remote from the heart, is emptied. Neither has it there any pulsation, nor, if it be there wounded, will it yield any blood. The same effects which we see follow from a ligature, are likewise often produced by disease; as when some tumour, by compression or an aneurism, intercepts the blood's motion from the heart. Experiments of this kind have been made on most of the arteries; anastomoses, however, or the blood flowing through a neighbouring branch, or the retrocession of the blood in a dying animal, form exceptions to this rule.

But the course or motion of the venous blood has been always more doubted; almost all the ancients have been persuaded, that the blood in the veins flowed through them, either from the heart or from the liver, to all parts of the body. Very few of them knew that this was an error. Several of them have, indeed, acknowledged it to be false in the pulmonary vein. But that the blood did not move from the heart in the vena cava, was known to still fewer anatomists among the ancients. Dr. William Harvey was the first who experimentally asserted the motion of the blood returning in the veins to the heart, in such a manner as to render the whole intelligible, and leave no room for doubt. The valves of the veins lead us to this truth. For the common use or office of these valves is, to determine the pressure that is made from any quarter upon the veins, towards the heart, by allowing no opportunity to the venous blood that has once entered the trunk to flow back to the branches. For, since the valves open upwards towards the heart, the blood enters and expands them; and those parts of the valves which project into the cavity of the vein, approach towards the axis, until the opposite sides, by meeting together, shut up the tube. Another office of the valves in the veins seems to be for sustaining the weight of the blood, that its upper columns may not gravitate upon the lower; nor the blood, flowing through the trunk, make too great a resistance against that which follows it through the branches. For if, from the slower motion of the blood, its weight or pressure shall, in any part, much exceed the impulse that drives it on, so as to cause some part of the column to descend by its weight, it is, in that case, immediately caught, and sustained in its relapse by the next adjacent valve, which hinders it from urging against the next succeeding column, and affords time and opportunity for some contiguous muscle, by its pressure or concussion, to propel the column. This is the reason why valves are placed in the veins of the limbs and necks, in which parts they are both more numerous and more robust than elsewhere. Moreover, the valves placed in the right side of the heart are so constructed, that they freely permit blood, air, or wax, to pass from the venous trunks of the cava into the heart, but deny any reflux from the heart into the veins. Again, ligatures, in a living person, make this circumstance more evident. When the veins of the limbs are tied, either by design or accident, about the hams, arms, ancles, or wrists, the limb below the ligature swells, the veins fill and distend themselves, and, when opened, make a free discharge of blood. But at the same time nothing of this kind happens above the ligature, nor any of the veins to be seen there. These ligatures will serve to keep the blood in any limb round which they are tied, that it may not return to the heart, and be lost through a wound in another part.

The experiments which have been made in living animals, to prove this course of the blood, are still more accurate. From them, it appears, that by tying any vein, in a living animal, near the cava, or belonging to the pul-

monary veins, that part always swells which is most remote from the heart, all below the ligature appearing distended with the retained blood, while above and next the heart they are pale and flaccid. Lastly, if the arteries are tied at the same time with the veins, these last remain flaccid and empty; but, upon removing the ligature from the arteries, the veins are immediately filled. In like manner, the infusion of poisons or medicinal liquors shew, that, into whatever vein you inject chemical acid spirits, the force of the poison is driven along with the blood to the heart itself. That the brain is affected with the narcotic virtue of opium, and the intestines and stomach with the virtue of purgatives and emetics injected into the veins, is a demonstration that the blood, with which these substances were mixed, had passed through the ramifications of the veins to the heart, and from thence through the whole body. We have another proof in the *transfusions* of blood; in which all the blood from the arteries of one animal is urged into the veins of another exhausted of blood; whereby the heart, arteries, and empty veins, of the latter, become so turgid, and well replenished, that they produce a remarkable degree of vivacity in the animal, or even cause it to labour under a plethora.

That the blood passes from the least arteries into the least veins, we are clearly taught by *anatomical injection*; where, by one arterial trunk, we easily fill all the arteries and veins, almost throughout the whole body, provided the liquor be very fluid, so as to pass easily into the vessels of the head, mesentery, heart, and lungs. The circulation of the blood is therefore now received by every one as a medical truth; namely, that all the blood of the human body is carried through the aorta, from the left cavity of the heart, to the extreme parts or converging ends of the arterial branches; from whence the whole mass is again transmitted into the least veins, which convey it to the larger, and from them into the cava and heart itself; in which course it perpetually goes and returns during life.

The course of the humours in the *lymphatic veins* which have valves, appears both from the nature of those veins, and from ligatures. For every lymphatic vein, when tied, swells between its smaller extremities and the thoracic duct; but grows flaccid between the duct and the ligature. All the valves in these, like those of the blood-veins, give a free passage for flatus and mercury to flow to the thoracic duct. But they make a resistance, and often an obstinate one, to any return the other way; although sometimes they have been known to yield. The *vapours* that moisten the whole cellular substance, the steams of the abdomen and other cavities, are all absorbed by the least pellucid veins, and so conveyed to the blood-veins, that their contained juices may pass on to the heart. And from thence it is that œdema ensues, when a vein is compressed by a ligature; because, by intercepting the course of the absorbing veins by the ligature, the vapours, being unabsorbed, stagnate. All the juices, therefore, in the human body, are driven out of the heart into the aorta; from whence they are all uniformly returned again to the heart, by the veins. To complete this circle, it only remains for us to find out a course for the blood from the right to the left cavities of the heart; but this first supposes us to be acquainted with the history of the lungs and the pulmonary vessels.

OF THE LUNGS.

The lungs are two large spongy substances, of a reddish colour in children, greyish in adult subjects, and bluish in old age. They fill the whole cavity of the thorax, one being seated in the right side, the other in the left, and are parted by the mediastinum and heart. They are convex next the ribs, concave next the diaphragm, and irregularly flattened and depressed next the mediastinum and heart. They are distinguished into the right and left lung; and each of these into two or three portions called *lobes*, of which the right lung has commonly three, and the left lung two. At the lower edge of the left lung, there is an indented

indented notch or sinus opposite to the apex of the heart, which is therefore never covered by that lung, even in the strongest inspirations; and consequently the apex of the heart and pericardium may always strike against the ribs; the lungs not surrounding the heart in the manner commonly taught. This sinus is expressed in Eustachius's Tables.

The vessels which compose part of the substance of the lungs are of three or four kinds; the air-vessels, blood-vessels, and lymphatics, to which we may add the nerves. The air-vessels make the chief part, and are termed *bronchia*. These bronchia are conical tubes, composed of an infinite number of cartilaginous fragments, like so many irregular arches or circles, connected together by a ligamentary elastic membrane, and disposed in such a manner as that the lower easily insinuate themselves within those above them. The bronchia are also divided, in all directions, into an infinite number of ramifications, which diminish gradually in size; and, as they become capillary, change their cartilaginous structure into that of a membrane. Besides these very small extremities of this numerous series of ramifications, we find that all the subordinate trunks, from the greatest to the smallest, send out from all sides a vast number of short capillary tubes of the same kind. Each of these tubes is widened at the extremity, and thereby formed into a small membranous cell, commonly called a *vesicle*. These small vesicular cells are formed into bundles, termed *lobules*; and, as the great branches are divided into small rami, so the great lobules are divided into several small ones. All the bronchial cells are surrounded by a very fine reticular texture of the small extremities of arteries and veins, which communicate every way with each other. The greatest part of this admirable structure is the discovery of the illustrious Malpighi.

The blood-vessels of the lungs are of two kinds; one common, called the *pulmonary* arteries and veins; the other proper, called the *bronchial* arteries and veins. The pulmonary artery goes out from the right ventricle of the heart; and its trunk, having run directly upward as high as the curvature of the aorta, is divided into two lateral branches; one going to the right, called the *right pulmonary* artery; the other to the left, termed the *left pulmonary* artery. Besides these capital blood-vessels, there are others called the *bronchial arteries and veins*, which are very small, but they follow the bronchia through all their ramifications. They communicate with the pulmonary arteries and veins in many places; and likewise with the arteries and veins of the œsophagus, and with the branches of the coronary artery and vein.

The principal use of the lungs is for respiration, in which they are chiefly assisted by the diaphragm and intercostal muscles. As soon as the intercostal muscles begin to contract, the arches of the ribs are raised together with the sternum, and placed at a greater distance from each other; by which means the cavity of the thorax is enlarged on the two lateral and anterior sides. At the same instant the diaphragm is flattened or brought toward a plane by two motions, which are apparently contrary; that is, by the contraction of the diaphragm, and dilatation of the ribs in which it is inserted. The external surface of the thorax being thus in a manner increased, and the cavity of the bronchia being at the same time, and by the same mean, less resisted or pressed upon, the ambient air yields to the external pressure, and insinuates itself into all the places where the pressure is diminished; that is, into the *aspera arteria*, and into all the ramifications of the bronchia, all the way to the vesicles. This is what is called *inspiration*. This motion of inspiration is instantaneous, and ceases in a moment, by the relaxation of the intercostal muscles; the elastic ligaments and cartilages of the ribs bringing them back at the same time to their former situation. This motion, by which the ribs are depressed and brought nearer to each other, is termed *expiration*. The pulmonary arteries and veins, which accompany the

bronchia through all their ramifications, and surround the vesicles, transmit the blood through their narrow capillary extremities, and thereby change or modify it, at least in three different manners. The first change or modification which the blood undergoes in the lungs, is to have the cohesion of its parts broken, to be attenuated, and, as it were, reduced to powder. The second is, to be deprived of a certain quantity of serum, which transpires through the lungs, and is what we commonly call the *breath*. The third is, to be in a manner re-animated by the impression of the air, whether the whole body of the air enters the blood, whether the common air is only the vehicle of some finer parts which are conveyed to it, or whether the air only compresses and shakes the blood as it passes round the bronchial vesicles in the reticular capillary extremities of the vessels.

The diaphragm almost alone performs the office of respiration in a healthy man at rest. The diaphragm is also the chief instrument of respiration in the case of fractured ribs or sternum, or where the ribs cannot be moved without exciting considerable pain. The force of the diaphragm also, in dilating the breast, is greater, according to the calculations that have been made, than all the rest of the powers which contribute to respiration. A great inspiration is somewhat hindered; because, during the greatest exertion of the diaphragm, the lowermost ribs are brought inwards, and thus the thorax is straightened. Left this should always happen, the intercostal muscles interfere in ordinary inspirations; in the very great ones, they are inferior to the diaphragm. The phrenic nerve, which is more easily irritated than in most other muscles, forces the diaphragm to perform its office. The lungs themselves are altogether passive or obedient to the action of the air; and also to that of the ribs and diaphragm, to which they are pressed into close contact on all sides.

But respiration, whether by the admixture of a subputrid vapour, or by some other method, certainly vitiates the air, and renders it unfit either for inflating the lungs or supporting flame; and lastly, it deprives that element of its elasticity. We may suppose that this happens from putrefaction, since the air is rendered pestilential by a crowd, and fevers of the most malignant kind are thus generated in a few hours. But, in whatever manner this is produced, we are certain that the air is vitiated in the lungs, loses its elasticity, and thus cannot keep the lungs distended, so as to transmit an increased quantity of blood through the dilated pulmonary arteries into the veins. Nor can the will dilate the breast beyond certain bounds, or assist that passage of the blood in an unlimited manner. A state of body, therefore, will take place, in which the blood cannot pass through the lungs. Thus is generated a new resistance to the blood continually coming from the heart. And in long retentions of the breath, as in making violent efforts, the venous blood, especially that coming from the head, stagnates before the right ventricle of the heart, which is shut, because it cannot evacuate itself into the lungs, and thus swells up the face with redness, sometimes bursts the veins of the brain, neck, intestines, kidneys, and lastly of the lungs and even right auricle of the heart. This stagnation of the blood occasions prodigious anxiety and uneasiness to the spirits; it is also the cause of death in compressed air, in drowned people, and such as are strangled, which is much more sudden than is commonly imagined. A living person, therefore, that he may remove those inconveniences which proceed from an obstruction of the passage of the blood, slackens the powers of inspiration, and excites those of expiration, which free the breast from an air too greatly rarefied. These powers are, at first, the elasticity of the ribs; which being drawn upwards out of their natural situation, as soon as the powers which elevated them cease to act, spontaneously place themselves, so as to make more acute angles with the sternum and vertebræ. To this end conduces likewise the elastic force of the bronchia and vesicles distended with air, which strive to contract themselves.

Hence

Hence expiration is performed more easily and quickly than inspiration; and hence it is the last action of dying people.

The inconveniences produced by expiration, excite new efforts for repeating the respiration; because the collapsed vessels of the lungs resist the blood expelled from the right ventricle of the heart. Hence the cause of death in those animals which expire in vessels exhausted of air. For their lungs, being void of air, become dense, solid, and heavier than water, whence they are rendered impervious to the blood. Of the same kind is the death of those who are killed by lightning, and, perhaps, by the noxious vapours of caverns. How admirable are the structure and mechanism in these organs of respiration! The uneasy sensations of a too long continued expiration, which arise from hindrances of the blood's passage through the lungs, excite into action the powers of inspiration, whereby the blood's passage through the lungs is rendered again more free and easy; and, *vice versa*, the uneasiness proceeding from a too long continued inspiration excite the powers of expiration.

Respiration seems somehow to agree with the pulsation of the heart, there being ordinarily three or four pulses to one respiration. And, if a greater quantity of blood is sent to the heart in a given time, the numbers both of the pulse and respiration are increased. This is the reason of the panting or short breathing, after exercise, or any considerable motion, which increases the return of the blood to the heart. If the blood meets with a resistance in the lungs, so that it cannot pass freely from the right into the left ventricle of the heart; then the respiration is increased, both in quickness and magnitude, in order to forward its course. And this is the cause of sighing, yawning, and panting; of which the first is a deep inspiration; the second a slow and very great one; and the third a frequent and imperfect one. The number of respirations, however, does not always increase with the pulse, as we see in those fevers where the lungs are not affected. The mucus, which lines the sensible membranes of the air-vessels in the lungs, may become troublesome, both by its quantity and acrimony; it has been known to cause even suffocation in a dropy of the lungs. Its quantity, adhesion, or acrimony, therefore, excite a cough; which operation, caused by an irritation of the organs of respiration, is performed by alternate large inspirations, succeeded by large and quick expirations, together with sudden shocks of the abdominal muscles; and by these means the mucus, and sometimes calculous matters, are expelled from the lungs.

Laughter differs from coughing in its cause, which resides commonly in the mind, or at least consists in a certain titillation of some of the cutaneous nerves; and also its action, which is one large inspiration succeeded by several imperfect quick expirations through the contracted glottis, the lungs being never totally evacuated of air. Hence laughter, in a moderate degree, conduces to health; because, instead of one full inspiration, many short inspirations and expirations happen, and thus the concussion is greater. Hence its danger of stagnating the blood; because the expiration is not full or entire, and the blood is admitted into the pulmonary artery without being suffered to pass through it. Weeping begins with a great inspiration, after which follow short alternate inspirations and expirations; and it is finished with a deep expiration, that is immediately joined by a large inspiration. Hence it has nearly the same good and bad effects; and, when moderate, it conduces to relieve the anguish arising from grief. An hiccup is a very great, sonorous, and sudden, inspiration. Sneezing consists of one large or deep inspiration, which is followed immediately with a powerful and sudden expiration; it evacuates with great violence any acrid or other substance irritating the nostrils.

Some of the secondary uses of respiration are to compress the abdominal viscera, so that the stomach, intestines, gall-bladder, receptacle of the chyle, bladder, intestine rectum, and the womb itself, may discharge their contents; that the aliments may be triturated or dissolved,

and the blood urged through the sluggish vessels of the liver, spleen, and mesentery. Respiration excites a kind of flux and reflux in the blood, so that it is alternately pressed back towards the extremities of the veins, and a little after is propelled towards the heart by an accelerated velocity. Moreover, inspiration serves to convey odours along with the air to the organ of smelling; and is also the principal means by which a new-born infant is enabled to perform the operation of sucking.

OF THE ABDOMEN.

The cavity of the abdomen is of an irregularly-oval figure, but still symmetrical. On the fore-side it is uniformly arched or oval, and its greatest capacity is even with the navel and nearest part of the hypogastrium. On the upper side it is bounded by a portion of a vault, very much inclined. On the back-side it is in a manner divided into two cavities by the jutting out of the vertebræ of the loins. On the lower-side it contracts gradually all the way to the edge of the pelvis; and from thence expands again as far as the os coccygis, and tubercles of the ischium, terminating in the void space between these three parts.

Having carefully removed the muscles of the abdomen, the first thing we discover is a very considerable membranous covering, which adheres immediately to the inner surface of the muscoli transversi, and of all the other parts of this cavity, and involves and invests all the viscera, as in a kind of bag. This membrane is named *peritonæum*, from a Greek word, which signifies to be spread around. The peritonæum, in general, is a membrane of a close texture, and yet very limber, and capable of a very great extension; after which it can recover itself, and be contracted to its ordinary size, as we see in pregnancy, dropsies, corpulency, and repletion. The uses of the peritonæum, in general, are, to line the cavity of the abdomen, to invest the viscera contained in that cavity as in a common bag, to supply them with particular coats, and to form productions, ligaments, connections, folds, vaginae, &c. A fine fluid transudes through the whole internal surface of the peritonæum, which prevents the inconveniences that might arise from the continual frictions and motions to which the viscera of the abdomen are exposed, either naturally or by external impulses.

The *ventriculus* or stomach, is a great bag or reservoir, situated partly in the left hypochondrium, and partly in the epigastrium. The figure of the stomach is oblong, incurvated, large, and capacious, at one end, and small and contracted at the other. We see this figure most evidently when the stomach is moderately filled with air, or with any other fluid. It has two openings, called the *orifices of the stomach*; one between the great extremity and the small curvature, the other at the end of the small or contracted extremity. The first opening is a continuation of the œsophagus; the other joins the intestinal canal, and is called the *pylorus*. The stomach is composed of several *tunica* or coats. These coats are commonly reckoned to be four in number; the outer or common, the fleshy or muscular, the nervous or aponeurotic, and the villous or inner coat; and they are afterwards subdivided several ways. The first or outermost coat is simply membranous, being one of the internal productions of the peritonæum. The second or muscular coat is made up of several planes of fibres, which may all be reduced to two; one external, the other internal. The external coat is longitudinal, though, in different respects, following nearly the direction of the curvatures and convexities of the stomach; and the internal plane is transversely circular. The third coat, commonly called *tunica nervosa*, but properly *tunica cellulosa*, is composed of capillary vessels and nerves, with a very large proportion of cellular substance. The fourth coat of the stomach has been termed by Fallopius *tunica villosa*, because, when it swims in clear water, something is seen in it like the pile of velvet. The ancient called it *tunica fungosa*; and perhaps this name agrees best with its true structure.

The

The *pylorus* is a fold or duplicature of the two inner coats of the stomach, the *nervosa* and *villosa*; and it is formed in part by a fasciculus of fleshy fibres fixed in the duplicature of the *tunica nervosa*, and distinguished not only from the other fleshy fibres of the extremity of the stomach, but also from those of the intestines, by a thin whitish circle, which appears even through the external or common coat, round the union of the stomach and intestines. The figure of the *pylorus* is that of a ring transversely flattened; the inner edge of which, or that next the centre, is turned obliquely towards the intestines. This inner edge runs naturally more or less into little plaits or gathers, like the mouth of a purse almost shut; all which particulars are very different from what figures and dried preparations would make us believe. It is therefore a kind of sphincter, which can contract the inferior orifice of the stomach, but seems not capable of shutting it quite close. The stomach receives in general whatever the mouth and tongue send thither through the canal of the *œsophagus*: but its particular use is to receive the aliments; to contain them for a longer or shorter time, in proportion as they are more solid or fluid; and to digest them, and to put them in a condition to be turned into that nutritious fluid called *chyle*. This operation, which goes by the general name of *digestion*, is performed partly by the *succus gastricus*, which flows continually from the *tunica villosa*, and partly by the continual contraction and relaxation of the muscular coat. These motions in men are but very weak, and no wise sufficient for digestion, without the assistance of the alternate motions of the diaphragm and muscles of the abdomen. The *pylorus*, or fleshy circle of the inferior orifice of the stomach, serves to retain the aliments in it till they have acquired a sufficient degree of fluidity to pass easily through that opening. But, by a particular irritation of the muscular coat of the stomach, and still more by a violent contraction of the diaphragm and muscles of the abdomen, the contents of the stomach may be very soon forced towards the small extremity, and pushed through the *pylorus* into the intestines. The gentle and alternate motions of the orbicular fibres of the muscular coat may also assist in sending through the *pylorus*, in the natural way, the aliment that is sufficiently digested. This was called the *peristaltic* or *vermicular motion*, by those who believed that it is successively reiterated, like that of earth-worms when they creep. Trituration might be a proper term for this operation, provided it be made to signify only a gentle agitation or action of the fleshy fibres in a substance continually moistened by the gastric liquor, and not a violent grinding of a dry substance.

Between the *pylorus* and the very lowest part of the abdomen lies a long canal, bent in a great many different directions by numerous convolutions, called the *intestines*. This canal, thus folded and turned, forms a considerable bulk, which fills the greatest part of the cavity of the abdomen; and it is connected through the whole extent to membranous productions or continuations of the *peritonæum*, but principally to those called the *mesentery* and *mesocolon*. The whole canal is generally about six or seven times as long as the subject; and it is divided into three portions, which are distinguished by particular names. In the small intestines, the three portions are named *duodenum*, *jejunum*, and *ileum*; and in the great intestines, *cæcum*, *colon*, and *rectum*. The *intestina tenuia*, or small intestines, form one continued uniform canal; and, although the three portions of it have three different names, yet we have no sufficient marks whereby to distinguish them, to fix the precise extent or length of each portion, or to settle its just limits.

The *intestina crassa*, or great intestines, are one continued canal, divided into three portions, like the small ones. The *intestinum cæcum* is only a round short broad bag, the bottom of which is turned downward, and the mouth or opening upward. It lies under the right kidney, and is hid by the last convulsion of the *ileum*. On one side of the bottom of the *cæcum* lies an appendix, resembling a small intes-

tine, nearly of the same length with the *cæcum*, but very slender. It is termed *appendicula vermiformis*, from its supposed resemblance to an earth-worm. The *colon* is the most considerable of all the intestines. From the *cæcum*, of which it is a continuation, it reaches to the lower part of the left hypochondrium. Its continuity is, however, a little interrupted by the *ileum*, which advances into the cavity of the colon, and, together with a certain fold of that intestine, forms what is called *valvula coli*. The capacious arch of the colon is connected by both extremities to the *regio lumbaris*, near the kidneys, by two particular ligaments, one on the right side, the other on the left, which are only small duplicatures of the *peritonæum*, more or less transverse. The last of the intestines is named *rectum*, or the *straight gut*, from its situation; for, when viewed directly forward, it appears to run down in a straight course from the last vertebra of the loins, on the fore-side of the *os sacrum*, all the way to the *os coccygis*, where it ends in what is called the *anus*. This intestine is a true continuation of the last convolution of the colon; and it is the repository of the whole intestinal canal. It has likewise a special relation to the bladder, and to the parts of generation in both sexes.

The intestines are not left to move at random in the cavity of the abdomen; but are artfully bound down by a membranous web, which prevents the intestinal convolutions from being intangled in each other, and from being twisted or compressed in all their different ways of meeting; and yet allows them a gentle floating, but limited motion. This web goes by the Greek name of *mesentery*, as being in some measure in the middle of the intestines. It is distinguished into two portions; one of which being very broad, and very much plaited, connects the small intestines; the other, which is long and incurvated, does the same office to the great intestines. These two portions form a kind of spiral roll, more or less plaited in its circumference. The first portion is the *mesentery*; the other is termed *mesocolon*. The *mesocolon* is the continuation of the *mesentery*; which, having reached the extremity of the *ileum*, contracts and changes its name. At this place, the particular lamina, which is turned to the right side, forms a small transverse fold, called *ligamentum coli dextrum*. Between the laminae of the *mesentery*, a great number of glands lie scattered through the cellular substance. These glands are of the number of those that anatomists call *glandulae conglobatae*, the structure of which is not as yet sufficiently known. The nicest anatomical injections have not hitherto given us any satisfaction about them; for, though they be made with all possible care, they always fill the folliculous texture of these glands; and though, by means of these injections, we may discover a great many vessels which were before invisible, we do not advance much nearer our purpose, because we cannot, by this method, distinguish the secretory, excretory, and blood-vessels from each other.

OF DIGESTION.

Both the pain of hunger, and the pleasure of gratifying the appetite, excite us to the performance of an action absolutely necessary for our support, viz. the taking a due portion of aliment, in order to counterbalance the waste of the body by the insensible perspiration and other evacuations; and for which purpose the functions of the abdominal viscera, hitherto described, were principally intended. The necessity of frequently taking food is increased by the blood, which being naturally of a saline quality, soon acquires an acrimonious putrescency, by the evaporation of its thin watery parts; and this evaporation being increased by the heat of the body, and the motion of the heart and arteries, nature calls strenuously for a recruit of the watery element, by which the cohesive globules of the blood are separated from each other, and hindered from running together into a solid mass. These truths are proved, not only from their causes, but likewise by the appearances which they exhibit in men and other animals

starved to death. For, in such, we commonly observe the breath sharp and fetid, the teeth loose by the dissolving acrimony of the juices, violent pains in the stomach, acute fevers, and even madness. The fresh chyle, prepared, for the most part, from acescent vegetable food, is of a consistence always thinner than that of the blood itself; being received into the circulation, it temperates the putrescent acrimony, dilutes the threatened coagulation, and reduces the whole mass to that moderate degree of saline nature which is congenial to man: and finally, the chyle, but more especially that derived from animal food, and likewise what is formed of farinaceous vegetables, being replenished with gelatinous lymph, serves to repair the consumption or waste which is made from the body itself, to the vacancies of whose broken solids it is applied by the causes which promote the growth of the body. The drink dilutes the cohesive diathesis of the blood, hinders its putrefaction, and carries off by the excretories such particles as are already putrid: and hence it is that a person may live for a long time without solid food, if he is supplied with drink; but, without drink, life subsists but a few days.

We are solicited to take food, as well from the pain of hunger, as from the pleasure received by the taste. The first of these proceeds doubtless from the folds or plicæ of the stomach, whose sensation is extremely acute, rubbing against each other by the peristaltic motion, and from a pressure of the diaphragm and abdominal muscles, by which the naked villi of the nerves on each side of the stomach are made to grate against those of the other, producing, at the same time, an intolerable sense of pain. Thus, we are effectually admonished of the dangers ensuing from too long abstinence or fasting, and excited to procure food or nourishment by labour and industry. The gastric liquor, becoming acid from fasting, may also perhaps conduce to excite the sense of hunger; but it will not produce any effect if it is putrescent. *Thirst* is perceived by the tongue, fauces, œsophagus, and stomach. For, whenever these very sensible parts, which are constantly and naturally moistened by mucous and salivary juices, grow dry from a deficiency of these humours, or are irritated by a redundancy of muriatic or alkalescent salts, a sense called *thirst*, which is much more intolerable and dangerous than the former, arises; this disagreeable sensation continues until the proportion of diluting water in the blood, being recruited, restores the necessary moisture and free secretion required in the parts before-mentioned. From hence we learn why thirst attends labour, which exhales a greater proportion of the watery perspiration; and why it is a symptom of fevers, where there is an obstruction of the exhaling vessels belonging to the tongue and fauces; and why simple water is less efficacious in abating thirst than acid liquors, that not only moisten and render fluid, but also, by their mild irritation of the tongue and mouth, provoke forward the humours, and at the same time correct their putrid tendency.

Although there are many instances of particular persons, and even of whole nations, who have supported life only with one kind of food, either vegetable or animal, or even from a small class of either of them; and, lastly, though some have lived altogether upon milk, or its whey; yet it seems to be necessary, both from the nature and fabric of the human body itself, as well as from certain experiments, that we ought to support life by the different kinds of food, so intermixed, that none of them may exceed their reasonable bounds; and this mediocrity we are taught from the loathing which follows any one kind of food continued for too long a time together. Animal food appears a necessary part of our nourishment, from the necessary vigour which we require. It alone contains the gelatinous lymph ready prepared for the recruit both of our fluids and solids; and this lymph, extracted from the broken vessels and fibres, easily passes in great abundance into the blood. An abstinence from animal food generally causes great weakness both to the body and stomach, being per-

petually attended with a troublesome diarrhœa. The use of vegetables is likewise extremely necessary in order to prevent a too great quantity of blood, and to hinder its putrescency. Too much animal food produces, as we see more particularly in Anthropophagi, the hot alkalescent scurvy, a fierce or savage temper, a peculiar fetor, and leprosy, with a lixivial corruption of all the juices; which are only to be cured by change of diet, in which a vegetable acidity abounds. Hence it is that we are furnished but with few canine teeth; and that our appetite in health, but more especially in disease, is stronger for acidulous vegetables, in proportion to our warmer temperature of body, and greater heat of the country, or the season of the year. Hence we see, that, in the hottest climates, people live either altogether upon vegetables, or use flesh meats but very rarely, and not without danger of acute diseases; while, in the colder countries, flesh is eaten freely with less danger; and hence bread, or a farinaceous aliment similar to it, is made a standing part of our food throughout the world.

The measure of our food is determined by hunger, which is different in different circumstances. Animal and farinaceous food nourishes most: other aliments ought to supply, by their quantity, what they want in their powers of nourishment. In general, we are nourished best by a somewhat spare diet, unless we are subjected to much labour. During digestion, the stomach is perfectly closed, both at its superior and inferior orifices; and, although the muscular fibres of the stomach contract, yet no food is propelled into the intestines, until it has been thoroughly digested; even milk itself is often retained in the stomach of strong animals several hours after a meal, without passing into the intestines. The aliments, either naturally containing air in themselves, or mixed with air in mastication, are macerated in the juices of the stomach. In consequence of the heat, this included air is expanded, and, by an operation somewhat similar to fermentation, breaks the cells in which it was included, and thus the contents of the stomach are reduced to a pulpy state. The solidity of animal substances is occasioned solely by their being impregnated with air, and the air being extricated or set free in the stomach, these substances are reducible to a friable or soluble state. This last fact is illustrated by Papin's digester. This air, set at liberty by the digestion, often, under the denomination of flatus, distends the stomach more than the food itself. During digestion there is no sense of hunger, for the nervous plicæ of the stomach are kept from grating on each other by the interposition of the food; and they are not affected by the gastric juice, which, in digestion, acts on the aliment.

Dr. Stevens, in an Inaugural Dissertation concerning Digestion, has published several experiments upon a German, who gained a miserable livelihood by swallowing stones for the amusement of the people. He began this strange practice at the age of seven, and had at that time continued in it about twenty years. He swallowed six or eight stones at a time, some of them as large as a pigeon's egg, and passed them in the natural way. Dr. Stevens thought this poor man would be an excellent subject for ascertaining the solvent power of the gastric juice in the human stomach. The doctor, accordingly, made use of him for this purpose. He made the German swallow a hollow silver sphere, divided into two cavities by a partition, and perforated with a great number of holes, capable of admitting an ordinary needle. Into one of these cavities he put four scruples and a half of raw beef, and into the other five scruples of raw bleak. In twenty-one hours the sphere was voided, when the beef had lost a scruple and a half, and the fish two scruples. A few days afterwards, this German swallowed the same sphere, which contained, in one cavity, four scruples and four grains of raw, and, in the other, four scruples and eight grains of boiled beef. The sphere was returned in forty-three hours: the raw flesh had lost one scruple and two grains, and the boiled one scruple and sixteen grains. Suspecting that, if these

these substances were divided, the solvent would have a freer access to them, and more of them would be dissolved. Dr. Stevens procured another sphere, with holes large enough to receive a crow's quill. He inclosed some beef in it a little nasticated. In thirty-eight hours after it was swallowed, it was voided quite empty. Perceiving how readily the chewed meat was dissolved, he tried whether it would dissolve equally soon without being chewed. With this view, he put a scruple and eight grains of pork into one cavity, and the same quantity of cheese into the other. The sphere was retained in the German's stomach and intestines forty-three hours; at the end of which time, not the smallest quantity of pork or cheese was to be found in the sphere. He next swallowed the same sphere, which contained, in one partition, some roasted turkey, and some boiled salt herring in the other. The sphere was voided in forty-six hours; but no part of the turkey or herring appeared, for both had been completely dissolved. Having discovered that animal substances, though inclosed in tubes, were easily dissolved by the gastric juice, the doctor tried whether it would produce the same effect upon vegetables. He therefore inclosed an equal quantity of raw parsnep and potatoe in a sphere. After continuing forty-eight hours in the alimentary canal, not a vestige of either remained. Pieces of apple and turnip, both raw and boiled, were dissolved in thirty-six hours.

It is a comfortable circumstance, that no animal, perhaps, except those worms which are hatched in the human intestines, can resist the dissolving power of the gastric juice. Dr. Stevens inclosed live leeches, and earth-worms, in different spheres, and made the German swallow them. When the spheres were discharged, the animals were not only deprived of life, but completely dissolved by the operation of this powerful menstruum. Hence, if any live reptile should chance to be swallowed, we have no reason to apprehend any danger from such an accident. And as the gastric juice of the human stomach is capable of dissolving, nearly with equal ease, both animal and vegetable food, this circumstance affords a strong and almost an irresistible proof, that nature originally intended man to feed promiscuously on both.

Live animals, as long as the vital principle remains in them, are not affected by the solvent powers of the stomach. "Hence it is," Mr. Hunter remarks, "that we find animals of various kinds living in the stomach, or even hatched and bred there; but the moment that any of these lose the living principle, they become subject to the digestive powers of the stomach. If it were possible, for example, for a man's hand to be introduced into the stomach of a living animal, and kept there for some considerable time, it would be found that the dissolvent powers of the stomach could have no effect upon it: but, if the same hand were separated from the body, and introduced into the same stomach, we should then find, that the stomach would immediately act upon it. Indeed, if this were not the case, we should find that the stomach itself ought to have been made of indigestible materials; for, if the living principle was not capable of preserving animal substances from undergoing that process, the stomach itself would be digested. But we find, on the contrary, that the stomach, which at one instant, that is, while possessed of the living principle, was capable of resisting the digestive powers which it contained, the next moment, viz. when deprived of the living principle, is itself capable of being digested, either by the digestive powers of other stomachs, or by the remains of that power which it had of digesting other things."

The fleshy fibres of the stomach being irritated by the flatus, the weight, and the acrimony, of the food, begin to contract themselves more powerfully than when the stomach is empty, and with a greater force in proportion as it is more full. And, first, the muscular stratum, which passes along the lesser curvature, draws the pylorus to the œsophagus; and, being inserted only into the left face of the former, draws it to the right. The principal stratum

of the circular fibres contracts the capacity of the stomach according to its length; grinds or intermixes its contents with the liquors; and determines them both, like the pressure of two hands placed opposite, to flow towards the pylorus: but this flux through the pylorus is not continual, on account of the valvula pylori, and likewise because this motion begins from some part that is more irritated, and, as we see by numerous experiments, part of it is very soon received into the blood. These alternate contractions at last terminate in a full evacuation. In this action of the stomach, there is nothing which resembles the trituration made by the strong gizzards of granivorous fowls, which some anatomists have falsely ascribed to the human stomach. The stomach, however, has a considerable degree of strength, since the contraction of its fibres is often more than a third part of their length; for we frequently see the stomach reduced to less than a third part of its diameter. The stomach is also frequently observed to be diminished to much less than its third part, even to the breadth of an inch, so that it can expel the smallest substances, and entirely evacuate itself.

The stomach being irritated by too great a quantity or acrimony of the food, by sickness, by a repulsion of the bile, or other causes, does, by an antiperistaltic or reverted motion of its fibres, drive its contents upwards through the open and relaxed œsophagus. Any part of the whole intestinal canal, from the pharynx to the rectum, may be constricted, either suddenly or slowly, by an antiperistaltic motion. If it happens suddenly to the upper parts of the stomach, the diaphragm, and likewise the abdominal muscles, being convulsed at the same time, it is called *vomiting*; if it is slowly performed, it may be called *rumination*; if the small, and particularly the great, intestines, return their contents upwards, the disease is called *ileus*. The effect of vomiting is partly from the pressure of the abdominal muscles depressing the false ribs, and urging the contents of the abdomen against the diaphragm, which, at the same time, contracting itself to a plane downwards, forces the stomach, as between the sides of a press, to throw up its contents.

The peristaltic motion, which is more particularly strong and evident in the small intestines, is the chief power by which the digested aliments are propelled along the intestinal tube. Any part of the intestine, irritated by flatus or any sharp or rough body, contracts itself, even after death, most violently in that part where the stimulus is applied, in order to free itself from the offending or distending body, which it expels into the next open part of the lax intestine; where, being received, it is again propelled forward, by exciting a like stimulus and contraction as before. This contracting motion of the intestines is made in various parts of the gut, either successively or at the same time, wherever the flatus or aliment excites a stimulus, without observing any certain order. So well fitted, however, are the intestines for this motion, that they even exceed the irritability of the heart. When they are not irritated, they remain at rest; and we may suppose this to be the cause why the fat is deposited in the abdomen. The principal stimulus is the air; next to that is the aliment; and lastly, the bile. This motion is performed by a sort of alternate creeping and revolution of the intestines, which dissection easily demonstrates in brute animals, and cases of wounds in the abdomen and ruptures have manifested it in the human species. Among so many inflexions, the weight of the aliment is but of little consequence, for it easily ascends or descends through the irritated intestine, which thus empties itself. This peristaltic motion of the intestines is performed by the constriction of their circular fibres, which empty the tube exactly, without injuring it against pins, needles, or any other sharp bodies accidentally introduced into it.

OF THE LIVER, &c.

The liver is a large and solid mass, of a dark red colour, a little inclined to yellow; situated immediately under the arch

arch of the diaphragm, partly in the right hypochondrium, which it fills almost entirely, and partly in the epigastrium, between the appendix ensiformis and spina dorsi, and terminating commonly in the left hypochondrium, into which it sometimes runs a considerable way. The liver may be divided into two lateral parts, called *lobes*; one of which is termed the *great or right lobe*, the other the *small or left lobe*. These two lobes are distinguished above by a membranous ligament, and below by a considerable scissure, lying in the same direction with the superior ligament.

The liver is composed of several kinds of vessels; the ramifications of which are multiplied in an astonishing manner, and form, by the intertexture of their capillary extremities, an innumerable collection of small pulpy friable corpuscles, which are looked upon to be so many organs designed to separate from the mass of blood a particular fluid, termed the *bile*. In these corpuscles the bile is secreted, and it is immediately collected in the same number of extremities of another kind of vessels, which unite by numerous ramifications, into one common trunk. These ramifications are termed *pori biliarii*, and the trunk *ductus hepaticus*; and the ramifications of these two kind of vessels are invested together by the capsula of the vena portæ. The ductus hepaticus, or trunk of the pori biliarii, joins another canal, called *ductus cysticus or vesicularis*; because it comes from the vesicula fellea: these two united ducts form a common trunk, named *ductus cholidochus*, because it conveys the bile. This duct, having reached the incurvation of the duodenum, insinuates itself through the coats of that intestine, and opens into its cavity by an oblong orifice rounded at the upper part, and contracted at the lower like the spout of an ewer.

The *gall-bladder* is a kind of small bag, shaped like a pear, narrow at one end and wide at the other. About one third of the body of this vesicula lies in a depression on the concave side of the liver, from the trunk or sinus of the vena portæ, where the neck is situated, to the anterior edge of the great lobe, a little toward the right side, where the bottom is placed; and in some subjects it advances beyond the edge, so as to oppose itself to the muscles of the abdomen, under the edges of the false ribs. Therefore when we stand, it lies in a plane inclined a little from behind forward. When we lie upon the back, it is almost inverted. When we lie on the right side, the bottom is turned downward, and it is turned upward when we lie on the left side; and these situations vary according to the different degrees of each posture. The gall-bladder is composed of several coats, the outermost of which is a continuation of that which invests the liver, and consequently of the peritonæum. The bile, which passes thro' the ductus hepaticus into the cholidochus, may be called *hepatic*; and that which is collected in the gall-bladder may be termed *cystic*. The hepatic bile flows continually through the ductus cholidochus into the duodenum; whereas the cystic bile flows only by reason of plenitude, or by compression.

The *pancreas* is a long flat conglomerate gland, situated under the stomach, between the liver and the spleen. It is composed of a great number of soft glandular molecule, combined in such a manner as to exhibit the appearance of one uniform mass on the outside, the surface of which is rendered uneven only by the numerous small convexities, more or less flattened. When these molecule are separated a little from each other, we find the pancreatic duct, which pierces the coats of the duodenum, and opens into the ductus cholidochus, commonly a little above the prominent point of the orifice of that canal; and sometimes it opens immediately into the duodenum.

The pancreatic juice seems principally of use to dilute the gall, to mitigate its acrimony, and mix it with the food. Hence it is poured into a place remote from the cystic duct as often as there is no cystis. Like the rest of the intestinal humours, this juice dilutes the mass of aliments, resolves them, and does every other office of the saliva.

The *spleen* is a bluish mass, something inclined to red, and of a long oval figure, being about seven or eight fingers breadth in length, and four or five in breadth. It is of a softish substance, and is situated in the left hypochondrium, between the great extremity of the stomach and the neighbouring false ribs, under the edge of the diaphragm, and above the left kidney. It is connected to the stomach by the vessels called *vasa brevia*; to the extremity of the pancreas, by ramifications of the splenic arteries and veins; and to the omentum, by ramifications which the same artery and vein send to the spleen. In man, the substance of the spleen is almost wholly vascular, that is, composed of the ramifications of all kinds of vessels. Being of a very soft and loose texture, it grows larger by distension when the stomach is empty, and becomes less again when it is pressed by the full stomach against the ribs. Hence the spleen is found large in those who die of lingering diseases; but in those who die suddenly, and in full health, it is small. The spleen seems to prepare the blood for supplying a sort of watery juice (probably of a sub-alkaline nature, and rendered somewhat sharp by the remora of the blood) to the bile. As to the old question, Whether the spleen prepares an acid to whet or sharpen the stomach; that opinion has been long discarded, as repugnant to the nature of all the animal juices.

The *omentum* is a large, thin, and fine, membranous bag, surrounded on all sides by numerous portions of fat, which accompany and even invest the same number of arteries and veins adhering closely to each other. The greatest part of it resembles a kind of flat purse, and is spread more or less on all the small intestines from the stomach to the lower part of the regio umbilicalis. Sometimes it goes down to the lower part of the hypogastrium, and sometimes does not reach beyond the regio epigastrica. It is commonly plaited or folded in several places, especially between the bands of fat.

The *kidneys* are two solid glandular bodies, situated in the posterior part of the cavity of the abdomen, on each side of the lumbar vertebrae, between the last false ribs and os ilium. The right kidney lies under the great lobe of the liver, and is consequently lower than the left, which lies under the spleen. We may distinguish three kinds of substances in the kidney; an exterior substance, which is thick, granulated, and in a manner cortical; a middle substance, which is medullary and radiated, called *striata, sulcata, or tubularis*, because it seems to be made up of radiated tubes; and an inner substance, which is only a continuation of the second, and terminates on the inside by papillæ; for which reason it goes under the name of *papillaris*. Each papilla lies in a kind of membranous calix or infundibulum, which opens into a common cavity, called the *pelvis*. This pelvis is membranous, being of the same structure with the calices, of which it is a continuation; and its cavity in man is not uniform, but distinguished into three portions, each of which contains a certain number of infundibula or calices, together with the papillæ which lie therein; and sometimes we find two or three papillæ in the same infundibulum.

After the infundibula have contracted in a conical form round the apices of the papillæ, each of them forms a small short tube or gullet, which, uniting at different distances along the bottom of the sinus of the kidney, form three large tubes which go out from the sinus, in an oblique direction from above downwards, and immediately afterwards unite into one trunk. This trunk becomes a very long canal, called the *ureter*. In men, the three tubes supply the place of what is called the *pelvis* in brutes, and might more properly be called the *roots or branches* of the ureters than the pelvis. The situation of the trunk, and of the roots and branches of each ureter, with respect to the renal artery and vein, is in the following manner: The artery is in the upper part of the sinus, and partly before the vein. The vein is about the middle, and between the

the artery and ureter. The ureter is in the lower part, a little behind the vein, and it is partly surrounded by one branch of the artery.

The *renal glands* are situated on the upper extremity of each kidney a little obliquely. They contain an unctuous viscid liquor, of a yellowish red colour, which, with age, changes gradually into a yellowish purple, a dark yellow, and a black yellow: sometimes it is perfectly black; but even then, if it be spread thin on a large surface, it appears yellow. It is sometimes found not only reddish, but mixed with real blood. The uses of these renal glands have not as yet been discovered; and all that we know about the liquor contained in them is, that it has somewhat the appearance of the bile. They are very large in the fœtus, and diminish in adults. These two phenomena well deserve our attention. They lie sometimes directly on the top of the kidneys, but seldom, if ever, on the gibbous part.

The Anatomical Plate V. affords a pretty accurate View of the Brain and different Viscera, as follows, viz.

Fig. 1. represents the *basis of the BRAIN.* *aa*, The anterior lobes of the brain. *bb*, The posterior lobes. *cc*, The cerebellum. *dd*, The lateral sinuses. *ee*, The vertebral arteries, as they pass between the first vertebra and the bones of the occiput. *f*, The vertebral sinus. *gg*, The dura mater. *h*, The foremost branch of the carotid artery.

The *TRUNK.* *1*, Trachea. *2*, The internal jugular vein. *3*, The subclavian vein. *4*, Vena cava descendens. *5*, Right auricle of the heart. *6*, The right ventricle, the pericardium being removed. *7*, Part of the left ventricle. *8*, Aorta ascendens. *9*, Arteria pulmonalis. *10*, Right lobe of the lungs. *11*, The left lobe. *12*, The diaphragm. *13*, The liver. *14*, The ligamentum rotundum. *15*, The bottom of the gall-bladder. *16*, The stomach, pressed down by the liver. *17*, The small intestines. *18*, The spleen.

Fig. 2. represents the *PERFECTED BRAIN.* *aa*, The anterior lobes of the cerebrum. *bb*, The lateral lobes of the cerebrum. *cc*, The two lobes of the cerebellum. *d*, Tuber annulare. *e*, Passage to the infundibulum. *f*, Medulla oblongata, which sends off the medulla spinalis thro' the spine. *gg*, That part of the os occipitis which is placed above. *hh*, The transverse processes of the first cervical vertebra. *ii*, The cervical vertebrae.

TRUNK. *1*, The gall-bladder. *2*, The pancreas. *3*, The spleen. *4*, *4*, The kidneys. *5*, Aorta descendens. *6*, Vena cava ascendens. *7*, *7*, The emulgent veins. *8*, *8*, The ureters. *9*, *9*, The iliac vessels. *10*, The intestinum rectum. *11*, The bladder of urine.

OF THE PELVIS.

The pelvis is bounded forward by the os pubis; backward by the os sacrum above, and coccygis below; laterally by the ilia above, and ischia below. In midwifery, a complete knowledge of these parts is a circumstance of considerable importance.

VESICA URINARIA, or BLADDER.—The bladder is a kind of membranous and fleshy pouch or bottle, capable of dilation and contraction, situated in the lower part of the abdomen immediately behind the symphysis of the ossa pubis, and opposite to the beginning of the intestinum rectum. It is divided into the body, neck, and bottom; into an anterior, posterior, and two lateral parts. The upper part is termed the *fundus* or *bottom*; and the neck is a portion of the lower part. Round the neck of the bladder the muscular fibres being closely connected, form what has been called *sphincter vesicae*. But this part is not a distinct muscle, nor is its action distinct from the rest of the muscular coat. At the top of the bladder above the symphysis of the ossa pubis, we observe a ligamentary rope, which runs up between the peritonæum and the linea alba of the abdomen, all the way to the navel, diminishing gradually in thickness as it ascends. This rope in the fœtus is in part a production of the inner coats of the bladder, which production is termed *urachus*.

The kidneys and bladder serve for the secretion of the

urine, which is effected in the following manner: The chyle, when it enters the blood, contains a very large portion of water, which would be liable to lodge in the cellular substance, if it was not expelled again from the body. A part of it is therefore exhaled through the skin; and another part, as large, or often larger than the former, is strained through the kidneys into the bladder, and is thus expelled out of the body.

Dr. Haller observed, "that the blood of the renal artery moving slower, as is generally believed, than that of the brain, and probably stored with more water, brought by the serpentine circles of the arteries, deposits great part of its water into the rectilinear tubes of the papillae. This water contains fine oils and salts, intermixed with earthy particles, or such other matters as are thin enough to pass through with it. The small diameter of the origin of each uriniferous duct, and its firm resistance, seems to exclude the thick oil, chyle, and the coagulable lymph; but, as these uriniferous ducts are always open, if the velocity of the blood be increased, or a morbid laxity of the parts supervenes, they easily transmit the above-mentioned thick parts of the blood along with the thinner. The disease hence arising, is called diabetes, which may be cured by restoring the kidneys to their former healthy state, by the use of astringents and tonics. The nerves have some power of contracting or relaxing these passages; and thus we see that urine, which in health is of a yellow colour, becomes watery from sudden grief. A vast quantity of it is prepared; equal to that of perspiration, and sometimes even more." Later physiologists explain the secretion of urine by observing, that part of the blood is changed by the kidneys into this fluid.

The urine, by fire or putrefaction, sometimes by disease, in some animals more easily than in others, changes into a volatile alkaline nature, intimately mixed with a fetid oil. This oil which is partly empyreumatic, yellow, volatile, tenacious, separable only by the greatest degrees of fire, is known by the denomination of phosphorus; it is a shining substance, taking fire spontaneously in the air. The urine abounds more with earth than any other juice of the human body, both of a cretaceous and sparry nature; the latter coming chiefly from the drink, the former from the solid parts of the body dissolved and mixed with the blood. That the urine is separated in the kidneys is shewn experimentally, by pressing it out of their vessels. That it descends by the ureters is shewn by the surprising swelling of the kidney, and that part of the ureter which is above, as well as the emptiness of that part which is below the ligature. In the bladder also, as well as in the kidneys and ureters, there is an immense swelling as often as the bladder cannot receive the urine, or cannot emit it. Nor does there seem to be any other way for the urine to pass. The bladder may be so distended with urine as to produce death; yet, in these cases, we never observe that the urine has found any passage through which it might escape into the pelvis. Again, when the ureters are obstructed with stones, so that the bladder receives nothing from them, it is either quite empty, or contains a very acrimonious and thick urine, manifestly indicating that the water can find no other way from the kidney into the bladder. And a careful attention to the manner in which mineral waters are discharged by urine, sufficiently demonstrates that there is no such rapidity therein as is commonly imagined; but the stimulus of the cold water received into the stomach, like the external cold applied to the skin, causes a constriction of the bladder and urinary parts, by which they are solicited to repeated discharges of the old urine which was before in the body, and not immediately of that which was last drunk. Again, the largeness of the renal vessels demonstrates, that they cannot receive much less than an eighth part of the blood of the whole body at a time, and consequently above 1000 ounces of blood are conveyed through the kidneys in an hour; and it will appear but a moderate allowance for twenty or even fifty ounces of water to distil from that quantity of blood in the same time.

Finally, it is certain that both men and brute animals perish if the ureters are obstructed by a ligature, or otherwise; we then observe also that no urine can be found in the bladder. We are not fully acquainted with the cause which retains the urine in the bladder. The sphincter is obscure; the situation of the bladder lying on the rectum may probably contribute to the retention of the urine. Certain it is that the urine does not flow spontaneously, even from a dead carcase.

By the urine, besides the particles of food and water, much matter that is noxious to the human body seems to pass off, especially calcareous earth reformed from the bones and solid parts, and which would not fail to produce bony crusts and calculi wherever it was stopped; a sparry or gypseous earth; and an acrid oil mixed with salt, so as to assume a volatile nature. The urine, by its retention, disposes to the generation of the stone and gout; when suppressed, it produces acute fevers, and several morbid affections of the brain.

THE PARTS OF GENERATION IN MALES.—The parts of generation in males consist of the spermatic veins and arteries; the testes, epididymis, and scrotum; the vasa deferentia, vesiculæ seminales, and prostates; the corpora cavernosa, urethra, integuments, &c. The *scrotum* is the cutaneous covering of the testes. Outwardly, it is a bag common to both, formed by a continuation of the skin of the neighbouring parts, and commonly very uneven, having a great number of rugæ on its outer surface. Interiorly, it is fleshy, and forms a muscular capsula for each testicle, termed *dartos*. Though it is a common covering for both testicles, it is nevertheless distinguished into two lateral parts by a superficial and uneven prominent line, which appears like a kind of suture, and from thence has been termed *raphe*. This line is a continuation of that which divides, in the same manner, the cutaneous covering of the penis; and it is continued through the perineum, which it divides likewise all the way to the anus. It is only superficial, and does not appear on the inside of the skin.

The *dartos* of the scrotum has been accounted a true cutaneous muscle; but it is chiefly a cellular substance condensed, with a great number of blood-vessels entering into its composition, but without fat. The particular coverings of the testes are commonly called *coats*; and they are reckoned to be three in number, the *tunica musculo-fasciata*, named *cremaster*, *vaginalis*, and *albuginea*. The first two are common to each testicle, and to the spermatic rope that belongs to it; and the third is peculiar to the testicle alone. The testes are two glandular bodies, situated near each other, without the abdomen, below the interstice between the groins in an adult. The ancients named them *adyami* or *gemini*. Their size is nearly that of a pigeon's egg, and they are of an oval figure, a little flattened at each side. But they are frequently unequal in size in the same person. Fabricius ab Aquapendente, was consulted frequently by persons who believed they had got a diseased testicle, because it was larger than the other one; but, upon examination, it was found they had no inconvenience from it. Each testicle is a spermatic gland formed by a vast number of fine whitish tubes, folded and twisted in different manners, and distributed in different fasciculi, between membranous septa; the whole being surrounded by a strong common covering, named *tunica albuginea*.

The seminal vessels are serpentine, firm, solid, and exceedingly small; they have been filled with quicksilver, &c. by several anatomists, but first by Dr. Monro, Hunter, and Haller. They are collected into above twenty bundles, divided by distinct cells or partitions, which descend from the *tunica albuginea* to conduct the arteries or veins. In each of these cells there is a seminiferous duct to convey the secreted humour from the testicle. The ducts form a net-work, adhering to the surface of the *albuginea*, and forming inosculations one with another. From this net-work, in the upper part of the testicle, ten or twelve ducts ascend; which, being contorted together

into folds, form as many vascular cones, that are joined together by an intermediate cellular substance; and, lying incumbent one upon another, they form the *epididymis*, which goes round the outer and posterior margin of the testicle, to which it adheres by its thicker head, joined with a good deal of cellular substance. While in its lower, middle, and more slender, part, it partly adheres, and is partly free; so as to intercept a sort of impervious bag between itself and the testicle. The vascular cones, at the upper part of the epididymis, by degrees uniting, form at length one duct, which composes the greater part of the testicle, and which grows larger as it descends, being largest at the bottom of the testicle; from whence again ascending along the posterior face of the testicle, in a contrary direction, it by degrees spreads open its spiral convolutions, and comes out much larger, under the name of *vas deferens*.

The spermatic arteries go out most commonly from the anterior part of the inferior aorta, near each other, and about an inch lower than the arteriæ renales. Their origin oftentimes varies: sometimes there are two on each side, one arising a little below the other; or at other times one comes from the aorta, the other from the renal artery on the same side; and here they give off branches to the *cremaster muscle*, &c.

The spermatic veins accompany the arteries, and have nearly the same course. The right vein ends commonly in the trunk of the vena cava, and sometimes it ends in the union of the right renal vein. After getting into the abdomen, they receive a branch which communicates with the vena porta.

The *vesiculæ seminales* are soft whitish knotted bodies, about three or four fingers breadth in length, one in breadth, and about three times as broad as thick, situated obliquely between the rectum and lower part of the bladder, in such a manner, as that their superior extremities are at a distance from each other, and their lower extremities are contiguous. Their inner surface is villous and glandular, and something similar to the inner surface of the gall-bladder, or like the cells of a honeycomb. This furnishes a particular fluid, which exalts, refines, and perfects, the semen that the *vesiculæ* receive from the *vasa deferentia*, and of which they are the reservoirs for a certain time.

The first portion of the urethra, or that which is not covered by the cavernous substance, and which, from the bladder to the bulb, is only a membranous canal, is sustained by a large solid whitish mass, of the figure of a chestnut, and situated between the bladder and the bulb of the urethra; its basis being towards the bladder, the apex or point towards the urethra, and the sides lying upward and downward. This body is termed the *prostate*, from a Greek word that expresses its situation before the *vesiculæ seminales*, and implies a plurality, because it appears to be divided into two lateral lobes by a hollow groove, which runs through its upper side from the basis to the apex. The inner substance is spongy, but very compact; and in each lobe there are several folliculi, which open into the first portion of the urethra. The spongy substance of the urethra, having reached the extremity of the *corpora cavernosa*, forms a large head called the *glans*, which crowns the three spongy pillars; with this difference, however, that it is a continuation of the spongy substance of the urethra, and only adheres to the extremity of the *corpora cavernosa*, without any direct communication. The figure of the *glans* is that of a rounded cone, a little flattened at the lower part, and with an oblique prominent basis, the circumference of which is something greater than that of the *corpora cavernosa*. All the convex surface of the *glans* is covered by a fine villous substance, and that again by a fine membrane, resembling the red part of the lips. The circumference of the basis of the *glans* has a double row of small papillæ, which may be reckoned sebaceous glands, from which a thick matter is discharged.

The *corpora cavernosa* are two ligamentary and very
2 limber

limber tubes, united laterally to each other through the greatest part of their length, and solid at their two extremities. By their union two external grooves are formed; one on the upper side, the other on the lower. The lower groove is something broader than the upper; and it is filled through its whole length by the *urethra*, which is the third spongy tube that composes the penis. It descends from its origin to the under end of the symphysis pubis; then it ascends before the symphysis to the root of the penis; and at last re-descends to the point of the glans. About a finger's breadth from this part it joins a cavernous substance, in shape like a pear, which is connected only to the lower convex side of the canal; and, afterwards being split on each side, invests it quite round. This body is called the *bulb* of the urethra, being larger than any other part of that canal, and divided interiorly by a very fine membranous septum into two lateral parts; and therefore, when it is inflated, it appears to be double, or with two heads. The inside of the canal of the urethra is lined by a fine membrane, full of capillary blood-vessels; and its surface is perforated by a great number of oblong holes, or small lacunæ of different sizes, the largest lying near the glans. The cavity of the urethra resembles nearly that of a small writing pen. It is not every where round, and towards the glans becomes broader and flatter on each side, especially in the glans itself, where there is a kind of oval or navicular fossula. The integuments which cover all these parts are three or four in number. The principal is named *preputium*; the inner surface of which is lined with a fine membrane from the opening all the way behind the basis of the glans, that membrane being folded from behind, forward, round the glans, covering very closely its whole villous surface, as far as the orifice of the urethra, where it joins the membrane which lines the inside of that canal. This proper membrane of the glans, and internal membrane of the preputium, form conjointly along the flat part of the glans, from its basis to the orifice of the urethra, a membranous duplicature, which, like a septum or mediastinum, divides this part into two lateral portions, and limits the motions of the preputium; for which reason it is called *frænum preputii*.

Several muscles are inserted in the parts which we have just described. They are six in number; two for the corpora cavernosa, two for the urethra, and two common muscles, called *transversales*. The arteries of these parts come chiefly from the *iliacæ internæ* or *hypogastricæ*, and the rest from the *iliacæ externæ* or *crurales*. The principal are termed *pudicæ*, of which one is external, the other internal. The distribution of the veins follows nearly that of the arteries; but they have more ramifications and communications, as in other places. The principal vein is that which runs along the whole superior groove formed by the union of the corpora cavernosa. It passes directly under the symphysis of the ossa pubis, between the two arteries. It is very large, and often double. The nerves of these organs come from the *lumbares* and *sacri*; and they communicate with the *sympatheticus maximus*, and *plexus mesenterici*. The nerves of the testicles are very small. They are formed by the renal and mesenteric plexus. They run along the spermatic cord; but it is exceedingly difficult to trace them into the testicle.

The semen masculinum is first formed in the testicle, and then conveyed by the *vasa deferentia* into the vesiculæ seminales, being propelled forward by the motion of the succeeding juices in the testicle; and perhaps, in some measure, though slowly, by the contraction of the cremaster. This supposition is confirmed by the numerous spires and convolutions formed by the epididymis, obstructing almost every kind of injection; and by the length of time that is required to fill the seminal vesicles again, after they have been once exhausted. The liquor brought from the testicles by the *vasa deferentia*, is yellowish, thin, and watery; but in the vesicula seminales it becomes somewhat thicker and higher coloured. It is white in man when it has been mixed with the liquor of the prostate. It has a

peculiar smell in each class of animals; and it is the heaviest humour in the human body. In water a part separates into a kind of cuticle, like a cobweb, that swims in the liquid; the greater part, which is seemingly of a pulpy nature, falls to the bottom. In the semen which is long retained by chaste people, shining globules mixed with the white liquor are easily to be seen. It has a very great quantity of mucus. That the semen is produced from the lymph of the blood, and that the chyle is added to the lymph, will appear probable from the sudden alacrity to venery that happens after eating, and which is lessened by fasting. It is compounded of the liquor of the testicles and seminal vessels, the former indeed being more evident in some animals, and the coagulable milk of the prostate gland. That liquor, however, only secundates, which is generated in the testicles, as we see in eunuchs, who, tho' they have the seminal vessels and prostate, are yet barren. The seminal fluid is retained in the vesicles as long as a man neither exercises venery, nor sports in imaginary dreams. It is always a stimulus to the animal appetite, as long as it is there present in any quantity. Besides this, there is a considerable strong, volatile, and odorous, part, of the semen re-absorbed into the blood, where it produces wonderful changes as soon as it begins to be formed; such as the protrusion of the beard, the covering of pubes, a change of the voice and passions, horns in cattle, &c. for these changes in the animal are not the consequences of age, but of the seminal fluid, and are always absent in eunuchs. The courage and vigour of castrated animals are constantly diminished; and, in like manner, the fierceness of their temper, and the strong smell of their whole body, are remarkably weakened. And, from the example of some animals, and even of mankind, it appears that the irritation of this fluid has occasioned death, by exciting convulsions. A retention of the semen may follow from a narrowness of the excretory duct, a schirrhosity of the prostate, and other causes not sufficiently known.

The quantity of semen expelled at one time from the human vesicles is but small, more especially in a man who has not long abstained from venery; and it is natural to think that the liquor can be but slowly produced from so small an artery. Its generation is accelerated by love, by the presence of the beloved woman; so that it defends the vessels with a sense of pain. Nature herself, therefore, enjoins venery, both for preserving the human race, and the health of every individual. That it comes from the testicle, is shewn by diseases; in which, the *vas deferens* being obstructed, a swelling of the testicle has ensued. The vesicles are never emptied, except by venereal actions and appetites. In order that the semen, which is only in a small quantity, should be projected with a considerable force, it is previously mixed with another fluid from the prostate. This gland prepares a thick, white, soft, cream-like, liquor, in large quantity, which is poured out at the same time, and from the same causes, with the semen itself, into a little channel at each side of the openings of the seminal vesicles, where, mixing with the seminal fluid, it imparts the white colour and viscosity which the semen possesses.

It was necessary for the canal of the urethra to be firm and capable of a direct figure, that it might be able to throw out the semen with sufficient vigour; and therefore a threefold cavernous body surrounds it. Into the cavernous body of the urethra, the blood is poured from the arteries, which come from deep branches sent off from the external hæmorrhoidals; the truth of which is demonstrated by the injection of any kind of fluid, which, being urged through the arteries, easily flows into those cellular spaces surrounding the urethra. These cells are not naturally turgid with blood, because there are veins open, and numerous enough in proportion, to receive and return what is poured in by the arteries; but, if the return is impeded by compressing those veins, the blood is then retained within the cellular spaces, while the arteries continue to carry it more swiftly and strongly than the veins

return

return it. Thus the stagnant blood distends the bulb of the urethra, together with its cavernous body, and the glans itself. This distension is generally performed at the same time, when the other cavernous bodies of the penis, with which this of the urethra has no communication, are likewise rigidly distended.

These cavernous bodies of the penis, having their spongy fabric distended in coition by the blood retained by the veins, and still propelled by the arteries, becomes rigidly turgid, and sustain the otherwise flaccid or but weakly filled urethra, in such a manner that it may be able to conduct the semen into the uterus. All this is demonstrated from the dissection of brute animals in the act of venery, from an artificial erection, and from the injection of liquid matters into the vessels of the penis. The causes of this erection are love; the desire of pleasure; the friction of the glans; various irritations of the bladder, testicles, femoral vessels, and urethra, from the urine, from abundance of good feed, from the venereal poison, from cantharides, whipping the parts, and, lastly, from convulsion of the nerves. The proximate cause of this distension remains still to be explained.

In order to distend the penis, there must be either a compression of the vein bringing back the blood from the cavernous bodies of the penis or urethra; or at least it is necessary that there should be a constriction of the smaller veins that every where open within the cavernous bodies, to hinder them from absorbing and returning the blood from the arteries. The first, however, may be effected by the levator, drawing up the prostate and bladder: but it is very probable, that, as we see in the nipples of the breasts, in the loose pendulous gills of the turkey-cock, and in the blushing or redness of the face from passions of the mind, erection may be produced without the immediate interposition of any peculiar muscle. This supposition is confirmed by brute animals, which all couple without the use of any erector muscle; by the erections which take place in animals totally different from man, and especially those which take place in birds very quickly; and by the inactivity of the erector muscles themselves in the libidinous erection of the penis, and from their unsuitableness for compressing the veins. It is also probable, that an erection may be produced by the numerous ramifications of the nerves exciting a convulsive constriction of the veins; while, at the same time, the arteries, by an increased velocity of the blood, bring more blood to the parts than the veins can carry off. The cause of this convulsion is perhaps inherent in these nervous sphincters themselves, and depends either on a mechanical irritation of the nervous fibres, or on the force of the imagination.

A long-continued and violent erection is at last accompanied with an expulsion of the semen; and this requires much greater force than is requisite for the erection only. For the semen is expelled when the irritation of the nerves is arrived at its greatest height: and in natural venery, when, at length, the cellular spaces of the urethra and its continuous glans, which are at last filled, become so far distended with a large quantity of warm blood, that the nervous papillæ, stretched out in the latter, become violently affected from the irritating or pleasing cause. The seminal vesicles are emptied by the levator muscles of the anus, which press them against the resisting bladder with a convulsive motion, excited either by a voluptuous imagination, or by the exquisite sensibility of the nerves of the glans, principally in its lower part, which is in the neighbourhood of the frenum. Hence the semen is never discharged with any of the urine in an healthy man; because the expulsion of it requires the bladder to be closed or drawn up firmly together; for, while lax, it affords little or no resistance to the seminal vesicles. The transverse muscles seem to dilate the canal of the urethra for the reception of the semen expressed from the vesicles. Soon afterwards the powers constricting the urethra are, from the irritation of the very sensible fabric of that canal, put into action. To this constriction conduces principally the

accelerator, which makes a powerful concussion of the bulb and adjacent part of the urethra, so as to propel its contents more swiftly. But that this may act firmly, the sphincter of the anus, together with that of the bladder, must be well shut. The accelerator muscle seems also principally concerned in the erection, by compressing the veins of the corpus cavernosum of the urethra. At the same time the *erectores penis*, as they are called, arising from the tubercles of the ischium, become tense, and are inserted into the cavernous bodies, sustaining the penis as a sort of medium between the transverse and perpendicular direction. Thus the semen is driven into the vagina, in a prolific coition: the whole action of which is very impetuous, and comes near to a convulsion; whence, if too often repeated, it wonderfully weakens the habit, and greatly injures the whole nervous system, as the maladies arising from thence, in consequence of the affection of the nerves, without which the semen cannot be expelled, seem to indicate.

The PARTS of GENERATION in FEMALES.

These are some of them external, and some internal; and they are all of them subordinated to one principal internal part, called the *uterus*, or *womb*. The other internal parts are the tubæ Fallopianæ, ovaria, vasa spermatica, ligamenta lata, the ropes or bands called *ligamenta rotunda*, and the canal of the uterus. The external parts are the pubes, the *alzæ nymphae*, clitoris, orifice of the urethra, and the orifice of the vagina. The uterus lies between the bladder and the intestinum rectum. It is a body inwardly hollow, outwardly of a whitish colour, of a solid substance, and, except in time of pregnancy, of the figure of a flat flask. The broadest portion is termed the *fundus*, and the narrowest the *neck*, which terminates at the extremity by a transverse opening. This opening is termed the *internal orifice of the uterus*; and, in the natural state, is so narrow, that only a small probe can be passed through it. The inner surface of the cavity of the uterus is lined by a very fine membrane, which at the fundus or broad portion is smooth and even; but, in the narrow portion which leads to the orifice, it is wrinkled in a particular manner. The portion of this membrane, which covers the bottom of the cavity, is perforated by a great number of considerable holes, through which small drops of blood may be observed to pass when the whole uterus is compressed; and sometimes it appears to have very small hairs or villi. These villi and holes are observed to be more or less tinged with blood in women who die in the time of their menses.

The uterus is covered by a portion of the peritoneum, which serves it for a coat, and is the continuation of that which covers the bladder and rectum, running up from the lower and posterior part of the bladder, over the anterior part of the uterus, and from thence over the fundus, and down the posterior side, and afterwards going to the rectum. On each lateral part or edge of the uterus this portion of the peritoneum forms a broad duplicature, which is extended on each side, more or less directly to the neighbouring lateral parts of the pelvis, forming what are termed the *broad ligaments*. The laminae of these duplicatures are connected by a cellular substance; and they contain the Fallopian tubes, the ovaria, a part of the spermatic vessels, and of those that go to the body of the uterus, the ropes called the *round ligaments*, the nerves, &c.

The ovaria are two whitish, oval, flat, oblong, bodies, situated on the sides of the fundus uteri, to which they are fixed by a kind of short round ligament. They are composed of a compact spongy substance, and of several little balls, or transparent vesiculae, called *ova*. The Fallopian tubes are two flaccid, conical, and vermiform, canals, situated more or less transversely on each side of the uterus, between the fundus and the lateral parts of the pelvis. Each of them is fixed by its narrow extremities in the corner of the fundus uteri, into which it opens, though by so narrow a duct as hardly to admit a large bristle. From thence their diameter augments by degrees all the way to the other extremity, where it is about one-third part of an

an inch. The body of the tubæ goes in a winding course, and their large extremity is bent towards the ovaria.

The blood-vessels of these parts are of different kinds, viz. the hypogastric arteries and veins, the ramifications of which belong chiefly to the body of the uterus; the spermatic vessels, and the two vascular ropes, called *ligamenta rotunda*, which might be more properly termed the *vascular ropes of the uterus* or of the *ligamenta lata*. The hypogastric branches are arterial and venal ramifications, arising from the artery and vein of the same name; which having reached the lateral edges of the uterus, are distributed to all its parts, both internal and external, forming a great number of incurvations and particular intertextures.

The spermatic vessels have nearly the same origin in females as in males, and likewise the same course and intertextures; but they never pass out of the abdomen, being wholly distributed to the ovaria and tubes; and they communicate with the uterine hypogastrics, and with the vascular ropes of the *ligamenta lata*. The veins are very large in proportion to the arteries, and these vessels send out lateral ramifications which seem to communicate with the *meseraicæ* and *vena portæ*. The vascular ropes, commonly called the *round ligaments*, are two long small fasciculi of arteries, veins, and ligamentous fibres, interwoven and connected together by a fine cellular substance; and they run in the great duplicature of the *ligamenta lata*, from each corner of the fundus uteri, as far as the annular openings of the abdominal muscles.

The pubis is that broad eminence at the lower part of the hypogastrium, between the two inguina, on which the hairs grow at a certain age. This eminence is owing to a particular thickness of the *membrana adiposa* which covers the fore-part of the ossa pubis, and some small portions of the neighbouring muscles. The longitudinal cavity which reaches from the middle and lower part of the pubes, within an inch of the anus, was by the ancients termed *sinus*; and they called the lateral parts of the cavity *alæ*, which is a more proper name than that of *labia*, commonly given to them. The *alæ* are more prominent, and thicker below than above. They are chiefly composed of the skin, cellular substance, and fat. The exterior skin is a continuation of that of the pubes and inguina. It is more or less even, and furnished with a great number of glandular corpuscles, from which a whitish ceruminous matter may be expressed; and after a certain age it is likewise covered in the same manner as the pubes. The inner side of the *alæ* is something like the red portion of the lips of the mouth; and it is distinguished every where from the external side by a kind of line, in the same manner as the red portion of the lips from the rest of the skin, being likewise thinner and smoother than the outward skin. A great number of pores are observable in it, and also numerous glandular corpuscles, which furnish a liquor more or less sebaceous; and these corpuscles are larger near the edges than in the other parts.

Near the inner edge of the inner surface of the *alæ*, on each side of the orifice of the vagina, we find a small hole more visible than the rest. These two holes are termed *lacunæ*, and they communicate by two small ducts with the same number of follicular bodies lying in the substance of the *alæ*, and which may be considered as small prostates, answering to the glandulæ prostaticæ inferiores in males. The other external parts are situated in the sinus, and hid by the *alæ*. Directly under the superior commissure lies the clitoris, with its cover, called *præputium*. A little lower is the orifice of the urethra; and below that is the orifice of the vagina, or great canal of the uterus. The circumference of this orifice is bordered, either by a membranous circle called *hymen*, or by fleshy portions, termed *caruncula myrtiformes*. On each side of the clitoris begins a very prominent fold, like a crista, which runs down obliquely on each side of the orifice of the urethra. These folds are termed *nymphae*, and they might likewise be named *crista clytoridis*. The clitoris appears at first sight like a small imperforated glans. Its upper and lateral sides are covered

by a kind of *præputium*, formed by a particular fold of a portion of the inner side of the *alæ*, which appears to be glandular, and to discharge a certain moisture, and its inside is granulated. By dissection, we discover in the clitoris a trunk and two branches, as in the penis, consisting of a spongy substance, and of very elastic coats, but without any urethra. The trunk of the clitoris is sustained by a *ligamentum suspensorium* fixed in the symphysis of the ossa pubis, and containing this trunk in its duplicature, nearly as in the other sex.

The *nymphae*, *cristæ clytoridis*, or, as they may likewise be termed, *alæ minores sive internæ*, are two prominent folds of the inner skin of the great or external *alæ*, reaching from the *præputium* of the clitoris to the two sides of the great orifice of the uterus. They begin very narrow, and, having increased in breadth in their course downward, they are again contracted at their lower extremity. They are of a spongy substance, intermixed with glands, several of which may be perceived by the naked eye. Their situation is oblique, their upper extremities lying near each other, and the lower at a much greater distance. In married women they are more or less flaccid and decayed.

By the urethra in females, we mean the urinary duct, the orifice of which is between the *nymphae*, below the glans of the clitoris. The body of the urethra is a spongy duct of the same structure as in males, but much shorter, situated directly under the trunk of the clitoris, and above the great canal of the uterus, adhering to each of these canals, between which it lies, by membranous filaments. It passes under the cartilaginous arch of the ossa pubis, and terminates by an oblique opening at the neck of the bladder, being bent a little downwards between its two extremities.

The vagina, or great canal, formerly called the *neck of the uterus*, is situated below the urethra, and above the extremity of the *intestinum rectum*, a little obliquely, being more raised on the inner and back-part than on the outer and fore-part. Its inner or posterior extremity joins the extremity of the body of the uterus, and surrounds its orifice. The anterior extremity forms the great orifice, which lies under that of the urethra, and above the fossula of the inferior commissure of the *alæ*. Its inner or concave surface has several transverse rugæ, and is covered by a particular membrane. The rugæ are formed by oblong narrow eminences, incurvated like portions of arches, placed very near each other, and disposed in such a manner as to divide the cavity of the canal into an upper and lower side. In general, these arches are very considerable in young persons; become gradually more superficial in married women, and are quite lost in time of delivery.

The exterior or anterior extremity of the great canal in virgins, and especially before the first eruption of the menses, is commonly bordered by circular membranous folds of different breadths, more or less smooth, and sometimes semilunar; which, in some subjects, leaves but a very small opening, in others a larger opening; and, in all, renders the external orifice narrower than the rest of the cavity. This fold, called *hymen*, is formed by the union of the internal membrane of the great canal with that on the inside of the *alæ*, and represents a membranous circle of different breadths, and sometimes uneven. This membranous circle is commonly ruptured in the consummation of marriage; is quite lost in delivery, and afterwards only some irregular portions of it remain; which, from their supposed resemblance to myrtle-leaves, have been termed *caruncula myrtiformes*. This circle may likewise suffer some disorder by too great a flux of the menses, by imprudence, levity, and other particular accidents.

MENSTRUATION.

The descriptions hitherto given of the female parts, are in common to all ages of the sex; but about the thirteenth year, or later, nearly at the same time when semen begins to form itself in the male, considerable changes are likewise produced in the female. For at this time the whole mass of blood begins to circulate with an increased force,

the breasts swell, and the pubes begins to be clothed: at the same time the menses in some measure make their appearance by a common law of nature, although in different countries both the time and quantity of the flux is different. But, before the menstrual flux commences, various symptoms of pain are excited in the loins; and pains resembling the cholic, an increased pulse, head-achs, cutaneous pustules, and a discharge of a whitish liquor, generally pronounce its approach. For now the fleecy vessels of the uterus, which in the state of the fœtus were white, and transfused a sort of milk, as in the young girl they transfused a serous liquor, now begin to swell with blood; the red parts of which are deposited through the vessels into the cavity of the uterus. This continues some days, while in the mean time the first troublesome symptoms abate, and the uterine vessels, gradually contracting their openings, again distil only a little serous moisture as before. But then the same efforts return again at uncertain intervals in tender virgins; till at length, by degrees, they keep near to the end of the fourth week, when the flux of blood follows, as before, which is periodically continued till between the forty-fifth and fiftieth year; though the diet, country, constitution, and way of life, cause a great variation in this discharge.

Since none but the human species are properly subject to this menstrual flux, (although there are some animals who, at the time of their vernal copulation, distil a small quantity of blood from their genitals,) and since the body of the male is always free from the like discharge, it has been a great inquiry in all ages, what should be the cause of this sanguine excretion peculiar to the fair sex? The attraction of the moon, which is known to raise the tides of the sea, has been, in all ages, supposed to produce this effect; other authors have referred it to a sharp stimulating humour, secreted in the genital parts themselves, the same which is the cause of the venereal disease. But, if the moon produces this effect, it would appear in all women at the same time, which is contrary to experience, since there is never a day in which there are not many women seized with this flux; nor are there fewer in the decrease than in the increase of the moon. As to any sharp ferment seated in the uterus, it will be always inquired for in vain, where there are none but mild mucous juices, and where venery, which expels all these juices, neither increases nor lessens the menstrual flux: for women deny that, during the time of their menses, they have any increased desire of venery; for at that time most of the parts are rather pained and languid; and the seat of venereal pleasure seems rather at the entrance of the pudendum than in the uterus, from which last the menses flow. Besides, that the menstrual blood is forced out by some cause exciting the motion of the blood against the vessels, appears most probable; because, by a retention, the courses have been known to break through all the other organs of the body, where no vellicating ferment could be seated, so as to burst open the vessels of each organ; and because the effect produced by the retention of the blood is not confined to those parts which pour out the venereal humour.

Nature has, in general, given women a more delicate body, and solids that are less elastic; their muscles are also smaller, with a greater quantity of fat interposed both between them and their fibres; the bones too are slenderer, and their surfaces have fewer processes and asperities, than in males. Moreover the pelvis of the female is, in all its dimensions, larger; the ossa ilia spread farther from each other; and the os sacrum recedes more backward from the bones of the pubes, while the ossa ischia depart more from each other below: however, the angle in which the bones of the pubes meet together to form an arch, is in the female considerably larger; which differences are confirmed by the observations of the best anatomists, and from necessity itself, which requires a greater space for a greater number of viscera in the pelvis.

The female infant new-born has her lower limbs very small; and the greater part of the blood, belonging to the

iliac arteries, goes to the umbilicals, sending down only a small portion to the pelvis. Hence the pelvis is small, and but little concave; so that the bladder and uterus itself, with the ovaries, project beyond the brim of the pelvis. But when the fœtus is born, and the umbilical artery tied, all the blood of the iliac artery descends to the pelvis and lower limbs, which of course grow larger, and the pelvis spreads wider and deeper; so that, by degrees, the womb and bladder are received into its cavity, without being any longer compressed by the intestines and peritonæum, when the abdominal muscles press upon the lower parts of the abdomen. When the increase is perfect, or nearly so, then in general we find those arteries of the uterus largest, and easily injected with wax, which in the fœtus were least; and all things are so changed, that the hemorrhoidal artery is now in place of the hypogastric, when formerly the umbilical had been the trunk of that artery. More blood, therefore, at that time comes into the uterus, vagina, and clitoris, than formerly used to do. At the same time, when the growth of the body begins considerably to diminish, and the blood, finding easy admittance into the completed viscera, is prepared in a greater quantity; and the appetite being now very sharp, in both sexes, a plethora consequently follows. In the male, it vents itself frequently by the nose, from the exhaling vessels of the pituitary membrane being dilated to so great a degree without a rupture, as to let the red blood distil through them; and now the semen first begins to be secreted, and the beard to grow. But in the female, the same plethora finds a more easy vent downward; being directed partly by the weight of the blood itself, to the uterine vessels now much enlarged, of a soft fleecy fabric, and seated in a loose hollow part, with a great deal of cellular fabric interperfed, which is very yielding and succulent, as we observe in the womb: for these causes, the vessels being easily distensible, the blood finds a more easy passage through the soft exhaling vessels, which open into the cavity of the uterus, as being there less resisted than in its return by the veins, or in taking a course through any other part; and at the same time the return of the blood from the uterus is impeded, both because the flexures of the arteries, from the increased afflux of the blood, become more serpentine and fit for retarding the blood's motion, and likewise because it now returns with difficulty through the veins. The blood is, therefore, first collected in the vessels of the uterus, which at this time are observed, in dissections, to be swelled; it is also accumulated in the arteries of the loins and the aorta itself, which, urging on a new torrent of blood, augments the force, so far as to discharge the red blood into the serous vessels of the uterus, which at first transmit an increased quantity of warm mucus, afterwards a reddish-coloured serum; and by suffering a greater distension, they at last emit the red blood itself. The same greater impulse of blood, determined to the genital parts, drives out the hitherto latent hairs, increases the bulk of the clitoris, dilates the cavernous plexus of the vagina, and whets the female appetite to venery. Accordingly we find, that the quantity of the menstrual flux, and the earliness of their appearance, are promoted by every thing that either increases the quantity or momentum of the blood with respect to the body in general, or directs the course of the blood more particularly towards the uterus; such as joy, lust, bathing of the feet, rich diet, warm air, and lively temperament of the body. It is diminished by those things which lessen plethora and the motion of the blood, as want, grief, cold air, sloth, and antecedent diseases.

When five or six ounces of blood have been thus evacuated, the unloaded arteries exert a greater force of elasticity, and, like all arteries which have been overcharged with blood, gradually contract themselves to a less diameter, so as at length to give passage only to the former thin exhaling moisture; but the plethora, or quantity of blood, being again increased from the same causes, a like discharge will always more easily ensue through the vessels of the uterus, after they have been once thus opened, than

than through any other part. Nor is there any occasion to perplex ourselves about the cause, why this periodical discharge is, for the most part, nearly regular or menstrual; for this depends upon the proportion of the quantity and momentum of the blood daily collected, together with the resistance of the uterus, which is to yield again gradually to the first course. This critical discharge of the blood, therefore, never waits for the interval of a month, but flows sooner or later, according as the greater quantity of blood in plethoric women is determined, by lust or other causes, towards the uterus. Finally, they cease to flow altogether, when the uterus, like all the other solid parts of the body, has acquired so great a degree of hardness and resistance, as cannot be overcome by the declining force of the heart and arteries, by which the blood and juices are driven on through all the vessels. This increased hardness in the old uterus is so remarkable in the arteries and ovaries, that it easily discovers itself both to the knife and the injections of the anatomist. But, in general, brute animals have no menses; because, in them, the womb is in a manner rather membranous than fleshy, with very firm or resisting vessels: besides, the difference of their posture never permits a natural hemorrhagy from the nostrils or other parts. They are wanting in men, because in that sex there is no spongy organ fit for retaining the blood; and likewise because the arteries of the pelvis are both harder, and less in proportion, than the veins; and thus the impetus of the blood is directed to the lower limbs, where the vessels are larger in proportion as those of the pelvis are smaller.

It will, perhaps, be demanded, why the breasts swell at the time of the approach of the menses? We are to observe, that the breasts have many particulars in their fabric common with the uterus; as appears from the secretion of the milk in them after the birth of the fœtus, which increases or diminishes in proportion as the lochial flux is either increased or diminished; from the similitude of the ferous liquor to milk or whey, which is found in the uterus of those who do not suckle their children; it is of a thin white consistence, and appears very evidently in the brute animals; also from the turgescence or erection of the papillæ or nipples of the breast by friction, analogous to the erection of the clitoris. The same causes, therefore, which distend the vessels of the uterus, likewise determine the blood more plentifully to the breasts; the consequence of which is an increased bulk and turgescence of the conglomerate glandules and cellular fabric which compose them.

OF HERMAPHRODITES.

Thus far we have considered the generative organs under their natural and proper conformation. But it sometimes happens in the human structure, and very frequently in that of brute animals, that from a *lusus naturæ*, or redundancy of parts, that mixture of conformation is produced, which is called *hermaphrodite*; a word formed of the Greek *Ἑρμαφροδίτη*, a compound of *Ἑρμης*, Mercury, and *Ἀφροδίτη*, Venus; q. d. a mixture of Mercury and Venus, i. e. of male and female. For it is to be observed, *Hermaphroditus* was originally a proper name, applied by the heathen mythologists to a fabulous deity, whom some represent as a son of *Hermes*, Mercury, and *Aphrodite*, Venus; and who, being desperately in love with the nymph *Salmacis*, obtained of the gods to have his body and hers united into one. The Greeks, therefore, call *hermaphrodites* *ανδρογυναι*, *androgyni*, q. d. men-women; whence persons formed with this plurality of sex are called *Androgynes*.

In a treatise by Mr. Hunter, in the 69th volume of the Philosophical Transactions, hermaphrodites are divided into *natural*, and *unnatural* or monstrous. The first belongs to the more simple orders of animals, of which there are a much greater number than of the more perfect. The unnatural takes place in every tribe of animals having distinct sexes, but is more common in some than in others. The

human species, Dr. Hunter supposed to have the fewest; but in the horse, sheep, and black cattle, they are very frequent. In the horse Dr. Hunter dissected, the testicles had come down out of the abdomen into the place where the udder should have been, and appeared like an udder, not so pendulous as the scrotum in the male of such animals. There were also two nipples, of which horses have no perfect form; being blended in them with the sheath or prepuce, of which there was none here. The external female parts were exactly similar to those of a perfect female; but instead of a common-sized clitoris, there was one about five or six inches long; which, when erect, stood almost directly backwards.

A foal ass very similar to the above was killed, and the following appearances were observed on dissection. The testicles were not come down as in the former, possibly because the creature was too young. It had also two nipples; but there was no penis passing round the pubes to the belly, as in the perfect male ass. The external female parts were similar to those of the she-ass. Within the entrance of the vagina was placed the clitoris; but much longer than that of a true female, being about five inches long. The vagina was open a little farther than the opening of the urethra into it, and then became obliterated; from thence, up to the fundus of the uterus, there was no canal. At the fundus of the common uterus it was hollow, or had a cavity in it, and then divided in two, viz. a right and a left, called the *horns* of the uterus, which were also pervious. Beyond the termination of the two horns were placed the ovaria, as in the true female; but the Fallopian tubes could not be found. From the broad ligaments, to the edges of which the horns of the uterus and ovaria were attached, there passed towards each groin a part similar to the round ligaments in the female; which were continued into the rings of the abdominal muscles; but with this difference, that there were continued with them a process or theca of the peritonæum, similar to the tunica vaginalis communis in the male ass; and in these there were found the testicles, but no vasa deferentia could be observed passing from them.

Concerning hermaphrodites of the human species much has been written, and many laws enacted about them in different nations. Dr. Parsons, in a treatise on this subject, endeavours to explode the notion as a vulgar error. According to him, all the hermaphrodites that have appeared were only women whose clitoris from some cause or other was overgrown; and, in particular, that this was the case with the Angola woman shewn at London as an hermaphrodite some time ago. The same opinion hath likewise been held by many eminent anatomists, namely, that those persons called hermaphrodites are only females whose clitoris protrudes beyond the nymphæ. The French anatomists, however, seem not only to have removed all doubts about the matter, but have defined the several varieties of this *lusus naturæ* that have yet been known to occur in the human subject. This defect, or perhaps redundancy, in the animal structure, is described by them as follows. "There is a depravation in the form of the parts intended by nature for propagation, when, besides those concealed parts that are found necessary for the discharge of prolific functions, the *puenda* of the other sex likewise appear. This monstrous production of nature is diversified in four different ways; of which three appear in males, and one in females. In men, the female pudendum, clothed with hair, sometimes appears contiguous to the perinæum; at other times, in the middle of the scrotum; at other times, which constitutes the third diversity, thro' that part itself which in the midst of the scrotum exhibits the form of a male pudendum, urine is emitted, as it were, from female parts. Near that which is the test of puberty, and above the pudendum, in females, the masculine genitals appear, conspicuous in all their three forms, one resembling the *vineam* or yard, the other like the two testicles: but for the most part it happens, that, of the two instruments of generation, one is feeble and inert; and

it is extremely rare that both are found sufficiently valid and proper for seats of love; nay, even in a great many, both these members are deficient and impotent, so that they can perform the office neither of a male nor of a female."

With respect to them, it appears, from a collation of all the circumstances which have been observed, that no perfect *androgynæ*, or real *hermaphrodite*, possesses the genuine powers of both sexes, in such a manner as to be qualified for performing the functions of either with success: the irregularity of their fabrication almost always consists in something superfluous added to one of the two sexes, which gives it the appearance of the other, without bestowing the real and characteristical distinction; and every *hermaphrodite* is almost always, in effect, a very woman. Since this monstrous exhibition of nature is not such as to abrogate the rights or destroy the character of humanity among human beings, this involuntary misfortune implies no right to despise those upon whom it is inflicted by nature, or to make them the sport and ridicule of the illiberal and licentious.

The Anatomical Plate VI. affords an accurate View of the Male and Female Parts of Generation, and of the *Lusus Naturæ* constituting the Hermaphrodites or Androgynes.

Fig. 1, represents the male organs. *aa*, The kidneys. *bb*, The ureters. *cc*, The renal glands. *d*, The trunk of the vena cava. *e*, Trunk of the aorta. *ff*, The emulgent arteries and veins. *gg*, The spermatic arteries and veins. *hh*, The iliac arteries. *ii*, The iliac veins. *kk*, The hypogastric arteries and veins, which run down upon the bladder and penis. *l*, The bladder. *m*, The bulb of the urethra. *n*, The penis. *oo*, The vasa deferentia. *pp*, The epididymes. *qq*, The testicles.

Fig. 2, represents the female parts. *1*, The womb. *2, 2*, The Fallopian tubes. *3, 3*, The fimbriæ. *4, 4*, The ovaria. *5*, The mouth of the womb. *6, 6*, The ligamenta rotunda. *7*, The rugous inside of the vagina. *8*, The orifice of the vagina.

Fig. 3, 4, and 5, represent the hermaphrodite conformation of the male genitals, as described above; and fig. 6, represents that which more particularly appertains to the female.

OF THE ARTERIES.

The heart throws the blood into two great arteries; one of which is named *aorta*, the other *arteria pulmonalis*. The *aorta* distributes the blood to all parts of the body, for the nourishment of the parts, and for the secretion of the different fluids. The *arteria pulmonalis* carries the venal blood through all the capillary vessels of the lungs. Both these great or general arteries are subdivided into several branches, and into a great number of ramifications.

The pulmonary artery goes out from the right ventricle of the heart; and its trunk having run almost directly upward as high as the curvature of the aorta, is divided into two lateral branches, one going to the right side, called the *right pulmonary artery*; the other to the left side, termed the *left pulmonary artery*. The right artery passes under the curvature of the aorta, and is consequently longer than the left. They both run to the lungs, and are dispersed through their whole substance by ramifications nearly like those of the bronchia, and lying in the same direction. From the pulmonary arteries the blood is returned by the veins; which, contrary to the course of the arteries, begin by very minute canals, and gradually become larger, forming at length four large trunks called *pulmonary veins*, which terminate in the left auricle.

The *aorta* is divided into the *aorta ascendens* and *aorta descendens*, though both are but one and the same trunk. It is termed *ascendens*, from where it leaves the heart to the extremity of the great curvature or arch. The remaining part of this trunk from the arch to the os sacrum is named *descendens*. The large branches of the *aorta* are these: two *arteriæ subclaviæ*, two *carotides*, one *cæliaca*, one *mesenterica superior*, two *renales* or *emulgentes*, one *mesenterica inferior*, and two *iliacæ*. The small branches are chiefly

the *arteriæ coronariæ cordis*, *bronchiales*, *œsophageæ*, *intercostales*, *diaphragmaticæ inferiores*, *spermaticæ*, *lumbares*, and *sacræ*. From the upper part the *aorta* sends out commonly three, sometimes four, large branches, their origins being very near each other. When there are four, the two middle branches are termed *arteriæ carotides*, the other two *subclaviæ*; and both are distinguished into right and left. The *carotid arteries* run directly up to the head, each of them being first divided into two, one external, the other internal: the external artery goes chiefly to the outer parts of the head and *dura mater*, or first covering of the brain; the internal enters the cranium through the bony canal of the os petrosum, and is distributed through the brain by a great number of ramifications. The *subclavian arteries* separate laterally, and almost transversely, each running toward that side on which it lies, behind and under the *claviculæ*, from whence they have their name. The left seems to be shorter, and runs more obliquely than the right. The *subclavian* on each side terminates at the upper edge of the first rib; and there, as it goes out of the thorax, takes the name of *arteria axillaris*. During this course of the *subclavian artery*, taking in the common trunk of the right *subclavian*, several arteries arise from it, viz. the *mammaria interna*, *mediastina*, *pericardica*, *diaphragmatica minor* five superior, *thymica*, and *trachealis*. The *thymica* and *trachealis* on each side are, in some subjects, only branches of one small trunk which springs from the common trunk of the right *subclavian* and *carotid*. They are generally small arteries, which run sometimes separate, and sometimes partly separate and partly joined. The *subclavian* sends off likewise the *mammaria interna*, *vertebrales*, *cervicales*, and sometimes several of the upper *intercostales*. The *axillary artery*, which is only a continuation of the *subclavian*, from the place where it goes out of the thorax to the axilla, detaches chiefly the *mammaria externa* or *thoracica superior*, *thoracica inferior*, *scapulares externa*, *scapularis interna*, *humeralis* or *muscularis*, &c. Afterwards it is continued, by different ramifications, and under different names, over the whole arm, all the way to the ends of the fingers.

The superior portion of the *aorta* descendens gives off the *arteriæ bronchiales*, which arise sometimes by a small common trunk, sometimes separately, and sometimes do not come immediately from the *aorta*. It next sends off the *œsophageæ*, which may be looked upon as *mediastinæ posteriores*, and the *intercostales*, from its posterior part, which in some subjects come all from this portion of the *aorta*, in others only the lowest eight or nine. The inferior portion of the descending *aorta*, as it passes through the diaphragm, gives off the *diaphragmaticæ inferiores* or *phrenicæ*, which however do not always come immediately from the *aorta*. Afterwards it sends off several branches anteriorly, posteriorly, and laterally.

The anterior branches are *cæliaca*, which supplies the stomach, liver, spleen, pancreas, &c. the *mesenterica superior*, which goes chiefly to the mesentery, to the small intestines, and to that part of the great intestines which lies on the right side of the abdomen; the *mesenterica inferior*, which goes to the great intestines on the left side, and produces the *hæmorrhoidalis interna*; and lastly, the right and left *arteriæ spermaticæ*. The posterior branches are the *arteriæ lumbares*, of which there are several pairs, and the *sacræ*, which do not always come from the trunk of the *aorta*. The lateral branches are the *capsulares* and *adiposæ*, the origin of which often varies; the *renales*, commonly termed *emulgentes*, and the *iliacæ*. The *iliac artery* on each side is commonly divided into the external or anterior, and internal or posterior. The internal *iliaca* is likewise named *arteria hypogastrica*; and its ramifications are distributed to the viscera contained in the pelvis, and to the neighbouring parts, both internal and external. The *iliaca externa*, which is the true continuation of the *iliac trunk*, and alone deserves that name, goes on to the inguen, and then out of the abdomen, under the *ligamentum Fallopii*; having first detached the *epigastrica*, which goes

goes to the muscoli abdominis recti. Having quitted the abdomen, it is called arteria cruralis, which runs down upon the thigh, and is distributed by many branches and ramifications to all the lower extremity.

The arteries themselves have arteries which are more particularly spread through their external cellular coat, which spring on all sides from the next adjacent small arterial trunks: they are numerous, and like net-work; they are very minute, but plainly appear, even in the fœtus, without injection. Nerves also descend, for a long way together, through the surface of the artery, and at last vanish in the cellular substance of the vessel; of which we have a specimen in the external and internal carotids, and in the arch of the aorta; and Dr. Waller has shewn them in several arteries in the thorax and abdomen. Do not the arteries seem to derive from these nerves a muscular and convulsive force, very different from that of their simple elasticity? Does not this force shew itself plainly enough in fevers, faintings, palsies accompanied with atrophy, and passions of the mind? Haller considers the artery as being in a manner insensible and unirritable; and if it is constricted by the application of poisons, he says it has every property of the dead skin. This, however, is not agreeable to the opinions of the present physiologists. The *sections* of the arteries are circular, because they are elastic; and this is the reason why, from the small arteries of the teeth, hemorrhages are sometimes fatal. The aorta, indeed, of the thorax and abdomen, the carotids of the neck, and some other arteries of the dead body, from their lessened extension, appear somewhat flat or depressed; but their round figure, or circular section, is every where restored by injection. Their elasticity is also evident by that powerful compressure, which a segment of a large artery makes upon the finger that distends it, and which is much stronger in a dead than in a living body. In the living body, indeed, this force yields to that of the heart; but instantly recovers itself when the heart is relaxed, and restores the artery to its former diameter; and this makes the *pulse*, which all arteries possess, although the systole and diastole can be perceived by the finger only in the larger, not in the smaller ones. The *strength* of the arteries is considerable enough: but as the dense hard network of the outer cellular coat refuses to yield to a distending force, it breaks without much difficulty, and almost easier than the coats of the veins; and hence aneurisms arise. But, in general, the trunks are, in all parts of the body, weaker, and the branches stronger in their coats; whence the impulse of the blood may exert a considerable effect upon the former, but least of all on the arteries of the limbs. Hence it is, that aneurisms are most frequently formed near the heart.

Nature has dispersed the arteries through the whole animal body, except in a few membranes where they have not yet been observed. She hath disposed of the trunks, every where, in places of safety; because wounds in the smaller trunks are always dangerous, and in the larger trunks frequently mortal. The skin is spread with numerous short and small arterial branches; but the larger trunks, defended by the skin and muscles, creep along near the bones. In general, the arteries are in proportion to the parts of the body to which they are sent. The largest go to the secretory organs, the brain, and spleen; the smaller ones to the muscular parts. The extremities of the arteries, which are either cylindrical or nearly so, send off smaller branches in greater abundance than the large arteries do, and these extremely small ramifications anastomosing with one another form a kind of net-work; as we see more particularly in all membranes. By this means, tho' the passage from the heart to any part of the artery is obstructed, the blood may nevertheless flow through the arteries which are near the obstructed one. Thus a gangrene or languor of the part is very strongly prevented, and the obstruction is more easily resolved by the repulsion of the obstacle into the larger part of the trunk. The least arteries are either changed by a continuation of their canals

into veins, or else a branch, sent out at right angles from the artery, is inserted by a like angle into a branch of small veins. Both these kinds of mechanism are demonstrated to us by the microscope, and the easy return of injections, through the veins into the arteries. A large artery is never observed to open into a vein.

In the viscera, we find the small arteries disposed not so much in net-work as in a fabric of a peculiar kind, wherein the small branches descend very thick, or in clusters parallel to the trunk, so as to resemble brushes, a variety of little trees or bushes, small serpents, or threads, according to the various disposition of the parts. Sometimes the arteries end in another manner, namely, by being converted into vessels of the smaller kinds, which are continuous to the arteries, and indeed real arterial trunks; as may be observed in the ophthalmic artery, by tracing the arteries of the tunica choroides, or the colourless ones of the circle of the uvea and iris. In other places the smaller vessels seem to proceed laterally as branches from the trunks of the least sanguineous arteries; and these again are drawn out into trunks still smaller. These are called *excretory ducts*. It is with difficulty that these vessels are filled with red blood; of this, however, we have examples in the kidneys, the liver, and the breasts. Indeed the blood, when vitiated, penetrates the excretory ducts of the whole body, even without hurting the vessels; nor is that aberration found to be productive of any evil consequence after the disorder of the blood is cured.

Another termination of the arterial extremities is into the exhaling vessels; and this manner of their ending is very frequent in all parts of the body. The whole skin, all membranes of the human body which form any close cavity, all the ventricles of the brain, the anterior and posterior chambers of the eye, all the adipose cells and pulmonary vesicles, the whole cavity of the stomach and intestinal tube, and the trachea, are all of them replenished with exhaling arteries of this kind. These emit a thin, watery, gelatinous, humour, which, by congestion, stagnation, or excess, is converted into a watery but coagulable lymph, as we see in several diseases, and in death. The exhalants are easily demonstrable from the watery sweat, that ensues after injecting the arteries with any warm liquor. In some places they exhale indeed not a thin vapour, but blood itself, as we see in the heart, the cellular fabric of the penis, urethra, clitoris, and nipple of the female breast; in all which blood in its natural state is poured out.

The arteries, in a living person, are always full of blood; since the jet or stream from an artery is not interrupted by alternate stops, while the heart is inactive, but flows on in a continued thread. The microscope also shews the arteries, in living animals, to be full both in their systole and diastole; nor can the circular fibres of the arteries so far contract themselves as entirely to evacuate these tubes. Every contraction of the ventricle sends a new wave of blood into the arteries; this wave seldom exceeds two ounces, and consequently bears only a small proportion to the whole circulating mass, yet it is so forcibly propelled by the heart as to drive the preceding waves before it. In consequence of this propulsion, the dimensions of the cylindrical artery are augmented, the arterial coats are pressed near each other, and the serpentine flexures are considerably increased, as we often see in injections. This dilatation of the artery, whereby its capacity is changed from a less to a greater circle, is the *pulse*, the diastole of which is an expansion of the artery beyond its natural diameter. This action is the characteristic of life; it results from the heart only, and is in no wise natural to the arteries themselves. Hence, when the motion of the heart is intercepted, whether by aneurism, ligature, or otherwise, pulsation of the arteries is to be felt; and hence a sudden cessation of the pulse, by a wound through the heart. The artery is proportionally more dilated, the more the velocity of the new wave exceeds that of the former one.

The blood's velocity in the arteries is diminished during the heart's systole, but increased during its diastole; at a medium its motion is somewhat less than one foot in a second of time. The constant plenitude of the arteries renders it impossible for us to perceive any succession in the pulses of different arteries; whence all the arteries of the body seem to beat at one and the same instant, whilst the heart strikes against the breast: and yet there is certainly a succession in the systole of the arteries, by which the aorta seems to contract successively, as it is filled with blood expelled from the heart; so that the part of the artery next the heart is first constricted, and thence the arterial contracting force gradually proceeds to the extremities. We have an instance of this in the intestines; and very evidently in insects, who have a long fistulous and knotted heart, manifestly contracting in a succession from the beginning to the end; but in the human arteries the successions are so quick as to be imperceptible.

The pulse is continued to, and ends in, the expillary and cylindrical arteries, or the originations of the veins. We have already mentioned the velocity with which the blood comes from the heart; but that velocity continually decreases. The transverse sections of all the arteries at a distance from the heart, are in one sum greater than the section of the aorta; and the aggregate area of their sections increases, but in an uncertain proportion, as the distance from the heart increases: the velocity will consequently decrease as the distance increases, for it must always be inversely proportional to the area of the tube through which the fluid runs. A considerable allowance must also be made for the great viscosity or tenacity of the blood, which entirely coagulates by rest; its circulatory motion alone overcomes the mutual attraction of its parts, and prevents it from adhering to the sides of the vessels in a coagulated state, as we see in aneurisms and wounds of the arteries, and after death. The opposition which the blood meets with in the branches, lessens its velocity in the trunk: and the opposition of torrents of blood to one another in the anastomoses of vessels also destroys some parts of its motion. We may easily perceive the amount of this retardation will be very considerable, although it be difficult to estimate it justly. In the larger trunks the blood of a living animal flows with the rapidity of a torrent: but, in the least branches, it creeps along very slowly, and begins to coagulate. It is also well known to surgeons, that a small branch of an artery near the heart bleeds more dangerously than a much larger one at a greater distance. The weight of the incumbent atmosphere, of the muscles and fleshy parts lying above the artery, and the contractile power of the vessel itself, also make a resistance to the heart; but they do not lessen the velocity of the blood, for they add as much in the diastole as they diminish in the systole. The pulse therefore ensues, because the anterior wave or column of blood moves on slower, while the subsequent or posterior wave comes faster; so that the preceding is an obstacle to the consequent blood. But since the force of the heart weakens as the blood goes on, and the contractile power of the arteries increases, the excess of the celerity of the consequent wave pushed on by the heart, above the celerity of the antecedent wave pushed on by the contractile power of the artery, will grow continually less and less; and, when the blood arrives to a certain distance, the celerities of both waves become equal, and the pulsation ceases. This place of equality in motion cannot be in the larger and more conspicuous arterial branches: for in them the wave last coming from the heart moves quicker than what went before. The inflammatory pulsation of the small arteries of the eye shews that they have a pulse. We may however safely conclude, that in the least red arteries the pulse at length begins to vanish. This is evident from the equable motion of the blood, as seen by a microscope, through the arteries of a frog. In the larger vessels, however, such as may be about the sixth part of a line in diameter, the pulse becomes imperceptible. In the least veins there is

no sensible pulsation or accelerated motion of the blood, whilst the heart contracts, demonstrable either by the microscope or any other experiment.

That the blood presses against the sides of the veins, appears from the furrows made on the bones over which they pass, and the swelling of the veins on being tied. Why then do not the veins beat? The reason seems to be, that the blood is more retarded immediately on its leaving the heart, than it is in the smallest vessels. Hence, the difference of the velocities of the consequent and antecedent waves is greatest at the heart, and grows gradually less, till it at last totally vanishes. The pulse is therefore the measure of the powers which the heart spends on the blood; because it is the immediate and full effect of those powers. Hence, *ceteris paribus*, the pulse is slow in the most healthy people, where there is no stimulus, nor any unnatural resistance; and where the heart is at liberty to propel the blood with ease. We must except those cases where there is some obstacle which prevents the blood from entering the aorta. For this reason the pulse in asthmatic people is slow. A debility or insensibility of the heart, when the usual stimulus is not capable of exciting it to contraction, also occasions a slow pulse. A strong full pulse is caused by the arteries being full, and the heart at the same time vigorous and powerful; a small pulse by the emptiness of the arteries, and a smaller wave of blood sent from the heart. A hard pulse denotes some obstacle or stimulus: or else that the heart's force, the thickness of blood, or the rigidity of the artery, are increased. A quick pulse denotes some stimulus, obstacle, or greater sensibility or irritability of the heart. The pulse is best felt where the artery lies exposed bare to the touch, upon some resisting bone; but obstructions sometimes render the pulse perceptible where it is never so naturally.

The pulse is slower in animals as they are larger or more bulky; because their heart, in proportion to the rest of the body, is less than that of smaller animals; it is also less irritable, and is obliged to propel the blood to a greater distance; whence, in large animals, the proportion between the resistances to be overcome and the force of the heart is less than the small ones. Hence, small animals are more voracious than large ones; as the whale and elephant. The pulse of a healthful person, in the morning, beats at least 65 in a minute; but, after the fatigue of the day, it will beat 80; and again, by the night's rest or sleep, it will become gradually less frequent, till in the morning you will find it returned to its primitive number of 65. For the motions of the muscles, and actions of the external and internal senses, the warmth of the atmosphere, and the action of the aliments, urge the venal blood on to the heart, whence a more than ordinary stimulus and a greater number of contractions. Hence also those paroxysms, or fits of increase, observable in all fevers towards the evening. Sleep retards the motion not only of the blood, but of all the other humours and actions in the body whatever.

A frequent and a quick pulse are often confounded; but they are in reality very different. The pulse is quicker in children, and becomes afterwards slower in persons as they grow older. The salient point beats 134 in a minute: the pulse of new-born infants, 120; and of old people, 60. A feverish pulse is usually between 96 and 120, to which number indeed it is often increased by laborious exercises alone; if it is increased to 130 or 140, (which last number we have never known it exceed,) the patient seldom recovers. The pulse beats slower in winter, and quicker in summer, by about ten strokes per minute; and, under the torrid zone it often increases to 120. The different passions of the mind variously accelerate, retard, and disturb, the pulse. Whatever obstructs the circulation is also found to accelerate the pulse; not from the laws of hydrostatics, or on account of the canal being made narrower, nor from the action of the soul; but by the strenuous and more frequently repeated contractions of the heart, in order to free itself from an irritating stimulus: thus an irritation from acrid blood is the cause of the frequent pulse in fevers.

In a healthy person, using sufficient exercise of body, the blood moves with such a velocity, as suffices to deliver as much of it by the vena cava to the heart, as is sent out by the aorta. But rest or inactivity of body, and a weakness of the contracting fibres of the heart and other muscles, frequently render the motion of the venal blood more difficult. Hence follow the varices in women with child, and the piles; which latter are also partly owing to the deficiency of valves in the vena portarum. Hence also the menses. And, when the veins return their blood too slowly to the heart, the subtle vapours stagnate; whence that frequency of œdematous swellings in weak people. The time in which an ounce of blood, sent out from the left ventricle of the heart, returns to the right, and which is commonly reckoned the time in which the greater circulation is performed, is uncertain. Suppose the quantity of blood thrown out of the heart at every pulsation to be $1\frac{1}{2}$ ounces, and the whole quantity of the blood to be 336 ounces, then a complete circulation is performed in the time of 224 pulsations; that is, in about three minutes!

OF THE VEINS.

The blood distributed through the body by the aorta and arteria pulmonaris, returns to the heart by three kinds of veins, called *vena cava*, *vena porta*, and *vena pulmonaris*. The vena cava carries back to the right auricle of the heart the blood conveyed by the aorta to all parts of the body, except what goes by the arteria coronaria cordis. It receives all this blood from the arterial ramifications in part directly, and in part indirectly. The vena portæ receives the blood carried to the floating viscera of the abdomen by the arteria cæliaca and the two mesentericæ; and conveys it to the vena hepatica, and from thence to the vena cava. The venæ pulmonares convey to the pulmonary sinus, or left auricle of the heart, the blood carried to the lungs by the arteria pulmonaris. And to these three veins two others might be added, viz. those which belong particularly to the heart, and to its auricles, and the sinuses of the dura mater.

The vena cava goes out from the right auricle of the heart by two large separate trunks, almost directly opposite to each other, one running upward, called *vena cava superior*; the other downward, called *vena cava inferior*. The vena cava superior is distributed chiefly to the thorax, head, and upper extremities, and but very little to the parts below the diaphragm. The vena cava inferior is distributed chiefly to the abdomen and lower extremities, and but very little to the parts above the diaphragm. The ancients called the superior vena cava *ascendens*; and the inferior, *descendens*; having regard only to the great tubes, and to their division into trunks and branches. Several moderns have retained these names, but in a contrary signification, to accommodate them to the motion of the blood, which descends by the vena cava superior, and ascends by the vena cava inferior.

The *superior* vena cava runs up from the right auricle of the heart, almost in a direct course for about two fingers breadth, lying within the pericardium, in the right side of the trunk of the aorta, but a little more anteriorly. As it goes out of the pericardium, it is inclined a little to the left hand, and then runs up a little higher than the curvature of the aorta. At this place it terminates by a bifurcation or division into two large branches or subordinate trunks, one of which runs towards the left side, the other towards the right. These two branches are named *subclavia*, as lying behind, and, in some measure, under the claviculæ, both in the same manner. They are of unequal lengths, because the trunk of the vena cava does not lie in the middle of the thorax, but towards the right side, where the left subclavian arises as well as the right; and consequently the left is the longest. The trunk of the superior cava, from where it leaves the pericardium to the bifurcation, sends out anteriorly several small branches, which sometimes arise separately, and sometimes by small common trunks. These branches are the vena mediastina, pericardica, diaphragmatica superior, thymica, mamma-

interna, and trachealis; the last of which go out sometimes behind the bifurcation. All these small branches from the trunk of the vena cava superior are termed *dextra*; and their fellows on the other side, called *sinistra*, do not arise from the trunk, because of its lateral situation, but from the left subclavian. Posteriorly, a little above the pericardium, the trunk of the superior cava sends out a capital branch, called *vena azygos*, or *vena sine pari*, which runs down on the right side of the bodies of the vertebrae dorsi, almost to the diaphragm; giving off the greatest part of the venæ intercostales and lumbares superiores. The two subclaviæ run laterally or toward each side; and terminate as they go out of the thorax, between the first rib and clavícula, immediately before the anterior insertion of the musculus scalenus. The right subclavian, which is the shortest of the two, commonly sends out four capital branches; the jugularis externa, jugularis interna, vertebralis, and axillaris; which last is rather a continuation than a branch of the subclavia. The left subclavian gives off the small veins on the left side, answering those on the right side that come from the trunk of the superior cava, viz. the mediastina, pericardica diaphragmatica superior, thymica, mamma interna, and trachealis. Next to these small veins called *sinistra*, it detaches another small branch called *intercostalis superior sinistra*; and then four large branches like those from the right subclavian, viz. the jugularis externa, jugularis interna, vertebralis, and axillaris; which are all termed *sinistra*. The external jugular veins are distributed chiefly to the outer parts of the throat, neck, and head; and send a small vein to the arm, named *cephalica*, which assists in forming a large one of the same name. The internal jugular veins go to the internal parts of the neck and head, communicating with the sinuses of the dura mater, and in several places with the external jugular veins. The vertebral veins pass through the holes in the transverse apophyses of the vertebrae of the neck, sending branches to the neck and occiput. They form the sinus venales of these vertebrae, and communicate with the sinuses of the dura mater. The axillary veins are continuations of the subclaviæ, from where these leave the thorax to the axillæ. They produce the mammae internæ, thoracicae, scapulares or humerales, and a branch to each arm; which, together with that from the external jugularis, forms the vena cephalica. Afterwards the axillary vein terminates in the principal vein of the arm, called *basilica*; which, together with the cephalica, is distributed by numerous ramifications to all parts of the arm, forearm, and hand.

The portion of the *inferior* vena cava, contained in the pericardium, is very small, being scarcely the twelfth part of an inch on the fore-part, and not above a quarter of an inch on the back-part. From thence it immediately perforates the diaphragm, to which it gives the venæ diaphragmaticæ inferiores or phrenicæ. It passes next behind the liver, through the great sinus of that viscus, to which it furnishes several branches, termed *venæ hepaticæ*. In this course it inclines a little towards the spina dorsi and aorta inferior; the trunk and ramifications of which it afterwards accompanies in the abdomen, all the way to the os sacrum; the arteria cæliaca and the two mesentericæ only excepted. Thus the inferior cava sends out on each side, in the same manner with the aorta, the venæ adiposæ, renales, spermaticæ, lumbares, and sacrae. Having reached to the os sacrum, it loses the name of cava; and, terminating by a bifurcation, like that of the descending aorta, it forms the two venæ iliacæ. These iliac veins having given off the hypogastricæ, with all their ramifications, to the viscera of the pelvis, and to some other external and internal neighbouring parts, go out of the abdomen, under the ligamentum Fallopii, and there take the name of *venæ crurales*. Each crural vein sends off numerous ramifications to all the lower extremity; besides the vena saphena, which goes out near the origin of the cruralis, and, running along this whole extremity, detaches many ramifications all the way to the foot.

Thus

Thus the veins, in many particulars, resemble the arteries. There are six; of which two answer to the aorta, and the remaining four to the pulmonary artery. Some count a seventh trunk, by taking in the *venæ hepaticæ*. Their basis is in the auricles of the heart, and their apices in the extremities of each branch through all parts of the body, excepting one instance in the liver; or we may reverse this order, and say the veins terminate in the heart. They often run parallel with, and accompany, the arteries. The fabric of the veins is tender, every where smooth, difficultly separable into distinct coats or membranes, like the arteries; and the cellular texture surrounding them is very easily distended. The veins both above and below the heart are surrounded, except in one place, with muscular fibres; every where, however, their substance is lax, like the cellular texture which joins the arteries to the adjacent parts; the veins are, nevertheless, every where sufficiently firm, and do not easily burst with inflated air; being in most instances stronger than the arteries themselves. But they burst much more easily in living than in dead animals, as appears from morbid instances in the arm, face, leg, thigh, &c. They do not preserve their cylindrical form after having been cut, but collapse together, so as to make their capacity appear like a slit; except they are sustained, and hindered from thus collapsing, by some strong cellular substance placed round them, as we see in the liver and womb. They are only slightly irritable, unless the stimulus be of the chemical or more acrid class; for, in that case, they contract themselves with a convulsive force greater than that of the arteries. They have no pulsation, unless the venous channel is somewhat obstructed; or when, in dying people, the blood is thrown back again from the right auricle into the descending and ascending cava, or when falling back from the brain.

The veins are much larger than their corresponding arteries, having the square of their diameter often double or triple, or almost quadruple; as may be seen near the emulgents and vessels of the kidneys. In general, however, the diameter of the veins is to that of the arteries as nine to four; yet the capacity of the capillary veins but little exceeds that of the arteries which accompany them. They differ likewise from the arteries in their division, having more numerous trunks and branches; for to one artery in the limbs, we usually meet with two veins: and there are many veins, as the external jugular, *vena portarum*, *azygos*, cephalic, basilic, and saphena, with which there are no corresponding arteries. The larger veins are also branched in a more net-like disposition, by forming more frequent anastomoses with one another than the arteries do. Many of the veins run near the surface of the body, especially in the limbs, neck, and head; they run a long way covered with little more than the bare skin, which is a circumstance we very rarely observe in arteries; and, for the same reason, they often separate from the arteries; following the surface of the parts next the skin, without their corresponding artery, which descends to a considerable depth, attended in its course by some small venous branch. In the smaller branches of the vessels, where they make net-like dispositions in the membranes and the internal fabric of the viscera, the veins and arteries commonly run contiguous one to the other; but here the veins have generally a less serpentine or inflected course than the arteries.

In the larger sanguiferous veins, *valves* are found in great plenty. The innermost membrane of the vein, being doubled, rises into the cavity of the vessel like a curtain, stretching itself farther along the vein every way, so as to form what may be called a kind of crescent; but the basis, which is the part that sustains the weight of the blood, is strongest, and grows out of the vein in the shape of a circular segment. The valve intercepts a space, of which the outer side is the vein itself, and the inner the valve; which, by its convexity, projects within the bore of the vein, so that the parabolic space or hollow mouth of the valve is always turned towards the heart. They are found in all the subcutaneous veins of the limbs, in those of the

neck, face, tongue, and penis: at the origin of the larger branches, there are two, three, four, and sometimes five, of them together, while in the smaller branches they are only single. These valves are wanting in the veins of the deep-seated viscera; namely, the brain, lungs, heart, and liver, and through the whole system of the *vena portarum*. They are also wanting in the kidneys and womb, (except one or two valves in the spermatic vein;) and, lastly, in those small blood-vessels which are less than the twelfth part of an inch in diameter. Sometimes, though rarely, they are found in the branches of the *vena azygos*, and at the mouths of the hepatic and renal veins; where Dr. Haller has sometimes observed a sort of wrinkles in the place of valves. In the smaller venous branches there are a set of long sharp-pointed or parabolical valves, of a more extended figure as the vein is smaller, which seem to resist the return of the blood more powerfully than the larger valves.

The veins have their origin, as we said before, from the terminations of the arteries. They sometimes arise by a continuation from the inserted branches, or from a reflection of recurved trunks of the smallest arteries. Others, again, are continued from veins less than those which carry blood; and also, in Dr. Haller's opinion, from the absorbing veins; but, as absorption by the red veins is now denied, that opinion must be rejected. Yet, that there are veins of a smaller class, but resembling those which convey blood, appears from the same experiments which demonstrate the pellucid arteries; thus there are small veins in the iris, and in the adnata tunica of the eye; nor is it to be doubted, that, in a healthy subject, small pellucid veins may be found in the vitreous body of the eye itself. Such have been sometimes seen by Wrisberg and others, after a fine injection or inflammation in the capsules of the lens and vitreous humour.

The Anatomical Plate VII. represents a just delineation of the HEART and BLOOD-VESSELS; and of which the following is an explanation.

FRONT VIEW.

A, The heart. B, The aorta ascendens. C, A trunk from which the right subclavian and right carotid arteries are sent off. (Those on the left side come off separately.) The subclavian artery passes over to the arm behind the subclavian vein. The carotid artery runs up to the head, partly covered by the internal jugular vein. D, The facial artery, which sends off the coronary arteries of the lips. E, The deep temporal artery. F, The descending aorta. G, The right common iliac artery, which divides into the external and internal iliacs. H, The femoral artery, which is a continuation of the external iliac artery. I, The anterior tibial artery, sending branches to the fore-part of the leg and upper-part of the foot.

1, The frontal vein running down to form 2, The facial vein. 3, Deep temporal vein. 4, Occipital vein. 5, The external jugular vein. 6, The internal jugular vein, lying on the outer and fore-part of the common carotid artery. 7, An arch on the palm of the hand, which runs partly to 8, The radial vein, and partly to 9, The ulnar vein. (The two last veins run close by the sides of their corresponding arteries.) 10, The cephalic vein. 11, The basilic vein, cut: on the left side it is entire. 12, Branches running up to form 13, The humeral vein. 14, The external thoracic veins running along with their arteries. (In many parts, the vessels are so small, that one trunk must represent both artery and vein.) 15, The axillary vein. 16, The subclavian vein, receiving the jugular and other veins from the head and neck. 17, The vena cava superior. 18, Veins from the upper-part of the foot forming 19, The anterior tibial vein, which lies close by the side of the corresponding artery. 20, The *venæ profundæ* femoris. 21, The upper part of the *vena saphena*. 22, The femoral vein. 23, The common iliac veins, formed of the external and internal iliacs. 24, Vena cava inferior. 25, The renal veins covering the arteries. 26, The diaphragmatic veins.

BACK

BACK VIEW.

A, The occipital vessels. B, The deep temporal vessels. C, The cervical vessels. D, The scapular vessels. E, F, Deep humeral branches communicating with others at the elbow. G, The posterior interosseous vessels. H, Intercoastal vessels. I, Arteriæ & venæ gluteæ. K, Sciatic vessels. L, Arteria & vena poplitea. M, Posterior tibial vessels. N, Fibular vessels. The vessels being so small, both vein and artery are represented by one trunk.

OF THE ABSORBENT SYSTEM.

The absorbent system, besides the glands, is divided into three parts, viz. the lacteals, the lymphatic vessels, and the thoracic duct. The lacteals belong to the intestinal tube; the lymphatics, to all the other parts of the body; and the thoracic duct is the common trunk which receives both the lacteals and lymphatics. We shall give a particular description of these, chiefly from Hewson, Mascagni, and Cruikshank, by whose industry this part of anatomy has been so greatly illustrated.

LYMPHATICS OF THE LOWER EXTREMITIES.—These may be divided into two kinds, viz. a superficial, and a deep-seated. The superficial consist of numerous vessels that lie between the skin and the muscles, and belong to the surface of the body or the skin, and to the cellular membrane which lies immediately under it. Numerous large branches of them can be readily enough discovered in the limbs of dropical subjects. Many of them run upon the top of the foot; one of which is represented in the annexed Anatomical Plate VIII. *Fig. 1. 10*; others are generally to be found just under the inner ankle; tubes have been introduced into two of them, whereby they have been filled the whole length of the lower extremity, as is seen in this figure.

The lymphatic glands of the groin are six, seven, eight, or upwards; they vary much in number: of these, some lie in the very angle between the thigh and the abdomen, and others lie a few inches down on the fore-part of the thigh. The lymphatic vessels enter the lowermost of these glands, which in the subject of this figure are four in number, viz. 15, 15; 16, 16. One or more of these branches, however, frequently avoids the glands, as at 17; which afterwards bends over it at 18 to the gland 19; from which vessels go to the other lymphatic glands 20, 20, that lie in the angle between the thigh and the abdomen, and sometimes a few enter no glands till they reach those on the inside of Poupart's ligament. Numerous lymphatics also pass into the inguinal glands from the superficial parts of the abdomen and pelvis. It is into these upper glands alone that the lymphatic vessels of the genitals enter, so that the venereal bubo, which arises in consequence of an absorption of matter from the organs of generation, is always seated in those upper glands; and the lower glands, 15, 15; 16, 16; are never affected, except by the regurgitation of the matter, or from their vicinity to the glands first diseased, which very seldom happens. And, as the upper glands are affected by the absorption of matter from the genitals, so the lower are commonly first affected from the absorption of the acrid matter of an ulcer, diseased joint, or carious bone, in the parts below these glands; a circumstance that may assist us in the diagnosis of these two kinds of buboes: remembering, however, that this rule may be liable to an exception from one or more of the lymphatic vessels passing the lower glands, and only entering at the upper, as is seen at 17, in the same figure.

In the penis three principal vessels commonly take their origin from the prepuce. These soon unite, but afterwards separate upon the middle of the dorsum penis into two parts; one of which goes to the inguinal glands on the right side, the other to those of the left. The deep-seated lymphatics arise from the glands and body of the penis, and accompany the arteries into the lower part of the pelvis. Hence, if venereal matter be absorbed by these vessels, the constitution may be affected without our being aware of it. The lymphatic vessels of the testicle are nu-

merous and very large for the size of this organ. They arise from its coats, from the body of the testicle, and from the epididymis; and, after running along the spermatic cord, they terminate in the lumbar glands. In their course they have few communications with each other. The lymphatics of the scrotum, which are also numerous, go chiefly to the glands of the groin, though some pass along with those of the testicle to the lumbar glands. The lymphatic vessels of the penis and scrotum having joined those of the thigh, a net-work is formed, which enters the abdomen under the edge of the tendon of the external oblique muscle, called *Poupart's ligament*: one of these vessels is seen in *Fig. 5. 24*. This plexus on the inside of Poupart's ligament consists of many branches; some of which embrace the iliac artery, of which one is seen at 27, but the greatest number of them pass up on the inside of the artery, as is seen in *Fig. 1. 21, 22*; and in *Fig. 5. 27*.

The superficial lymphatics of the inferior extremity are the trunks of those vessels which absorb from the skin and the cellular membrane immediately under it; but they likewise communicate with the deep-seated absorbents: and the same thing is to be observed with respect to the lymphatics on all the other parts of the surface of the body. Upon these vessels, from the foot to the groin, there are commonly no other lymphatic glands than those of the ham. But this rule has likewise some exceptions: for, even at the lower part of the leg, there is a very small one in the subject from which this plate was taken, as represented in *Fig. 1. 13*, and in another subject Mr. Hewson saw a small lymphatic gland near 14; from which it may be concluded, that the lymphatic glands, even in the human body, are in number and situation different in different subjects.

Besides these superficial lymphatic vessels which lie above all the muscles, there are others deeper seated, that lie among the muscles, and accompany the arteries; and like the veins, one lies on each side of the artery. Of these the principal trunks can be discovered by cutting down to the posterior tibial artery, near the inner ankle. By introducing tubes into these parts, they may be injected; as hath been done in several subjects, one of which is represented in *Fig. 2. of the same plate*. From the inner ankle at 13, these vessels pass up along with the posterior tibial artery, being hid among the muscles on the back-part of the tibia. About the middle of the leg they sometimes, though rarely, enter a small gland at 15, which has been supposed to exist more frequently than it really does. Afterwards they are seen in the back-part of the ham, still lying close to the artery, and in the ham they pass through two or three glands which are commonly found there, viz. 18, 19, 20. But, after they have passed these glands, they commonly divide into two or three branches, which accompany the crural artery, and pass with it through the perforation in the triceps muscle. The muscle is divided in the preparation from which this figure was taken, in order to give a better view of the lymphatics; and the cut ends of the muscle appear at 6, 6, though not very distinctly, from their being shrunk by drying. The lymphatic vessels having perforated the triceps, pass up with the artery, as is seen at 22, 23, and sometimes enter a gland 24, which is deeper seated than those that appear in the groin: from this gland they pass into the superficial glands, represented at 15, 15; 16, 16; where the lymph of the deep-seated and of the superficial lymphatics is mixed, and is conveyed into the body by the vessels seen just above in the same figure. At this part likewise the lymph from the penis and scrotum is mixed with that brought by the two sets of lymphatics from the lower extremities; and the whole enters the abdomen, under Poupart's ligament, by the plexus of vessels represented in *Fig. 1. 21*, and in a part of it in *Fig. 5. 24*.

Fig. 1. represents the lower extremity, with its more superficial lymphatic vessels; No. 1, is the spine of the os ilium; 2, the os pubis; 3, the iliac artery; 4, the knee. The other references have been explained in the course of

the description. *Fig. 2.* gives a back view of the lower extremity, dissected so as to shew the deeper-seated lymphatic vessels which accompany the arteries. 1, The os pubis. 2, The tuberosity of the ischium. 3, That part of the os ilium which was articulated with the os sacrum. 4, The extremity of the iliac artery appearing above the groin. 5, The knee. 6, 6, The two cut surfaces of the triceps muscle, which was divided to shew the lymphatic vessels that pass through its perforation along with the crural artery. 7, The edge of the musculus gracilis. 8, The gastrocnemius and soleus, much shrunk by being dried, and by the folcus being separated from the tibia to expose the vessels. 9, The heel. 10, The sole of the foot. 11, The superficial lymphatic vessels passing over the knee to the thigh. 12, The posterior tibial artery. 13, A lymphatic vessel accompanying the posterior tibial artery. 14, The same vessel crossing the artery. 15, A small lymphatic gland through which this deep-seated lymphatic vessel passes. 16, The lymphatic vessel passing under a small part to the soleus, which is left attached to the bone, the rest being removed. 17, The lymphatic vessel crossing the popliteal artery. 18, 19, 20, Lymphatic glands in the ham, through which the lymphatic vessel passes. 21, The lymphatic vessel passing with the crural artery through the perforation of the triceps muscle. 22, The lymphatic vessel, after it has passed the perforation of the triceps, dividing into branches which embrace the artery. 24, A lymphatic gland belonging to the deep-seated lymphatic vessel. At this place those vessels pass to the fore-part of the groin, where they communicate with the superficial lymphatic vessels. 25, A part of the superficial lymphatic vessels appearing on the brim of the pelvis.

ABSORBENT VESSELS of the TRUNK.—The lymphatics of the lower extremities having now reached the trunk of the body, and having passed under Poupart's ligament, appear upon the sides of the ossa pubis near the pelvis, at *Fig. 5.* 24, 24. A part of them passes up along with the iliac artery upon the brim of the pelvis; and another part dips down into the cavity of the pelvis, and joins the internal iliac artery near the sciatic notch. At this place they are joined by the lymphatics from the contents of the pelvis, particularly from the bladder and the vesiculæ seminales in the male, and from the uterus in the female; and there are likewise several branches which pass through the sciatic notch from the neighbourhood of the glutæi muscles. The lymphatic vessels of the uterus, like its blood-vessels, are much enlarged, and therefore easily distinguished, in the pregnant state of that organ. Besides those lymphatic vessels which dip down into the cavity of the pelvis on the inside of the external iliac artery at 27, there are others which keep on the outside of that artery upon the psoas muscle, some of which are seen on the left side in the same plate at 28. Of these, one part passes up to the loins at 32, and goes under the aorta in different branches, getting from the left side to the right, and joining the thoracic duct. Another part passes under the iliac arteries, and appears upon the os sacrum at 30, making a beautiful net-work, joining the lymphatics of the right side, and passing under the iliac artery, to form the network 31, upon the upper part of the right psoas muscle. The lymphatic vessels of the right side, joined by some from the left, having now reached the right lumbar region, appear there in the form of a plexus of large vessels, and pass through several glands, which occupied the spaces 33, 33; but, not being injected in the subject, they are not represented. At this part likewise they receive large branches, under the aorta, from the plexus on the left side of the loins, as is mentioned before; and having at last got up as high as the second, or more frequently the third, lumbar vertebra, they all join, and form a single trunk called the *thoracic duct*, which is seen at 36. At this part they are likewise joined by the lacteals, which shall be next described.

The lacteal vessels, so called from their commonly con-

veying a fluid that is of the colour of milk, are found in two sets which communicate with each other; the internal begin from the inner surface of the intestines, where each lacteal is at first formed upon the surface of the villi by numerous small radiated branches, with orifices destined to imbibe the nutritious fluid or chyle: from the cavity of the intestines these vessels pass obliquely through their coats, uniting as they go, so as to form larger branches. These branches run on the outside of the intestines, to get to that part which is next the mesentery. From the intestines they run along the mesentery and mesocolon, towards the spine; passing through the lacteals in their way to the conglobate or mesenteric glands. These glands divide the lacteals into two regions: from the intestines to the glands these vessels are called *lacteæ primi generis*; and from the glands to the thoracic duct, *lacteæ secundi generis*. The lacteals of the *jejunum* are larger and more numerous than those of the *ilium*. Those of the small intestines, as they run upon the mesentery, commonly accompany the superior mesenteric artery, and unite, as they proceed, into larger branches; so that by the time they arrive at the root of the mesentery, they are of a considerable size, as may be seen in *Fig. 5.* 34. From the mesenteric artery they descend by the sides of the aorta, and open at last into the thoracic duct 36; the lacteals, or rather the lymphatics of the large intestines, run somewhat differently. Into the thoracic duct at 36, likewise enters the lymph of the other abdominal viscera. The lymphatics of the glandulæ renales, or renal capsulæ, terminate in the renal plexus. The lymphatic vessels of the spleen pass from the concave side of that viscus, along with the splenic artery in the sinuosity of the pancreas, by the lymphatic vessels of which they are joined. Two sets of lymphatic vessels belong to the stomach, the one running upon its smaller, and the other upon its greater, curvature. Of these, the former accompanies the coronary artery, and passes through some lymphatic glands that lie by its sides. The other set passes from the great curvature of the stomach, partly to the left and partly to the right side. Several branches proceed under the duodenum, and others over it; which all open into the thoracic duct, near the termination of the large trunk of the lacteals, as seen at 36. The thoracic duct is therefore the common trunk which receives the absorbent vessels of the lower extremities, the lacteals, and the lymphatics of the abdominal viscera. The lymphatics of the liver, like those of the other viscera, are in two sets; one of which lies upon the surface of the organ, and the other accompanies the large blood-vessels in its centre. The lymphatics on the concave surface run towards the portæ, where they join those which come from the centre of the liver along with its large blood-vessels. After they get from the liver, they are found to be very numerous. They pass into glands on the vena portarum; and afterwards end in the thoracic duct, near the root of the superior mesenteric artery. It is remarkable, that the valves of those lymphatic vessels which run upon the surface of the liver, can readily be made to give way, so that they may be injected from their trunks to their branches, with great minuteness.

The thoracic duct, which receives all the vessels that we have yet described, differs in its size in different subjects; but it is always smaller in its middle than at its beginning, as is seen in the plate. Sometimes its lower part 36, is larger in proportion than there represented: and that enlargement has been called *receptaculum chyli*; it is considerable in some quadrupeds, in turtle, and in fish: but many anatomists have denied that there is any part of the thoracic duct in the human subject that deserves the name of *receptaculum*, having never seen any thing like a pyriform bag, as it has been described, but merely an enlargement not unlike a varix, and that only in few subjects; it generally appears only a little larger at its middle than at its ends. This lower extremity of the thoracic duct is formed by the union of two or three very large trunks or lymphatic vessels, which are spread out upon the spine, those of the right

right side lying below the right crus diaphragmatis, and those of the left passing between the aorta and the spine; whilst the thoracic duct itself lies at first behind the aorta; but afterwards passes from that upwards, and a little to the right side, till it gets before the first vertebra of the loins.

The superficial lymphatics of the lungs form a beautiful net-work, the larger branches running chiefly between the lobules, the smaller passing over them; and here, as well as on the liver, and other parts, there are numerous valves, the existence of which has been denied by some authors. From the surface they pass to the root of the lungs, and there they go through the bronchial glands. At this place they are joined by the deep-seated absorbents, which creep along the branches of the trachea, and likewise on those of the pulmonary artery and vein. Having left the glands, the principal part of those from the left lung form a trunk which terminates in the thoracic duct, behind the division of the trachea into its right and left branches. The rest of the absorbents of the left lobe pass through glands behind the arch of the aorta, and which are likewise common to those of the heart. They run at last into the thoracic duct near its termination in the red veins. After leaving the bronchial glands, the absorbents of the right lung form three or four principal trunks; one of which commonly ascends on the fore-part of the vena cava superior, and opens into the lymphatic trunk, that terminates in the veins of the right side of the neck. The rest of these trunks go into the thoracic duct at the root of the lungs; and near this place the absorbents of the right and left lungs communicate pretty freely together.

The absorbents of the heart, which have been known only by the latest anatomists, come from its superficial and deep parts. These afterwards form principal trunks which accompany the coronary arteries and veins, and like them the largest belong to the left ventricle. The absorbent accompanying the right coronary artery passes into the trunk, which terminates in the right subclavian vein; while the other, accompanying the left artery, goes to the upper end of the thoracic duct. The thoracic duct, after receiving the vessels before mentioned, passes behind the ascending aorta, and goes to the left side, terminating in the angle between the jugular and subclavian vein. But, just before its termination, it generally goes higher up than the angle, and then bends down towards it; as seen in *Fig. 5. 42, 43.* Sometimes, though rarely, there are two thoracic ducts instead of one. Sometimes the duct splits near the upper part of the thorax; and the two branches, after spreading out from one another, commonly unite again at their termination in the angle between the jugular vein and the subclavian veins.

LYMPHATICS OF THE HEAD AND NECK.—The lymphatics of the head, like those in other parts of the body, are in two sets; one belonging to the outer, the other to the inner, parts. Those on the outside of the head accompany the blood-vessels, and pass through glands in their way to the neck. Those accompanying the temporal artery go through small glands at the root of the zygomatic process, while the absorbents of the occiput pass through others behind the mastoid process of the temporal bone. From the different parts of the face, the lymphatics chiefly accompany the branches and trunk of the facial artery. They come from the inner angle of the eye, from the nose, lips, and cheeks. Some of these pass through small glands on the outside of the buccinator muscle, while the principal branches go through larger glands on the outer and under side of the lower jaw, near the corresponding blood-vessels, and the inferior maxillary gland. Others run through the glands on the upper and under end of the parotid gland. The lymphatics of the inner side of the nose run principally with the internal maxillary artery, and pass through the glands behind the angle of the lower jaw, where they are joined by others from the inner part of the mouth. Deeper than this, and near the internal jugular vein, the lymphatics of the tongue, and parts about the os hyoides, pass through the glands which belong likewise

to those of the deep parts of the head. The glandula thyroidea has many lymphatic vessels, which can be inflated by blowing air into the cells of the gland: these vessels pass on each side of the trachea, one part going into the trunk, which terminates in the right subclavian and jugular, and the other joining the thoracic duct upon the left side near its termination.

In the plate of Absorbent Vessels, *Fig. 5.* exhibits the trunk so prepared as to shew the lymphatics and the thoracic duct: 1, Is the neck. 2, The shoulder. 3, The arm. 4, The outer end of the clavicle. 5, The extremity of the first rib. 6, The subclavian muscle. 7, The rib. 8, The trachea. 9, The aorta ascendens. 10, The spine. 11, Vena azygos. 12, The aorta descendens. 13, The celiac artery. 14, The superior mesenteric artery. 15, The right crus diaphragmatis. 16, The kidney. 17, The right emulgent artery. 18, The common iliac artery. 19, The division of the common iliac into the external and internal iliac arteries. 20, The cavity of the pelvis. 21, The spine of the os ilium. 22, The groin. 23, A lymphatic gland in the groin, into which lymphatic vessels from the lower extremity are seen to enter. 26, The psoas muscle with lymphatic vessels lying upon its inside. 27, A plexus of lymphatics, which having passed over the brim of the pelvis at 25, having entered the cavity of the pelvis, and received the lymphatic vessels belonging to the viscera contained in that cavity, next ascends, and passes behind the iliac artery to 29, 29, The right psoas, with a large plexus of lymphatics lying on its inside. 30, 30, The plexus lying on each side of the spine. 31, 31, 31, Spaces occupied by the lymphatic glands; which are not here represented, not having been injected in the subject. 32, The trunk of the lacteals lying on the under side of the superior mesenteric artery. 33, The same, dividing into two branches; one of which passes on each side of the aorta, that of the right side being seen to enter the thoracic duct at 34. 34, The thoracic duct beginning from the large lymphatics. 38, The thoracic duct passing under the curvature of the aorta to get to the left subclavian vein. 39, A plexus of lymphatic vessels passing upon the trachea from the thyroid gland to the thoracic duct. 40, The upper part of the thoracic duct lying between the left carotid and the left jugular vein, and passing behind that vein downwards and outwards towards the angle between the left jugular and the left subclavian. 41, The extremity of the thoracic duct entering the angle between the left jugular and the left subclavian vein. 46, That network passing under the right subclavian vein, and under the subclavian muscle, the clavicle being removed. The other numbers are explained in the course of the descriptions.

LYMPHATICS OF THE UPPER EXTREMITIES.—Like the leg, each arm has two sets of lymphatic vessels: one set, which lies immediately under the integuments, belongs to the skin and the cellular membrane connecting it to the muscles; the other accompanies the large arteries, and belongs to the parts deeper seated. The superficial set of lymphatic vessels are numerous, and may be discovered in emaciated dropical subjects, by a careful dissection on the fore and back part of the arm. Of the deep-seated lymphatics of the arm, two commonly accompany each artery, in the same manner as the veins do: having reached the upper end of the arm, they go through the axillary glands, where they are joined by the lymphatics from the mamma and side of the thorax, and also by those from the shoulder. From these glands larger branches run under the clavicle, and form a trunk, which receives those from the head and neck already described. In *Fig. 3.* some of the lymphatics are seen running on the back-part of the fore-arm at 6, 6, most of them passing on its outside, and twisting to the fore-part, near the head of the radius, as at 7. But in this representation, there is a vessel which passes towards the inside, under the inner condyle of the os humeri at 8, and sends a branch amongst the muscles; which branch perforates the interosseous ligament, getting between the radius and ulna to the fore-part, where it joins a deep-seated

one that had accompanied the radial artery. In this figure, which exhibits a back view of the fore-arm and hand, 1, Is the hand. 2, The lower extremity of the radius. 3, The lower extremity of the ulna. 4, The muscles on the back of the fore-arm turned aside to exhibit a deep-seated lymphatic vessel which perforates the interosseous ligament to get to the fore-part. 5, The olecranon. The vessels have been already referred to.

In *Fig. 4.* the lymphatic vessels are seen on the fore-part of the upper extremity; those superficial branches which passed on the outside of the back of the fore-arm appearing now on the fore-part at 8; and ascending under the skin that covers the supinator longus, and the biceps, they enter some glands in the axilla at 12, 12, whilst that vessel which passed on the inside of the back of the fore-arm under the internal condyle, appears on the fore-part at 9, and just above the condyle enters a gland 10, and then passes up on the inside of the arm, communicating with a lymphatic from the fore-part of the wrist, and passing to the axillary glands. A superficial lymphatic is seen under the skin, on the fore-part of this extremity just above the wrist; a pipe was introduced at 7, and the vessel thereby injected with mercury. Passing under the integuments over all the muscles, this vessel joins the lymphatic from the back-part of the fore-arm at 11, and there forms a plexus which passes under the integuments, on the inside of the arm, to the axillary glands at 12. Besides these superficial lymphatics upon the upper extremity, others lie near the radial artery; one is injected with a pipe fixed at 13. This vessel accompanies the radial artery, and passes 14, first under the interosseous, and then under the ulnar, artery, which in this subject runs over the muscles. Near the part where it passes under the interosseous artery, it receives the branch from the back of the fore-arm. After passing under these arteries, this lymphatic appears on the inside of the brachial artery at 15, where it is deep-seated. Ascending close to that artery, and near the middle of the arm, it passes through the two glands 16, 16; after which it appears considerably enlarged, goes under one of the arteries anastomoticæ at 17, 18, and then ascends to the lymphatic glands in the axilla 19, 19. In this figure, which exhibits a fore view of the upper extremity, 1, Is the scapula. 2, The clavicle. 3, The extremity of the brachial artery. 4, The muscles lying on the inside of the arm. 5, The inner condyle of the os humeri. 6, The lower extremity of the radius. The subsequent numbers denoting the vessels have been explained in the description.

These vessels, however, as they here appear, although represented from a successful injection, are only a part of the large lymphatic vessels of the arm; and there are some accompanying the ulnar and interosseous arteries, that are not here injected. They should moreover be considered as only trunks of the lymphatics; since it is probable, that every (even the smallest) part of this, as well as all other parts of the body, has some of these vessels adapted to absorption. That this is the case seems to be proved by the experiments made with the variolous matter; for at what part soever of the arm that matter is inserted, the lymphatic vessels take it up and carry it into the body, as can be traced by its inflaming the conglobate glands thro' which these vessels pass. In *Fig. 5.* the termination of all the lymphatic vessels is exhibited. Two of the trunks of those of the left arm are seen at 42. They pass under the clavicle, whose cut end is seen at 4; and under the subclavian vein. Here, having joined, they form the large trunk 43, which appears just above the left subclavian vein, and joins the extremity of the thoracic duct at its entrance into the angle between that vein and the jugular. The lymphatic vessels of the right side form four considerable trunks, which join near their termination. These trunks are, 1. One from the upper extremity, which appears at 47, lying above the clavicle between the subclavian artery and vein: this trunk is formed by the lymphatics 44, which come up with the brachial artery, and the plexus 45, which likewise belongs to the arm, and passes

under the subclavian vein. 2. The trunk of the lymphatic vessels of the right side of the head and neck, which passes down on the outside of the jugular vein, as is shewn at 48. 3. A lymphatic from the thyroid gland: this vessel is seen at 49, passing under the right jugular vein to get to the others. 4. A trunk from the lungs of the right side: this trunk is distinctly traced under the subclavian vein to its termination, in common with the others, at the union of the jugular and subclavian veins.

OF THE CHYLE.

The chyle is a white juice extracted from the aliments, and afterwards mixed with the blood. That its principal composition is of water and oil, seems evident from the sweetness of its taste, from the whiteness of its colour, from its ascendent and coagulable nature, and from its lightness, by which it swims on the blood; in all which properties in very much resembles an emulsion. It is composed of a vegetable farina, with animal lymph and oil. It every where retains the properties of the volatile and oily aliments. It changes into milk with very little alteration. But afterwards it becomes more manifestly glutinous; since the pellucid serum it contains, either by exhaling the watery part, or by applying an intense heat, coagulates into a kind of jelly. Haller has attributed the first cause of motion in the chyle, and of its absorption, chiefly to the attraction of the capillary vessels, which observe alternate pulses with the peristaltic contraction of the intestine. The attractive force fills the villosity; the peristaltic force empties the villosity, and moves the chyle farther forward. The rest of its motions seem to depend on the strength of the membrane of the lacteal vessel itself, which, even after the death of the animal, expels the chyle, so that the vessels become pellucid which before were milky. The alternate compressing force of the diaphragm is also of some efficacy in this case. The chyle, mixed with the blood, does not immediately change its nature, as we learn from the milk which is afterwards made of it; but after it has circulated through the body, fomented with heat, and mixed with a variety of animal juices, it is at length so changed, that a part of it is deposited in the cellular substance under the denomination of fat; a part of it is configured into the red globules; another part changes into serum; and the watery parts go off, in some measure, by urine, in some measure by perspiration; while a small part is retained in the habit to dilute the blood.

OF ABSORPTION.

As there is a secretion upon the different surfaces, and into the different cavities of the body, for the purposes of the constitution, so there is likewise an inhalation or an absorption. For example: if food be taken into the stomach and intestines, it is there digested, and, being converted into chyle, it is in that form taken into the blood-vessels. If garlic be applied to the skin, it gets into the body, and is smelt in the breath with as much certainty as when taken into the stomach, where its juices are absorbed by the lacteals. So, likewise, terebinthinate medicines applied to the skin are soon smelt in the urine; and cantharides in a blister affect the urinary passages. In the same manner fluids are taken from different cavities of the body into the vascular system. Thus the water of an *ascites* and an *anasarca* are occasionally taken up and carried by the blood-vessels to the intestines and kidneys, and evacuated by stool or by urine. And the pus of an abscess is sometimes absorbed and carried to different parts of the body, and there deposited, or is evacuated by the intestines or urinary passages. So also fluids injected into cavities, as that of the chest or belly of living animals, soon find their way into the blood-vessels. These circumstances are admitted by anatomists amongst the unquestionable facts of physiology. Nor do anatomists differ in their opinions about the mode in which these fluids are taken up; for it is universally allowed to be by absorption, or that there

are small orifices adapted to imbibe them: the only question is, what the vessels are to which these orifices belong, whether to the lymphatic system, or to the common veins?

That the common veins did the office of absorbing both the chyle and the lymph, was the opinion of anatomists before Asellius discovered the lacteals; but after his time few doubts were entertained of the lacteals absorbing at least a part of that fluid. Yet many anatomists have been so tenacious of the old opinion, as still to believe that the veins partly performed that office, or absorbed some of the chyle, and carried it to the liver. However, upon taking a review of all the arguments in favour of the doctrine that the common veins are the instruments of absorption, that doctrine appears to have no other support than respect for the authority of our predecessors. And, although this idea was formerly so generally received, yet there were even then some physiologists who reasoned better on the subject; and amongst the first of these was Glisson, who attributes to those vessels the office of carrying back to the blood-vessels the lymph which had lubricated the cavities of the body. M. Noguez, likewise, speaks of absorption by the lymphatics. Hambergerus also seems to have had this idea of their office: and Frederic Hoffman has expressed the doctrine of the lymphatics being absorbents very completely, in his *Medic. Ration. System. lib. i. sect. 2. cap. 3.* This opinion has also been adopted, and supported with additional arguments, by doctors Hunter and Monro; who, besides shewing the fallacy of the experiments brought in favour of the common veins doing the office of absorption, have advanced the following arguments to prove that the lymphatics perform it. First, Their great analogy with the lacteals, with which they agree in their coats, in their valves, in their manner of ramifying, in their passage through the lymphatic or conglobate glands, and in their termination in the thoracic duct, and in short in every circumstance with regard to their structure. Secondly, The passage of the venereal, variolous, and other, poisons, into the constitution; these poisons first making an ulcer, and then being absorbed along with the matter of the ulcer and infecting the whole body. That in such cases they are not absorbed by the common veins, but by the lymphatics, appears from their inflaming these lymphatics in their course, and by their generally inflaming a conglobate gland before they enter the system; a strong argument in favour of their being taken up by the lymphatic vessels which pass through these glands in their way to the thoracic duct. Such, then, seems to be the purpose for which the lymphatic vessels were provided; that is, to do the office of absorption; an office of the greatest importance to the animal: no wonder, therefore, that there should be a system set apart for performing it, and not only in man and quadrupeds, but also in birds, fish, amphibious animals, and perhaps even in insects of the minutest kind.

OF THE NERVES.

THERE are forty pair of nerves in all, of which ten come from the encephalon, and the other thirty have their origin from the spinal marrow. Of the ten pair which come from the encephalon, the first is the *olfactory*, which long had the name of the *mamillary processes* of the brain; because in cows and sheep, which were most commonly dissected by the ancients, the anterior ventricles of the brain are extended forwards upon these nerves, and adhere so firmly to them, that they seem to make the upper side of the nerves. Each of them being large where it begins to be stretched out, and gradually becoming smaller as it approaches the cribriform bone, was imagined to resemble a nipple. The tender structure and sudden expansion of these nerves on such a large surface, render it impossible to trace them far; which has made some authors deny them to be nerves; but, when we break the circumference of the cribriform lamella, and then gently raise it, we may see the distribution of the nerves some

way on the membrane of the nose, where they form a beautiful net-work.

The *second* pair of nerves are the *optic*, which make a large curve outwards, and then run obliquely inwards and forwards, till they unite at the fore-part of the sella turcica; they then divide, and each runs obliquely forwards and outwards to go out at its proper hole in the sphenoid bone, accompanied with the ocular artery, to be extended to the globe of the eye, within which each is expanded into a very fine cup-like web, that lines all the inside of the eye, to within a little distance of the edge of the crystalline lens, and is universally known by the name of *retina*. The retina of a recent eye, without any preparation, appears a very fine web, consisting of fibrils so extremely small, that each expanded optic nerve cannot exceed in diameter the 32,400th part of a hair! There are also some blood-vessels arising from its centre to be distributed on it: and if these vessels lose their tone, and remain preternaturally distended; no object affects our retina, though the eye externally appears sound; or this may be one cause of an amaurosis or gutta serena. From a partial distention of these vessels, or paralysis of a part of the retina, the central part, or the circumference, or any other part, of objects may be lost to one or both eyes.

The *third* pair rise from the anterior part of the process annularis; and, piercing the dura mater a little before and to a side of the ends of the posterior clinoid processes of the sphenoid bone, run along the receptacula, or cavernous sinuses, at the side of the ephippium, to get out at the foramina lacera: after which each of them divides into branches; one of which, after forming a little ganglion, is distributed to the globe of the eye; the others are sent to the musculus rectus of the palpebra, and to the atollens, adductor, depressens, and obliquus minor, muscles of the eye-ball. These muscles being principal instruments in the motions of the eye-lid and eye-ball, this nerve has the name of *motor oculi*. The distention of a considerable branch of the carotid, which passes over this nerve near its origin on each side, may possibly be the reason of the heaviness in the eye-lids and eyes, after drinking hard, or eating much.

The *fourth* pair, which are the smallest nerves of any, derive their origin from the back-part of the base of the testes; and then making a long course on the side of the annular protuberance, enter the dura mater a little farther back than the third pair, to run also along the receptacula, to pass out at the foramina lacera, and to be entirely spent on the muscoli trochleares, or superior oblique muscles of the eyes. These muscles being employed in performing the rotatory motions, and the advancement of the eye-balls forward, by which several of our passions are expressed, the nerves that serve them have the name of *pathetici*.

The *fifth* pair are large nerves, rising from the annular processes, and then sinking close by the receptacula at the sides of the sella turcica, each becomes in appearance thicker, forms a distinct ganglion, and goes out of the skull in three great branches. The first branch is the *ophthalmic*, which runs through the foramen lacerum to the orbit, having in its passage thither a connection with the sixth pair. It is afterwards distributed to the ball of the eye with the third; and to the nose with the olfactory. The small fibres which this first branch of the fifth and third pair of nerves send to the eye-ball, being situated on the optic nerve, and, after piercing the sclerotic coat, running along the choroid coat on the outside of the retina in their course to the uvea or iris, may be a cause of the sympathy between the optic nerve and the uvea; by which we more readily acquire the habit of contracting the iris, and thereby lessen the pupil, when too strong a light is excluded; and, on the contrary, enlarge the pupil when the light is too faint. This, with the sympathy which must arise from some of the nerves of the membrane of the nostrils being derived from this first branch of the fifth pair of nerves, may also be the cause, why an irritation

of the retina, by too strong light, may produce sneezing, as if a stimulus had been applied to the membrane of the nose itself; why pressing the internal canthus of the orbit sometimes stops sneezing; why irritation of the nose or of the eye causes the eye-lids to shut convulsively, and make the tears to flow plentifully; and why medicines put into the nose do great service in diseases of the eyes. In the *megrim*, all the branches of the nerves discover themselves to be affected: for the forehead is racked with pain; the eye-ball is pained, and feels as if it was squeezed; the eye-lids shut convulsively, and make the tears trickle down, and an uneasy heat is felt in the nose. Hence we can understand, where external medicines will have the best effect when applied to remove this disease, to wit, to the membrane of the nose, and to the forehead; why alternate pressure near the superciliary hole of the frontal bone, or sneezing, sometimes gives immediate relief in the *megrim*; why the sight may be lost by an injury done to the supra-orbital branch; and how it may be restored by agitation of that branch of this nerve. The second branch of the fifth pair of nerves may be called *maxillaris superior*, from its serving principally the parts of the upper jaw. It goes out at the round hole of the sphenoid bone, and sends immediately one branch into the channel on the top of the antrum maxillare; the membrane of which and the upper teeth are supplied by it in its passage; as are likewise the cheek, upper lip, and nostril. Hence a pain in the teeth of the upper jaw occasions a gnawing pain deep-seated in the bones of the face, with swelling in the eye-lids, cheek, nose, and upper lip; and, on the other hand, an inflammation in these parts, or a *megrim*, is often attended with a sharp pain in the teeth. Hence, an obstruction in the duct of the maxillary sinus, which obliges the liquor secreted there to find out a preternatural route for itself, may be occasioned by the pain of the teeth. Hence, the upper lip often suffers when the palate or nose is ulcerated. The third, or *maxillaris inferior*, branch of the fifth pair going out of the oval hole of the sphenoid bone, serves the muscles of the lower jaw, and the muscles situated between the os hyoides and jaw. All the salivary glands, the amygdalæ, and the external ear, have branches from it. It has a large branch lost in the tongue, and sends another through the canal in the substance of the lower jaw, to serve all the teeth there, and to come out at the hole in the fore-part of the jaw, to be lost in the chin and under-lip. Hence a convulsive contraction of the muscles of the lower jaw, or the mouth's being involuntarily shut, a great flow of spittle or salivation, a pain in the ear, especially in deglutition, and a swelling all about the throat, are natural consequences of a violent irritation of the nerves of the lower teeth in the tooth-ach; and pain in the teeth and ear is as natural a consequence of an angina. Hence alternate pressure on the chin may sometimes relieve the violence of a tooth-ach. Hence destroying the nerves of a tooth by actual or potential cauteries, or pulling out a carious tooth, so often removes immediately all these symptoms. Hence no cure is to be found for some ulcers in the upper or lower jaw, but by drawing a tooth. Hence in cancers of the upper lip, the salivary glands are in danger of being affected, or the disease may be occasioned in the lip by its beginning in the glands.

The *sixth* pair, which is the smallest except the fourth, rises from the fore-part of the corpora pyramidalis; and each, entering the dura mater behind the posterior clinoid process of the sphenoid bone, has a long course below that membrane, and within the receptaculum at the side of the sella turcica, where it is immersed in the blood of the receptacle. It goes afterwards out at the foramen lacerum into the orbit, to serve the abductor muscle of the eye. A defect in this nerve may therefore be one cause of strabismus. In the passage of this nerve below the dura mater, it lies very contiguous to the internal carotid artery, and to the ophthalmic branch of the fifth pair of nerves. At the place where the sixth pair is con-

tiguous to the carotid, a nerve either goes from each of them in an uncommon way, to wit, with the angle beyond where it rises obtuse, to descend with the artery, and to form the beginning of the intercostal nerve, according to the common description; or, according to other authors, this nerve comes up from the great ganglion of the intercostal, to be joined to the sixth here.

The *seventh* pair comes out from the lateral part of the annular process, behind where the medullary processes of the cerebellum is joined to that tuber; and each being accompanied with a larger artery than most other nerves, enters the internal meatus auditorius, where the two large bundles of fibres, of which it appeared to consist within the skull, soon separate from each other: one of them entering by several small holes into the vestibule, cochlea, and semicircular canals, is stretched on this inner camera of the ear in a very soft pulpy substance; and being never seen in the form of a firm cord, such as the other part of this and most other nerves become, is called the *portio mollis* of the auditory nerve. The other part crosses the cavity of the tympanum, where it has the name of *chor-da tympani*. It also pierces through the parotid gland, and divides into a great many branches, which are dispersed in the muscles and teguments that cover all the side of the upper part of the neck, the whole face and cranium, as far back as the temples, including a considerable part of the external ear. Its branches having thus a considerable connection with all the three branches of the fifth pair, and with the second cervical, occasion a considerable sympathy of these nerves with it. Hence in the tooth-ach, the pain is sometimes very little in the affected tooth, compared to what it is all along the side of the head and in the ear. Hence probably the relief of the tooth-ach from blisters applied behind or before the ear, or by a hot iron touching the antihelix of the ear. By this communication or connection possibly too it is, that a vibrating string held between one's teeth, gives a strong idea of sound to the person who holds it, which no body else can perceive. Perhaps too the distribution of this nerve occasions the head to be so quickly turned upon the impression of sound on our ears.

The *eighth* pair of nerves rise from the lateral bases of the corpora olivaria in separated fibres; and, as they are entering the anterior internal part of the holes common to the os occipitis and temporum, each is joined by a nerve which ascends within the dura mater from the tenth of the head, the first, second, and inferior, cervical nerves: this has the name of the *nervus accessorius*. The eighth pair gives nerves to the tongue, larynx, pharynx, and ganglion of the intercostal nerve; and, being disjoined from the ninth and intercostal, runs straight down the neck behind the internal jugular vein, and at the external side of the carotid artery. As it is about to enter the thorax, a large nerve goes off from each side: the branch of the right side turns round from the fore to the back part of the subclavian artery, while the branch of the left side turns round the great curve of the aorta; and both of them mounting up again at the side of the œsophagus, to which they give branches, are lost at last in the larynx. These are called the *recurrent nerves*, which we are desired to shun in the operation of bronchotomy. The muscles of the larynx being in a good measure supplied with nerves from the recurrences, it is to be expected, that the cutting of them will greatly weaken the voice, though it will not be entirely lost so long as the superior branches of the eighth pair are entire. The recurrences themselves often send off small nerves to the pericardium, and to join with the branches of the intercostals that are distributed to the heart. After these branches are sent off, the par vagum on each side descends behind the great branch of the trachea, and gives numerous filaments to the lungs, and some to the heart in going to the œsophagus. The one of the left side running on the fore-part of the œsophagus, communicates by several branches with the right one in its descent to be distributed to the stomach.

stomach. From the distribution of this *par vagum*, we may learn, how tickling the fauces with a feather or any such substance, excites a nausea and inclination to vomit; why coughing occasions vomiting, or vomiting raises a cough. Hence we see how the nervous asthma, the tussis convulsiva, and chin-cough, are attended with a straitening of the glottis; why food difficult to digest occasions the asthma to weakly people; and why emetics have frequently cured the asthma very speedily; why an attempt to vomit is sometimes in danger of suffocating asthmatic people; why the superior orifice of the stomach is so sensible as to be looked on as the seat of the soul by some anatomists; why people subject to distensions of the stomach have so often the sensation of balls in their breast and throat; why the *globus hystericus* is so often attended with a violent stranguation at the glottis.

The *ninth* pair of nerves comes from the inferior part of the corpora pyramidalia, to go out of the skull at their proper holes of the occipital bone. After their egress they adhere for some way firmly to the eighth and intercostal; and then sending a branch, that in many subjects is joined with branches of the first and second cervical nerves, to be distributed to the thyroid gland, and muscles on the fore-part of the trachea arteria, the ninth is lost in the muscles and substance of the tongue. Some authors have thought this nerve, and others have esteemed the third branch of the fifth pair of nerves, to be the proper gustatory nerve.

The *tenth* pair rises in separate threads from the sides of the spinal marrow, to go out between the os occipitis and first vertebra of the neck. After each of them has given branches to the great ganglion of the intercostal, eighth, ninth, and first, cervical nerves, it is distributed to the straight oblique, and some of the extensor, muscles of the head. As the intercostal is about to enter the thorax, it forms another ganglion, from which nerves are sent to the trachea and to the heart; those designed for the heart joining with the branches of the eighth, and most of them passing between the two great arteries and the auricles to the substance of that muscle. The intercostal after this consisting of two branches, one going behind, and the other running over the fore-part of the subclavian artery, forms a new ganglion, where the two branches unite below that artery; and, then descending along the sides of the vertebrae of the thorax, receives branches from each of the dorsal nerves; which branches appearing to come out between the ribs, have given the name of *intercostal* to the whole nerve. The almost universal connection and communication which this nerve has with the other nerves of the body, may lead us to understand the following and a great many more phenomena: Why tickling the nose causes sneezing; why the too great quantity of bile in the cholera occasions vomiting as well as purging; why people vomit in cholics, in inflammations or other irritations of the liver, or of the ducts going from it and the gall-bladder; why a stone in the kidneys, or ureters, or any other cause irritating those organs, should so much more frequently bring on vomiting and other disorders of the stomach, than the stone or any other stimulating cause in the bladder does; why vomiting is a symptom of danger after child-birth, lithotomy, and other operations on the parts in the pelvis; why the obstructions of the menses are capable of occasioning stranguations, belching, cholics, stomach aches, and even convulsions in the extremities; why vesicatories, applied from the ears to the clavicles of children labouring under the tussis convulsiva, are frequently of great service; why worms in the stomach or intestines excite an itching in the nose, or grinding of the teeth; why irritations in the bowels or the belly occasion sometimes universal convulsions of the body.

The SPINAL NERVES rise generally by a number of separated fibres from both the fore and back part of the medulla spinalis; and soon after form a little knot, or ganglion, where they acquire strong coats, and are extended into firm cords; but the ganglion is entirely form-

ed by the posterior bundle. They are distinguished by numbers, according to the vertebrae from between which they come out; the superior of the two bones forming the hole through which they pass, being the one from which the number is applied to each nerve. There are generally said to be thirty pair of them: seven *cervical*, which come out between the vertebrae of the neck; twelve *dorsal*, between the vertebrae of the back; five *lumbur*, between the vertebrae of the loins; and six pair from the false vertebrae.

The *first* cervical pair of the nerves sends its largest branches backwards to the extensor muscles of the head and neck; and many fibres advance so far as to be connected with the portio dura of the auditory nerve. Hence possibly it is, that a clavus hystericus changes suddenly sometimes from the forehead to a violent pain and spasm in the back-part of the head and neck. The *second* cervical has a large branch that comes out at the exterior edge of the sterno-mastoideus muscle, and it is afterwards distributed to the integuments of the side of the neck and head, parotid gland, and external ear, being connected to the portio dura of the auditory nerve, and to the first cervical. The remainder is spent on the levator scapulae and the extensors of the neck and head. The irritation of the branches of this nerve in an inflammation of the parotid gland, is probably the cause why the neck is pained so far down as the clavicle, the head is drawn towards the shoulder of the affected side, and the chin is turned to the other side. The *third* pair of the neck passes out between the third and fourth cervical vertebrae; having immediately a communication with the second, and sending down a branch, which, being joined by a branch from the fourth cervical, forms the *phrenic* nerve. This nerve enters the thorax between the subclavian vein and artery; and then, being received into a groove formed for it in the pericardium, it has its course along this capsula of the heart, till it is lost in the middle part of the diaphragm. The other branches are distributed to the muscles and integuments at the lower part of the neck and top of the shoulder. No wonder then that an inflammation of the liver or spleen, an abscess in the lungs adhering to the diaphragm, or any other cause capable of irritating the diaphragm, should be attended with a sharp pain on the top of the shoulder, as well as wounds, ulcers, &c. of this muscle itself. If the irritation of this muscle is very violent, it may occasion that convulsive contraction of the diaphragm which is called a *hiccough*; and therefore an hiccough in an inflammation of the liver has been justly declared to be an ill symptom. An irritation of the thoracic nerves which produces sneezing may sometimes free the phrenic nerves from any spasm they occasion: so that sneezing sometimes takes away the hiccough; and a derivation of the fluid of the nerves any other way may do the same thing; or the hiccough may also be sometimes cured by drawing up into the nose the smoke of burning paper or other acrid fumes, swallowing pungent or aromatic medicines, and by a surprise, or any other strong application of the mind in thinking, or in distinguishing objects: or, when all these have failed, it has been put away by the brisk stimulus of a blistering plaster applied to the back. The *fourth* cervical nerve, after sending off that branch which joins with the third to form the phrenic, and bestowing twigs on the muscles and glands of the neck, runs to the arm-pit, where it meets with the fifth, sixth, and seventh, cervicals, and first dorsal, that escape in the interstices of the muscoli scaleni, to come at the arm-pit, when they join, separate, and re-join, in a way scarcely to be rightly expressed in words; and, after giving several considerable nerves to the muscles and integuments which cover the thorax, they divide into several branches, and are distributed to all the parts of the superior extremity. The situation of these branches in the axilla may let us see how a weakness and atrophy may be brought on the arms by long-continued pressure of crutches, or such other hard substances, on this part; and

and the course of them from the neck to the arm may teach us how much better effects vesicatories, or stimulating nervous medicines, would have, when applied to the skin covering the transverse processes of the vertebrae of the neck, or at the axilla, than when they are put between the shoulders, or upon the spinal processes, in convulsions or palsies of the superior extremities, where a stimulus is required.

The *twelve* dorsal nerves of each side, as soon as they escape from between the vertebrae, send a branch forward to join the intercostal, by which a communication is made among them all; and they soon likewise give branches backward to the muscles that raise the trunk of the body, their principal trunk being extended outwards to come at the furrow in the lower edge of each rib, in which they run toward the anterior part of the thorax, between the internal and external intercostal muscles, giving off branches in their course to the muscles and integuments of the thorax. The *six* lower dorsal nerves give branches to the diaphragm and abdominal muscles. May not the communications of all these nerves be one reason, why the parts they serve act so uniformly and conjunctly in respiration, and conspire together in the convulsive motions of coughing, sneezing, &c. The twitching spasms that happen sometimes in different parts of the muscles of the abdomen, by an irritation on the branches of the lower dorsal nerves, are in danger of occasioning a mistake in practice, by their resemblance to the cholic, nephritis, &c. The communications of these lower ones with the intercostals, may serve to explain the violent effort of the abdominal muscles in a tenesmus, and in child-bearing.

The *five* lumbar nerves on each side communicate with the intercostal and with each other, and give branches backwards to the loins. Branches of the second, third, and fourth, make up one trunk, which runs along the fore-part of the pelvis; and is spent on the adductor muscles, and on the integuments on the inside of the thigh. This nerve is called the *obturator*, or *posterior crural nerve*. Whoever attends to the course of these lumbar nerves, and of the spermatic vessels and nerves upon the psoas muscle, with the oblique passage of the ureter over that muscle, will not be surpris'd, that when a stone is passing in this canal, or even when it is inflamed, the trunk of the body cannot be raised erect, without great pain; or that the skin of the thigh becomes less sensible, and the thigh is drawn forward, and that the testicle often swells and is drawn convulsively towards the ring of the abdominal muscles.

The *six* pair of the false vertebrae consist each of small posterior branches sent to the hips, and of large anterior branches. The first, second, and third, after coming through the three upper holes in the fore-part of the os sacrum, join together with the fourth and fifth of the loins, to form the largest nerve of the body, which is well known by the name of *sciatic* or *ischiatric* nerve. This, after sending large nerves to the different parts of the pelvis, and to the external parts of generation and the podex, as also to the muscles of the hips, passes down to the bone of the thigh at its back-part, giving off nerves to the neighbouring muscles and integuments. A little above the ham, where it has the name of *popliteus nervus*, it sends off a large branch that passes over the fibula, and, sinking among the muscles on the anterior external part of the leg, runs down to the foot, to be lost in the upper part of the larger toes, supplying the neighbouring muscles and integuments every where in its passage. By attending to the particular distribution of the nerves of the inferior extremities, we may see why people with fractured legs, especially where there are splinters, should be subject to convulsive startings of the fractured member: Why, upon tying the blood-vessels in an amputation of the leg, the patients should sometimes complain of violent pain in their toes; why such patients should also be troubled with startings; why, for a considerable time after the amputation of the diseased limb, when the sup-

uration is well advanced, they should complain of pain in the fore which occasioned the amputation.

The branches of the four last cervical nerves, and of the first dorsal, which are bestowed on the superior extremities, and the two crurals, with the sciatic, which are distributed to the inferior extremities, are much larger proportionally to the parts they serve, than the nerves of the trunk of the body, and especially of the viscera; and for a very good reason, that in the most common necessary actions of life, a sufficient quantity of fluid, on which the influence of nerves seems to depend, may be supplied to the muscles there, which are obliged to perform more frequent and violent contractions than those of any other parts. The size of the nerves of the inferior extremities seems larger proportionally than in the superior extremities; the inferior extremities having the weight of the whole body to sustain, and that frequently at a great disadvantage. What the effect of the nerves here being injured is, we see daily. When people happen, by sitting wrong, to compress the sciatic nerve, they are incapable for some time after to support themselves on the affected extremity; and this is still more remarkable in the sciatica or hip-gout, in which the member is not only weakened, but gradually shrivels and wastes.

The NERVES of the HUMAN BODY are represented in the Anatomical Plate IX. of which the following is an explanation, viz.

FRONT VIEW.

1, The first branch of the fifth pair of nerves. 2, The second branch of the fifth pair. 3, The third branch of the fifth pair. 4, The trunk of the eighth pair cut. 5, The recurrent nerve. 6, The great sympathetic nerve. 7, The uppermost ganglion of the great sympathetic nerve. 8, The ramus splanchnicus of the great sympathetic nerve. 9, A branch of the sub-occipital, or tenth pair of the head, joining with the great sympathetic nerve. 10, The first cervical nerve. 11, The seventh cervical nerve; the intermediate cervicals come out in a similar manner. 12, The phrenic nerve. 13, The axillary plexus. 14, The muscular nerve of the arm. 15, The articular nerve. 16, The spiral nerve. 17, The radial nerve. 18, The ulnar nerve. 19, The first intercostal nerve. 20, The last intercostal nerve: the other ten come out in the same manner. 21, The first lumbar nerve. 22, The last lumbar nerve: the three intermediate lumbar nerves come out in a similar way. 23, Branches from the external thoracic nerves running down upon the side of the thorax. 24, Branches sent off from the intercostal and lumbar nerves to supply the outer part of the thorax and abdomen. 25, Nerves of the os sacrum. 26, The obturator nerve. 27, The anterior crural nerve. 28, A branch of the anterior crural nerve, which runs near the vena saphena major. 29, The anterior tibial nerve running down to the foot.

BACK VIEW.

1, The recurrent nerve. 2, A branch of the fourth cervical nerve, joining the recurrent one before it terminates on the musculus trapezius. 3, Branches of the fifth pair, perforating the scalenus medius to be spent upon the rhomboid muscles. 4, Branches of the sub-occipital nerve, running to the small muscles at the under and back part of the head. 5, Posterior branches of the cervical nerves. 6, Posterior branches of the dorsal nerves. 7, Posterior branches of the dorsal and lumbar nerves running to the erector muscles of the back. 8, Posterior branches of the dorsal nerves, penetrating the intercostal muscles. 9, Branches from the last dorsal, and from the lumbar nerves, supplying the lumbar and abdominal muscles. 10, Branches from some of the lower cervical nerves, running to the muscles on the back-part of the scapula. 11, The articular nerve. 12, A branch from the axillary plexus running to the musculus latissimus dorsi. 13, Another branch from the axillary plexus running to the latissimus dorsi and serratus magnus. 14, The spiral nerve. 15, The

15, The ulnar nerve. 16, Small branches coming through the holes in the back-part of the os sacrum running to the muscles, &c. there. 17, A small branch running out between the os sacrum and os coccygis. 18, The end of the cauda equina running through the canal at the back-part of the os sacrum. 19, The sciatic nerve. 20, Branches from the sciatic nerve to the muscles on the back-part of the pelvis. 21, Branches from the sciatic nerve to the muscles, &c. about the anus. 22, Branches from the sciatic nerve to the glutæus maximus and muscles, at the upper and back part of the thigh. 23, Trunk of the sciatic nerve, sending off branches to the muscles on the back-part of the thigh. 24, The fibular nerve sent off from the sciatic one. 25, The posterior tibial nerve, which is a continuation of the sciatic nerve.

The Nerves of the Eye-ball are shewn in a separate figure.

OF THE NERVOUS FLUID.

The nature and properties of the fluid or liquor which passes through the nerves, hath been a subject of considerable debate among physiologists. Some have imagined the liquor of the nerves to be capable of vast explosion like gun-powder, or of violent sudden rarefaction like air, or of strong ebullition like boiling water, or of effervescence like the mixture of acids with alkaline liquors. But, as the mass of blood from which this fluid is derived is not possessed of any such properties, we cannot suppose the blood to furnish what it has not in itself. Besides, all these operations are too violent for the brain or nerves to bear; and, when they are once begun, they are not so quickly controuled or restrained, as experience teaches us the nerves can, which may be suddenly made to cease from acting. We are not sufficiently acquainted with the properties of an æther, or electrical effluvia, pervading every thing, to apply them justly in the animal œconomy; and it is as difficult to conceive how they should be retained or conducted in a long nervous cord. These are difficulties not to be surmounted. The surest way of judging what kind of liquor this of the nerves must be, is to examine the liquors of similar parts of the body. All the glands separate liquors from the blood much thinner than the compound mass itself; such is the liquor poured into the cavity of the abdomen, thorax, ventricles of the brain, the saliva, pancreatic juice, lymph, &c. Wherever there is occasion for secreted liquors being thick and viscid, in order to answer better the uses they are intended for, nature has provided reservoirs for them to stagnate in, where their thinner parts may be carried off by the numerous absorbent veins dispersed on the side of those cavities; or they may exhale where they are exposed to the open air. The mucus of the nose becomes viscid by stagnation; for, when it is immediately secreted, it is thin and watery, as appears from the application of sternutatories, &c. The cerumen of the ears is of a watery consistence, when just squeezing out. The mucus of the alimentary canal grows thick in the lacunæ. The bile in the hepatic duct has little more consistence than lymph; that in the gall-bladder is viscid and strong. The urine is much more watery as it flows from the kidneys, than when it is excreted from the bladder. The seed is thin in the testicles, and is concocted in the vesiculæ seminales, &c. Hence we may safely conclude, that a thin liquor is secreted in the cortex encephali or spinal marrow; and seeing the thinness of the secreted liquors is generally, as the divisions of the vessels, into small subtle branches, and that the ramifications within the skull are almost infinitely subtle, the liquor secreted in the encephalon may be determined to be among the finest or thinnest of fluids.

The liquor or fluid in the nerves moves constantly, equally, and slowly, unless when its course is altered by the influence of the mind, or by the pressure of some neighbouring active organ. We have not, however, and perhaps cannot have, any idea of the manner in which the mind and body act upon each other; but, if we al-

low that the one is affected by the other, which none deny, and that the fluid of the nerves (whatever name people please to give it) is a principal instrument which the mind makes use of to influence the actions of the body, or to inform itself of the impressions made on the body, we must allow that the mind can direct this instrument differently, particularly as to quantity and celerity, tho' we must remain ignorant of the manner how many phenomena, depending on this connection of mind and body, are produced. Thus we would in vain attempt to account for animals continuing, after their heads were struck off or their hearts were cut out, to perform actions begun before they suffered any injury.

All objects of sense, when applied to their proper organs, act by impulse; and this action is capable of being increased by increasing the impelling force. In tangible objects, it is clearly evident, that the closer they are pressed to a certain degree, the more distinct does the perception come. Odorous particles need the assistance of air moved rapidly to affect our nose: sapid substances, that are scarcely sufficient to give us an idea of their taste by their own weight, are assisted by the pressure of the tongue upon the palate: the rays of light collected drive light bodies before them: sound communicates a vibration to all bodies in harmonic proportion with it. The impulses made thus by any of these objects on the nerves, which are full of liquor, press their sides or extremities, and their liquor is prevented from flowing so freely as it did. The canals being all full, this resistance must instantaneously affect the whole column of fluids in the canals that are pressed, and their origins, and have the same effect as if the impulse had been made upon the origin itself. To illustrate this by a gross comparison, Let any one push water out of a syringe, through a long flexible pipe fixed to the syringe; and he is sensible of resistance or a push backwards, the moment any one stops the orifice of the pipe, or closes the sides of it with his fingers. This impulse made on the nerves, and thus communicated to their origin, varies according to the strength or weakness, the quickness or slowness, the continuance or speedy removal, the uniformity or irregularity, the constancy or alteration, &c. with which objects are applied to the nerves. The various kinds of impulses which the different classes of objects make, occasion in animals, which ought to have accurate perceptions of each object, a necessity of having the different organs of the senses variously modified, so that the several impulses may be regularly applied to the nerves in each organ; or, in other words, we must have different organs of the senses fitted to the different classes of objects. As the objects have one common property of impulse, so all the organs have most of the properties of the organ of touching in common with the papillæ of the skin. This is evident in the nose and tongue: we can also perceive it in some operations of the eyes, as we may likewise do in some cases where matter is collected in the internal ear.

These properties common to the different objects and organs, occasion frequently uncommon effects in the application of an object to an organ proper to another object of sensation; for, sometimes we have the same idea as if the object had been applied to its own proper organ; at other times the object is as it were changed, and we have the idea as if the organ had had its own proper object applied to it. Thus, for example, light is the proper object to be applied to the eye, to give us an idea of colours; yet, when all light is excluded from the eyes, an idea of light and colours may be excited in us by coughing, sneezing, rubbing or striking the eye-ball. A cane vibrating, so as not to excite sound perceptible to the ear, applied to the teeth, raises a strong idea of sound; as a little insect creeping in the meatus auditorius also does. The fingers applied to two rough surfaces, rubbing on each other, are sensible of the sound they make; surgeons of any practice in the cure of fractured bones can bear witness to the truth of this. The fingers dipped in acid

and several other acrid liquors, have a sensation very like to tasting. Smelling and tasting, every body knows, are subservient and assisting to each other. From such examples we have further proof of one general cause of our sensations, to wit, impulse from the objects; and of such a similarity and relation in the organs, as might give reason for imagining that any one of them would be capable of producing the effect of another, if the impulses of the different objects could be regularly applied to each. Hence light and sound may affect insects and other animals that have not eyes or ears. If the impulse of an object is applied with due force, but irregularly, a confused idea of the object is raised. If the application of the impulse is regular, but the force with which it is applied too weak, our perception of the object is too faint. One may whisper so low as not to be heard. If the application of objects is too violent, and there is any danger of the tender organs of our senses being hurt or destroyed, an uneasy sensation we call *pain* is raised, whatever may be the organ thus injured. The object of feeling affects every organ; thus pressure, stretching, cutting, pricking, acrid salts, pungent oils, great heat, violent cold, &c. occasion pain, wherever they are applied. Besides, every particular organ can be affected with pain by the too violent application of its own proper object. Too much light pains the eyes; very loud sounds stun the ears; very odorous bodies and too rapid objects hurt the nose and tongue. This is a sure proof that the objects of our senses all act, and that the organs are all impressed, in nearly the same way.

Whenever the uneasy sensation, *pain*, is raised by the too strong application of objects, a sort of necessity is as it were imposed upon the mind, to endeavour to get free of the injuring cause, by either withdrawing the grieved part of the body from it, as one draws back his hand when his finger is pricked or burnt; or the injuring cause is endeavoured to be forced from the body, as a tenesmus excites the contraction which pushes acrid faeces out of the rectum. In both these operations, a convulsive contraction is immediately made in the part hurt, or in the neighbourhood of it; and, if the irritation is very strong or permanent, the greater part of the nervous system becomes affected in that spasmodic or convulsive way. Is it this necessity which obliges the mind to exert herself in respiration, or in the action of the heart, when the lungs or heart are gorged with blood? or the iris to contract the pupil, when the eye is exposed to a strong light? or sneezing to be performed when the nose is tickled, &c. Will not a stimulus of any nerve more readily affect those with which it is any where connected, than the other nerves of the body? May not this sympathy serve as a monitor of the mind to employ the organs furnished with nerves thus connected, to assist in freeing her of any uneasy sensation, rather than to make use of any other organs? Will not this in some measure account for many salutary operations performed in the body, before experience has taught us the functions of the organs performing them?

This nifus of the mind to free the body from what is in danger of being hurtful, may serve to explain the phenomena of a great many diseases, after we are acquainted with the distribution of the particular nerves; and from this we can understand the operation of medicines that stimulate; and may learn how, by exciting a sharp but momentary pain, we may free the body of another pain, that would be more durable; and that, by having it thus in our power to determine a flow of the liquor of the nerves to any particular part, for the benefit of that part, or the relief of any other diseased part, we can do considerable service by a right application of the proper medicines.

OF THE BURSAE MUCOSÆ.

AS the *bursæ mucosæ* are organs which form a very curious part of our structure, a perfect knowledge of them will frequently be found useful in practice; yet, notwith-

standing the necessity of being well acquainted with these material parts of the human frame, anatomists, even the latest and most accurate, have not paid that attention to the subject which its importance seems to require. It is well known that the tendons of the muscles, at the wrists and ankles, and in their course along the fingers and toes, are conducted in sheaths. Winslow observed, that these sheaths were lined with thin and smooth membranes; and Albinus remarked, that where these ligamentary sheaths were absent, sacs were frequently interposed between the tendons and the bones over which these tendons moved. To these sacs, he gave the name of *bursæ mucosæ*; and in his admirable work, the History of the Muscles, he describes several of them. Dr. Monro thinks, and not without just grounds, that Winslow had not sufficiently examined the extent and structure of the membranes lining the ligamentous sheaths of the tendons; and he also makes it appear, that Albinus did not perceive, as is really the case, any similarity between these membranes and the sacs which he described under the name of *bursæ mucosæ*. Some of the later anatomists, professor Monro thinks, have not sufficiently attended to Albinus's discovery; and that others, especially the learned Haller, have mistaken the nature of the *bursæ*, supposing them to be formed of cellular membrane, like that which covers the belly of the muscles; while the greater number of the later writers on anatomy have contented themselves with repeating the description given by Albinus, and have never attempted to throw farther light on the subject.

The *bursæ mucosæ* are only to be found in the extremities of the body; they are in all 140, *thirty-three* in each superior, and *thirty-seven* in each inferior, extremity. Many of them are placed on the inner sides of the tendons, between these and the bones. Many others cover not only the inner but the outer sides of the tendons, or are interposed between the tendons and external parts, as well as between those and the bones. Some are situated between the tendons and external parts only or chiefly; some between contiguous tendons, or between the tendons and the ligaments of the joints. A few are interposed where the processes of bones play upon the ligaments, or where one bone plays upon another.

Where two or more tendons are contiguous, and afterwards separate from each other, we generally find a common *bursa* divided into branches, with which it communicates; and a few *bursæ* of contiguous tendons communicate with each other. Some *bursæ*, even in young and healthy children, communicate with the cavities of the joints; and in many old persons such communications are often formed by use or worn by friction, although there had been no lameness nor complaint of pain made by the person on that account during life. There is some little difference, in different persons, as to the manner in which contiguous sacs communicate with each other, or with the cavities of the joints. And, particularly, we have observed, that a *bursa* as large as a hen's egg, which is placed behind the tendon of the extensors of the leg, in some persons has no communication with the cavity of the joint of the knee; but, in the greater number of children, as well as adults, we find the opening large enough to allow one or two fingers to pass from the *bursa* into the joint.

We are at first sight struck with the resemblance which the structure of the *bursæ* bears to that of the capsular ligaments of the joints; and, the more attentively we pursue the comparison, the more just and perfect their agreement will be found. 1. The internal membrane of the ligaments of the joints, like that of the *bursæ*, is thin and dense. 2. It is connected to the external ligaments by the common cellular substance. 3. Between it and the bones, layers of cartilage or the articular cartilages are interposed. 4. At the sides of the joint, where it is not subjected to violent pressure and friction, the adipose substance is connected with the cellular membrane. 5. Within the cavities of the joints we observe masses of fat projecting which are covered with similar blood-vessels, and with similar
fimbriae

fimbriae or fringes hanging from their edges. 6. In the knee we may observe the upper part of such a mass of fat, forming what has been called the *muclaginous gland of the joint*; and the under part of it projecting into the bursa, behind the ligament which ties the patella to the tibia. 7. The liquor which lubricates the bursa has the same colour, consistence, and properties, as that of the joints; and both are affected in the same manner by heat, mineral acids, and ardent spirits. 8. In some places the bursa constantly communicate with the cavities of the joints; in others they generally do so: from which we may infer a sameness of structure.

Mr. Gooch, in his Treatise, takes notice of a wound into one of these bags on the side of the knee, which from the discharge he concluded to have been in the burfal ligament, but it healed kindly, and gave him to suspect that these bags may be the seat of disorders not yet adverted to. He hath also given the following list of as many of them as had fallen under his observation: 1. *Deltoides*: a large one situated under this muscle, upon the acromion scapulae. 2. *Biceps brachii*: a small one investing the tubercle of the radius, both on the side where the tendon is fixed, and also on the other side, where there is no tendon. It adheres strongly to the whole tubercle, and loosely to part of the supinator brevis, under which it lies, as well as under the tendon of the biceps. 3. *Iliacus internus & psoas*: a large thin and pliable one is found upon the ischium, beneath the tendons of the iliacus internus and psoas, as they pass down to their insertions in the os femoris. It is attached to these tendons, and to the anterior surface of the capsular ligament; and this sacculus sometimes communicates with the joint. 4. *Latissimus dorsi & teres major*: one is situated between the extremities of the tendons of these muscles, adhering strongly to them. 5. *Gluteus maximus*: a large thin one, firmly connected by a small part of it to the back of the trochanter, immediately under the termination of the gluteus medius, and is loosely attached to the rest of the trochanter, and the tendon of the gluteus maximus. 6. *Gluteus medius*: a small one situated between the termination of its tendon and that of the pyriformis, adhering to both. 7. *Gluteus minimus*: a small thin one, attached to its tendon and the trochanter major. 8. *Gemini*: a small one between them and the termination of the obturator internus, connected to both, and to that part of the capsula of the joint which lies under the gemini. 9. *Biceps cruris*: one is situated between the end of its tendon exteriorly, and the capsular ligament of the knee, adhering to both. 10. *Seminembranosus*: a small one lies between its tendon, which runs between the inner condyle of the tibia, and the capsular ligament of the joint. 11. *Cruralis & vasti*: behind the tendons of the cruralis and vasti there is a thin but large one, connected to those tendons before they join, and after their junction it is fixed to the patella; it also adheres to the capsula of the joint that expands itself over the bone. 12. *Gracilis, sartorius, & semitendinosus*: under the extremities of the tendons of these muscles is a large one, adhering to them on one side, and on the other to the capsular ligament of the knee, and on the side where these tendons play. 13. *Gemellus*: a large one lies under its inner head, firmly attached to its tendinous origin, also to the extremity of the semitendinosus, and the capsula of the knee near the anterior condyle. 14. *Soleus*: the tendon of the soleus passes over the upper part of the os calcis, between which and the bone lies a large sacculus, and near that is found a glandular body, which furnishes a mucous fluid for the more effectual lubrication of these parts, that are in such constant motion in walking. 15. *Tibialis anticus*: a small one is fixed to the tendon a little before its termination, where it plays on the top of the foot. 16. *Peroneus longus*: one lies under the tendon of this muscle, where it plays over the os cuneiforme, on the outside of the foot.

The admission of air into these cavities is productive of the worst consequences; this hath led Dr. Monro into ma-

ny arguments, which prove the absolute necessity, where any operation requires an opening of these cavities, of preventing, as much as possible, any admission of air; and the directions which he gives for conducting the operation so as to avoid this inconvenience, are admirable. Among other operations on which he enlarges, is that for the reduction of the incarcerated hernia. He shews that the cutting of the peritonæum, or tendons of the abdominal muscles, contributes little to the fatal consequences which frequently attend the operation; but that all, at least the most dangerous, of the bad symptoms, arise from the opening of the hernial sac, and the consequent admission of air. He therefore justly condemns the common mode, universally recommended, of opening the hernial sac before cutting the tendons of the abdominal muscles. After the integuments are cut through, and the sac is exposed to view, he advises to cut the tendon, and to reduce the hernia without opening it. His arguments for the propriety of this practice, and the answers which he gives to objections that may be made against it, are well supported.

OF NUTRITION, GROWTH, LIFE, and DEATH.

THERE appear many concurring causes why growth is continually rendered less and less. Many vessels seem to be stopped up, both because they are compressed by the neighbouring torrent of blood flowing through the great arterious tube, and because the blood, being now become more viscid, more easily coagulates. But the harder kind of food that is used, throws into the blood more terrestrial parts; which, being carried through the whole body along with the nutritious juice, renders all the parts harder, as the bones, teeth, cartilages, tendons, ligaments, vessels, muscles, membranes, and cellular texture; so that an increase of hardness may be perceived in them, even by touching them with the finger. Wherefore, since the blood flows from the heart through fewer canals, and since all parts which should be lengthened or distended grow harder, it necessarily follows, that those which ought to increase in bulk, will yield less and less to the impulse of the heart.

But the heart likewise, which is the part that is first consolidated among all the soft ones, increases less than any other part of the whole body; and, while the much more tender limbs and softer viscera are distended, the proportional bulk of the heart to the rest of the body grows continually less and less, till at last its proportion to the body of the adult becomes eight times less than what it was in a new-born infant. At the same time, from that very density which it has so quickly acquired, it becomes less irritable, and is contracted less frequently within a given time. Thus, while the resisting forces are augmented, the distending ones are at the same time diminished.

There will therefore, sooner or later, be an end of the increase of bulk; and that will happen so much the sooner as the heart has had the more frequent and vivid contractions: but this cessation of growth will take place when the cartilaginous crusts of all the bones are become so thin, that they cannot yield to the increase of the bony part. In women, the menses seem to put an earlier than usual stop to the growth. In cartilaginous fishes, the growth is perpetual. There is no state in which nature by a perennial progress induces a continual decrease from the first conception. It is said however to take place, when there is neither any increase of bulk, nor yet does any visible decrease take place. For we are all perpetually consuming. Nor do we only lose the fluid parts of our bodies, but in short even those which are reckoned to be the most solid. For even the bones are changed; and the teeth, which are harder than the bones, increase in bulk when the attrition of the opposite teeth has ceased to wear them away, and therefore their elements are changed: even the fibres of ivory in an elephant's tooth, after having been divided by the entrance of a leaden bullet, have grown

grown in a curve direction, and completely inclosed the ball. The bony juice likewise is changed; for in some cases the bones grow soft, in others they swell out in bony tumours; even cicatrices themselves have a manifest growth, otherwise they would not be sufficient in an adult person to close up a wound which he had received when a boy; and a great quantity of the earthy part of our bodies goes off by urine, as is seen in some diseases.

The cause of the destruction of the solid parts is in their perpetual extension and retraction, at every pulse of the heart, of which there are an hundred thousand every day; and by this motion even metals themselves are worn. Other causes are from the friction of the fluid against the solid parts; from the wearing away of all the membranes which cover moveable parts, either on the surface or in the internal cavities of the body; in the alternate swelling and subsiding of the muscles; and in the attraction and pressure which our fleshy parts exert. But all the parts of our body are the sooner worn away, in proportion as they are composed of a greater quantity of gluten and a less quantity of earth; for that gluten when it is extended, if the extension has been a little superior to the force of its cohesion, must of necessity fall away and be carried off from the earthy parts. Thus wrinkles or furrows are generated; such as are visible in the arteries of old men. The cellular texture, which otherwise would be dissolved into water or jelly, is worn away by the impetus of the blood pressing against the neighbouring blood-vessels and muscles, by friction, and by perpetual alternate flexion and extension.

The decrease would be very quick, and indeed there would be no great distance between the beginning of our life and its end, unless these losses were repaired. The fluids are quickly restored by food, as appears from the example of a chicken, in which blood is generated out of its aliment within two days. The fat, however, and red globules of blood, are formed out of the fat; the lymphatic juice from jelly; the mucus from mucus; and the rest of the humours from these and water. A gelatinous juice is brought from the aliments, through the arteries, to all parts of the body, and exudes into all parts of the cellular texture. The furrows, which we might imagine to be made in the inmost arterial membrane by the impetus of the blood, are filled up by a viscid matter brought into them by the lateral pressure; nor is it possible that these furrows can be overfilled, because every exuberant particle of nutritious juice must necessarily be carried off by the current of the blood. This juice will not be deficient while there is a sufficient quantity of aliment; and while there is more rest, and less resistance, in the bottom of the furrow than elsewhere, which must always be the case, because the bottom is that part of the vessel which is at the greatest distance from the main current of the blood flowing through it. There seem to be certain powers in the air, by which the aliment is attached to the solid parts, although we are ignorant of the manner in which they act.

The decrease of the cellular texture arising from attraction or pressure, will be repaired by the viscid vapour exhaled from the artery, and pressing towards those places which stand in need of reparation by the force of the neighbouring arteries and compressing muscles, its aqueous part being pressed out and reformed. The gluten repairs most of the organic parts, tendons, and membranes; being formed into a new cellular texture, as in the fœtus. The waste which takes place in moveable parts adhering by their other extremity to the rest of the body, can be repaired by protrusion alone, while the lymph fills up the intervals or hollows that are thus produced.

When the growth of the body can proceed no farther, obesity is produced, which is a kind of imitation of real growth. This proceeds from the fat generated by the aliment; which by reason of the impetus of the blood being lessened, and its entering the smallest vessels with more difficulty, is carried to the sides of the vessels; enters the lateral ones and the inorganic pores of the arteries; exudes

into the cellular texture; and there, the power of coagulation of the blood, and the absorption by the veins, being now diminished, the fat is consequently collected.

We feel the beginnings of decay even in youth itself. Even in that blooming season, the solid elements of the body are augmented, the chinks through which the humours flow are lessened, small vessels are obliterated, and the greater attraction of the cellular texture has added a density to the whole body. Throughout the whole body, that hardness occasioned by age is very conspicuous, in the bones now wholly brittle, in the skin, in the tendons, in the conglobate glands, in the arteries, and likewise in the weight of all the parts, and of the brain itself. The parts most exercised by motion soonest grow rigid, as is observable in those limbs of mechanics which are most used in their several occupations. Moreover, the arteries also continue to become more dense, more narrow, and even to be quite filled up, as well by the internal pressure of the blood flowing through the large arterial tube, as by the attraction of the cellular texture of which the greater part of the artery consists. An infinite number of parts of the cellular texture cease to be nourished; for the smallest arteries, which hitherto brought them nourishment, are now obliterated, and cease to convey more nourishment. The extending force being removed, the cellular floculi draw themselves together, contract the little spaces intercepted between them, degenerate into membranes, or substances of a hard texture, which intercept, and as it were choke up, other vessels. The gelatinous vapour likewise concretes in the small hollows of the cellular texture, and unites with the sides of these hollows into a hard solid. The muscles degenerate into hard dense tendons destitute of all irritable power, because the blood which they contained is expelled, and their fibres are condensed.

At the same time the nerves become more and more callous to the impressions of the senses, and the muscles grow less sensible to the solicitations of the animal powers; thus the contractile force of the heart, the frequency of its pulsations, and consequently the whole force which drives the blood into the smallest vessels, are diminished. The quantity of humours is diminished in a dense body, as is evident in the perspiration, semen, humours of the eye, and of the conglobate glands; the vapour also which bedews the solid parts of the body every where decreases. For this reason, nutrition now languishes, because there are more parts of the body which require nourishment, and less nutritious juice. Nor is the quantity of humours only diminished; they themselves are likewise corrupted. They were mild and viscid in children: but these same humours are in old men acrid, salt, scetid, with a great quantity of earth. This circumstance is owing to the use of salt or putrid food, which generate acrimony in the fluids; and the acrimony by a continual use of vitiated aliments perpetually increases, being at the same time augmented by a decreased perspiration and alvine evacuation necessary for carrying off the putrid liquamen. Hence the fetor of the urine, of the breath, and the difficult healing of wounds. But the worst quality of the humours is, that they abound with earthy particles, which are either such as are collected insensibly from the aliments after the secretions have become less free, or such as are carried off from the solid parts and returned into the blood; as is proved by the presence of earth in some diseases, and by the nature of the gouty earth. The quantity of this earth is continually increasing, especially if the nutritious liquor abounds with it: hence the brittleness of the bones, and the hardness of all the other parts, increases. This earth is likewise every where deposited in the cellular texture, but chiefly in the coats of the arteries, and produces crusts, which are at first callous, and then of a bony or stony nature.

The hardness or rigidity of the whole body, the decrease of the muscular powers, and the debility of the senses, constitute old age,—an evil, alas! which sooner or later

later attends every mortal. It makes an earlier attack on those who have been subjected to violent labour, or given themselves up to pleasure, or lived upon unwholesome diet; than on those who have followed a moderate way of life, and used temperance in their diet, or if they have removed from a cold to a warm country. If these causes continue their operation of rendering the matter of the body more dense, of diminishing its irritability, and augmenting the quantity of earth, it is not possible but decrepid old age must follow. In it the senses are almost destroyed, the natural power of the muscles is extremely weak, the limbs lose their strength, the feet especially are not sufficient for supporting and directing the body. The callous insensibility of the nerves cannot be incited to perform the office of generation; the very intestines become inactive, and refuse to answer to the accustomed solicitations: by the induration of the cartilages interposed between the vertebrae, the body bends forward; by the falling out of the teeth, the jaws but ill support the wrinkled lips; and lastly, the heart loses one half of the frequency of its pulsation, which it had in the infant state.

Thus, at last natural death necessarily follows; but very many people are carried off before this time by diseases. Scarcely one in a thousand exceeds the age of ninety: one or two perhaps may be found in a century that live to the age of 150. Man is long-lived when compared with other animals; he is also more tender than any of them, has looser flesh, and softer bones. Among the long-lived people, it is not easy to say what was the cause of that privilege. England seems to excel all other nations in producing old men: and in general the inhabitants of temperate climates live longest. The commonalty has almost solely afforded these rare examples of longevity; as indeed, from the more numerous class, we might expect a greater number of examples. Sobriety; a moderate and not very rich diet; a mildness of manners; a mind not endowed with very great vivacity, but cheerful, and little subject to care; all conduce to long life. Among animals, fowls are longer lived than many others, but fishes the most of all; the latter have the smallest heart, and the slowest growth, and their bones are never hardened.

Death happens sometimes, but rarely, from mere old age. This we say happens when the powers, first of the muscles subject to the will, then of those that are subservient to the vital functions, and lastly, of the heart, gra-

dually fail; so that old men cease to live through mere weakness, rather than through the oppression of any disease. We have often observed the same kind of death in brutes. The heart becomes unable to propel the blood to the extremities, the pulse and heart desert the feet and hands; yet the blood continues to be sent from the heart into those arteries that are next to it, and to be again carried back to it: thus the flame of life is supported for a little while; but it is soon extinguished, for the heart itself being totally deprived of its powers, and not irritable by the blood to any effectual motion, cannot drive the blood through the lungs, that the aorta may receive its due quantity. The utmost force of respiration is exerted in order to open a passage to the blood through the lungs, until even the powers, given by nature for performing the action of inspiration, become unequal to their task, and cease altogether. The left side of the heart neither receives blood, nor is irritated, and therefore remains at rest; the right ventricle, and lastly the auricle of the same side, for a while receive the blood brought by the veins from the cold and contracted limbs, and being thus irritated they continue to beat weakly. But lastly, when the rest of the body has become perfectly cold, and the fat itself congealed, even this motion ceases, and death becomes complete.

We would call that death, when the whole irritable nature has left the heart; for the mere resting of the heart is not without hope of a revival of motion: neither does the putrefaction of any part of the animal body demonstrate the death of the whole animal; nor does its insensibility or coldness do so; but all these circumstances joined together, and perpetually increasing, with the stiffness which follows the coagulation of the fat by rest and cold, can only be admitted signs of death in any doubtful case.

The dead body now hastens to putrefaction. The fat, water, and gluten, in consequence of separation and dissolution, evaporate: the earth, deprived of its bonds of union, insensibly moulders away, and mixes itself with the dust: the spirit departs whither God hath destined it. By death it is indestructible; as may be proved by an attention to the following fact, that many dying people, though their bodily powers are wasted, and their bodies are even decayed, give evident signs of a serene, vigorous, and happy, mind.

ANATOMY OF THE GRAVID UTERUS.

TO investigate what happens in the interior parts of a female during the production of a new living animal, is indeed a very arduous undertaking. We shall first relate what experience shews to be true, and then add the hypotheses by which the learned have endeavoured to supply what she does not teach. How few particulars are yet attained, and how difficultly they are attainable, in so obscure a speculation, must be obvious to every candid and impartial mind.

To throw the utmost light upon so delicate a subject, we shall begin with the most simple animals, and afterwards take notice of what nature has added in others whose fabric is more compounded. The smallest animals, then, which have very few or no limbs, the least distinction of parts, the shortest life, and the vital functions both few and very familiar to one another, bring forth young ones like themselves, with no distinction of sexes; all of them are fruitful, and none imparts fecundity to the rest. Some animals exclude their young through a certain cleft of their bodies; from others, limbs fall off, which are completed into animals of a kind similar to those from which they have fallen. This kind of generation is extended very wide, and comprehends the greater part of animal life. Those again, which are a little more compounded,

all bring forth their young; yet in such a manner, that a certain particle peculiar to themselves is generated in their bodies, dissimilar to the whole animal, and contained in some involucre, within which lies the germ that is afterwards to become similar to its parent; this is commonly called the *ova*, or *egg*.

Animals that are still more complex have both eggs, and male semen besides; so that both sexes are joined in the same individual; and this class is the most numerous. The *male semen* is that active substance which it is necessary to sprinkle on eggs to render them prolific, although it never grows alone into a new animal. In this class, therefore, a juice is prepared by its own proper organs, which is likewise poured on the eggs through organs proper to itself, but different from the former, in order to generation. Those animals are much more numerous which have both a male juice and female eggs; yet cannot fecundate themselves, but require true coition. For two animals of this kind must so agree in the work of fecundation, that each impregnates the other with its male organs, and again suffers itself to be impregnated in its female ones by the male parts of the other.

Approaching nearer and nearer to man, we come next to that class, of which, some individuals have only male
S A organs,

organs, and the same males sprinkle their seed on the female eggs of others. Several of the animals with cold blood sprinkle their seed upon the eggs after they are poured out of the body of the mother. Warm animals inject their semen into the uterus of the female. If eggs are generated in the female, she expels the lifeless embryo included in shells or membranes; but, if a living foetus, she then retains it so long as that it may be born free from any involucre. The difference between these oviparous and viviparous animals is so small, that in the same class, and the same genus, some animals lay eggs, others produce live foetuses; and lastly, the same animal sometimes lays eggs, and sometimes brings forth live young.

From this speculation it appears, that all animals are produced from others similar to themselves; many form a part only of a similar one; others from an egg of a peculiar structure; but that all these have no need of male semen. Lastly, the more moveable and lively animals only, whose bodies are of a more complicated structure, are endowed with a double system for generation; and the difference of sexes seems to be added for the bond of social life, and for the safety of a less numerous progeny. For the effusion of this male juice into the female organs, both sexes are inflamed with the most vehement desires; the male indeed has the most lively ones; for, since the female is always prepared for the venereal congress, it was necessary for the male to be more strongly excited, especially at the time when he abounded with good and prolific seed, which indeed is the principal incentive to venery in him. In females, of the brute kind especially, some inflammation in the vagina, which excites an intolerable itching, seems the principal cause of venereal desire.

Nature has added to the womb, both in women and in quadrupeds, a vagina, or round membranous cavity, easily dilatable, which, as we have already seen, embraces and surrounds the projecting mouth of the uterus; it descends obliquely forward under the bladder, resting upon the rectum, with which it adheres, and lastly opens under the urethra, with an orifice a little contracted. This opening, in the foetus and in virgins, has a remarkable wrinkled valve, formed of the skin and cuticle of the vagina, under the denomination of *hymen*, which serves to exclude the air or water: since only the human race have this membrane, it is perhaps not without some kind of moral use. It is circular; except that a part of it is sometimes wanting under the urethra, and it is broader behind. Being insensibly worn away by copulation, its lacerated portions at last disappear. The caruncles, which are called *myrtiformes*, are partly the remains of the shattered hymen, and partly the rugæ and the valves of the mucous lacunæ hardened into a kind of flesh.

At the entrance of the vagina are prefixed two cutaneous appendages, called *nymphæ*, continued from the cutis and gland of the clitoris; and these, being full of cellular substance in their middle, are of a turgescient or distensible nature; they are jagged and replenished with sebaceous glandules on each side, such as are also found in the folds of the prepuce of the clitoris. Their use is principally to direct the urine, which flows between them both from the urethra, that it might run off and not trickle down the skin, in which office the nymphæ are drawn together with a sort of erection. These membranous productions descend from the cutaneous arch surrounding the clitoris, which is a part extremely sensible, and wonderfully prurient; it is composed, like the penis, of two cavernous bodies, arising from the same bones, and afterwards conjoining together in one body, but without including any urethra. It is furnished with blood-vessels, nerves, and levator muscles, and a ligament sent down from the synchondrosis of the os pubis; like the penis in men, the clitoris grows turgid and erect in the time of coition, but less so in modest women; from friction, however, the clitoris always swells up and is erected. The muscle, termed *osii vaginae constrictor*, rising from the sphincter ani and receiving an accession from the

os ischium, covers the venal plexus, comes forward by the sides of the labia, and is inserted into the crura of the clitoris; it seems to compress the lateral venal plexuses of the vagina, and to retard the return of the venal blood. The transverse muscle of the urethra, and the bundle from the sphincter inserted into it, have the same situation as in men.

When a woman is invited either by moral love, or a lustful desire of pleasure, and admits the embraces of the male, the penis, entering the vagina, rubs against its sides, until the male seed breaks out and is poured into the uterus. In like manner, as in the male, the attrition of the very sensible and tender parts excites a convulsive constriction of all the parts of the vagina. By these means the return of the venous blood being suppressed, the clitoris, especially in salacious women, grows turgid and erect, the nymphæ on each side swell, as well as the venal plexus, which almost surrounds the whole vagina, and the pleasure is increased to the highest pitch: in consequence of which there is expelled, by the muscular force, but not perpetually, nor equally in all women, a quantity of lubricating mucous liquor, of various kinds. The principal fountains of this are seated at the opening of the urethra, where there are large mucous sinuses placed in the protuberant margin of this uriniferous canal. Moreover, at the sides of the urethra in the bottom of the sinuses which are formed by the membranous valves sulcated upwards, two or three large mucous sinuses open into the vagina. Lastly, at the sides of the vagina, between the bottoms of the nymphæ and the hymen, there is an opening, on each side, from a very long duct; which, descending towards the anus, receives its mucus from a number of very small follicles.

But the same action which, by increasing the pleasure to the highest degree, causes a greater conflux of blood to the whole genital system of the female, occasions a much more important alteration in the interior parts. For the hot male semen, penetrating the tender and sensible cavity of the uterus, which is itself now turgid with influent blood, there excites, at the same time, a turgescence and distention of the lateral tubes, which are very full of vessels creeping between their two coats, and distended with a great quantity of blood. These tubes, thus copiously filled and florid with red blood, become erect, and the ruffle or fringed opening of the tube ascends and is applied to the ovary. In the truth of all these changes, we are confirmed by dissections of the human body and brute animals, and from the appearances of the parts when diseased.

But, in a female of ripe years, the ovary is extremely turgid, with a lymphatic coagulable fluid, with which also the vesicles are distended. In a prolific copulation, some one of the more ripe vesicles is burst, a manifest cleft appears, which at length pours out a clot of blood. Within this vesicle, after copulation, a kind of flesh grows up, at first flocculent, then granulated, and like a conglomerate gland, consisting of many kernels joined together by a cellular substance; which flesh, by degrees becoming larger and harder, fills the whole cavity of the vesicle, and is hardened into the nature of a schirrhus, in which, for a long time, a cleft, or a vestige of one, remains. This is the *corpus luteum*, common to all warm quadrupeds, in which some late celebrated anatomists have said they found a sort of juice before copulation; which, however, experience does not admit, since there is no corpus luteum before that event. Nor is the vesicle, which is the human ovum, contained in a vessel like a cup.

The tube compressing the ovarium in prolific coition, is said to press out and absorb a mature ovum, from a fissure in the outer membrane, from whence it is continued down, by the peristaltic motion of the tube, to the uterus itself; which peristaltic motion begins from the place where the first contact was made, and urges the ovum downward successively to the opening in the fundus uteri; from which time conception may be said to have taken place. All this is performed, not without extreme pleasure

ture to the future mother, nor without a peculiar sort of grateful sensation of the internal parts, which become thereby highly irritated or convulsed, in a degree threatening to induce a swoon. From this moment *conception* may be said to take place, and the outlines of a new animal begin to be evolved by the gravid uterus.

Dr. Hunter having made an elegant Dissection of the Pelvis, and Female Parts, we have annexed a faithful representation of the same, in Plate I. of the GRAVID UTERUS, of which the following is an explanation:—A, The mons veneris. BB, The section of the skin and adipose substance, which was thrown open to shew the pelvis. C, The cartilaginous surface of the sacrum, by which it was joined to the os ilium. DD, The os pubis, cut thro' near the symphysis. E, The external muscles, on the back-part of the pelvis, cut through. F, The muscles which lie on the outside of the os pubis, cut through. G, The crus clitoridis, where it was fixed to the ischium, which is removed. H, The sphincter vaginae. I, The transverse muscle of the perinaeum. K, The sphincter ani. L, The bladder, almost empty, compressed between the anterior part of the womb and the upper side of the vagina. M, The levator ani and coccygeus muscles, by dissection turned down from the contents of the pelvis over the cut surface. N, The whole substance of the vagina, cut from the neck of the womb and bladder, and turned down over the rectum, to shew the orifice of the womb. O, The anterior lip of the orifice. P, The posterior lip of the same. When the vagina was thus opened, the lateral support being removed, the os uteri pushed out exactly as represented in the plate.

What we have hitherto advanced, coming under the testimony of our senses, may be either confirmed or corrected. What follows is rather conjectural; and its development is the more difficult, as we have few experiments to determine the facts, and even those experiments we have are discrepant with one another. At the first outset a difficult question immediately presents itself. Whence proceed the first stamina of the animal? Are they from each parent, and is the new animal formed by a junction of the seeds? The similarity of the offspring to both parents seems to confirm the opinion. If analogical reasoning might be permitted, we might adduce numerous examples from the vegetable kingdom which clearly shew that the offspring is a compound of each parent. The opinion is still farther confirmed by morbid and vicious habits being conveyed from both parents to their children. On the other hand, we have no certain proof that seed exists in the female; and again, animals may be propagated without any mixture of seeds. Lastly, the resemblance of the young animal to its father seems only to shew, that in the male seed there is some power, which alone can form the soft matter of the little embryo; in like manner this same power, in peculiar animals, lengthens the pelvis, dilates the thorax, expands the horns, &c.

Some anatomists have attributed every thing to the father, especially after the noted animalcula system came under the microscope, whose figure perfectly agreed with that of the embryo in all animals. But then there is wanting a proportion between these animals and the number of foetuses produced. Another objection to this doctrine is, that in most of the animal tribes animalcula are not to be found. And lastly, there is too great a similarity between these animalcula and those commonly found in other fluids, which always preserve their own peculiar shape, and are never observed to be changed by growth from a simple worm into a handsome articulated animal, wholly dissimilar from themselves. Other anatomists, not less celebrated or less worthy of credit, have taught that the foetus existed in the mother and maternal ovary; which the male semen might enliven and variously modify, so that, at length, it might be brought into the world a perfect animal. Certainly the male must give some addition to that sex which produces the foetus from its own body; which addition is necessary in some tribes of ani-

mals, but in others, even the most fruitful, may be wanting. This, however, concerns only the materials: but we are as much at a loss concerning the formation; namely, by what means the rude and shapeless mass of the first embryo is fashioned into the beautiful shape of the human body. We readily reject such causes as a fortuitous concurrence of atoms, the blind attractions between the particles of the nutritious juices, and the strength of ferments, not knowing the reasons how they operate; the soul is certainly an architect unequal to the task of producing such a beautiful fabric; and, as we can never form any adequate ideas of the internal models, we shall refer them to those hypotheses, which the desire of explaining what we ardently wish to know has produced. Experience indeed seems to agree with the following deductions which reasoning affords, namely, that this most beautiful frame of animals is so various, and so exquisitely fitted for its proper and distinct functions of every kind, and the offices and manner of life for which the animal is designed; that it must be calculated according to laws more perfect than any human geometry; that the ends have been foreseen in the eye, in the ear, and the hand; so that to these ends every thing is most evidently accommodated: it appears, therefore, certain, that no cause can be assigned for it below the infinite wisdom of the Creator himself. Again, the more frequently, or the more minutely, we observe the long series of increase through which the shapeless embryo is brought to the perfection necessary for animal life, so much the more certainly does it appear, that those parts which are observed in the more perfect foetus, have been present in the tender embryo, although their situation, figure, and composition, seem at first to have been exceedingly different from what they are at last; for an unwearied and laborious patience has discovered the intermediate degrees by which the situation, figure, and symmetry, are insensibly formed. Even the transparency of the primary foetus alone conceals many things which the colour afterwards added does not generate, but only renders conspicuous to the eye. And it sufficiently appears that those parts which eminent anatomists have supposed to be afterwards generated, and to be added to the primeval ones, have been all contemporary with the primeval parts, but only small, soft, and colourless. It is highly probable, that for a long time the latent embryo neither increases, nor is agitated, except by a very gentle motion of the humours, which we may suppose to librate from the heart into the neighbouring arteries, and from these into the heart of the foetus. But we may also suppose, that the stimulus of the male semen excites the heart of the foetus to greater contractions, so that it insensibly evolves the complicated vessels of the rest of the body by the impulse of the humours, and propagates the vital motion through all the canals of the little body of the animal, quicker in some parts, and slower in others; and that thence some parts seem to be produced very early, others to supervene afterwards; and lastly, some do not appear until a long time after birth, as the vesicles of the ovaries, the vessels of the male testicles, the teeth, hairs of the beard, and horns of brute animals. In all animals, heat assists this evolution; in the more simple ones, whose vessels are few, and less complicated in their various organs, heat is the sole instrument of bringing it to perfection.

After the human ovum is brought down into the uterus, we become sensible of its change of shape in a few days. The ovum itself sends out every where soft branchy flocculi from the superficies of its membrane hitherto smooth, which adhere to, and inoculate with, the exhaling and resorbing flocculi of the uterus. This adhesion happens every where in the uterus; but chiefly in that thick part which is interposed between the tubes, and is called the *fundus uteri*. Thus the thin serous humour of the uterus, proceeding from its arterial villi, is received into the slender venous vessels of the ovum, and nourishes it together with the foetus. Before this adhesion, if at any time it does not adhere, it is nourished either by its own or by absorbed

absorbed juices. At this time, the ovum abounds with a great proportion of a limpid watery liquor, which, like the white of an egg, hardens by heat, or by mixture with alcohol. The foetus remains long invisible, being never seen before the seventeenth day, when it is an unformed mass of mere mucus in a cylindrical shape. When some distinction of parts is visible, it has a very great head, a small slender body, no limbs, and is fixed by a broad flat navel to the obtuse end of the ovum. Henceforward the foetus continually increases as well as the ovum, but in an unequal proportion: for while the arterial serum is conveyed by more open passages into the vessels of the ovum, the foetus, which seems to receive, by its very capacious umbilical vein, the greatest part of the nourishment, increases very fast. The ovum also increases, but in a less degree; and the proportion both of it and its water to the foetus continually diminishes. The fleshy productions of the ovum lessen, they do not cover so much of its surface, and are gradually covered with a continued membrane. Those, however, which sprout from the obtuse end of the ovum increase, and are by degrees formed into the *placenta*.

Such is the general appearance of the ovum in the second month; from which time it changes only by increasing in bulk. That part of the ovum fixed to the uterus makes about a third of its whole surface, and is in the form of a flat round dish or plate; succulent, fibrous, full of protuberances, but throughout perfectly vascular; these tubercles change into others of the same kind; it is for the most part accurately, and often inseparably, connected with the uppermost part of the uterus. This substance, called the *placenta*, is remarkable for its large vessels, is of a thin cellular texture, and collects the vessels every where, but chiefly in the circumference of its greatest circle; the exhaling arteries of the uterus corresponding with the veins of the placenta, and the arteries of the placenta with the veins of the uterus. In the common surface of the uterus and placenta, a communication is made, by which the uterus sends to the foetus, first that white serous liquor not unlike milk, and lastly, as it seems, red blood itself. This communication of the humours seems to be demonstrated by the suppression of the menses in women with child, whose blood must be turned into another channel; by the loss of blood which follows a separation of the placenta in a miscarriage; and by the blood of the foetus being exhausted from an hæmorrhage in the mother; by hæmorrhages that ensue from the navel-string, so as to kill the mother when the placenta has been left adhering to the uterus; and, lastly, by the passage of water, quicksilver, tallow, or wax, injected from the uterine arteries of the mother into the vessels of the placenta, as is confirmed by the most faithful observations of eminent anatomists. That blood is sent into the foetus is evinced by the magnitude of the sinuses of the uterus and placenta; the diameter of the serpentine arteries of the uterus; the hæmorrhage that follows, even when the placenta is very slightly hurt; but especially by the motion of the blood, which, in a foetus destitute of a heart, could only be given to the humours of the foetus by the blood of the mother.

The nourishment of the foetus, from the beginning to the end of its full time, is without doubt conveyed to it through the *umbilical vein*. This vein, arising from the exhaling vessels of the uterus, and from the umbilical artery with which it is continuous, makes the venous sinuses under the surface of the placenta; when all its branches are collected, it forms a large trunk that is twisted, though not so much as its concomitant arteries, into circular folds; it is sufficiently long to allow a free motion: after being surrounded with cellular mucus including also other vessels, and the whole being covered with a continuation of the amnios, it is known by the name of the *umbilical cord*. The umbilical vein, after forming some protuberances, enters through the navel, in an arch made by a parting of the skin and abdominal muscles, and goes to the proper sinus of the liver, into which the smaller portion of the blood that it conveys is poured through the

slender ductus venosus into the vena cava seated in the posterior fossa of the liver; but the greater part of its blood goes through the large hepatic branches, which constantly arise from its sulcus, and remain even in the adult; and the blood goes thence to the heart by the continuous branches of the vena cava. The sinus, or left branch of the vena portarum itself, is a part of the umbilical vein, and its branches bring the blood from the placenta to the cava, while the right branch alone carries the mesenteric and splenic blood through the liver.

But this is not all the use of the placenta; for the foetus sends great part of its blood to the placenta by two large *umbilical arteries*, which are continued in the direction of the aorta; and, after giving some slender twigs to the femorals, with still smaller arteries to the pelvis, they ascend reflected in the direction of the bladder, surrounded with the cellular plate of the peritonæum, and with some fibres spreading to them from the bladder and urachus; they then proceed on the outside of the peritonæum into the cord at the navel, in which, passing alternately in a strait and contorted course, they form various twistings and windings, somewhat sharper than those of the vein which they play round; and at last they arrive at the placenta, whose substance is entirely made up of their branches, in conjunction with those of their corresponding veins, and a slippery cellular substance following both vessels; so that the kernels themselves, that are conspicuous in the placenta, are convolutions of those vessels. By these branches the blood seems to pass through the minuter arteries of the placenta into the veins of the maternal uterus, that after undergoing the action of the lungs by the mother's respiration, it may return again in an improved state to the foetus. What other reason can be assigned for such large arteries, which carry off above a third part of the blood of the foetus?

But it will perhaps be asked, Whether the foetus is nourished by the mouth likewise? Whether it drinks the lymphatic liquor contained in the cavity of the amnios, which is coagulable unless putresced, and in the middle of which the foetus swims, and whose origin is not sufficiently known? Whether this opinion is not in some measure confirmed by the open mouth of the foetus, and the analogy of chickens, which are under a necessity of being nourished from the contents of the egg only? to which add the absence of a navel-string in some foetuses; the quantity of meconium filling the large and part of the small intestines; the similitude of the liquor found in the cavity of the stomach to that which fills the amnios; the proportionable decrease of the liquor amnii, as the foetus enlarges; the glutinous threads which are found continued from the amnios through the mouth and gula, into the stomach of the foetus; the true feces found in the stomach of the foetus of quadrupeds; the open mouth of the foetus, which we have accurately observed; the gaping of a chicken swimming in this liquor, and its attempts as it were to drink it up? Again, What are the fountains or springs from whence this lymph of the amnios flows? whether it transudes through the invisible vessels of the amnios, or through certain pores from the succulent chorion, which is itself supplied from the uterus? It must be confessed, that these inquiries labour under obscurities on all sides; notwithstanding which, says Haller, there seems more probability for them than otherwise, since the liquor is of a nutritious kind, at least in the first beginnings of the foetus, and is derived from the uterus.

The foetus continues to advance in growth; the limbs gradually sprout from the trunk, under the form of tubercles; and the other outworks of the human fabric are by degrees beautifully finished, and added to the rest. The manner in which all this is performed anatomists have not hitherto sufficiently described. We shall not therefore enter fully on the subject; yet it seems necessary to submit the following compendium to the reader's consideration.

The embryo which we first observed in the uterus of the mother was a gelatinous matter, having scarcely any properly-

perly-defined shape, and of which one part could not be distinguished from another. There was, however, in that gluten a heart, which was the cause of life and motion; there were vessels which generated the humour of the amnios; there were therefore vessels of the umbilicus, the little trunks of which, being received from the fœtus, are at that time very large. There was a head and spinal column, bearing a larger proportion to the other parts of the body than they do afterwards. There were likewise, without doubt, all the rest of the viscera, but, being pellucid and of a mucous nature, they were not so apparent as they would have been had they been more opaque and solid. But in the whole fœtus, an immense quantity of water is mixed together with a very little earth, as the cellular texture surrounds it in a state between fluid and solid, having large drops of water interposed between the particles of the solid parts. To this vivifying gluten, or white of the egg, which is of the nature of lymph, there is added in birds a yolk, which is of an oily nature: in man something of a milky nature, not altogether unlike the yolk of an egg, is added to the coagulable lymph. That the blood is perfected from the fat by the proper powers of the fœtus, we are persuaded from the example of birds. From it are insensibly prepared all the other humours; but all of them at first mild, glutinous, void of taste, colour, and smell. It is long before they acquire their peculiar nature and properties, and some of them are not produced till many years after birth, for instance the semen.

The vessels are the earliest or oldest parts of the body, and are prepared in the original delineation of the embryo. What first appears in an egg during the time of incubation, having any distinct form, are venous circles: and these veins produce the arteries, by which they both receive their juice, and the motion of that juice. They are not generated mechanically from an obstacle against which the arterial blood strikes. At first the trunks of the veins are conspicuous, afterwards the branches which convey the humours to the trunks. If they were produced from the arteries reflected, the branches would first be seen, and the trunks would be formed last. Neither could the arterial blood, driven back by an obstacle, form those most beautiful circles, and bring back the vessels into the heart. It would rather flow irregularly through the cellular texture. And the primeval heart would soon lose its life, unless as much of the humours returned to the heart as was sufficient to keep up its pulsations.

There are, therefore, in the primeval fœtus, such as we first observe it, some parts more perfect and conspicuous; and others involved, invisible, and very small. The heart is the most perfect; it is the only moveable and irritable part; although it is in many respects different from what it is in an adult person. The brain is large and fluid; the vessels first appear formed near the heart, and are visible in the back. The viscera, muscles, nerves, and limbs, are not yet to be seen; nor the bones, whose first appearance is a mucus, nor the vessels of the rest of the body. The other visible portion of the fœtus is the abdomen, of which the umbilical capsule is an immense hernia.

To this embryo is superadded motion, in man almost of the heart alone; as also in birds, whose formation does not take place without heat rather greater than that of the human body: yet, without the heart, heat destroys, instead of forming, the fœtus. In the beginning the proportion of the heart to the rest of the body is the greatest; and is ever after continually growing less. Its pulsations are also at this time the most frequent, and are very powerful for impelling the humours, and distending and producing the vessels of the soft and tender fœtus. The viscosity of the vital humours which collect the earthy elements is opposed to the force of the heart, and by that means the formation of the fœtus is assisted. For there is in the embryo both an impelling force, which extends the parts longitudinally; and a resisting force, which mo-

derates the increase, and regulates the lateral pressure, and thus the distention. By the force of the heart, the artery, with all its surrounding cellular texture, is lengthened; its folds are stretched, and the artery itself is dilated. The blood by its lateral pressure makes an effort against the almost-blind branches of the arteries, fills and evolves them, and sets them off at more obtuse angles: thus are produced spaces which make very little resistance, in which the gluten is deposited. In the very substance of the artery itself, while it is every where dilated, between its inconceivably small solid threads, are prepared little reticulated spaces like a stretched-out net, which are equally fit for receiving humours. The largest of these are framed round the heart and in the head, whither the impulse of the heart drives the humours in a straight direction; and in the placenta: the smaller ones are in the inferior parts of the body, whence the umbilical arteries subtract the greatest part of the blood.

The fœtus increases very quickly, as is most evident in the example of a chicken, whose length the twenty-second day is to its length the first day at least as 1,000,000 is to 1; and the whole increase of bulk in the bird during the remainder of its life does not exceed the fifth part of the increase of the egg the first day. For the fœtus has a larger and more irritable heart, vessels larger in proportion, and likewise more numerous and relaxed, and the solid parts are mucous and distensible. The breast is later of coming to perfection, being surrounded with membranes so fine that they cannot be seen. The embryo not only increases in bulk, but is so remarkably altered in shape, as to be brought forth totally unlike the appearance it had at first. It is probable, that the limbs are produced from the elongated arteries; that they are laterally knit together by a certain gluten; that they are separately evolved; that at first they sprout out very short, but afterwards increase by insensible degrees, and appear divided into distinct articulations; as the wings of a butterfly are formed from vascular net-work. Thus likewise the right ventricle of the heart is expanded by the blood coming to it in greater quantity; and, being increased by degrees, equals the left.

On the other hand, the cellular texture, from its glutinous aqueous nature, by earthy particles being continually brought to it, becoming insensibly harder, by a gentle attraction contracts its parts, which were before straight, into various flexures; and ties the auricles to the heart, from which they were as yet at a distance. So the muscles draw out processes from the bones by their continual pulling, and open small cavities into large cells: the same likewise incurvate the bones, and give them different shapes. Pressure also can do a great deal; to it we must attribute the descent of the testicles into the scrotum, after the irritable force of the abdominal muscles has taken place; to this also we must ascribe the repulsion of the heart into the breast, when the integuments of the breast are larger; to it we are to ascribe the length of the breast and the shortness of the abdomen, and the smaller size of the viscera of the latter; because the air received into the lungs dilates the cavity of the thorax. But even the bones are variously hollowed out by the pressure of the muscles, blood-vessels, and even of the very soft brain itself; and by the same means flesh is changed into a tendinous substance.

The power of derivation brings the blood into the pelvis and lower extremities from the closed umbilical arteries: this same power, when the foramen ovale is contracted by the auricles being drawn towards the heart, evolves the right ventricle of the heart. So when the vessels of the yolk have taken up the whole length of the egg, and can receive no farther elongation, it dilates the umbilical arteries of the chick, and produces a new membrane with incredible celerity. On the other hand, but still by the same power, after the blood has got an easy passage through some vessels of any part, the other parts which do not afford a like easy passage increase the less.

Thus the head grows less after the lower limbs have begun to increase in bulk.

Yet the head of the fœtus is large, every where membranaceous, in a few places cartilaginous on the earlier days of gestation, with a mouth deeply cut, and with very long jaws. In the fœtus come to maturity, there are also rudiments of the teeth, which have a great deal of membrane as an appendage; the brain, at first fluid, and always soft, is itself very large, with large nerves; the eyes are big, and the pupil shut by a membrane; the breast is very short, but capable of extension, on account of a great quantity of cartilage; the abdomen is large, surrounded with membranes, and contains a very large liver; the bile is insipid and mucous; the intestines are irritable, and full of soft green excrement. When the fœtus has at last arrived at its state of maturity, the kidneys are divided into lobes, are large, and have very big capsules; the pelvis is very small, so that the bladder, ovaries, and tubes, project from it; the genital system is dense, not yet evolved, nor preparing its juices; all the glands are large, particularly the conglobate ones, and full of a ferrous juice; the skin is at first pellucid, then gelatinous, and at last covered with a soft cuticle and sebaceous ointment; the fat is first gelatinous, and then grumous; the tendons soft, succulent, and not yet shining.

Those who have asserted that the fœtus respire in the uterus have made very few experiments: they have not even attended to the fact, that the fœtus in utero swims in a body of water; and that the lungs of a fœtus immersed in water always sink: nor have they given due consideration to the evident shortness of the breast, and the smallness of the lungs. Whether it can take in air through the vagina of the mother is very difficult to be determined; but we suspect it to be possible in a certain situation, that a well-grown fœtus, which is not too much compressed, may sometimes draw in air, while it is in the birth.

As the fœtus grows larger, so the uterus increases proportionally. The general figure of the uterus is oviform; the fundus answering to the largest extremity of the egg, and the cervix and os uteri to the small end: but the fundus is larger and more flat, or less pointed, in proportion to the lower extremity of the uterus, than one end of an egg is to the other; and the whole uterus seems more or less compressed, so as to be broader from right to left, than it is from the fore-part backwards. Besides these more constant deviations, the figure of the uterus differs from the regular oviform, from a variety of accidental causes, as it adapts itself to the neighbouring parts, to the attitude of the body, and to the position of the contained child. In order to conceive these varieties more easily, we must remember that in most cases the uterus is not so completely filled as to be upon the full stretch. Were it out of the body, and filled artificially, it would easily contain more than it actually does. Thus the uterus, like a bladder of water not quite full, is plastic, and moulds itself into various shapes from accidental circumstances.

As the surrounding parts resist the pressure or weight of the uterus unequally, according to their different natures, the uterus swells out in some places, while in others it is pressed inwards. Thence it is, that the brim of the bony pelvis has commonly the effect of a belt girding that part of the uterus, and the projections of the spine, and of the psoæ and iliac vessels, mould the outside of the uterus into corresponding cavities. That the different attitudes of the mother's body should produce alterations in the figure of the uterus, needs not a particular explanation or proof. The weight of the uterus itself, and of the adjacent viscera, being differently directed, must produce some change in its form corresponding to every change of posture, especially as the parts against which the uterus will rest its weight, in the different postures of the body, are of such different natures.

The same plastic state of the uterus makes it adapt its

figure to the circumstances of the child within, and vary as those change. We not only in dead bodies see the parts of the child making a variety of different projections on the outside of the uterus; but, in the living body, all the same variety is frequently manifest to the touch, in examining the outside of the abdomen. The round projecting ball made by the child's head or buttocks is commonly very perceptible, and in many instances smaller projecting parts are so distinctly felt through the containing parts of the abdomen, as to leave no room to doubt of their being knees or elbows.

To illustrate this fact, and to display the situation and connection of the womb, under the above-mentioned circumstances, Dr. Hunter has given a Front View of the Pregnant Uterus at its full time, with the containing parts turned back, so as to shew the external coat and vessels of the womb, and parts contiguous. These are represented in Plate II. of the GRAVID UTERUS, of which the following is an explanation:—AA, The fore-part of the chest, just below the breasts, where the trunk was cut through. BB, The two upper angles of the integuments, muscles, and peritonæum, turned back over the cartilaginous margin of the chest. CC, The two inferior angles, turned down over the groin, thigh, and anterior spine of the os ilium, on each side. D, The upper end of the longitudinal incision, at the pit of the stomach. E, The lower end of the same incision carried down to the symphysis of the ossa pubis. F, The umbilical or falciform ligament of the liver, which runs upwards on the inside of the abdominal muscles. GG, The epigastric artery and vein, projecting through the peritonæum. H, The small lobe of the liver, situated in the highest part of the epigastric region. I, The omentum, spread over the small intestines in the epigastric region. K, The lower and middle part of the omentum, which had been pushed up by the womb, and lay in numerous small folds pressed together. L, The omentum in the right side. M, The omentum in the left side, which came down before the Fallopian tube, &c. NN, Two turns of the small intestines. O, The womb, possessing all the umbilical and hypogastric regions: its surface is interspersed with a number of small vessels, the greatest part of which are veins; they were filled with blood only, and therefore gradually disappeared after the subject had been preserved some time: its situation is a little oblique, and towards the right side: the navel was a little higher than the part upon which the letter O is placed. The form of the womb is a little irregular, at some places projecting more than at others; this seemed partly owing to its being moulded upon the neighbouring bowels, particularly at its fundus, and partly to its contents; whence P, A swelling towards the left side of the womb, where the middle of the placenta adhered; and Q, A swelling on the right side, where the buttocks of the child lay, and where the child could be distinctly felt through its substance. RR, The round ligaments: the left is longer than the right, because of the oblique situation of the womb. SS, The Fallopian tubes: in the right side, little more than the beginning of the tube is seen, the rest running down behind the womb.

The small or lower end of the uterus is placed in the cavity of the pelvis. This generally contains the greater part of the child's head, and fills up the cavity of the pelvis so completely, as to press the vesica urinaria against the symphysis pubis, and the rectum against the hollow of the sacrum. The os uteri is directed against the coccyx, or the lower part of the sacrum. The body and fundus of the uterus, which for the most part contains all the rest of the child and the placenta, is so placed in the anterior part of the abdomen, from the brim of the pelvis upwards to the epigastric region, as to be under and before all the other bowels in immediate contact with the parietes abdominis, occupying the whole space from one hip-bone to the other, and a proportionable space from these bones upwards as far as the epigastric region. When the uterus rises up from the cavity of the pelvis into the hypogastric

hypogastric and umbilical regions of the abdomen by its increasing bulk, it is no wonder that it should instantly mount up before the small intestines. Their attachment to the loins by the mesentery, would seem to render this necessary; but there is another cause which co-operates towards this effect, and which almost as certainly prevents the epiploon from falling down before the uterus, though that membrane is naturally so loose, that we might conceive it to be spread out indifferently either before or behind the body of the uterus. Yet in fact this fatty membrane is commonly found pushed up by the uterus, and crowded all round the fundus uteri, with the small intestines in the epigastric and adjacent parts of the hypochondriac regions. The cause of all this would appear to be the specific lightness of those parts in comparison of that of the uterus. The intestines contain some air, and the epiploon a good deal of oil, which gives them lightness, and buoys them up above the uterus.

Whoever has any tolerable notion of the shape of the abdomen, and situation of the cavity of the pelvis, must understand that the axis of the uterus is very far from the perpendicular line, its lower end being turned backwards, and its upper end in proportion turned forwards. This obliquity changes with the attitude of body, and from many other causes. When erect, the weight of the uterus presses the fore-part of the abdomen into a greater roundness, and then the axis of the uterus approaches nearest to the transverse or horizontal line; and, in a recumbent posture, the contrary happens from a similar cause. In the case of a first pregnancy, the uterus stretches itself higher up in the epigastric region, and its axis comes nearer to the longitudinal or vertical direction, because the parietes of the abdomen do not easily give way, and do not swell forwards in any great degree; but in a woman who has had many children there is a more loose and pendulous abdomen, and thence the uterus does not shoot upwards, but rather forwards, and takes more of the transverse situation. This oblique direction of the uterus, approaching to the transverse, is more remarkable in very short women; because in them the chest is so near the pelvis that the uterus is stopped in its ascent, and forced to shoot forwards. The same thing happens, and for a like reason, when the pelvis is very narrow. For in this case the uterus must be higher, as no part of it can be lodged in the cavity of the pelvis. In a very short and crooked woman, with a very narrow pelvis, upon whom Dr. Hunter saw the Cæsarian section performed, the fundus uteri was turned not only forwards, but even a little downwards. As she lay upon the table, the navel and hypogastrium could not be seen; the navel being situated on what might have been called the posterior and inferior part of the abdominal tumour. And to expose that part of the abdomen to the surgeon, it was necessary with two assisting hands to lift up the fundus uteri, or the most prominent part of the abdomen; without which the hypogastric region would have been inaccessible. Indeed, it was an appearance which, without having seen, it was almost impossible to have conceived.

The obliquity of the uterus towards the right or left side is not commonly, indeed cannot be, very considerable. A small degree of lateral obliquity is very common; and it is natural to suppose that in a reclined posture, the middle projection of the lumbar vertebræ will throw a little more than one half of the uterus into the lateral cavity between the spine and one hip-bone. In fact, we know that in all the last months of the utero-gestation the abdomen is often more full on one side than on the other. Women say in such a case, that the child lies one side; and they judge rightly. Where the child lies, the bulk must both be more considerable and more permanent; but where there is only uterus, placenta, and water, the swelling will be softer, and project less. When the child lies more in one side than in the other, the limb of that side is weaker, more benumbed, and more liable to cramps and ædematous swellings. That an awkward position of the

child will occasion spasms in the limb, experience testifies with the clearest evidence. Many women feel that the one depends upon the other; and, from particular motions of the child, can certainly prognosticate ease or pain till it shall alter its situation again.

It is a common observation, that the ligaments and tubes of the pregnant uterus are attached lower upon the side of the uterus than they were before pregnancy. If the reason of this has not been so generally known, it is nevertheless evident. The peritoneal coat of the uterus makes the broad ligament on each side, much in the same manner as the analogous membrane of the intestinal tube makes the mesentery. When a woman is not pregnant, this ligament is of considerable breadth, the spermatic vessels pass between its two laminae, the round ligament runs downwards, and outwards, on its anterior surface, and the tube runs in loose serpentine turns upon its upper edge. But, in proportion as the circumference of the uterus grows larger, the broad ligaments grow narrower, their posterior lamella covering the posterior surface, and their anterior lamella covering the anterior surface of the uterus itself. As a proof of what has been said, we observe that the round ligaments do not now run down on the fore-part of the broad ligaments, but upon the fore-part of the body of the uterus itself; a proof that the peritonæum, which covers the uterus at this part, is the very membrane which before pregnancy made the anterior lamella of the broad ligament. Farther, in proportion as the fundus uteri rises upwards, and increases in size, the upper part of the broad ligament is so stretched, that it clings close to the side of the uterus, so that in reality the broad ligament disappears, no more of it remaining than its very root; viz. its upper and outer corner, where the group of spermatic vessels pass over the iliacs immediately to the side of the uterus. In this state, though the small end of the tube opens into the same part of the uterus as before impregnation, yet the tube has a very different direction; instead of running outwards in the horizontal direction, it runs downwards, clinging to the side of the uterus. And behind the fimbriae lies the ovarium, for the same reason, clinging close to the side of the uterus. The fimbriae and ovarium are commonly placed upon the iliac vessels, or fleshy brim of the pelvis, behind the group of spermatic vessels.

The round ligaments run almost perpendicularly downwards from the fundus uteri to their passage through the muscles; they are considerably enlarged in thickness, and are so vascular, that when injected, they seem to be little more than a bundle of arteries and veins. Their arteries are all convoluted. Both their arteries and veins are branches principally of the spermatics, and both evidently anastomose with their respective external vessels in the groin, or upper part of the labia. Even in this enlarged state of the round ligaments, it is very difficult to say how they terminate in the groin; they appear to be insensibly lost.

The ovaria seem to have undergone no remarkable change, except that one which contains the corpus luteum; which for the most part can be distinguished by a rounded fullness, and frequently a considerable prominence, sensible both to the sight and touch, upon the middle of which there is a small pointed cavity or indentation like a cicatrix. Upon slitting the ovarium at this part, the corpus luteum appears a round body, of a very distinct nature from the rest of the ovarium. Sometimes it is oblong or oval, but more generally round. Its centre is white, with some degree of transparency; the rest of its substance has a yellowish cast, is very vascular, tender, and friable, like glandular flesh. Its larger vessels cling round its circumference, and thence send their smaller branches inwards through their substance. A few of these larger vessels are situated at the cicatrix or indentation on the outer surface of the ovarium; and are there so little covered, as to give that part the appearance of being bloody when seen at a little distance. When there is only one child, there is only one corpus luteum; and two in case

of twins. Dr. Hunter, who had frequent opportunities of examining the ovaria with care in several cases of twins, always found two corpora lutea. In some of these cases there were two distinct corpora lutea in one ovarium; in others, there was a distinct corpus luteum in each ovarium. In a variety of different cases, it has been found that the sex of the foetus has no relation to the corpus luteum being in the right or left ovarium.

Those who say that the uterus grows thicker in the same proportion that its bulk is increased, have probably been deceived by examining the uterus of a woman who died some hours or days after delivery. In that contracted state the uterus is often found even two inches thick; but in all those Dr. Hunter examined, in the natural distended state, though there was some difference, the thickness of the uterus was but a little more considerable than before impregnation. When not injected, its more common thickness is from one to two thirds of an inch; when its vessels, and particularly its veins, are pretty well filled with wax, its thickness is thereby considerably increased, more especially where the placenta is fixed, on account of the number and size of the vessels at that part. For this reason only, perhaps, the uterus is thickest at that part, and for this reason too it is commonly thicker towards the fundus than the cervix. In respect of thickness, a good deal of variety has been observed, and such inequalities in the same uterus, that, even where the placenta did not adhere, the uterus has been almost twice as thick at one part as at another. We have always observed in opening the uterus, that its thickness is more considerable than one could have imagined it to be by feeling it externally, where there is a fluctuation of the water. Its substance is so soft, that the fluctuation then felt is like that of water in a thin bladder.

To shew the elevated position of the womb in advanced pregnancy, and its situation with respect to the ligaments, tubes, intestines, and whole mass of the abdominal viscera, Dr. Hunter has furnished an elegant Dissection of the Parts, which we have given in Plate III. of the GRAVID UTERUS, and of which the following is an explanation. AA, The thighs cut through. B, The back bone cut through above the diaphragm. C, Part of the eighth rib. DD, The integuments and muscles at the back-part of the chest. E, The inferior flap of the abdominal muscles, &c. F, Part of the mons veneris, turned aside with the abdominal muscles. G, The respective part of the left side. H, The margin of the chest covered by the peritoneum and muscles, which are turned over it. I, The ensiform cartilage. KK, The lower ribs and other containing parts, cut down longitudinally. L, The posterior and lower part of the right cavity of the chest. M, The trunk of the descending aorta. N, The œsophagus. O, The upper convex surface of the diaphragm. P, That part of the centrum tendinosum of the diaphragm which is in the right side. Q, The trunk of the lower cava tied, close to the upper surface of the diaphragm. RR, The cut edge of the pleura. SS, The cut edge of the peritoneum. T, The inside of the transversus muscle covered with the peritoneum. U, The great or right lobe of the liver. V, The small lobe of the liver. W, The falciform ligament, or remains of the umbilical vein, cut off as it enters the fissure of the liver. X, The colon passing up from the caecum to the liver. YY, The colon with its appendiculae adiposæ running towards the left side. ZZ, The beginning or root of the omentum. aaaa, The small intestines brought to view by cutting off the omentum a little below the edge of the liver. b, The womb; upon its surface we can trace, though obscurely, its veins. c, The round ligament running down to its passage into the groin. d, The Fallopian tube running backwards on the inside of the os ilium. e, The fimbriated end of the tube, lying behind the side of the womb. f, The prominent corner of the womb, where the buttocks or loins of the child were distinctly felt before the part was opened.

Of the VESSELS of the GRAVID UTERUS.

There is no circumstance in which the gravid uterus differs more from the unimpregnated state, than in the size and termination of its vessels. The arteries, both spermatic and hypogastric, are very much enlarged. The hypogastric is commonly considerably larger than the spermatic, and we very often find them of unequal sizes in the different sides. They form a large trunk of communication all along the side of the uterus; and from this the branches are sent across the body of the uterus, both before and behind. The cervix uteri has branches only from the hypogastrics, and the fundus only from the spermatics; or, in other words, the hypogastric artery gives a number of branches to the cervix, besides sending up the great anastomosing branch, and the spermatic artery supplies the tube and fundus uteri before it gives down the anastomosing branch on the lateral parts of the uterus. All through the substance of the uterus there are infinite numbers of anastomosing arteries, large and small, so that the whole arterial system makes a general net-work, and the arteries are convoluted, or serpentine, in their course. Hardly any of the larger arteries are seen for any length of way upon the outside of the uterus. As they branch from the sides, where they first approach the uterus, they disappear by plunging deeper and deeper into its substance.

The veins of the uterus would appear to be still more enlarged in proportion than the arteries. The spermatic and hypogastric veins in general follow the course of the arteries, and like them, anastomose on the side of the uterus. From thence they ramify through the substance of the uterus, running deeper and deeper as they go on, and without following precisely the course of the arterial branches. They form a plexus of the largest and most frequent communications which we know of among the vessels of the human body. And this they have in common with the arteries that their larger branches go to, or rather come from, that part of the uterus to which the placenta adheres; so that when the venous system of the uterus is well injected, it is evident that that part is the chief source of the returning blood. Here too, both the large and small veins are continued from the placenta to the uterus, and are always necessarily broken upon the separation of these two parts. The veins are without valves, and are therefore easily injected. In injecting them, we observe that at first they become turgid, and project on the outer surface of the uterus; but in proportion as we throw a greater quantity of wax into these vessels, they grow more flat and obscure; because the uterus itself becomes more filled and tense, which has the effect of compressing the veins that run in its substance.

Mr. Cruikshank is the first, in this school of anatomy, who observed the lymphatics in the gravid uterus; he also injected them with mercury, and traced them with great success in several subjects. They are more numerous, and many of them larger, than could have been imagined; from which it is manifest, that a copious absorption is carried on in the uterus towards the mother. The lymphatics pervade its substance universally; its peritoneal coat appears, like that of a calf's spleen, to be interwoven with a crowded plexus of these vessels; and where they get to the sides of the uterus, when filled with mercury, some of them are even larger than a goose-quill. Some are remarkably varicose, or enlarged at particular places. They pass from the sides of the uterus, many with the spermatic vessels, but the greater number and the larger with the hypogastrics. Of these last, some pass into the glands on the side of the vagina; others meet with no glands till they have reached the side of the pelvis, where they run into the glands of the iliac plexus, or shoot backwards into the glands of the sacral plexus; from both of which they pass into the lumbar plexus, where they are lost among the absorbents of the lower extremities, and the external parts of generation.

Besides the lymphatic vessels of the uterus, there are others belonging to the ovary and Fallopian tubes, which follow the course of the spermatic arteries and veins. They anastomose with the lymphatics of the uterus, and terminate in glands which are placed upon the sides of the lumbar vertebrae, near the origin of these blood-vessels. Here they become mixed with the lymphatics of the lumbar plexus, and enter along with them into the lower end of the thoracic duct. The spermatic lymphatics enlarge during pregnancy in the same manner as the blood-vessels; and for this reason they are then both most readily seen and injected. The reason why the blood-vessels, lymphatics, and nerves, of the ovary and Fallopian tubes, have their origin in the loins, is the same with that of the origin of similar vessels and nerves in the male. The ovary and Fallopian tubes are not placed in the cavity of the pelvis in the early foetal state, but upon the psoe muscles, some little way under the kidneys. It is natural, therefore, that their vessels and nerves should arise near the vessels and nerves of these organs.

All the uterine nerves come from the intercostals, and pass in the form of plexuses with the blood-vessels, as in the other abdominal viscera; so that there is a spermatic and hypogastric plexus of each side attending the vessels of the same name. They are principally the branches of two large cords of the intercostals, which run down before and on each side of the aorta in the abdomen, much in the same manner as the trunks of the intercostals run down upon the sides of, and behind, that artery. On the left side this large cord comes down from the semilunar ganglion, partly as a continuation of the anterior cord of the intercostal from that part where it is forming the semilunar ganglion, and partly as a plexus of nervous filaments coming down more forwards from the ganglion itself. This cord passes down before the beginning of the renal artery, all along the side of the aorta. In its way it receives branches from the intercostal, and gives off branches, so that it has the appearance of a plexus, though the principal cord can always be distinguished. It gives off the renal plexus, which is situated upon the side of the uppermost vertebra lumborum, and passes to the sinus of the kidney, behind the renal vein; but both before, and behind, and above, and below, the renal artery. Opposite to the third vertebra lumborum, the cord gives off two large branches, and some small filaments of nerves, which run down with and before the spermatic artery. This spermatic plexus may be distinctly traced, with the artery, into the ovary and adjacent parts, at the upper part of the broad ligament. Immediately below the origin of the spermatic plexus, opposite to the same third vertebra lumborum, two large branches come from the trunk of the intercostal nerve, in the common direction of these communicating branches; viz. forwards, downwards, and inwards, which join the great cord, and make it larger from this junction downwards. On the right side the cord comes from the semilunar ganglion, close to the root of the superior mesenteric plexus and artery, giving a few branches only to the renal plexus, and runs down on the right of the aorta, as the other on the left. And on the right side the renal plexus, which comes chiefly from the semilunar ganglion, as it passes towards the kidney, behind the vena cava and renal vein, sends down the spermatic plexus behind the beginning of the renal, which soon joins and passes with the spermatic vessels of this side.

The two cords, right and left, may be said to constitute a lumbar plexus all along the aorta, which makes the basis of the plexuses which accompany the branches of that artery; or they may be considered as the anterior cords of the intercostals in the abdomen. At the upper part of the fourth vertebra lumborum, the right cord gives down a considerable branch with the iliac artery, which, branching, forms a kind of sheath-like plexus upon the artery in its way to the groin. At the bifurcation of the aorta, the right and left cord unite upon the fore-part of the aorta, and make a plexus from that part directly downwards as

far as the lower part of the fifth vertebra lumborum, and then finally divide into what we may call the right and left hypogastric nerve. On the right side a large branch comes from the trunk of the intercostal, on the side of the fourth vertebra lumborum, which passing downwards, and inwards, behind the right iliac artery, joins the plexus of the two united cords before the last vertebra lumborum.

The hypogastric nerve passes round the side of the pelvis, between the peritonaeum and the hypogastric vessels, and upon the inside of the ureter. At the middle of the side of the pelvis, where the hypogastric vessels divide, the nerve splits into a double range of branches; viz. posterior and anterior. The posterior range goes to the side of the rectum, some branches passing to the back-part, and others to the fore-part, of the gut; and the first and uppermost of those branches are manifestly reflected upwards upon the gut, directing their course towards the colon. The anterior range of branches is the largest, and may be considered as the continuation of the trunk of the hypogastric nerve, in the form of a plexus. Where the hypogastric vessels are passing to the side of the uterus and vagina, this nerve, situated behind them, spreads out in branches like the portio dura of the seventh pair, or like the sticks of a fan, with many communications which are sent to the whole side of the uterus and vagina. The uppermost branches pass upwards, in the duplicature of the broad ligament, towards the fundus uteri. The branches, as they go to lower parts of the organ, pass less obliquely, then horizontally, and the lowest of all run downwards on the side of the vagina. The greatest crowd or number of these branches go to the os tincæ, and the adjacent parts of the uterus and vagina.

The substance of the uterus is rendered remarkably soft and loose in its texture by pregnancy; so that, when an incision is made into it, the wound can easily be made to open wide; or if a narrow piece of the uterus be cut quite out through and through, it is so loose and flexible, that it can be readily drawn out to at least double its natural thickness. This laxity appears to depend on two causes, viz. the great quantity of large vessels in its composition, and the loose connection between the fasciculi of its fibres. It would seem probable that utero-gestation enlarges the cellular connecting membrane, as well as the vessels of the uterus. When we speak of the muscular fibres, it is difficult to treat the subject with precision. We neither know their external appearance, nor their internal composition. They only manifest themselves to our senses, when numbers of them are collected into bundles, and make what we commonly call muscular fasciculi. In living bodies they manifest themselves by motion in the part, which we suppose is produced by a contraction or accretion of the fibres themselves; but that change in the nature of a muscular fibre, which is the cause of its contraction, is not certainly known. This contraction in some parts is voluntary, in others involuntary, and in some it is both. In some parts it is quick, and in others very slow. The motion which is actually observed in the uterus of living women, is involuntary and slow. It is commonly believed to be muscular motion, and the fibres peculiar to the substance of the uterus are believed to be muscles. In the quadruped, the cat particularly, and the rabbit, the muscular action, or the peristaltic motion of the uterus, is as evidently seen as that of the intestines, when the animal is opened immediately after death. In many parts, particularly of the internal surface of the uterus, these fibres have the same striking fasciculated appearance which we observe in common muscles; yet they are of a paler colour, and appear to be of a harder texture. When we know more of the nature of muscular fibres, we shall perhaps be able to account for this variety. Dr. Hunter took considerable pains to trace the arrangement of the uterine fasciculi; but, except upon its inner surface, he observed nothing but irregularity and confusion. On the inner surface itself he observed some variety, and always, where the placenta adheres, a good deal of irregularity.

In a woman who died seven days after delivery, he gave up the uterus entirely to this pursuit, and examined the fibres very carefully. He stretched it gradually in warm water, then inverted it, to have a full view of its inner surface. The remains of the decidua had been melted down, and passed off with the lochia, so that the fasciculated stratum of muscular fibres appeared to be bare, and to make the internal surface of the uterus. In a great number of places, but particularly where the placenta had been fixed, the fasciculi left oval spaces between them for the passage of arteries and veins, somewhat like those separations in the tendinous fibres of the abdomen and loins, where vessels pass out to the cellular membrane and integuments. The cervix uteri, where the penniform rugæ are situated, had not such regular nor so large fasciculi as the rest of the uterus. In the body of the uterus the fibres were regularly circular. The fundus was made up of two concentric circular plains of fibres, at the very centre of which was the orifice of the Fallopian tube. The better to conceive this arrangement of the internal muscular fibres, we may suppose each corner of the fundus uteri, where the tube is inserted, to be stretched or drawn out, so as to make two horns, or a bifid fundus, as in the quadruped; then, if we understand the inner fibres to be circular in every part of the uterus, we understand clearly how they will be circular in the human uterus upon its body, and likewise circular and concentric at each corner of the fundus.

When this internal stratum was removed, the fasciculated appearance and regular direction of the fibres was less and less apparent, in proportion as it was dissected outwards; which seemed in a great measure to be owing to the infinite number of the branches and communications of the large veins. The outer stratum in general was firmer and less vascular; that is, had fewer large vessels, and therefore was more dense than the middle and inner stratum. But the lateral parts of the uterus, where both the spermatic and hypogastric vessels first come to it, and anastomose upon its outside, are excepted in this general observation.

Dr. Hunter had afterwards the most favourable occasion that could be desired, for examining the fibres upon the inside of the uterus. It was the uterus of a woman who died at the end of the ninth month, without being in labour, and without having any flooding or discharge of waters. When he had examined and taken out all the contents, he attended particularly to the internal surface of the uterus. He found it every where covered with a thin stratum of the decidua, through which the muscular fibres appeared, but with some degree of obscurity.

The mouth of the uterus differs considerably in the different times of utero-gestation. For the greatest part of the nine months, that is, till the cervix uteri be fully distended, there is a projection of both the anterior and posterior lip of the os tincæ; and in some women this continues till the very time of labour. But in most women, when they are at their full time, or very near it, the os uteri is flat, and makes only a small rugous hole, often not readily discoverable by the touch on the lower or posterior part of the rounded lower edge of the uterus. The border of this orifice, and the internal surface of the uterus, for an inch or more all around, is full of little irregular cavities. These contain a tough gluten, which shoots across, and plugs up the inner part of the orifice. This gluten is commonly squeezed out from all the lacunæ, by the dilatation of the os uteri in the beginning and progress of the labour; and so, losing its hold, it falls out. In the dead body, when the part is kept some days in water, the gluten swells out more and more from all these cavities, and then separates entirely. Then the innumerable lacunæ which contained it, being empty, are very visible. And if the gluten has been thus carefully taken away, and be floated in water, its external surface is seen beautifully ornamented with all the processes which were drawn out of the innumerable lacunæ.

To illustrate the foregoing observations on the Pelvis, and Vessels of the Pregnant Womb, we have annexed Plate IV. of the GRAVID UTERUS, which represents a most elegant dissection performed by Dr. Hunter, and of which the following is a description. AA, The thighs cut through. BB, The lower angles or flaps of the abdominal muscles and peritoneum turned aside. CC, A front view of the womb, with the external covering dissected off, to shew the veins, arteries, &c. DD, The os pubis of each side cut through, above the foramen magnum ischii. EE, The small branch of the ischium which joins the os pubis cut through. F, The perineum. GG, The labia pudendi: the upper part of those, the nymphæ and the extremity of the clitoris are cut off. H, A large caruncula myrtiformis. I, The vagina: at the lower part of this passage, the deeper black part of this surface, in this figure, represents the cavity of the vagina leading backwards as well as upwards; and where this letter, I, stands, is seen the upper or anterior part of the vagina which is united to the bladder and urethra, and which is pressed downwards by the viscera that lie over it. At the upper point of this dark oval orifice, the tuberosity of the urethra is seen, with the orifice of the meatus urinarius. K, The body of the clitoris cut through; in the middle of which two small arteries are seen almost contiguous, viz. one in each corpus cavernosum. LL, The crura and erectores clitoridis. These lie more horizontally than in the natural state; the ossa pubis, &c. which suspend them, being removed; and they are stretched or lengthened, from the bones of the pelvis being drawn a little asunder that the contents might be better seen.

CONTENTS of the PREGNANT UTERUS.

The pregnant uterus may be said to contain the secundines, liquor amnii, and the foetus. The secundines make the lining of the uterus, and the immediate covering of the child; they form the chain of connection and communication between the bodies of the mother and child, and carry on that wonderful influence upon which the life and health of the child depend. There is an obvious division of them, into the navel-string, the placenta, and the membranes. A very singular peculiarity in the secundines is, that there is not any appearance of fat in them, let the mother or child be ever so adipose, at any period of utero-gestation, neither in the sound or natural, nor in the morbid, state of parts. What, upon a careless examination, appears to be fat upon the inner surface of the placenta in many cases, is an accumulation of a substance somewhat like a tough jelly, with an opaque and yellowish cast; and what often appears like slender ramifications of fat upon the outer surface, in reality is not fat, but ossifications in that part of the decidua.

The navel string and placenta have been in part already described. The foetus is connected to the placenta by the navel-string; which may be defined, a long vascular rope, composed of two arteries and a vein, covered with coats derived from the membranes, and distended with a quantity of viscid gelatinous substance, to which the bulk of the cord is chiefly owing. The cord always arises from the centre of the child's belly, but its point of insertion in the cake is variable. If the placenta adhere to the fundus, or is fixed over the mouth of the uterus, it is then of a round form, and the cord arises from its middle; but, if the placenta adhere elsewhere, the cord is inserted nearer its edge. Its shape is seldom quite cylindrical; and its vessels are sometimes twisted or coiled, sometimes formed into longitudinal sulci. Its diameter is commonly about the thickness of an ordinary finger, and its length sufficient to admit the birth of the child with safety, though the placenta should adhere at the fundus uteri. In length and thickness, however, it is liable to considerable variation. The extremity next the foetus is generally strongest; and somewhat weaker and more slender next the placenta, according to its place of insertion; which, though commonly not far from the centre, is sometimes very near the edge.

This suggests an important advice to practitioners, to be cautious of pulling the rope to extract the placenta when they feel the sensation of its splitting as it were into two divisions, which will proportionally weaken its resistance, and render it liable to be ruptured with a very slight degree of force in pulling.

The placenta, cake, or after-birth, is a thick, soft, vascular, mass, connected to the uterus on one side, and to the umbilical cord on the other. It differs in shape and size; it is thickest at the centre, and gradually becomes thinner towards the edges, where the membranes go off all round, making a complete bag or involucre to surround the waters, funis, and child. Its substance is chiefly vascular, and probably in some degree glandular. The ramifications of the vessels are very minute, which are unravelled by maceration, and, when injected, exhibit a most beautiful appearance, resembling the bushy tops of a tree. It has an external convex, and an internal concave, surface. The former is divided into a number of small lobes and fissures, by means of which its adhesion to the uterus is more firmly secured. This lobulated appearance is most remarkable when the cake has been rashly separated from the uterus; for the membrana decidua, or connecting membrane between it and the uterus, being then torn, the most violent and alarming hemorrhages frequently ensue. The internal concave surface of the placenta is in contact with the chorion, and that with the amnios. From its internal substance arise innumerable ramifications of veins and arteries, which inosculate and anastomose with one another; and at last the different branches unite, and form the funis umbilicalis. The after-birth may adhere to every part of the internal surface of the uterus, as at the posterior and anterior, superior and lateral, parts; and sometimes, though more rarely, part of the cake extends over the orificium uteri; from whence, when the orifice begins to dilate, the most frightful and dangerous floodings arise. But the most common place of attachment of the cake is from the superior part of the cervix to the fundus. Twins, triplets, &c. have their placenta, sometimes separate, and sometimes adhering together. When the placenta adhere, they have generally the chorion in common; but each foetus has its distinct amnios. They are commonly joined together, either by an intervening membrane, or by the surfaces being contiguous to one another; and sometimes the vessels of the one cake anastomose with those of the other. The human placenta, according to Dr. Hunter, and others who believe that the child is nourished by a secreted liquor, is composed of two distinct systems of parts, a spongy or cellular, and a vascular substance; the spongy or cellular part, formed by the decidua, being derived from the mother, the more internal vascular part belonging entirely to the foetus; but, according to those who are of opinion that a real circulation is carried on between the mother and the child, the placenta is chiefly composed of vessels which are connected by the common cellular substance.

The membranes consist, externally, of two layers of the spongy chorion, called *decidua*, and *decidua reflexa*; internally, of the true chorion, and the amnios. They form a pretty strong bag, commencing at the edge of the cake, going round the whole circumference, and lining the internal surface of the womb. When separated from the uterus, this membranous bag is slender and yielding, and its texture is readily destroyed by the impulse of the contained fluid, the pressure of the child, or of the finger in touching; but in its natural state, while it lines the womb, and is in close contact with its surface, the membranous bag is tough and strong, so as to give a considerable degree of resistance. It is also strengthened in proportion to the different layers of which it is composed, whose structure we shall proceed to explain more particularly.

1. The *membrana decidua*, or that lamella of the spongy false chorion which is in immediate contact with the uterus, is originally very thick and spongy, and exceedingly vascular, particularly where it approaches the placenta.

At first, there is a small intervening space between it and the ovum, which is filled with a quantity of gelatinous substance. It gradually becomes more and more attenuated by stretching, and approaches nearer to the decidua reflexa; and about the fifth month the two layers come in contact, and adhere so as to become apparently one membrane.

2. The *decidua reflexa*, in its structure and appearance, is similar to the former, being rough, fleshy, and vascular, on its external surface. In advanced gestation, it adheres intimately to the former membrane, and is with difficulty separated from it. The decidua reflexa becomes thicker and more vascular as it approaches the placenta, and is then blended with its substance, constituting the cellular or maternal part of the cake, as it is termed by Dr. Hunter. The other or more internal part belongs to the foetus, and is styled the *fatal* part of the placenta. The double decidua is opaque in comparison of the other membrane; the blood-vessels are derived from the uterus, and can be readily traced into it. Dr. Hunter supposes that the double decidua lines the uterus nearly in the same manner as the peritonæum does the cavity of the abdomen, and that the ovum is inclosed within its duplicature.

3. The *true chorion*, or that connected with the amnios, is the firmest, smoothest, and most transparent, of all the membranes, except the amnios; and, when separated from it, has a considerable degree of transparency. It adheres closely to the internal surface of the cake, which it covers immediately under the amnios, and gives also a coat to the umbilical cord. It is connected to the amnios by means of a gelatinous substance, and is easily separated from it.

4. The *amnios*, or internal membrane, forms the external coat of the umbilical cord. This lateral lamella of the membranous bag is the most thin, attenuated, and transparent, of the whole; and its vessels are so delicate, that they can hardly be discovered: their diameters are so small as to be incapable, in their natural state, of admitting globules of red blood. It is, however, firmer and stronger than the chorion, and gives the greatest resistance in the breaking of the membranes. The small bag, called *vesicula umbilicalis*, formerly described, and only conspicuous in the early months from its situation, is placed between the amnios and chorion, near the attachment of the cord; and, from the colour of its contents, has been mistaken for the urachus: but there is no allantois in the human subject. The allantois in quadrupeds is an oblong membranous sac, or pouch, placed between the chorion and amnios. This membrane communicates with the urachus, which in brutes is open, and transmits the urine from the bladder to the allantois.

5. The *waters* are contained within the amnios, and are called the *liquor amnii*. They are purest, clearest, and most limpid, in the first months; acquiring a colour, and becoming somewhat ropy, towards the latter end. They vary in different subjects, both in consistence and quantity; and, after a certain period, they proportionally diminish as the woman advances in her pregnancy. This liquor does not, in any respect, resemble the white of an egg; it is generally saltish, and therefore unfit for the nutrition of the child: some of it may perhaps be absorbed by the foetus, but the child is chiefly nourished by the navel-string. Water is sometimes collected between the chorion and amnios, or between the lamellæ of the chorion. This is called the *false water*. It is generally in much smaller quantity than the true water; and, without detriment to the woman, may flow at any time of pregnancy.

The foetus is commodiously adapted to the cavity of the uterus, and describes an oblong or oval figure; its several parts being collected together in such a manner as to occupy the least possible space. The spine is rounded, the head reclines, and the knees are drawn up to the belly, while the heels are drawn backwards towards the breech, and the hands and arms are folded upwards and downwards. The head of the child is generally downwards. This does not proceed, as was commonly alleged, from the funis

funis not being exactly in the middle of the child's body, for it is not suspended by the funis: the reason is, because the superior parts are much larger, and heavier in proportion, than the inferior. When other parts present, it seems owing to the motion of the child altering its figure when the waters are much diminished in quantity, or to circumvolutions of the cord: when the position is once altered, it becomes confined or locked in the uterus, and cannot easily resume its original posture. As the figure of the fœtus is oval, and the head naturally falls to the most depending part of the uterus, the vertex generally points to the os tincæ, with the ears diagonally in the pelvis. The fœtus is mechanically disposed to assume this position from its peculiar figure and construction, particularly by the bulk of the head and articulation with the neck, by the action of its muscles, and by the shape and construction of the cavity in which it is contained.

When a child is newly born, and left unconfined, however it may fling its limbs in starts, yet for the most part, when quiet, it gathers itself up into the oval form, as it lay in the womb. Were it not for art, this natural habit would be preserved, and man would take rest, like the quadruped, with all his limbs folded up.

The size and weight of a child's body at birth is generally over-rated, inasmuch that we are often told of children weighing from fifteen to twenty pounds. So far is this from being true, that Dr. Hunter declares, he never knew an instance of a child that weighed twelve pounds, and the greatest number are but little above *half* that weight. Dr. Macaulay was at great pains to ascertain the

ordinary bulk of new-born children, by weighing several thousands that were born in the British lying-in hospital; the result was, that the smallest weighed a little above four pounds, the largest eleven pounds two ounces, but the greatest number weighed from five to eight pounds, *avoirdupois*.

To shew the general position of the child in the womb at or about its full time, Dr. Hunter has favoured us with an elegant dissection, which we have represented in Plate V. of the GRAVID UTERUS. Indeed the four former of these plates represent dissections of the same subject, an unfortunate female, who expired suddenly at nearly the end of the ninth month of her pregnancy. The arteries and veins, and most of the different vessels, were injected with wax, and are now in Dr. Hunter's collection. These engravings demonstrate the different appearances of the gravid uterus, in the same order that its different membranes were dissected off; the last of which being removed, exhibits, as in Plate V. a view of the child, of its full size, just before birth. The navel-string is cut, tied, and turned to the left side over the edge of the womb. At the fundus the investing membranes are likewise turned over the edge of the womb, that they might be more apparent. On opening the uterus, the body of the child was found covered with a white greasy mucus, which is commonly seen on children at their birth. This is represented at the upper part of its back, where it was intersected with lines, from the wrinkles and motion of the child's body. Every part is delineated just as it was found; not so much as one joint of a finger having been moved to shew any part more distinctly, or to give a more picturesque effect.

COMPARATIVE ANATOMY.

THE principal advantages of Comparative Anatomy are the following: First, it furnishes us with a sufficient knowledge of the different parts of animals, to prevent our being imposed upon by such authors as have delineated and described several parts from brutes as belonging to the human body. Secondly, it helps us to understand several passages in the ancient medical writers, who have taken many of their descriptions from brutes, and reasoned from them: their reasonings have often been misapplied, and consequently wrong explained, by the moderns. The third and great use we reap from this science, is the light it casts on several functions in the human œconomy, about which there have been so many disputes among anatomists. These differences of opinion, by exhibiting the structure of the same parts in different animals, and by comparing the several organs employed in performing the same action, which in the human body is brought about by one more complex, will be in a great measure done away.

All quadrupeds have a covering of hair, wool, &c. to defend them from the injuries of the weather; which varies in thickness according to the season of the year, and difference of the climate. Thus in Russia and the northern countries the furs are very thick and warm; while the little Spanish lap-dogs, and Barbary cows, have little or no hair at all. The *cutis* and *cuticula* in quadrupeds are disposed much in the same way as the human, but they are more elastic. Immediately under this there is a very thin cutaneous muscular substance, called *panniculus carnosus*, which is common to all quadrupeds, the porcine kind excepted; this principally covers the trunk, serving to shrivel the skin, in order to drive off insects, their tails and heads not being sufficient for this purpose, while their extremities are employed in their support and progression.

It has probably been from observing some muscles of the human body, such as the *platysma myoides*, *cremaster*, and *frontales*, and the collapsed tunica cellulosa of the emaciated subjects, to resemble this thin muscle, that some of the older anatomists reckoned such a *panniculus* among the common integuments of the human body. Most of the quadrupeds want clavicles, whereby their anterior

extremities fall upon their chest, so as to make their thorax proportionally narrower than the human. This small distance of their anterior extremities is very necessary for their uniform progression. Apes indeed, and squirrels, have clavicles, to allow them a more full use of their extremities in climbing; but they walk ill on all fours.

ANATOMY of a DOG.

We may first observe of this animal, as indeed of most quadrupeds, that its legs are much shorter in proportion to its trunk than in man, the length of whose steps depends entirely on the length of his inferior extremities: however, to balance this, the trunk of the animal is proportionally longer and smaller, and his spine more flexible, by which he is able at each step to bring his posterior extremities nearer to his anterior. His common integuments are much like those of other quadrupeds; only they allow little or no passage for sweat; but, when he is over-heated, the noxious and superfluous matter finds an exit by the salivary glands; for he lolls out his tongue, and flavers plentifully. We are not, however, to suppose, that because a dog does not sweat, he has no insensible perspiration. That a dog perspires is evident, because one of these animals can trace another by the scent of his footsteps; which could not happen, if a large quantity of perspirable matter was not constantly going off. We may also observe, that the *rabies canina* is a disease peculiar to dogs, foxes, wolves, and others of that genus; for though the bite of other mad animals, such as cats, or hogs, and even poultry, will produce the disease, no fair instance has ever been brought of any of these animals being originally seized with this malady.

The pyramidal muscles are wanting in the dog; to supply which, the rectus is inserted fleshy into the os pubis. The *omentum* reaches down to the os pubis; which, considering the posture of the animal, we shall find to be a wise provision, since its use is to separate an oily liquor for lubricating the guts, and facilitating their peristaltic motion. So, in our erect posture, the natural gravity of the oil will determine it downward; but, in the horizontal position

sition of these creatures, if all the intestines were not covered, there would be no favourable derivation of the fluid to the guts lying in the posterior part of the abdomen, which is the highest; and besides, had the omentum reached much farther down in us, it would not only have supplied too great a quantity of oil to the lower part of the abdomen, but we should have been in continual danger of herniæ; and even at present the omentum frequently passes down with some of the other viscera, and forms part of these tumours. To these, however, the dog is not subject, as his viscera do not press so much on the rings of the abdominal muscles, and besides are prevented from passing through by a pendulous flap of fat. The inferior and anterior lamella of the omentum is fixed to the spleen, fundus of the stomach, pylorus, liver, &c. in the same way as the human; but the superior, having no colon to pass over, goes directly to the back-bone. This serves to explain the formation of the small omentum in the human body; which is nothing but the large omentum, having lost its fat, passing over the stomach and colon, where it re-assumes its pinguedo, so proceeds, and is firmly attached to the liver, spine, &c.

This animal's stomach, though resembling the human in its shape, is somewhat differently situated. It lies more longitudinal, as indeed all the other viscera do, to accommodate themselves to the shape of the cavity in which they are contained; that is, its inferior orifice is much farther down with respect to the superior than the human: by this means the gross food has an easier passage into the duodenum. Again, the fundus of the human stomach, when distended, stands almost directly forwards, which is occasioned by the little omentum tying it so close down to the back-bone, &c. at its two orifices; but, it not being fixed in that manner in the dog, the fundus remains always posterior: this also answers very well the shape of the different cavities, the distance between the cardia and fundus being greater than that between the two sides. It seems to be much larger in proportion to the bulk of the animal than the human, that it might contain a greater quantity of food at once; which was very necessary, since this animal cannot at any time get its sustenance as men do. The turbilion is not so large, nor is there any coarction forming the *antrum Vilesi*, as in the stomach of man. It is considerably thicker and more muscular than ours, for breaking the cohesion of their food, which they swallow without sufficient chewing. Hence it is evident the force of the stomach is not so great as some anatomists would have it, nor its contraction so violent; otherwise that of dogs would be undoubtedly wounded by the sharp bones, &c. which they frequently swallow; for the contraction is still greater than in the human stomach, which is much thinner. The rugæ of the tunica villosa are neither so large, nor situated transversely, as in the human, but go from one orifice to the other: the reason of which difference is, perhaps, that they might be in less danger of being hurt by the hard substances this creature frequently feeds on; and for the same reason there is not the like coarction at their pylorus.

The intestines of this animal are proportionally much shorter than ours; for the food which these creatures mostly use, soon dissolves, and then putrefies; on which account there was no occasion for a long tract of intestines; the food being required to be quickly thrown out of the body. The same is to be observed of all the carnivorous animals. The muscular coat of the intestines is also thicker and stronger than the human, to protrude the contents quickly and accurately. The valvulæ conniventes are less numerous, and in a longitudinal direction; and the whole tract of the alimentary canal is covered with a slime, which lubricates the intestines, saves them from the acrimony of the excrementitious part, and facilitates its passage.

The duodenum differs considerably in its situation from the human. For in man it first mounts from the pylorus upwards, backwards, and to the right side; then passes down by the gall-bladder; and, going over the right kid-

ney and superior part of the psoas muscles, makes a curvature upwards; and passes over the back-bone and vena cava inferior, to the left hypochondrium, where it gets through the omentum, mesentery, and mesocolon, to commence jejunum, being firmly tied down all the way, the biliary and pancreatic ducts entering at its most depending part. Whereas in the dog, the duodenum is fixed at the pylorus to the concave surface of the liver, and hangs loose and pendulous with the mesentery backwards into the cavity of the abdomen; then turning up again, is fixed to the back-bone, where it ends in the jejunum; the bile and pancreatic juice are poured into it at the most depending part. Therefore the same intention seems to have been had in view in the formation of this part in both, viz. the giving the chyle, after the liquors of the liver and pancreas are poured into it, a disadvantageous course, that so it might be the more intimately blended with the humours before its entry into the jejunum, where the lacteals are very numerous. And thus, by reason of their different posture, the same design (though by a very different order of the parts) is brought about in both.

The other small guts are much the same with ours, only shorter. The great guts are also shorter and less capacious than in the human body; and we take it for a general rule, that all animals that live on vegetable food have not only their small guts considerably longer, but also their great guts more capacious, than such creatures as feed on other animals. Hence man, from this form of his intestines, and that of the teeth, seems to have been originally designed for feeding on vegetables chiefly; and still the most of his food, and all his drink, is of that class. The reason of this difference seems to be, that as animal food is not only much more easily reduced into chyle, but also more prone to putrefaction, too long a remora of the juices might occasion the worst consequences. So it was necessary that their receptacles should not be too capacious; but, on the contrary, being short and narrow, might conduce to the seasonable discharge of their contents. Whereas, vegetable food being more difficultly dissolved and converted into an animal nature, there was a necessity for such creatures as fed on it to be provided with a long intestinal canal, that this food in its passage might be considerably retarded, and have time to change its indoles into one more agreeable to our nature.

The *appendix vermiformis* justly enough deserves the name of an *intestinum cæcum* in this subject, though in the human body it does not; and it has probably been from the largeness of this part, in this and some other animals, that the oldest anatomists came to reckon that small appendix in man one of the great guts. On its internal surface we observe a great number of mucous glands. As all these throw out slime, their principal office would seem to be the procuring a sufficient quantity of that matter for the purposes above-mentioned. Still, however, there seems to be some unknown use for this organ in other animals; for the *appendicula vermiformis* in them is either of great size or of great length. In a rat, it is rather larger than the stomach; in others, as swine, and some of the animals which live on vegetables, it has long convolutions, so that the food must be lodged in it for a long time. Thus, probably, some change takes place in the food, which requires a considerable time to effectuate, and, though unknown to us, may answer very useful purposes to the animal.

The colon, in the dog, has no longitudinal ligaments; and consequently this gut is not purged up in different bags or cells as the human: nor does this intestine make any circular turn round the abdomen; but passes directly across it to the top of the os sacrum, where it gets the name of *rectum*.

The mesentery is considerably longer than in the human body; that, in his horizontal situation, the intestines may rest securely on the soft cushion of the abdominal muscles. The fat is here disposed in the same way, and for the same reason, as in the omentum. The interstices between the

fat are filled with a fine membrane. Instead of a great number of glandulæ vague to be found in the human mesentery, we find the glands few in number, and those are closely connected together; or there is only one large gland to be observed in the middle of the mesentery of a dog, which from its imagined resemblance to the pancreas and the name of its discoverers, is called *pancreas Asellii*; but the resemblance, if there is any, depends chiefly on the connection, the structure being entirely different. The reason why this in man is as it were subdivided into many smaller ones, may possibly be, that as the guts of a human body are proportionally much longer than those of this creature, it would have been inconvenient to have gathered all the *lacteals primi generis* into one place; whereas, by collecting a few of these vessels into a neighbouring gland, the same effect is procured much more easily. Whether the food in this animal needs less preparation in its passage through these glands, is a matter very much unknown to us; though it is certain that some changes really take place.

The *pancreas* in man lies across the abdomen, tied down by the peritonæum; but, the capacity of this creature's abdomen not allowing of that situation, it is disposed more longitudinally, being tied to the duodenum, which it accompanies for some way. Its duct enters the duodenum about an inch and a half below the ductus communis.

The *spleen* of this animal differs very much from ours both in figure and situation. It is much more oblong and thin, and lies more according to the length of the abdomen, like the pancreas. Though the spleen of this creature is not firmly tied to the diaphragm (which was necessary in our erect posture to hinder it from falling downwards), yet by the animal's prone position, its posterior parts being rather higher than the anterior, it comes to be always contiguous to this muscle, and is as effectually subjected to an alternate pressure from its action as the human spleen is.

The human *liver* has no fissures or divisions, unless we reckon that small one between the two *pylæ*, where the large vessels enter: whereas in a dog, and all other creatures that have a large flexion in their spine, as lions, leopards, cats, &c. the liver and lungs are divided into a great many lobes by deep sections, reaching the large blood-vessels, which in great motions of the back-bone may easily lap over one another; and are thus in much less danger of being torn or bruised, than if they were formed of one entire piece, as we really see it in horses, cows, and such creatures as have their back-bone stiff and immoveable. There is no *ligamentum latum* connecting the liver to the diaphragm, which in our situation was necessary to keep the viscus in its place: whereas, in this creature, it naturally gravitates forwards, and by the horizontal position of the animal is in no danger of pressing against the vena cava; the preventing of which is one use generally assigned to this ligament in man. Had the liver of the dog been thus connected to the diaphragm, the respiration must necessarily have suffered; for this muscle is here moveable at the centre as well as at the sides. But in man the liver is fixed to the diaphragm, mostly at its tendinous part; that is, where the pericardium is fixed to it on the other side; so that it is in no danger of impeding the respiration, being suspended by the mediastinum and bones of the thorax. In consequence of this viscus being divided into so many lobes, it follows, that the hepatic ducts cannot possibly join into one common trunk till they are quite out of the substance of the liver; because a branch comes out from every lobe of the liver; all of which, by their union, form the hepatic duct: whence we are led to conclude, that the hepato-cystic ducts, mentioned by former authors, do not exist. The gall-bladder itself is wanting in several animals, such as the deer, the horse, the ass, &c. but in place of it, in such animals, the hepatic duct, at its beginning, is widened into a reservoir of considerable size, which may answer the same purpose in them that the gall-bladder does in others.

The *kidneys* in this animal are situated much in the same way as in the human subject; but have no fat on their inferior surface, where they face the abdomen, and are of a more globular form than the human. The reason of these differences will easily appear, if we compare their situation and posture with those in a man, who walks erect. They are placed in this subject in the inferior part of the body, so are not subject to the pressure of the viscera, which seems to be the principal cause of the fatness of those organs in us, and perhaps may likewise be the cause of our being more subject to the stone than other animals. Hence there is no need of any cellular substance to ward off this pressure where there would necessarily be fat collected; but the superior part of their kidneys is somewhat covered with fat, lest they should suffer any compression from the action of the ribs and spine.

In the internal structure there is still a more considerable difference: for the *papillæ* do not here send out single the several *tubuli uriniferi*; but, being all united, they hang down in form of a loose pendulous flap in the middle of the pelvis, and form a kind of septum medium; so that a dog has a pelvis formed within the substance of the kidney. The only thing that is properly analogous to a pelvis in man, is that sac or dilatation of the ureters formed at the union of the *ductus uriniferi*. The external part of the kidney of a dog somewhat resembles one of the lobes of the kidney of a human foetus: but in a human adult the appearance is very different; because, in man, from the continual pressure of the surrounding viscera, the lobes, which in the foetus are quite distinct and separated, concrete, but the original cortical substance is still preserved in the internal parts of the kidney. The reason of these particularities may probably be, that the liquors of this animal, as of all those of the carnivorous kind, being much more acrid than those of such as live on vegetable food, its urine must incline much to an alkalescency, as indeed the smell and taste of that liquor in dogs, cats, leopards, &c. evidently shew, being fetid and pungent, and therefore not convenient to be long retained in the body. For this end it was proper, that the secretory organs should have as little impediment as possible by pressure, &c. in the performing their functions; and for that design the mechanism of their kidneys seems to be excellently adapted.

The *glandulæ* or *capsulæ atrabiliaræ* are thicker and rounder than the human, for the same reason as the kidneys; and the *ureters* are more muscular than the human, because of the unfavourable passage the urine has through them; they enter the bladder near its fundus. The bladder differs considerably from the human; and first in its form, which is pretty much pyramidal or pyriform. This shape of the dog's bladder is likewise common to all quadrupeds, except the ape and those of an erect posture. In men it is by no means pyriform, but has a large sac at its posterior and inferior part: this form depends entirely on the urine gravitating in our erect posture to its bottom, which it will endeavour to protrude; but, as it cannot yield before, being contiguous to the os pubis, it will naturally stretch out where there is the least resistance, that is, at the posterior and lateral parts; and, were it not for this sac, we could not so readily come at the bladder to extract the stone either by the lesser or lateral operation of lithotomy. Most anatomists have delineated this wrong; so much, that none have justly painted it, excepting Cowper in his *Myotomia*, and Mr. Butty. It has certainly been from observing it in brutes and young children, that they have been led into this mistake.

As to its *connection*, it is fastened to the abdominal muscles by a process of the peritonæum, and that membrane is extended quite over it; whereas in us its superior and posterior parts are only covered by it: hence in man alone the high operation of lithotomy can be performed without hazard of opening the cavity of the abdomen. Had the peritonæum been spread over the bladder in its whole extent, the weight of the viscera in our erect posture would have

have fo borne upon it, that they would not have allowed any confiderable quantity of urine to be collected there; but we muft have been obliged to difcharge its contents too frequently to be confiftent with the functions of focial life; whereas, by means of the peritonæum, the urine is now collected in fufficient quantity, the vifcera not gravitating this way. We may take it for a general rule, that thofe creatures that feed upon animal food have their bladder more mufcular and confiderably stronger, and lefs capacious, than thofe that live on vegetables, fuch as horfes, cows, fwine, &c. whofe bladder of urine is perfectly membranous, and very large. This is wifely adapted to the nature of their food: for, in thefe firft, as all their juices are more acrid, fo in a particular manner their urine becomes exalted; which, as its remora might be of very ill confequence, muft neceffarily be quickly expelled. This is chiefly effected by its ftimulating this vifcus more strongly to contract, and fo to difcharge its contents, tho' the irritation does not altogether depend upon the ftretching, but likewise arifes from the quality of the liquor.

Their *fpermatic veffels* are within the peritonæum, which is fpread over them, and from which they have a membrane like a mefentery; fo that they hang loofe and pendulous in the abdomen; whereas, in us, they are contained in the cellular part of the peritonæum, which is tenfely ftretched over them. At their paffage out of the lower belly, there appears a plain perforation, or holes; hence the adult quadruped, in this refpect, refembles the human fœtus. And from obferving this in quadrupeds, has arifen the falfe notion of *hernia* or *rupture* among authors. This opening, which leads down to the tefticle, is of no difadvantage to them, but evidently would have been to us; for, from the weight of our vifcera continually gravitating upon thefe holes, we muft have perpetually laboured under enterocæles, which they are in no hazard of, as in them this paffage is at the higheft part of their belly, and, in their horizontal pofture, the vifcera cannot bear upon it.

The *ferotum* is fhorter and not fo pendulous as the human in all the dog kind that want the *veficulæ feminales*, that the feed at each copulation might the fooner be brought from the teftes, thus in fome meafure fupplying the place of the *veficulæ feminales*; for the courfe of the feed through the *vafa deferentia* is thus fhortened, by placing the fecerning veffels nearer the excretory organs. The want of *veficulæ feminales* at the fame time explains the reafon why this creature is fo tedious in copulation. The ftructure of the *tefticles* is much the fame with the human, as are likewise the *corpus pyramidale*, *varicofofum*, or *pampiniforme*, and the *epididymis* or excretory vefsel of the tefticle. The *vafa deferentia* enter the abdomen where the blood-veffels come out; and, paffing along the upper part of the bladder, are inferted a little below the bulbous part of the urethra.

The *præputium* has two mufcles fixed to it; one that arifes from the fphincter ani, and is inferted all along the *penis*; and this is called *retractor præputii*. But the other, whofe office is directly contrary to this, is cutaneous; and feems to take its origin from the mufcles of the abdomen, or rather to be a production of their tunica carnofa. The *corpora cavernofa* rife much in the fame way as the human: but thefe foon terminate; and the reft is fupplied by a triangular bone, in the inferior part of which there is a groove excavated for lodging the urethra. There are upon the penis two protuberant bulbous flefhy fubftances, refembling the glans penis in man, at the back of which are two veins, which, by the *erectores penis* and other parts, are compressed in the time of coition; and, the circulation being ftopped, the blood diftends the large cavernous bodies. After the penis is thus fwelled, the vagina, by its contraction and fwelling of its corpus cavernofum, which is confiderably greater than in other animals, gripes it clofely; and fo the male is kept in action fome time contrary to his will, till an opportunity be given for bringing a quantity of feed fufficient to impregnate the female: and

thus, by that *orgafmus veneris* of the female organs, the want of the *veficulæ feminales* is in fome meafure fupplied. But as it would be a very uneasy pofture for the dog to fupport himfelf foely upon his hinder feet, and for the bitch to fupport the weight of the dog for fo long a time; therefore, as foon as the bulbous bodies are fufficiently filled, he gets off and turns averfe to her. Had then the penis been pliable as in other animals, the urethra muft of neceffity have been compressed by this twifting, and confequently the courfe of the feed intercepted; but this is wifely provided againft by the urethra's being formed in the hollow of the bone. After the emiffion of the feed, the parts turn flaccid, the circulation is reftored, and the bulbous parts can eafily be extracted. The *prof-tata* feems here divided into two, which are proportionally larger than the human, and afford a greater quantity of that liquid. The *uterus* of the multiparous animals is little elfe but a continuation of their vagina, only feparated from it by a fmall ring or valve. From the uterus two long canals mount upon the loins, in which the fœtuses are lodged: thefe are divided into different facs, which are ftrongly constricted between each fœtus; yet thefe contractions give way in the time of birth. From thefe go out the *tubæ Fallopianæ*, fo that the ovaria come to lodge near the kidneys.

We ought next to examine the ftructure of the thorax and its contents. But firft it may not be amifs to remark of the *diaphragm* in its natural fituation, that it is in general more loofe and free than the human; which is owing to its connection with the neighbouring parts in a different manner from ours. The human diaphragm is connected to the pericardium; which again, by the intervention of the mediastinum, is tied to the fternum, spine, &c. but here there is fome diftance between the diaphragm and pericardium. We obferve further, that its middle part is much more moveable, and the tendinous parts not fo large. And indeed it was neceffary their diaphragm fhould be fomewhat loofe, they making more ufe of it in difficult refpiration than man. This we may obferve by the ftrong heaving of the flanks of an horfe or dog when out of breath; which corresponds to the rifing of the ribs in us.

The difpofition and fituation of the *mammæ* vary as they bear one or more young. Thofe of the uniparous kind have them placed between the posterior extremities, which in them is the higheft part of their bodies, whereby their young get at them without the inconvenience of kneeling. Nevertheless, when the creatures are of no great fize, and their breaft large, as in fheep, the young ones are obliged to take this pofture. In multiparous animals, they muft have a great number of nipples, that their feveral young ones may have room at the fame time, and thefe are difpofed over both thorax and abdomen; and the creatures generally lie down when the young are to be fuckled, that they may give them the moft favourable fituation. From this it does not appear to be from any particular fitnefs of the veffels at certain places for giving a proper nourifhment to the child, that the breasts are fo placed in women as we find them, but really from that fituation being the moft convenient both for mother and infant.

The *fternum* is very narrow, and confifts of a great number of fmall bones, moveable every way; which always happens in creatures that have a great mobility in their spine. The *mediastinum* is pretty broad. The pericardium is not here contiguous to the diaphragm, but there is an inch of diftance between them, in which place the fmall lobe of the lungs lodges; and by this means the liver, &c. in this animal, though continually preffing upon the diaphragm, yet cannot difturb the heart's motion.

The *heart* is fited with its point almoft directly downwards, according to the creature's pofture, and is but very little inclined to the left fide. Its point is much fharpier, and its fhape more conoidal, than the human. Here the names of *right* and *left* ventricles are proper enough, tho' not fo in the human; which ought rather to be called *anterior* and *posterior*, or *superior* and *inferior*. The animal has

the *vena cava* of a considerable length within the thorax, having near the whole length of the heart to run over ere it gets at the *sinus Lowerianus dexter*. In men it enters the pericardium as soon as it pierces the diaphragm, which is firmly attached to it, and immediately gets into the *sinus Lowerianus*; which sinus, in the human subject, by the oblique situation of the heart, is almost contiguous to the diaphragm: and by this we discover, that several authors have taken their delineations of the human heart from brutes; which is easily detected by the shape and situation of the heart, and the long *vena cava*, within the thorax. This situation of the heart of the dog agrees best with the shape of its thorax, which is lower than the abdomen.

The egress of the large blood-vessels from the heart is somewhat different from the human; for here the right subclavian comes off first; and as a large trunk runs some way upwards before it gives off the left carotid, and splits into the carotid and subclavian of the right side, then the left subclavian is sent off. So that, neither here, properly speaking, is there an *aorta ascendens* more than in the human; but this name has probably been imposed upon it from observing this in a cow, where indeed there is an ascending and descending aorta. From this specialty of the distribution of the vessels of the right side, which happens, though not in so great a degree, in the human subject, we may perhaps in some measure account for the general greater strength, readiness, or facility of motion, which is observable in the right arm. We believe, upon measuring the sides of the vessels, the surface of the united trunk of the right subclavian and carotid is less than that of the left subclavian and carotid, as they are separated. If so, the resistance to the blood must be less in that common trunk than in the left subclavian and carotid. But, if the resistance be smaller, the absolute force with which the blood is sent from the heart being equal, there must necessarily be a greater quantity of blood sent through them in a given time; and, as the strength of the muscles is, *ceteris paribus*, as the quantity of blood sent into them in a given time, those of the right arm will be stronger than those of the left. Now children, being conscious of this superior strength, use the right upon all occasions; and thus from use comes that great difference which is so observable. But, if by any accident the right arm is kept from action for some time, the other from being used gets the better; and those people are left-handed. For it is not to be imagined, that the small odds in the original formation of the vessels should be sufficient to resist the effect of use and habit, (instances of the contrary occur every day;) it is enough for our present argument, that, where no means are used to oppose it, the odds are sufficient to determine the choice in favour of the right. Now, because it is natural to begin with the leg corresponding to the hand we have most power of, this is what gives also superiority to the right leg. This difference is not peculiar to man, but is still more observable in those creatures in whom the same mechanism obtains in a greater degree. Observe a dog at a trot, how he bears forward with his right side; or look at him when scraping up any thing, and we shall presently see that he uses his right much oftener than his left foot. Something analogous to this may be observed in horses; who are never considered to gallop well, unless the right leg be presented first. It has been the opinion of some anatomists, that left-handed people, as well as those distinguished by the name of *ambidexter*, (who use both hands promiscuously,) have the two carotid and subclavian arteries coming off in four distinct trunks from the arch of the aorta; but no appearance of this kind has ever been observed in such bodies as have been examined for this purpose; though indeed these have been but few, and more experience might throw greater light on the subject.

The *thymus* of the dog is proportionally much larger than ours; whereas the *glandula thyroidea* is much less, and is divided into two distinct parts, or there are two separate glands: which is not the case in man. The reason

of this difference is unknown, as is likewise the use of the gland itself. It is generally remarked, that these two glands supply the place of each other; that is, in such animals as have a large *thymus*, the *glandula thyroidea* is smaller, and *vice versa*. Hence we are naturally led to ascribe the same use to both, viz. the separation of a thin lymph for diluting the chyle in the thoracic duct before it be poured into the blood; then, if we consider the different formation of the thorax in both, we shall readily account for the variety in the bulk of these two glands. Respiration being chiefly performed in man by the widening of the chest, the lungs at every inspiration must press upon the *thymus*, and consequently diminish it: but the diaphragm, yielding more in the dog's inspiration, this gland is not so much pressed by the lungs, and so will be larger; and hence the *glandula thyroidea* will be proportionally less. Again, from the posture of this creature, we shall see that it was much more convenient for a dog to have the most part of the diluting lymph supplied by the *thymus*, since, the neck being frequently in a descending posture, the lymph of the thyroid gland would have a very disadvantageous course to get to the thoracic duct: whereas in the human body, the *thymus* is really below the lacteal canal, where it makes its curvature before it opens into the subclavian; and consequently there is a necessity of a considerable share of the diluting liquor being furnished by the thyroid gland, which is situated much higher; so that its lymph has the advantage of a perpendicular descent.

We may here observe, that the *thoracic duct* in a dog has no curvature before it enters the subclavian vein, the horizontal position of this animal allowing a favourable course to the chyle, so as not to need that turn to force its passage into the blood. It may likewise be observed, that such animals as walk horizontally, have the valves of the thoracic duct fewer in number than others. The horse has only a single pair; while, on the contrary, the ape resembles man in having several valves. Thus the lymph is forwarded in its passage, and the weight of it diminished.

The *lungs* of the dog are divided into more numerous lobes, and deeper, than they are in man, for the same reason as the liver. The left side of the thorax in this animal bears a greater proportion to the right than in man; the one being nearly as three to two, the other as four to three. In quadrupeds, as well as in man, the lungs are closely applied to the containing parts; although this has been denied by some authors.

We consider it as a general rule, that all quadrupeds, as having occasion to gather their food from the ground, are provided with longer necks than man: but as a long neck not only gives the advantage of too long a lever to the weight of the head, but also, when the animal is gathering his food, makes the brain in danger of being oppressed with too great a quantity of blood, by the liquor in these arteries having the advantage of a descent, while that in the veins must remount a considerable way contrary to its own gravity; it was therefore necessary that a part of the length of the neck should be supplied by the length of the jaws. Thus we see horses, cows, &c. who have no occasion for opening their mouths very wide, yet have long jaws. Bull-dogs indeed, and such animals as have occasion for very strong jaws, must of necessity have them short; because, the longer they are, the resistance to be overcome acts with a longer lever. Another exception to this general rule is, such animals are furnished with something analogous to hands to convey their food to their mouths, as cats, apes, &c. The teeth of the dog plainly shew it to be of the carnivorous kind; for there are none of them made for grinding the food, but only for tearing and dividing it. It has six remarkable sharp teeth before, and two very long tusks behind; both of which the ruminating animals want. These are evidently calculated for laying very firm hold of substances, and tearing them to pieces; and the vast strength of the muscles inserted into the lower jaw assists greatly in this action; while the molars

ares have sharp cutting edges, calculated for cutting flesh, and breaking the hardest bones.

The tongue, in consequence of the length of the jaws, is much longer than ours; and, as this creature feeds with his head in a depending posture, the bolus would always be in danger of falling out of the mouth, were it not for several prominences or papillæ placed mostly at the root of the tongue, and crooked backwards in such a manner, as to allow any thing to pass easily down to the jaws, but to hinder its return. By the papillæ also the surface of the tongue is increased, and a stronger impression is made on the sensation of taste. In some animals who feed on living creatures, these tenter-hooks are still more conspicuous; as in several large fishes, where they are almost as large as their teeth in the fore-part of their mouth, and nearly as firm and strong. When we open the mouth of a dog, we see the amygdalæ very prominent in the posterior part of it; so that it would appear at first view, that these were inconveniently placed, as being continually exposed to injuries from the hard substances this animal swallows: but, upon a more narrow scrutiny, we find this inconvenience provided against by two membranous capsulæ, into which the amygdalæ, when pressed, can escape, and remove themselves from such injuries. The *velum pendulum palati* is in this creature considerably longer than in man, to prevent the food from getting into his nose; which would happen more frequently than with us, because of its situation while feeding.

In the dog, as well as in other quadrupeds, there is no *uvula*; but then the *epiglottis*, when pressed down, covers the whole rima entirely, and naturally continues so: there is therefore a ligament, or rather muscle, that comes from the os hyoides and root of the tongue, that is inserted into that part of epiglottis where it is articulated with the cricoid cartilage, which serves to raise it from the rima, tho' not so strongly but that it may with a small force be clapped down again. It may be asked, however, Why the uvula is wanting here, and not in man? This seems to be, that quadrupeds, who swallow their food in an horizontal situation, have no occasion for an uvula, though it is necessary in man on account of his erect situation.

In the upper part of the pharynx, behind the cricoid cartilage, there is a considerable gland to be found, which serves not only for the separation of a mucous liquor to lubricate the bolus as it passes this way, but also to supply the place of a valve, to hinder the food from regurgitating into the mouth, which it would be apt to do by reason of the descending situation of the creature's head. In man, this muscle of the epiglottis is wanting, its place being supplied by the elasticity of the cartilage. The *œsophagus* is formed nearly in the same way as the human. Authors indeed generally allege, that quadrupeds have their gullet composed of a double row of spiral fibres decussating one another; but this is peculiar to ruminating animals, who have occasion for such a decussation of fibres. The action of these may easily be observed in a cow chewing her cud.

The canine nose is generally longer than that of man, and its external passage is much narrower. The internal structure is also better adapted for an acute smelling, having a larger convoluted surface on which the *membrana scheideriana* is spread; and this is to be observed in most quadrupeds, who have the ossa spongiosa commonly large, and these too divided into a great number of excessively fine thin lamellæ. The sensibility seems to be increased in proportion to the surface; and this will also be found to take place in all the other senses. The elephant, which has a head large in proportion to its body, has the greatest part of it taken up with the cavity of the nose and frontal sinuses; which last extend almost over their whole head, and leave but a small cavity for their brains. A very nice sense of smelling was not so absolutely necessary for man, who has judgment and experience to direct him in the choice of his food; whereas brutes, who have only their senses, must of necessity have these acute; some having

one sense in greater perfection than others, according to their different way of life. We not only conclude, *a priori*, from the large expanded *membrana scheideriana*, that their sense of smelling is very acute, but we find it so by cows and horses distinguishing so readily between noxious and wholesome herbs, which they do principally by this sense.

The external ear in different quadrupeds is differently framed, but always calculated to the creature's manner of life. In shape it commonly resembles the oblique section of a cone from near the apex to the basis. Hares, and such other animals as are daily exposed to insults from beasts of prey, have large ears directed backwards, their eyes warning them of any danger before; rapacious animals, on the other hand, have their ears placed directly forwards, as we see in the lion, cat, &c. The slow hounds, and other animals that are designed to hear most distinctly the sounds coming from below, have their ears hanging downwards; or their ears are flexible, because they move their head for the most part with greater difficulty than man. Man again, who must equally hear sounds coming from all quarters, but especially such as are sent from about his own height, has his external ear placed in a vertical manner, somewhat turned forward. In short, wherever we see a specialty in the make of this organ in any creature, we shall, with very little reflection, discover this form to be more convenient for that creature than another. The animal also has the power of directing the cone of the ear to the sonorous body without moving the head. There are some differences to be observed in the structure of the internal ear in different animals; but we know so very little of the use of the particular parts of that organ in the human subject, that it is altogether impossible to give reasons for these variations in other creatures.

All quadrupeds have at the internal canthus of the eye a strong firm membrane with a cartilaginous edge, which may be made to cover some part of their eye; and this is greater or less in different animals as their eyes are more or less exposed to dangers in searching after their food. This *membrana nictitans*, as it is called, is not very large in the dog. Cows and horses have it so large as to cover one half of the eye like a curtain, and at the same time it is transparent enough to allow abundance of the rays of light to pass through it. Fishes have a cuticle always over their eyes, as they are ever in danger of that inconstant element, the water. In this then we may also observe a sort of gradation. Quadrupeds have also a seventh muscle belonging to the eye, called *suspensorius*. It surrounds almost the whole optic nerve, and is fixed into the sclerotic coat as the others are. Its use is to sustain the weight of the globe of the eye, and prevent the optic nerve from being too much stretched, without obliging the four straight muscles to be in a continual contraction, which would be inconvenient; at the same time this muscle may be brought to assist any of the other four, by causing one particular portion of it to act at a time.

The next thing to be remarked is the figure of the *pupil*, which is different in different animals, but always exactly accommodated to the creature's way of life, as well as to the different species of objects that are viewed. Man has it circular, for obvious reasons; an ox has it oval, with the longest diameter placed transversely, to take in a larger view of his food; cats, again, have theirs likewise oval, but the longest diameter placed perpendicularly; they can either exclude a bright light altogether, or admit only as much as is necessary. The pupil of different animals varies in wideness, according as the internal organs of vision are more or less acute. Thus cats and owls, who seek their prey in the night, or in dark places, (and consequently must have their eyes so formed as that a few rays of light may make a lively impression on the retina,) have their pupils in the day-time contracted into a very narrow space, as a great number of rays would oppress their nice organs; while in the night, or where the light is faint, they open the pupil, and very fully admit the rays.

In the same way, when the retina is inflamed, a great number of rays of light would occasion a painful sensation; therefore the pupil is contracted: on the contrary, in dying people, or in a beginning amaurosis, it is generally dilated, as the eyes on such occasions are very difficultly affected, and as it were insensible.

The posterior part of the choroid coat, which is called *tapetum*, is of different colours in different creatures. For oxen, feeding mostly on grass, have this membrane of a green colour, that it may reflect upon the retina all the rays of light which come from objects of that colour, while other rays are absorbed: thus the animal sees its food better than it does other objects. Cats and owls have their tapetum of a whitish colour; and for the same reasons have the pupil very dilatable, and their organs of vision acute. And we shall find, that all animals see more or less distinctly in the dark, according as their tapetum approaches nearer to a white or black colour. Thus dogs, who have it of a greyish colour, distinguish objects better in the night than man, whose tapetum is dark brown, and who sees worst in the dark of any creature. The difference then of the colour of the tapetum, as indeed the fabric of any other part in different creatures, always depends on some particular advantage accruing to the animal in its peculiar manner of life from this singularity.

The brain is proportionally much smaller in all quadrupeds than the human; but, as in man, it is divided into cerebrum and cerebellum, and these two parts bear nearly the same proportion to one another as in us. There was no occasion for so great a quantity of brain in those animals as in man: since in them all its energy is employed in their progression, while man has a great waste of spirits in the exercise of his reason and intellectual faculties. And, besides this, a great bulky brain would be inconvenient to these creatures, inasmuch as it would add considerably to the weight of the head; which, having the advantage of a long lever to act with, would require a much greater force to support it than it now does; for the heads of the greatest part of quadrupeds are not near so heavy as they would at first sight seem to be, from the sinus frontales being produced a great way upwards to enlarge the organs of smelling. The pits in the anterior part of their skulls are much more conspicuous than in the human cranium; which may be occasioned by the depending posture of these creatures heads while they gather their food; the brain at this time gravitating much on the bones while they are as yet soft, will gradually make impressions upon them at these places where it rises into eminences. This is prevented in man mostly by his erect posture. The second process of the *dura mater*, or *tentorium cerebelli superexpansum*, is considerably thicker and stronger in most quadrupeds than in man; especially in such of them as are very swift of foot, as hares and rabbits, and that most when they are old. This membrane is generally ossified, or we find the place of it supplied by a bone, that it may the more effectually keep off the superincumbent vein from the cerebellum in their rapid motions, which otherwise would be of bad consequence.

The olfactory nerves are very large, and justly deserve the name of *processus mamillares*. They are hollow, and consist of a medullary and cineritious substance, and at first sight appear to be the anterior ventricles of the brain produced; but in man they are small, and without any discernible cavity. The reason of this is sufficiently evident, if we consider how this animal's head is situated; for the lymph continually gravitating upon the inferior part of the ventricles, may thus elongate and produce them; but from this very inferior part the olfactory nerves rise, and are sent immediately through the os ethmoides into the nose. Hence the ancients, thinking they were continued hollow into the nose, believed they were the emunctories of the brain. In the brain of sheep, which, by its firm texture, is the best subject of any for searching into the structure of this part, we evidently see, that the name of the *sigmoid cavity* was very properly applied by the ancients

to the lateral ventricles of the brain; which are really of a greater extent than they are ordinarily painted by the anatomists, reaching farther backwards, and forwards again under the substance of the brain. The cortical and medullary parts, as well as the corpus callosum, are similar to those parts in man.

The *nates* and *testes* deserve this name much better here than in the human body, with respect to each other. They are larger in the quadruped; and hence we perceive that there is no great reason for ascribing the different operations to any particular size or shape of these parts. They are here also of different colours: the nates being of the colour of the cortical, and the testes of the medullary, substance of the brain; whereas in man they are both of one colour. The reason of these differences, and others of the like nature, we shall not pretend to determine; for we have hitherto such an imperfect knowledge of the brain itself, that we are entirely ignorant of the various uses of its different parts. We may in general conclude, that the varying in one animal from what it is in another, is fitted to the creature's particular way of living.

The *rete mirabile Galeni*, situated on each side of the *fella turcica*, about which there has been so much dispute, is very remarkable in most quadrupeds. This plexus of vessels is nothing else than a continuation of the internal carotid arteries, which, entering the skull, divide into a vast number of minute branches running along the side of the *fella turcica*, and, uniting afterwards, are spent on the brain in the common way. Galen seems with justice to suppose, that this plexus of vessels serves for checking the impetuosity of the blood destined for the brain. The structure of the brain differing but very little in all quadrupeds, it will be needless to examine it in any other.

ANATOMY of a COW.

The next species of quadrupeds we propose to consider, is the ruminant kind, of which we have an example in the cow; and accordingly shall take the fœtus of the animal *in utero*, that we may first remark some things that are peculiar to it in that state, and afterwards proceed to examine its viscera as a ruminant animal.

The form of a cow's *uterus* differs from the human, in having two large cornua. This is common to it with other brutes; for a bitch has two long *cornua uteri*. But these again differ (as being multiparous and uniparous) in this, that in the bitch's cornua the fœtuses are contained; whereas here there is only part of the secundines, being mostly the allantois with the included liquor. The muscular fibres of the uterus are more easily discovered; its internal surface has a great number of spongy, oblong, protuberant, glandular bodies, fixed to it. These are composed of vessels of the uterus terminating here. In an impregnated uterus, we can easily press out of them a chylous mucilaginous liquor; they are composed of a great many processes or digituli, and deep caverns, answering to as many caverns and processes of the placenta. Their resemblance has occasioned the name of *papilla* to be given them; and hence it was that Hippocrates was induced to believe that the fœtus sucked *in utero*. The papillæ are found in all the different stages of life, in the various stages of pregnancy, and likewise in the unimpregnated state. It is not easy to determine whether the uterus grows thicker or thinner in the time of gestation. The membranes, it is plain, (by the stretching of the parts,) must be made thinner; but then it is as evident, that the vessels are at that time enlarged, upon which principally the thickness of any part depends; so there seems to be as much gained the one way as is lost the other.

The *os uteri* is entirely shut up by a glutinous mucilaginous substance, that is common to the females of all creatures when with young; by this the external air is excluded, which would soon make the liquors corrupt; it also prevents the inflammation of the membranes and the hazard of abortion. By this means also the lips of the womb are kept from growing together, which they would otherwise

otherwise certainly do at this time. There are mucous glands placed here to fecern this gluten, which on the breaking of the membranes with the contained waters make a sapo that lubricates and washes the parts, and makes them easily yield. The first of the proper involucri of the fœtus is the chorion.

The *chorion* is a strong firm membrane, on whose external surface are dispersed a great many red fleshy bodies of the same number, size, and structure, with the papillæ, with which they are mutually indented. They have been called *cotyledones*, from *κοτυλη*, "cavity." This is greatly disputed by some authors as a name very improper; but we think without reason, since the surface that is connected to the papillæ is concave, though when separated it appears rather convex. To shun all dispute, they may be called properly enough *placentulæ*, since they serve the same use as the placenta in women. The separation of these from the papillæ without any laceration, and our not being able to inject coloured liquors from the vessels of the glands of the uterus into the placentulæ, seem to prove beyond a reply, that there can be here no anastomoses between the vessels: on their coats run a great number of vessels that are sent to the several placentulæ, on the external side next to the uterus; whereas in creatures that have but one placenta, as in the human subject, cats, dogs, &c. the adhesion is somewhat firmer. The placenta are likewise joined to the papillæ in the cornua uteri.

The *allantois* is a fine transparent membrane contiguous to the former. It is not a general involucrium of the fœtus in the mother, for it covers only a small part of the amnios. It is mostly lodged in the cornua uteri. In mares, bitches, and cats, it furrounds the amnios, being every where interposed between it and the chorion. In sheep and goats it is the same as in the cow; and in swine and rabbits it covers still less of the amnios. This sac is probably formed by the dilatation of the urachus, which is connected at its other end to the fundus of the bladder, through which it receives its contents; and a great quantity of urine is commonly found in it. The membrane is doubled at the extremity of the canal, to hinder the return of the urine back into the bladder. Its vessels are so excessively fine and few, that we cannot force an injected liquor farther than the beginning of this coat. This membrane is so far analogous to the cuticula, as not to be liable to corruption, or easily irritated by acrid liquors.

The third proper integument of the fœtus is the *amnios*. It is thinner and firmer than the chorion; it has numerous ramifications of the umbilical vessels spread upon it, the lateral branches of which separate a liquor into its cavity. This is the proper liquor of the amnios; which at first is in a small quantity, afterwards increases for some months, then again decreases; and, in a cow near her time, the quantity of this liquor is not above a pound. This membrane does not enter the cornua uteri in this creature, being confined to the body of the uterus; whereas the *allantois* occupies chiefly its cornua. There are two *venæ umbilicales*, and but one in the human subject; because the extreme branches coming from the several placentulæ could not unite so soon as they would have done had they come all from one cake as in the human. There is a small round fleshy body that swims in the urine of cows, mares, &c. which is the *hippomane* of the ancients. Several idle opinions have been entertained as to its use; but that seems to be still unknown, or how it is generated or nourished, for it has no connection with the fœtus or placenta.

The umbilical vein joins the *vena portarum* in the *capsula Glissoniana*, without sending off any branches as it does in the human subject. This vein soon after birth turns to a ligament; yet there are some instances where it has remained pervious for several years after birth, and occasioned an hæmorrhage. We may next observe the duct called *canalis venosus*, going straight from the capsula Glissoniana to the *vena cava*; this turns also afterwards to a ligament. The umbilical arteries rise at acute angles

from the internal iliacs, whatever some may say to the contrary; these also become impervious.

The pulmonary artery coming from the right ventricle of the heart divides into two: the largest, called *canalis arteriosus*, opens into the descending aorta; the other divides into two, to serve the lungs on each side. The *foramen ovale* is placed in the partition between the right and left auricles. At the edge of the hole is fixed a membrane, which when much stretched will cover it all over; but more easily yields to a force that acts from the right auricle to the left, than from the left to the right. After what has been said, we may easily understand how the circulation is performed in a fœtus. The blood, being brought from the placenta of the mother, is thrown into the capsula Glissoniana, where it is intimately blended with the blood in the *vena portarum*: then part of this blood goes directly into the *vena cava* by the *ductus venosus*; the rest passes through the liver. First, then, the whole is sent from the *vena cava* into the right auricle, from whence part of it is sent by the *foramen ovale* into the left auricle; the rest passes into the right ventricle, then into the pulmonary artery; then the greatest share it receives is sent immediately into the descending aorta by the *canalis arteriosus*, and the remainder circulates through the lungs, and is sent back by the pulmonary veins into the left auricle; which, with the blood brought there by the *foramen ovale*, is sent into the left ventricle, from whence it is driven by the aorta through the body. The great design of this mechanism is, that the whole mass of blood might not pass through the collapsed lungs of the fœtus; but that part of it might pass through the *foramen ovale* and *canalis arteriosus*, without circulating at all through the lungs.

This was the opinion that universally prevailed till the end of the last century, when it was violently opposed by Mr. Mery, who is very singular in several of his opinions. He will not allow that the *foramen ovale* transmits blood from the right to the left auricle, but on the contrary from the left to the right; and that for no other reason, but because he observed the pulmonary artery in a fœtus larger than the aorta. Mr. Winslow endeavours to reconcile these two opinions, by saying the blood may pass either way, and that it is here as it were blended. His reason is, that, on putting the heart in water, the *foramen ovale* transmits it any way. Mr. Rohault, professor of anatomy at Turin, and formerly one of Mery's scholars, strongly defends his master, and criticises Mr. Winslow. What he principally builds on, is the appearance this *foramen* has in some dried preparations; but this Mr. Winslow will not allow as proof. After all, the common opinion seems the most rational.

We now come to consider the cow as a ruminant animal. There are no *dentes incisores* in the upper jaw; but the gums are somewhat hard, and the tongue rough. This roughness is occasioned by long sharp-pointed papillæ with which the whole substance of it is covered. These papillæ are turned towards the throat; so that by their means the food, having once got into the mouth, is not easily pulled back. The animals therefore supply the defect of teeth by wrapping their tongue round a tuft of grass; and so, pressing it against the upper jaw, keep it stretched, and cut it with the teeth of the under jaw; then, without chewing, throw it down into the *œsophagus*, which in these creatures consists of a double row of spiral fibres decussating one another. All animals which ruminate must have more stomachs than one; some have two, some three; our present subject has no less than four. The food is carried directly down into the first, which lies upon the left side, and is the largest of all; it is called *γαστήρ*, *ventriculus*, and *χοιλία*, by way of eminence. It is what is called by the general name of *paunch* by the vulgar. There are no rugæ upon its internal surface; but instead of these there are a vast number of small blunt-pointed processes, by which the whole has a general roughness, and the surface is extended

to several times the size of the paunch itself. The food, by the force of its muscular coat, and the liquors poured in here, is sufficiently macerated; after which it is forced up hence by the œsophagus into the mouth, and there it is made very small by mastication; this is what is properly called *chewing the cud*, or *rumination*; for which purpose the *dentes molares* are exceedingly well fitted: for, instead of being covered with a thin crust, the enamel on them consists of perpendicular plates, between which the bone is bare, and constantly wearing faster than the enamel, so that the tooth remains good to extreme old age; and by means of these teeth the rumination is carried on for a long time without any danger of spoiling them. After rumination, the food is sent down by the gullet into the second stomach; for the œsophagus opens indifferently into both. It ends exactly where the two stomachs meet; and there is a smooth gutter with rising edges which leads into the second stomach, from thence to the third, and also to the fourth; however, the cow has a power to direct it into which it will. Some tell us, that the drink goes to the second; but that might be easily determined by making them drink before slaughter. The second stomach, which is the anterior and smaller, is called *κεντροφαλός*, *reticulum*, *honey-comb*, the *bonnet*, or *king's-hood*. It consists of a great number of cells on its internal surface, of a regular pentagonal figure, like to a honey-comb. Here the food is farther macerated; from which it is protruded into the third, called *εξυγός*, or *omasum*, *vulgo* the *manyplies*, because the internal surface rises up into a great many plicæ or folds, and *stratum super stratum*, according to the length of this stomach. There are numberless glandular grains like millet-seeds dispersed on its plicæ, from which some authors call the stomach the *millet*. From this it passes into the fourth, whose names are *νυστρον*, *abomasum*, *caille*, or the *red*, which is the name it commonly has because of its colour. This much resembles the human stomach, or that of a dog; only the inner folds or plicæ are longer and looser; and it may also be observed, that in all animals there is only one digestive stomach, and that has the same coagulating power in the fœtus as the fourth stomach in this animal; whence this might not improperly be called the only true stomach. *Caille* signifies *curdled*; and hence the French have given that as a name to this fourth stomach, because any milk that is taken down by young calves is there curdled. It is this fourth stomach, with the milk curdled in it, that is commonly taken for making runnet; but, after the bile and pancreatic juice enter, this coagulation is not to be found, which shews the use of these liquors. There are other creatures which use the same food, that have not such a mechanism in their digestive organs. Horses, asses, &c. have but one stomach, where grass is macerated, and a liquor for their nourishment extracted, and the remainder sent out by the anus very little altered. From this different structure of the stomach in these creatures, a ruminant animal will be served with one-third less food than another of equal bulk: graziers are sufficiently acquainted with this. The reason is, that ruminating animals have many and strong digestive organs; all their food is fully prepared, and almost wholly converted into chyle: but a horse's stomach is not fitted for this; so that he requires a much greater quantity of food to extract the same nourishment.

The *duodenum* is formed here much the same way as in a dog, and the general intention kept in view with regard to the mixture of the bile and pancreatic lymph. The great guts here hardly deserve that name, their diameter differing very little from that of the small ones; but, to compensate this, they are much longer proportionally than a dog's, being convoluted as the small guts are. The cæcum is very large and long. The digestion of the cow, as well as some other animals, is accompanied with a peculiar kind of action called *rumination*; the intention of which seems to be, that the food may be sufficiently comminuted, and thus more fully acted upon by the stomach: for it is not observed that a calf ruminates as long as it is

fed only upon milk, though the action takes place as soon as it begins to eat solid food; but it is to be observed, that, as long as a calf feeds only upon milk, the food descends immediately into the fourth stomach (which, as has been already mentioned, seems only capable of performing the operation of digestion), without stopping in any of the first three. The rumination does not take place till after the animal has eaten a considerable quantity; after which she lies down, if she can do it conveniently, and begins to chew; though the operation will take place in a standing posture, if she cannot lie down. In this action a ball is observed to rise from the stomach with great velocity, almost as if shot from a musket. This ball the animal chews very accurately, and then swallows it again, and so on alternately, till all the food she has first eaten has undergone this operation. This is easily explained from the structure of the œsophagus, which has one set of fibres calculated for bringing up the grass, and another for taking it down again. By means of rumination, the cow extracts a much larger proportion of nourishment from her food than those animals which do not ruminate; and hence she is contented with much worse fare, and smaller quantities of it, than a horse; hence also the dung of cows, being much more exhausted of its fine parts than horse-dung, proves much inferior to it as a manure.

The *spleen* differs not much either in figure or situation from that of a dog's: but it is a little more firmly fixed to the diaphragm, there not being here so much danger of this viscous being hurt in the flexions of the spine. The *liver* is not split into so many lobes in this creature as either in a man or dog; which depends on the small motion this creature enjoys in its spine, which made such a division needless. Their *vesica urinaria* is of a pyramidal shape. It is very large, and more membranaceous; for, the urine of these creatures not being so acrid as that of carnivorous animals, there was no such occasion for expelling it so soon.

The male is provided with a loose pendulous *scrotum*, and consequently with *vesiculæ seminales*. The female organs differ from those of a bitch mostly as to the form of the cornua uteri, which are here contorted in form of a snail. In this, and in all uniparous animals, they contain only part of the secundines; but in bitches, and other multiparous animals, they run straight up in the abdomen, and contain the fœtus themselves.

The situation of the *heart* is much the same with that of a dog, only its point is rather sharper: in us, the heart beating continually against the ribs, and both ventricles going equally far down to the constitution of the apex, it is very obtuse; but here the apex is made up only of the left ventricle, so is more acute. The *aorta* in the cow is justly divided into *ascending* and *descending*, though this division is ill-founded either in a dog or man; and it has certainly been from this subject that the older anatomists took their descriptions when they made this division; for here the aorta divides into two, the ascending and descending.

ANATOMY of FOWLS.

Fowls have a particular covering of feathers different from all other creatures, but exactly well suited to their manner of life; for it not only protects them from the injuries of the weather, but serves them in their progression through that thin aerial element in which they are for the most part employed; and, as some fowls live much in the water, their feathers being continually besmeared with an oily liquor keeps the water from soaking into their skins, and prevents the bad effects which it would infallibly otherwise produce. Fowls have the strongest muscles of their whole body inserted into their wings; whence we may observe, that it is altogether impossible for man to buoy himself up into the air like birds, even though he had proper machines in place of wings, unless he were likewise provided with muscles strong enough for moving them, which he has not. In the next place, their wings are not placed in the middle of their bodies, but a good deal further for-

wards; whence it would at first view appear, that their heads would be erect, and their posterior parts most depending when raised in the air: but by stretching out their heads, which act upon the lever of a long neck, they alter their centre of gravity considerably; and also by filling the sacs or bladders in the inside of their abdomen with air, and expanding their tail, they come to make the posterior part of their bodies considerably higher; and thus they fly with their bodies nearly in an horizontal situation. Hence we find, that if their necks are kept from being stretched out, or their tails cut away, they become incapable of flying any considerable distance. The largeness of the wings in different fowls varies according to the occasions of the creature. Thus birds of prey, who must fly a considerable way to provide their food, have large strong wings; whereas domestic birds, who find their nourishment almost every where, have very short and but small wings.

Carnivorous animals are provided with strong crooked claws for catching their prey: water-fowls use them for swimming; and, principally for this purpose, have a strong firm membrane interposed between the toes. There is a beautiful mechanism to be observed in the toes of fowls, which is of considerable use to them. For their toes are naturally drawn together, or bent, when the foot is bent: this is owing to the shortness of the tendons that pass over them, which is analogous to our heel: and that the toes are set in the circumference of a circle, as our fingers are: hence, when the foot is bent, the tendons must consequently be much stretched; and, since they are inserted into the toes, must of necessity bend them when the foot is bent; and, when the foot is extended, the flexors of the toes are again relaxed, and the toes therefore expanded. This is also of great use to different kinds of fowls; thus the hawk, descending with his legs and feet extended, spreads his talons over his prey; and, the weight of his body bending his feet, the toes are contracted, and the prey is seized by the talons. This is also of great use to water-fowls; for, had there been no such contrivance as this, they must have lost as much way when they pulled their legs in as they had gained by the former stroke; but, as the parts are now framed, whenever the creature draws in its foot, the toes are at the same time bent and contracted into less space, so that the resistance made against the water is not near so great as before; on the contrary, when they stretch their foot, their toes are extended, the membrane between them expanded, and consequently a greater resistance made to the water. Again, such fowls as live mostly in the air, or have occasion to sustain themselves on branches of trees in windy weather, and even in the night-time when asleep, while all their muscles are supposed to be in a state of relaxation; such have no more to do but lean down the weight of their bodies, and their toes continue bent without any muscles being in action; and whenever they would disentangle themselves, they raise up their bodies, by which their foot, and consequently their toes, are extended.

The rostrum, bill, or beak, of fowls, is composed of two mandibulae, and, as in quadrupeds, the upper one has no motion, but what it possesses in common with the head. But parrots are an exception to this rule; for they can move the upper mandible at pleasure: this is exceedingly convenient, as it enables them to lay hold of whatever comes in their way. Carnivorous fowls have their beaks long, sharp, and crooked; domestic fowls, such as the hen kind, &c. have strong short beaks, commodiously fitted to dig up and break their food; the water-fowls, again, have long, or very broad scoop-like beaks, which is most convenient for them. The sternum of fowls is much larger proportionally than the human, and has a ridge rising in its middle for the more commodious origin of the muscles that move the wings. It is also less moveable than ours; for, had it been very moveable, a great deal of the force employed for moving the wings would at every contraction of the muscles have been lost, or else some other muscles must have come in play to keep the sternum firm; but

this additional weight would have been inconvenient for their progression.

ANATOMY of a COCK.

Though this kind of birds lives upon food somewhat similar to that of man, yet, as they have no teeth to separate or break down this food, we should expect to find something to compensate the want of teeth, something remarkable in the organs of digestion: we shall therefore begin with these parts. The *oesophagus* of the cock runs down its neck, somewhat inclined to the right side; and terminates in a large membranous sac, which is the *ingluvies* or crop, where the food is macerated and dissolved by a liquor separated by the glands, which are easily observed every where on the internal surface of this bag. The effect of this maceration may be very well observed in pigeons, who are sometimes in danger of being suffocated by the pease, &c. they feed upon, swelling to such an immense bulk in their *ingluvies*, that they can neither get upwards nor downwards. If it be a favourite fowl, it might be preserved by opening the sac, taking out the pease, and sewing up the wound. The food, getting out of this sac, goes down by the remaining part of the *oesophagus* into the *ventriculus succenturiatus*, or *infundibulum Peyerii*, which seems to be a continuation of the gullet: it has several glands, for separating a liquor to dilute the food still more before it comes into the true stomach or gizzard, *ventriculus callosus*. The gizzard consists of two very strong muscles, covered externally with a tendinous aponeurosis, and lined on the inside by a very thick firm membrane, which we evidently discover to be a production of the cuticula. This might have been proved in some measure *à priori*, from observing, that this membrane, which in chicks is only a thin slight pellicle, by degrees turns thicker and stronger the more attrition it suffers: but there is no other animal substance, so far as we know, which grows more hard and thick by being subjected to attrition, except the cuticula. Hence may be drawn some kind of proof of what has been affirmed concerning the tunica villosa of the stomach and intestines in the human body, viz. that it was in part a continuation of the epidermis; nay, all the hollow parts of the body, even arteries, veins, &c. seem to be lined with a production of this membrane, or one analogous to it. The use of the internal coat of the stomach of fowls, is to defend the more tender parts of that viscus from the hard grains and little stones these creatures swallow. The use of the gizzard is to compensate for the want of teeth; and it is well fitted for this purpose from the great strength it possesses.

The digestion of these animals is performed merely by attrition, as is evinced by many experiments; and it is further assisted by the hard bodies they swallow. We see them daily take down considerable numbers of the most solid little rugged flints they find; and these can serve for no other purpose than to help the trituration of their aliments. After these pebbles, by becoming smooth, are unfit for this office, they are thrown up by the mouth. Hence fowls that are long confined, though ever so well fed, turn lean for want of these stones to help their digestion. But this was put beyond all dispute by Mr. Tauvry, who gave a piece of metal to an ostrich, convex on one side, and concave on the other, but carved on both; and, opening the creature's body some time after, it was found, that the carving on the convex side was all obliterated, while the engraved character remained the same as before, on the concave side, which was not subjected to the stomach's pressure: this circumstance could not have happened had digestion been performed by a menstruum, or any other way whatsoever; but may be easily solved by allowing a simple mechanical pressure to take place. We are, however, by no means to conclude from this, as some have too rashly done, that in the human body digestion is performed by simple attrition; otherwise we may, with equal strength of reason, by as good arguments drawn from what is observed in fishes, prove that the aliments are dissolved

solved in our stomachs by the action of a menstruum. But this method of reasoning is very faulty; nor can it ever bring us to the true solution of any philosophical or medical problem. It is very plain, since the structure of the parts of the human stomach are so very different from that of this creature, that it is foolish and unreasonable to imagine both of them capable of producing the same effects. At each end of the stomach, there are as it were two particular faces of a different texture from the rest of the stomach, not consisting of strong muscular fibres; they seem to be receptacles for the stones, (especially at the end which is farthest from the orifice,) while the digested aliment is protruded into the intestines.

The *duodenum* begins near the same place at which the *œsophagus* enters; yet notwithstanding the vicinity of these two tubes, the aliments are in no danger of getting out before they are perfectly digested, by reason of a protuberance, or *septum medium*, between the orifices; and in those creatures who have such a strong muscular stomach, it is a matter of great indifference whether the entry of the *œsophagus* or *pylorus* be highest, provided that the entry from the *œsophagus* does not allow the food to regurgitate, since the force of the stomach can easily protrude it towards the *duodenum*. This gut is mostly in the right side, and hangs pendulous in their abdomen, having its two extremities fixed to the liver. The *ductus choledochus* enters near its termination, where it mounts up again to be fixed to the liver; and left, by the contraction of the intestines, the bile should pass over without being intimately blended with the chyle, that duct enters downwards, contrary to the course of the food, and contrary to what is observed in any of the animals we have yet mentioned. But still the general intention is kept in view, in allowing these juices the fairest chance of being intimately blended with the food.

The *small guts* are proportionally longer than those of carnivorous birds, for the general cause already assigned. At the end of the ilium they have two large *intestina caca*, one on each side, four or five inches long, coming off from the side of the rectum, and ascending; and we find them containing part of the food: these serve as reservoirs to the fæces; which, after some remora, there regurgitate into what soon becomes the rectum; which, together with the excretories of urine and organs of generation, empties itself into the common cloaca. The small intestines are connected by a long loose mesentery, which has little or no fat accompanying the blood-vessels, there being no hazard of the blood's being stopped. The *pancreas* in the cock lies between the two folds of the *duodenum*, and sends two or three ducts into this gut near the biliary duct. Their *spleen* is of a round globular figure, situated between the liver and stomach; and between these and the backbone it enjoys the same properties as in other animals, viz. large blood-vessels, &c. All its blood is sent into the *vena portarum*, and has a perpetual confluxation. It has no excretory, as far as we know. Their *liver* is divided into two equal lobes by a pellucid membrane, running according to the length of their body. The shape of their *gall-bladder* is not much different from that of quadrupeds; but it is thought to be longer in proportion to the size of the animal, and is farther removed from the liver. The principal difference to be remarked in the *heart*, is the want of the *valvule tricuspidæ*, and their place being supplied by one fleshy flap. The *lungs* are not loose within the cavity of the thorax, but fixed to the bone all the way; neither are they divided into lobes, as in those animals that have a large motion in their spine. They are two red spongy bodies, covered with a membrane that is pervious, and which communicates with the large vesicles or air bags that are dispersed over their whole abdomen; which vesicles serve two very considerable uses. The one is to render their bodies specifically light, when they have a mind to ascend and buoy themselves up when flying, by distending their lungs with air, and also straiten their *trachea arteria*, and so retain the air. Secondly, they supply the

place of a muscular *diaphragm* and strong abdominal muscles; producing the same effects on the several contained viscera as the muscles would have done, without the inconvenience of their additional weight; and conducting as much to the exclusion of the egg and fæces.

When we examine the upper end of the *trachea*, we observe a *rima glottidis* with muscular sides, which may act in preventing the food or drink from passing into the lungs; for there is no *epiglottis*, as in man and quadrupeds. The *trachea arteria*, near where it divides, is very much contracted; and their voice is principally owing to this contraction. If you listen attentively to a cock crowing, you will be sensible that the noise does not proceed from the throat, but deeper; nay, this very pipe, when taken out of the body, and cut off a little after its division, and blown into, will make a squeaking noise, something like the voice of these creatures. On each side, a little higher than this contraction, there is a muscle arising from their sternum, which dilates the *trachea*. The cartilages, of which the pipe is composed in this animal, go quite round it; whereas in men and quadrupeds they are discontinued for about one-fourth on the back-part, and the intermediate space is filled up by a membrane. In place of a muscular *diaphragm*, this creature has nothing but a thin membrane connected to the pericardium, which separates the thorax and abdomen. But besides this, the whole abdomen and thorax are divided by a longitudinal membrane or *mediastinum* connected to the lungs, pericardium, liver, stomach, and to the fat lying over the stomach and guts, which is analogous to an *omentum*, and supplies its place.

The *lymphatic system* in birds consists, as in man, of lacteal and lymphatic vessels, with the thoracic duct. The lacteals indeed, in the strictest sense, are the lymphatics of the intestines; and, like the other lymphatics, carry only a transparent lymph; and, instead of one thoracic duct, there are two, which go to the jugular veins. In these circumstances, it would seem that birds differ from the human subject, so far at least as we may judge from the dissection of a *goose*, the common subject of this inquiry, and from which the following description is taken. The lacteals run from the intestines upon the mesenteric vessels: those of the *duodenum* pass by the side of the pancreas; afterwards they get up the *cæliac artery*, of which the superior mesenteric is a branch. Here they are joined by the lymphatics of the liver, and then they form a plexus which furrounds the *cæliac artery*. Here also they receive a lymphatic from the gizzard, and soon after another from the lower part of the *œsophagus*. At the root of the *cæliac artery* they are joined by the lymphatics from the *glandulæ renales*, and near the same part by the lacteals from the other small intestines, which vessels accompany the lower mesenteric artery; but, before they join those from the *duodenum*, they receive from the rectum a lymphatic, which runs from the blood-vessels of that gut. Into this lymphatic some small vessels from the kidneys seem to enter at the root of the *cæliac artery*. The lymphatics of the lower extremities probably join those from the intestines. At the root of the *cæliac artery* and contiguous part of the *aorta*, a net-work is formed by the vessels above described. From this net-work arise two thoracic ducts, of which one lies on each side of the spine, and runs obliquely over the lungs to the jugular vein, into the inside of which it terminates, nearly opposite to the angle formed by the jugular and subclavian vein. The thoracic duct of the left side is joined by a large lymphatic, which runs upon the *œsophagus*. The thoracic ducts are joined by the lymphatics of the neck, and probably by those of the wings, where they open into the jugular veins. The lymphatics of the neck generally consist of two large branches on each side of the neck, accompanying the blood-vessels; and these two branches join near the lower part of the neck, and form a trunk which runs close to the jugular vein, and opens into a lymphatic gland; from the opposite side of this gland a lymphatic comes out, which ends in the jugular vein. On the left side, the

whole of this lymphatic joins the thoracic duct of the same side: but, on the right side, part of it goes into the inside of the jugular vein a little above the angle; whilst another joins the thoracic duct, and with that duct forms a common trunk, which opens into the inside of the jugular vein, a little below the angle which that vein makes with the subclavian. This system in birds differs most from that of quadrupeds, in the chyle being transparent and colourless, and in there being no visible lymphatic glands, neither in the course of the lacteals, nor in that of the lymphatics of the abdomen, nor near the thoracic ducts.

The *kidneys* lie in the hollow excavated in the side of the back-bone, from which there is sent out a bluish-coloured canal running along by the side of the *vas deferens*, and terminating directly into the common cloaca. This is the *ureter*, which opens by a peculiar aperture of its own, and not at the penis. Fowls having no *vesica urinaria*, some authors thought that they never passed any urine, but that it went to the nourishment of the feathers: but this is false; for that whitish substance covering their greenish faeces, and which turns afterwards chalky, is their urine.

The *testicles* are situated one on each side of the back-bone; and are proportionally very large in proportion to the creature's bulk. From these run out the *vasa feminifera*; at first straight, but, after they recede farther from the body of the testicle, they acquire an undulated or convoluted form, as the epididymis in man. These convolutions partly supply the want of *vesiculæ seminales*: they terminate in the penis, of which the cock has two, one on each side of the common cloaca, pointing directly outwards. They open at a distance from each other, and are very small and short; whence they have escaped the notice of anatomists, who have often denied their existence. In birds there is no prostate gland. This is what is chiefly remarkable in the organs of that male.

The *racemus vitellorum*, being analogous to the ovaria in the human subject, are attached by a proper membrane to the back-bone. This is very fine and thin, and continued down to the uterus. Its orifice is averse with respect to the ovaria; yet notwithstanding, by the force of the *orgasmus venereus*, it turns round and grasps the *vitellus*, which in its passage through this duct called the *infundibulum*, receives a thick gelatinous liquor secreted by certain glands. This, with what it receives in the uterus, composes the white of the egg. By this tube then it is carried into the uterus. The shell is lined with a membrane: and in the large end there is a bag full of air, from which there is no outlet.

The *uterus* is a large bag, placed at the end of the *infundibulum*, full of wrinkles on its inside; here the egg is completed, receiving its last involucre, and is at last pushed out at an opening on the side of the common cloaca. From the testes in the male being so very large in proportion to the body of the animal, there must necessarily be a great quantity of semen secreted; hence the cock is salacious, and becomes capable of impregnating many females. The want of the *vesiculæ seminales* is in some measure supplied by the convolutions of the *vasa deferentia*, and by the small distance between the fecerding and excretory organs. The two *penees* contribute also very much to their short coition; at which time the opening of the uterus into the cloaca is very much dilated, that the effect of the semen on the vitelli may be greater. A hen will of herself indeed lay eggs; but these are not impregnated, and yet they appear entirely complete.

We come now to consider the nutrition of the foetuses of oviparous animals, and shall give a short history of an egg, and of the changes brought on by incubation. The shell of an egg becomes more brittle by being exposed to a dry heat. It is lined every where with a very thin, but somewhat tough, membrane; which, dividing at or very near to the obtuse end of the egg, forms a small bag, where air only is contained. In a new-laid egg, this folliculus appears very little, but becomes larger when the egg is kept.

The albumen, or white of an egg, is contained in concentric membranes, but is not all of the same consistence; for the exterior part of it is thin, and diffuses itself almost like water when the membranes are broken; whereas its anterior part is more viscous. The white of an egg can make its way through the shell, as appears from its wasting by keeping, especially if exposed to gentle heat.

The globular vitellus, or yolk, would seem to be no other than a liquor inclosed in a membrane; because, whenever the membrane is broke, it runs all out; and is specifically heavier than the white. The chalazæ are two white spongy bodies, rising very small from the opposite sides of the membrane of the yolk, but gradually become larger as they are stretched out from it in an oblique direction with regard to the two ends of the egg. If we compare the chalazæ to the extremities of an axis passing through the spherical vitellus, this sphere will be composed of two unequal portions, its axis not passing through its centre; consequently, since it is heavier than the white, its smaller portion must always be uppermost in all positions of the egg.

The yellowish-white round spot, called *cicatricula*, is placed in the middle of the smaller portion of the yolk; and therefore always appears on the superior part of the vitellus. The *cicatricula* seems to be composed of several circles of different colours; and, in a fecundated egg, contains the embryo or chick. Eggs, whose obtuse ends are all rubbed over with linseed-oil, or such other substances as block up small pores, are as fit for bringing forth chickens, when incubated by a hen, as other eggs are. After incubation, the *folliculus aris* is gradually extended; till, near the time of the exclusion of the chick, it occupies more than a third of the cavity of the shell. The extended folliculus does not collapse, upon being exposed to the pressure of the atmosphere, after incubated eggs are opened. By incubation the albumen becomes thinner and more turbid, especially on its upper part near the air-bag, where it is also first consumed: and it is afterwards diminished towards the sharp end of the egg, till at last nothing of it is left except a white cretaceous substance at the lower part of the shell.

As the part of the white nearest to the *cicatricula* is wasted, its membrane and the *cicatricula* still approach nearer, till they become contiguous. This membrane of the albumen is what is commonly called the *chorion*. Some time before the albumen is quite consumed, what remains of it is placed at the lower part of the egg; and therefore the yolk is interposed between it and the membrane which immediately contains the foetus. The white of a fecundated egg is as sweet and free from corruption, during all the time of incubation, as it is in a new-laid egg. I tasted, smelled, and swallowed, says Dr. Monro, the whites of eggs during all the states of incubation, both when they were raw and boiled, and constantly found them sweet; and therefore cannot imagine how Bellini could affirm it to have a heavy abominably ungrateful taste, a stinking smell, and not only to occasion, when swallowed, a troublesome sensation in the stomach and guts, but to prove purgative. He must unluckily have examined none but subventaneous eggs: which is further confirmed by his description of the small particles in the colligated albumen, that reflect light so strongly as the eye cannot bear it. Very soon after incubation, the volume of the yolk appears increased; and, by its rising then nearer to the upper part of the egg, we may conclude that its specific weight decreases. The yolk becomes pale and more fluid for some time, especially on the side next to the chick, where its bulk also soonest increases; but afterwards the membranes of the yolk turn firmer and stronger, and the liquor in them is less in quantity, and becomes more viscous. As the chick increases, the yolk is depressed in the middle; and is soon brought into a form something like to a horse-shoe, in the middle of which the chick is lodged. The yolk remains fresh and uncorrupted all the time of incubation, and is always coagulable.

Not long before the exclusion of the chick, the whole yolk is taken into its abdomen. The whole albumen and vitellus are not consumed by the chick: for some part of the humours of the egg escapes through the shell, and is not supplied by any thing from without; as evidently appears by an egg's becoming so much specifically lighter as to swim in water after incubation, though it sunk in it when recent.

The chalazæ remain long without being considerably changed, unless that they are brought nearer to each other by the crescent form of the yolk; at last they degenerate into a dry chalky substance. The cicatricula very soon is enlarged by incubation; and, being buoyed up on the top of the yolk to the superior part of the egg, it is placed very near to the air-bag; and, when both increase, they become contiguous. The cicatricula is called *amnios*, when it becomes large, and contains the *colliquamentum* or liquor in which the chick is immersed. The quantity of the *colliquamentum* gradually increases till the fifteenth or sixteenth day of incubation; on the eighteenth, it is all consumed; and, in the three following days, scarcely any moisture can be observed on the internal surface of the *amnios*. The liquor of the *amnios* is more clear and transparent than the colligated white; its taste is more salt, and it has no observable smell. Its consistence is at first a little viscous, then it becomes more fluid, and afterwards turns a little ropy again. We can say nothing of the particular times when it does or does not coagulate by heat: for it is in so small quantity during the greater part of the time of incubation, that one can scarcely gather as much in a spoon as is fit to make any experiment with: and when all the egg is boiled hard, it adheres so closely to the white, that it is hardly possible to distinguish the one from the other. Malpighius, speaking of the egg between the fourteenth and nineteenth day, says, "That this thin diaphanous liquor of the *amnios* was sometimes forced, by boiling, into a white starchy substance;" which Dr. Monro's trials also confirmed.

The allantois and its contained urine are to be seen in an egg, as well as in the secundines of viviparous animals. Though the heart is among the first parts of the chick that can be distinguished, yet the umbilical vessels are seen much about the same time that the heart is observed. The umbilical vessels gradually disperse their branches upon the *amnios*, upon the vitellus, and upon the membranes of the albumen: the extremities of the much greater number, being immersed into the white, are extended proportionally as it is colligated. Near the end of incubation, the umbilical vessels begin to shrivel and decrease, till at the exclusion they are very small.

The embryo is seen in an egg at first in the form of a small worm: then its carina or spine, with the large prominences, that afterwards shew themselves to be the brain and eyes, appear; the other bowels seem hanging from the spine; the chasm of the mouth discovers itself; the extremities sprout out; the viscera are gradually covered with the integuments; and at last the beak, nails, and feathers, are seen; after which all the parts become stronger and firmer, the proportional bulk of the head decreasing. After all the parts of the chick are formed, it is always found lying on the side, with its neck greatly bent forward, the head being covered with the upper wing, and the beak placed between the thighs. When the shell is opened after the chick is large and strong, it may be seen to bounce and spurn, sometimes opening its mouth wide, especially if it is stirred or pricked. The mouth, œsophagus, and ingluvies, are always found moist; but never contain any quantity of liquor that can be collected or will run out in drops. The bulbous glandular part of the œsophagus immediately above the stomach, or what Peyer calls the *infundibulum*, and the stomach, are full of a liquor, in the youngest chick we can dissect, and continue full the whole time of incubation; neither *infundibulum* nor stomach having yet the tendinous firmness they have in adults; nor can we observe the dry pellicle which is so easily sepa-

rated from these parts in hens. This liquor of the stomach is at first thin and more watery; afterwards it becomes curdy; and at last resembles a greyish white mucus, unless that some part of it frequently is coloured yellow or green by a mixture of bile. It always coagulates, by boiling, into a firm yellowish white substance. A little time before the exclusion, the chick may frequently be heard making the same piping sound that hatched chickens make. In three eggs, which were opened in this state, the beak of the chick had perforated the membrane of the folliculus æris. The shell at the obtuse end of the egg frequently appears cracked some time before the exclusion of the chick. The chick is sometimes observed to perforate the shell with its beak; but in those Dr. Monro saw tumbling out of the shell, it was broke off irregularly, at the place where the membrane of the folliculus æris was joined to it. After the exclusion the yolk is gradually wasted, being conveyed into the small guts by a small duct, its membranes gradually contract themselves, and the duct becomes shorter. On the tenth day after exclusion, the vitellus was no larger than a small pin's head, and the duct was scarcely one-twentieth part of an inch long.

From this history of the egg, we shall endeavour to deduce the manner in which the colligated white is taken in by the chick. Authors generally seem to agree, that the oviparous foetus, while very young, receives its nourishment by the navel; but several of the best reputation have been of opinion, that afterwards it is conveyed by the month. Let us examine the arguments they have used in proof of this, and then subjoin some negative reasons which they have not noticed.

Bellini has described the cicatricula, or *sacculus amnii*, with the chalazæ first formed in the back of the hen; to which, according to him, the vitellus is afterwards joined, and the white is acquired as they pass down the oviduct. He says, the chalazæ are composed of numerous canals, which open into the *amnios*, and send out their roots into the cavity of the yolk, and into the white. It is easy to conceive what consequences may be drawn from this description, by those who assert the nourishment to be carried by the mouth, viz. That here are direct passages into the cavity where the chick is, which can take up the liquors no other way than by the mouth. We deny, however, that the *sacculus amnii* is formed before the vitellus; on the contrary, the vitellus is evidently to be seen before the cicatricula or chalazæ can be discerned. We also deny the chalazæ (if they are canals) to have the least communication with the *amnios*, at any time, or in any state of the egg, otherwise than as they are both adhering to the membrane of the vitellus; upon which, or within which, no particular fibres, no canals, are stretched to the cicatricula. Every one has it in his power to examine these facts. If then the facts are denied, the consequences cannot be admitted.

Since there are no canals passing through the yolk, that open into the *sacculus colliquamenti*, and the cicatricula comes to be placed on the upper part of the yolk, and contiguous to the air-bag, it is evident, that the *liquor amnii* must be furnished by the chick, which being covered with feathers, having no mammæ, bladder of urine, or large salivary glands, can only supply it by the branches of the umbilical vessels spread on the *amnios*. Harvey affirms, that a liquor is found in the mouth and ingluvies of the chick, which he concludes to be the *colliquamentum* or liquor amnii, from their resemblance; from the quantity of the contents of the stomach; from the chick's being seen to open its mouth; and from the necessity creatures are in of swallowing, or of forcing back by vomiting, whatever is introduced to the root of their tongue. As to the resemblance, we do not see how the comparison can be made, since the liquor in the mouth and crop is in such a small quantity. But, suppose that a sufficient quantity was collected, the two liquors agreeing in their several properties would not of itself be a sufficient proof of their being the same; and if, for argument's sake, the liquor in the crop

was granted to be in a very large quantity, and to agree in every property with that in the amnios, it would certainly appear in the same form for some time in the stomach; whereas it is always found very different there in the larger fœtus; and Harvey confesses as much in this place: therefore it may be concluded, that it does not go down into the stomach. If ever any thing like fœces has been seen in the crop of chickens, as has been alleged by some, it might be no more than the yellow or green-coloured substance brought up from the stomach.

Though creatures that respire are under a necessity of either swallowing, or forcing back by vomiting, whatever is introduced beyond their fauces, it cannot be thence concluded that a fœtus is under the same necessity; for, as it does not exercise respiration, it will suffer no inconvenience by a liquor lodging near to the glottis; whereas creatures that breathe cannot allow any substance to remain there without danger of the glottis being stopped, or of such substances falling down the trachea, either of which would be of bad consequence; which the animal prevents, by forcing such substances out of such a dangerous situation. But, to enforce the negative of the colliquamentum passing by the mouth, observe, that there are only three days in which this passage can most probably be supposed to happen, which are from the fifteenth to the eighteenth day of incubation: for before the fifteenth, the quantity of the liquor amnii is encreasing, which is no great sign of its being swallowed; and after the eighteenth, this liquor is not to be seen. If, then, the liquor amnii were all swallowed between the fifteenth and eighteenth days, the stomach ought to be fuller at this time, and its contents should be thinner, more pellucid, &c. like to the colliquamentum; which, however, does not happen. Besides, if we suppose the power of digestion so strong as to expel this liquor as fast as it is taken down in these three days, it would certainly follow, that this powerful digestion continuing in the three succeeding days, while there is no liquor to be swallowed, the stomach ought to be quite emptied; which every one who opens the stomachs of chickens at this time will see it is not. And, lastly, as a more direct proof still against Harvey, Dr. Monro broke the shells of several incubated eggs, while the colliquamentum was in large quantity; and, before the amnios was opened, he saw the chickens open their mouths very wide several times, but could not observe the quantity of the liquor in which they lay at all lessened. He afterwards carefully dissected the chickens, and found no other than the common small quantity in the crops, and the ordinary curdy mucus in the stomach; which seems to be a demonstration that they do not swallow. After such convincing proofs, we shall only desire the reader to compare the posture of a chick, and of a hen while she swallows liquors, that they may see the posture of the chick's neck to be most unfavourable to the supposition of deglutition being performed; and then shall conclude with a very short history of incubation, assigning the most probable reasons of the several appearances.

By the heat of the hen, assisted possibly by the action of the air contained in the folliculus aeris, the albumen becomes thinner, especially where it is most exposed to these forces; and the vitellus in the same manner becomes specifically lighter, and therefore readily rises in the white. And as, by being divided into two unequal portions by its axis the chalazæ, it presents the smaller portion to the incubating heat at first; so the change in consequence of incubation being soonest and most produced here, and the cicatricula being enlarged at the same time, the smaller portion of the yolk becomes much lighter; and therefore is buoyed up to the superior part of the egg; whereby the folliculus aeris and the membranes of the cicatricula become contiguous when they enlarge, and the vitellus can never be in hazard of compressing the tender embryo; and the umbilical vessels are situated so as to have their extremities immersed in the liquors that first undergo the proper change, for being imbibed by their orifices. The

incubation continuing, the white is still more and more colliquated, and the umbilical vessels are proportionally extended, the veins to absorb it, and the arteries to throw out any particles that are unfit for the chick till they are farther prepared. When the white in the upper part of the egg is exhausted, its membranes become contiguous to the amnios; and thereby, the membranes involving the fœtus, becomes sufficiently strong to resist the motions of the chick, when its ease or safety prompt it at any time to spurn. The powers of incubation above-mentioned, assisted by the pulsation and conquassatory motions of the numerous umbilical vessels spread on the yolk, dissolve that humour more, and render some part of it fine enough to be taken up by the small extremities of the umbilical vein, some of which penetrate its membrane: by which the liquor at last becomes thicker; and the membrane, being in part emptied, will more easily yield to the weight of the chick; and is pressed into the form of a horse-shoe, while the net-work of the vessels extended on this membrane renders it stronger and firmer. The folliculus aeris not only assists in colliquating the albumen, but, when the humours of the egg come to occupy a less space, by escaping through the shell, and by being changed into the solid substance of the chick, the folliculus enlarging, keeps the chick and humour steady, without danger of being disordered and broken by the motions of the egg. Branches of the umbilical vessels being distributed to the amnios, the arteries will pour out their liquors into its cavity in greater quantity than the veins can take them up, as long as the fœtus is weak: but, whenever the fœtus becomes stronger, and consequently the absorbent power of the veins increases, they will take up the fluid of the amnios faster than the arteries pour it in, and its quantity will be diminished till it is quite exhausted. This absorption will go on more speedily in proportion also to the umbilical vessels being less distended with albumen, whereby there is less resistance to the progressive motion of the absorbed liquors; which probably is the reason of the colliquamentum being all taken up between the fifteenth and eighteenth days. By the constant circulation and renewal of all these humours of the egg, they keep fresh and uncorrupted in a fecundated egg; but corrupt soon in a subventaneous one, or in such whose fœtus dies in the time of incubation. Wherever vessels are not sufficiently filled, they contract themselves; and therefore, the albumen being exhausted in the last days of incubation, the umbilical vessels gradually shrivel, which prevents the danger of an hæmorrhage when the chick is separated from its membranes. But, as the white is not sufficient at this time fully to supply the chick, the yolk is taken into its body; and, being there pressed, it is thrown gradually by the proper duct into the guts to supply that defect. The vessels and glands which open into the alimentary tube separate at least as much liquor as will moisten it; and the stomach, having no callous strong crust on its internal surface, will separate more than it can do in the adult; and in the mean time the glands of the infundibulum pour out a liquor that is always thicker as the chick increases, till it becomes a very thick white mucus: and therefore the contents of the stomach of the fœtus in the egg must have the appearance above described, and will be slowly passing off into the intestines. The shell at the obtuse end of the egg becoming more brittle, by being so long exposed to a dry heat, and the membranes losing their toughness when their moisture is exhausted, the chick very easily tears them, and breaks off that end of the shell, to make its way into the common atmosphere. The mother having no juices prepared within her body to give to the chick for food after it is hatched, and its organs for taking in and digesting aliment being for some time too weak to supply it sufficiently with nourishment, the vitellus is made to supply these deficiencies, till the chick is sufficiently confirmed and strong; after which it is no longer the subject of our present inquiry. We therefore proceed to finish our anatomical observations on the domestic fowls.

These creatures, as was observed of fowls in general, have no teeth. Some, indeed, have an appearance of teeth; but these are only small processes or serræ rising out from the mandible, without any socket, &c. which would have been needful, as they swallow their food entire. But their tongue is made somewhat firm, lest it should be hurt by the sharp points of the grain on which they feed. It is of a triangular figure, and pointed before; and, as by their depending posture their meat is in hazard of falling out of their mouths, to prevent this, there are several small pointed papillæ standing out upon their tongue and palate, with their points inclined backwards, allowing an easy passage to the food, but hindering it to return. We have here no velum palatinum, uvula, or epiglottis; and, in place of two large holes opening into the nose, there is only a long narrow rima furnished with strong muscles; and a similar rima supplies the place of a glottis. Fowls have a power of shutting both at pleasure; the nature of their food seems not only to exempt them from the hazard of its getting into the nose or trachea, but its sharp points would hurt an uvula or epiglottis. Hence we see with what difficulty they swallow dough or other sort of food that can be easily moulded into any form. When we examine the upper end of the trachea, we observe a rima glottidis with muscular sides, which may act in preventing the food or drink from passing into the lungs, for there is no epiglottis, as in man and quadrupeds.

Their *cranium* is more cellular and cavernous than ours. By this means their heads are light, yet strong enough to resist external injuries; for the enlarging of the diameter of bones contributes to their strength. By this cavernous *cranium* the organ of smelling is supposed to be considerably enlarged; and farther, finging birds, as is observed by Mr. Ray and Mr. Derham, have the cavernous structure of the brain still more observable: and we are told that the cavity of the tympanum communicates with the cells. Their brain is covered with the common membranes, but its external surface is not formed into so many gyæ or convolutions as ours. Its anterior part is quite solid, of a cineritious colour, and so far resembles the *corpora striata* as to give rise to the olfactory nerves. The whole of it appears to us as imperfect, and we can scarcely determine whether there be any thing analogous to a third or fourth ventricle; neither the *corpus callosum*, *fornix*, *nates*, or *testes*, &c. can be observed here; which parts therefore cannot be imagined as absolutely necessary for the functions of life, since we find these creatures perform them sufficiently well. Their organ of smelling is very large, and well provided with nerves; hence they have this sensation very acute. Ravens and other birds of prey give a sure proof of this, by their being able to find out their prey, though concealed from their sight, and at a considerable distance. Those birds that grope for their food in the waters, mud, &c. have large nerves, which run quite to the end of their bills, by which they find out and distinguish their food.

The anterior part of their eyes, instead of having the sclerotic coat contained, so as to make nearly a sphere as in us, turns all of a sudden flat; so that here the sclerotic makes but half a sphere; and the cornea rises up afterwards, being a portion of a very small and distinct sphere: so that in these creatures there is a much greater difference between the sclerotic and cornea than in us. Hence their eyes do not jut out as in man and quadrupeds. As most of these creatures are continually employed in hedges and thickets, that their eyes might be secured from these injuries, as well as from too much light when flying in the face of the sun, there is therefore a very elegant mechanism in their eyes. A membrane rises from the internal canthus, which at pleasure, like a curtain, can be made to cover the whole eye; and this, by means of a proper muscle that rises from the sclerotic coat, and, passing round the optic nerves, runs through the *musculus oculi attolens* and palpebra, to be inserted into the edge of this membrane. Whenever this muscle ceases to act, the membrane by its

own elasticity again discovers the eye. This covering is neither pellucid nor opaque, both which would have been equally inconvenient; but, being somewhat transparent, allows as many rays to enter as to make any object just visible, and is sufficient to direct them in their progression. By means of this membrane it is that the eagle is said to look at the sun. Quadrupeds also have a small *membrana nictitans*.

Besides, all fowls have another particularity, the use of which appears not so well understood; and that is, a longish black triangular purse, rising from the bottom of their eye just at the entry of the optic nerve, and stretched out into their vitreous humour, and perhaps it gives some threads to the crystalline. To this the French (who were the first that took notice of it in their dissections before the Royal Academy) gave the name of *bourse noire*. It may possibly serve to suffocate some of the rays of light, that they may see objects more distinctly without hurting their eyes. It has a connection with the vitreous, and seems to be joined also to the crystalline humours. If we suppose it to have a power of contraction, (which may be as well allowed as that of the iris,) it may so alter the position of the vitreous and crystalline humours, that the rays from any body may not fall perpendicularly upon the crystalline; and this seems to be necessary in them, since they cannot change the figure of the anterior part of their eye so much as we do: and, as this animal is exposed often to too great a number of rays of light, so they have no tapetum, but have the bottom of their eye wholly black on the retina; and in consequence of this, fowls see very ill in the dark.

They have no external ear; but in its place a tuft of very fine feathers covering the *meatus auditorius*, which easily allows the waves of sound to pass them, and likewise prevents dust or any insect from getting in. An external ear would have been inconvenient in their passage through thickets, and in flying, &c. A liquor is separated in the external part of the ear, or *meatus auditorius*, to lubricate the passage, and farther prevent the entrance of any insects, &c. The *membrana tympani* is convex externally; and no muscles are fixed to the bones of their ear, which are rather of a cartilaginous consistence: any tremulous motions impressed on the air are communicated in these creatures merely by the spring and elasticity of these bones; so, probably, the membrane is not so stretched as in the human ear by muscles. The semicircular canals are very distinct, and easily prepared.

We shall next consider carnivorous birds, commonly called *birds of prey*; and for an example shall take a *stannet* or small hawk. The principal difference to be observed in them, is in their chylopoietic viscera, which may be accounted for from their different way of life. Immediately under their clavicles, we observe the *oesophagus* expanded into their *ingluvies*, which is proportionally less than in the granivorous kind, since their food does not swell so much by maceration: and for the same reason, there is a less quantity of *menstruum* to be found there. They have also a *ventriculus succenturiatus*, plentifully stored with glands, situated immediately above their stomach, which is much more thin and musculo-membranous than in the granivorous kind; and this difference, which is almost the only one we find between the two different species of fowls, is easily accounted for from the nature of their food, which acquires less attrition, being easier of digestion than that of the other kind; nevertheless, it seems requisite it should be stronger than the human, to compensate the want of abdominal muscles, which are here very thin. The same mechanism obtains in this creature's duodenum, that we have hitherto observed. As being a carnivorous animal, its guts are proportionally shorter than those of the granivorous species, for the reason first given, viz. its food being more liable to corrupt, is therefore not proper to be long detained in the body; and for that reason it has no intestina cæca, of which the other fowls

fowls have a pair. The difference in their wings, beaks, and claws, are obvious; and have been already in some measure observed.

ANATOMY of AMPHIBIOUS and AQUEOUS ANIMALS.

Aqueous animals are generally divided into such as have lungs, and such as want them. The first species differ so inconsiderably from an ox or any other quadruped, that a few observations may be sufficient to give an idea of their internal structure; for this purpose, we shall first examine that species which most resembles man in the internal structure, the *tortoise*. The covering of this animal is composed of a shell so remarkably hard and firm in its texture, that a loaded waggon may go over it without hurting the shell or the animal within it. In the young, this shell grows harder in proportion as its contents expand; and this creature never changes its shell as some others do: hence it was necessary for it to be composed of different pieces; and these are more or less distinct in different animals. Its feet are small and weak, and are exceedingly slow in motion. It has neither tongue nor teeth; to make up for which, its lips are so hard as to be able to break almost the hardest bodies. The alimentary canal very much resembles that of the other class. The principal difference is in the circulation of the blood. The heart has two distinct auricles, without any communication; and under these, there is the appearance of two ventricles similar in shape to those of the former class: but they may be considered as one cavity; for the ventricle sends out not only the pulmonary artery, but likewise the aorta; for there is a passage in the septum by which the ventricles communicate freely, and the blood passes from the left into the right one. From the aorta the blood returns into the right auricle, while that from the pulmonary artery returns to the left auricle, from which it is sent to the left ventricle, &c. so that only a part of the blood is sent to the lungs, the rest going immediately into the aorta; hence the animal is not under the necessity of breathing so often as otherwise it would be.

From the base of the right ventricle goes out the pulmonary artery and aorta. The pulmonary artery is spent upon the lungs. The aorta may be said to be three in number; for the aorta sinistra ascends through the pericardium in company with the pulmonary artery; and afterwards turns down, and sends off a considerable branch, which splits into two; one of which joins the right aorta, while the other is distributed upon the liver, stomach, intestines, &c. What remains of this aorta runs to the kidneys and posterior extremities of that side. An aorta descends, &c. after piercing the pericardium, runs down and communicates with the branch already mentioned, is distributed upon the right kidney and inferior extremity, and also upon the bladder and parts of generation. An aorta ascends, after getting out of the pericardium, supplies the fore-legs, neck, and head. The blood of the superior part of the body returns to the right auricle by two jugular veins, which unite after perforating the pericardium. From the inferior part, it returns to the same auricle by two large veins: one on the right side receives the blood from the right lobe of the liver; the other on the left side receives the blood from the left lobe, and also a trunk which corresponds with the inferior vena cava in other animals. The pulmonary vessels run in the left auricle in the common way.

The absorbent system in the turtle, like that in the former class, consists of lacteals and lymphatics, with their common trunks the thoracic ducts; but differs from it in having no obvious lymphatic glands on any parts of its body, nor plexus formed at the termination in the red veins. The *lacteals* accompany the blood-vessels upon the mesentery, and form frequent net-works across these vessels: near the root of the mesentery a plexus is formed, which communicates with the lymphatics coming from the kidneys and parts near the anus. At the root of the mesentery on the left side of the spine, the lymphatics of

the spleen join the lacteals; and immediately above this a plexus is formed, which lies upon the right aorta. From this plexus a large branch arises, which passes behind the right aorta to the left side, and gets before the left aorta, where it assists in forming a very large receptaculum, which lies upon that artery.

From this receptaculum arise the thoracic ducts. From its right side goes one trunk, which is joined by that large branch that came from the plexus to the left side of the right aorta, and then passes over the spine. This trunk is the thoracic duct of the right side; for, having got to the right side of the spine, it runs upwards on the inside of the right aorta, towards the right subclavian vein; and, when it has advanced a little above the lungs, it divides into branches, which near the same place are joined by a large branch, that comes up on the outside of the aorta. From this part upwards, those vessels divide and subdivide, and are afterwards joined by the lymphatics of the neck, which likewise form branches before they join those from below. So that between the thoracic duct and the lymphatics of the same side of the neck, a very intricate net-work is formed; from which a branch goes into the angle between the jugular vein and the lower part or trunk of the subclavian. This branch lies therefore on the inside of the jugular vein, whilst another gets to the outside of it, and seems to terminate in it, a little above the angle between that vein and the subclavian.

Into the above-mentioned receptaculum the lymphatics of the stomach and duodenum likewise enter. Those of the duodenum run by the side of the pancreas, and probably receive lymphatics from it, and a part of those of the liver. The lymphatics of the stomach and duodenum have very numerous anastomoses, and form a beautiful net-work on the artery, which they accompany. From this receptaculum likewise (besides the trunk already mentioned, which goes to the right side) two other trunks, nearly equal in size, arise; one of which runs upon the left side, and the other upon the right side, of the left aorta, till they come within two or three inches of the left subclavian vein; where they join behind the aorta, and form a number of branches which are afterwards joined by the lymphatics of the left side of the neck; so that a plexus is here formed as well as upon the right side. From this plexus a branch issues, which opens into the angle between the jugular and subclavian vein.

The circulation in serpents and crocodiles is similar to that of the turtle; but we find only one ventricle. The blood goes from the right auricle to the ventricle which sends out the pulmonary artery and aorta; the blood from the pulmonary artery returns to the left auricle, that from the aorta going to the right auricle, and both the auricles opening into the ventricle.

The frog and lizard differ from the former animals, in having only one auricle and ventricle: and besides, the ventricle sends out a single artery, which afterwards splits into two parts; one to supply the lungs, the other runs to all the rest of the body: from the lungs and from the other parts the blood returns into the auricle.

ANATOMY of FISHES.

With respect to Fishes we may first observe, that they have a very strong thick *cuticle*, covered with a great number of scales, laid one on another like tiles on houses. This among other arguments is supposed to prove the human epidermis to be of a squamous structure; but the scales resemble the hairs, wool, feathers, &c. of the creatures that live in air; and below these we observe the proper *cuticula* and *cutis*. The generality of fishes, particularly those shaped like the cod, haddock, &c. have a line running on each side. These lines open externally by a number of ducts, which throw out a mucous or slimy substance, that keeps the skin soft and clammy, and seems to serve the same purpose with the mucous glands or ducts which are placed within many of our internal organs. In the next place, these creatures have neither superior nor inferior

inferior extremities, as quadrupeds and fowls; for their progression is performed in a different way from either of those species of animals: for this purpose they are provided with machines, properly consisting of a great number of elastic beams, connected to one another by firm membranes, and with a tail of the same texture; their spine is very moveable towards the posterior part, and the strongest muscles of their bodies are inserted there. Their tails are so framed as to contract to a narrow space when drawn together to either side, and to expand again when drawn to a straight line with their bodies; so, by the assistance of this broad tail, and the fins on their sides, they make their progression much in the same way as a boat with oars on its sides and rudder at its stern. The perpendicular fins situated on the superior part of their body keep them in *aquilibrium*, hindering the belly from turning uppermost; which it would readily do, because of the air-bag in the abdomen rendering their belly specifically lighter than their back; but, by the resistance these fins meet with when inclined to either side, they are always kept with their backs uppermost. It may next be observed, that these creatures have nothing that can be called a *neck*, since they seek their food in an horizontal way, and can move their bodies either upwards or downwards, as they have occasion, by the contraction or dilatation of the air-bag; a long neck, as it would hinder their progression, would be very disadvantageous in the element they live in.

The *abdomen* is covered on the inferior part with a black-coloured thin membrane resembling our peritoneum. It is divided from the thorax by a thin membranous partition, which has no muscular appearance; so that we have now seen two different sorts of animals that have no muscular diaphragm. These creatures are not provided with *teeth* proper for breaking their aliment into small morsels, as the food they use is generally small fishes, or other animals that need no trituration in the mouth, but spontaneously and gradually dissolve into a liquid chyle. Their teeth therefore serve to grasp their prey, and hinder the food they have once caught from escaping again. For the same purpose, the internal cartilaginous basis of the branchiæ, and the two round bodies situated in the posterior part of the jaws, have a great number of tenter-hooks fixed into them, in such a manner as that any thing can easily get down, but is hindered from getting back. The water that is necessarily taken along with their food in too great quantities to be received into their jaws in deglutition, passes between the interstices of the branchiæ and the flap that covers them.

The *oesophagus* in these creatures is very short, and scarcely distinguished from their stomach; and the food lies almost equally in both. The stomach is of an oblong figure. There are commonly found small fishes still retaining their natural form in the stomach of large ones; but, when touched, they melt down into a jelly. From this, and the great quantity of liquors poured into their stomachs; we may conclude, that digestion is solely brought about in them by the dissolving power of a menstruum, and that no trituration happens here. The *guts* of these animals are very short, making only three turns; the last of which ends in the common cloaca for the feces, urine, and semen, situated about the middle of the inferior part of their bodies.

To that substance which we call *pancreas*, some give the name of *intestinula cæca*. It consists of a great number of small threads, like so many little worms, which all terminate at last in two larger canals, that open into the first gut, and pour into it a viscous liquor much about the place where the biliary ducts enter. That kind of pancreas formed of *intestinula cæca* is peculiar to a certain kind of fishes; for the cartilaginous, broad, and flat, kind, as the skate, sole, flounder, &c. have a pancreas resembling that of the former class of animals. Their intestines are connected to the back-bone by a membrane analogous to a mesentery. Their *liver* is very large, of a whitish colour, and lies almost wholly in the left side, and contains a great

deal of fat or oil. The *gall-bladder* is situated a considerable way from their liver; and sends out a canal, the cystic duct, which joins with the hepatic duct just at the entry into the gut. Some fibres are stretched from the liver to the gall-bladder; but nobody has hitherto discovered any cavity in these cords: so in this animal it should seem impossible that the bile can be carried into the gall-bladder in the ordinary way; and consequently it must either be secreted on the sides of that sac, or regurgitate into it from the canalis choledochus. Here we may make the same remark as upon the biliary ducts of fowls, viz. that hepato-cystic ducts exist in the one as well as the other. This, for example, is very obvious in the salmon, where large and distinct ducts run from the biliary ducts of the liver, and open into the gall-bladder.

The *spleen* is placed near the back-bone, and at a place where it is subject to an alternate pressure from the contraction and dilatation of the air-bag, which is situated near it. Since, in all the different animals we have dissected, we find the spleen attached to some part that may give it a concussion; as in the human subject and quadrupeds, it is contiguous to the diaphragm; in fowls, it is placed between the back-bone, the liver, and the stomach; in fishes, it lies on the faccus aerius; and since we find it so well served with blood-vessels, and all its blood returning into the liver, we must not conclude the spleen to be an *inutile pondus*, only to serve as a balance to the animal *pro æquilibrio*, but particularly designed for preparing the blood for the liver.

The only *organs of generation* in this animal, are two bags situated in the abdomen uniting near the podex. These in the male are filled with a whitish firm substance called the *milt*; and in the female with an infinite number of little ova clustered together, of a reddish yellow colour, called the *roe*. Both these at spawning-time we find very much distended; whereas at any other time the male organ can scarcely be distinguished from the female; nor is there any proper instrument in the male for throwing the seed into the organ of the female, as in other creatures. We shall not take upon us to determine the way whereby the female sperm is impregnated; but we find that the spawn of frogs consists of small specks wrapped up in a whitish glutinous liquor; these specks are the rudiments of the young frogs, which are nourished in that liquor till they are able to go in search of their food. Spallanzani has found, that the eggs of frogs, toads, and water-newts, are not fecundated in the body of the female; that the male emits his semen upon the spawn while it is flowing from the female; and that the foetus pre-exists in the body of the female. But whether impregnation takes place in the same manner in fishes, he has not yet been able to determine, though he seems to think it probable; for, in the same way, the ova of fishes are thrown out and deposited in the sand, the male being for the most part ready to impregnate them, and they are hatched by the heat of the sun. It is curious enough to remark with what care they seek for a proper place to deposit their ova, by swimming to the shallow, where they can better enjoy the sun's rays, and shun the jaws of other large fishes. The river-fishes, again, spawn in some creek free from the hazard of the impetuous stream. But whether this mixture be brought about in fishes by a simple application of the genitals to each other, or if both of them throw out their liquors at the same time in one place, and thus bring about the desired mixture, it is not easy to determine; the latter, we think, seems most probable. These creatures are so shy, that we cannot easily observe their manner of copulation, and we are consequently but little acquainted with their natural history. Frogs, it is very evident, do not copulate; at least no farther than to allow both sexes an opportunity of throwing their sperm. Early in the spring the male is found for several days in close contact upon the back of the female, with his fore-legs round her body in such a manner that makes it very difficult to separate them; but there is no penetration. At this time
the

the female lays her spawn in some place that is most secure, while the male emits his sperm upon the female spawn.

After raising up the black peritonæum in fishes, there comes in view an oblong white membranous bag, in which there is nothing contained but a quantity of elastic air. This is the *swimming-bladder*; it lies close to the back-bone, and has a strong muscular coat, whereby it can contract itself. By contracting this bag, and condensing the air within it, fish can make their bodies specifically heavier than water, and so readily fall to the bottom; whereas, the muscular fibres ceasing to act, the air is again dilated, and they become specifically lighter than water, and so swim above. According to the different degrees of contraction and dilatation of this bladder, they can keep higher or lower in the water at pleasure. Hence flounders, soles, raia or skate, and such other fishes as want this sac, are found always groveling at the bottom of the water: it is owing to this that dead fish (unless this membrane has been previously broken) are found swimming on the surface with their bellies uppermost; for the back-bone cannot yield, and the distended sac is protruded into the abdomen, and the back is consequently heaviest at its upper part, according to their posture. There is here placed a glandular substance, containing a quantity of red blood; and it is very probable that the air contained in the swimming-bladder is derived from this substance. From the anterior part of the bag go out two *processes* or *appendices*, which, according to the gentlemen of the French academy, terminate in their fauces. In a variety of other fishes we find communications with some parts of the alimentary canal, particularly the œsophagus and stomach. The salmon has an opening from the fore-end of the air-bag into the œsophagus, which is surrounded by a kind of muscular fibres. The herring has a funnel-like passage leading from the bottom of the stomach into the air-bag; but it is not determined whether the air enters the air-bag by this opening, or comes out by it: the latter, however, seems to be the more probable opinion, as the glandular body is found in all fishes, whereas there are several without this passage of communication. At the superior part of this bag there are other red-coloured bodies of a glandular nature, which are connected with the kidneys. From them the *ureters* go down to their insertion in the *vesica urinaria*, which lies in the lower part of the abdomen; and the urethra is there produced, which terminates in the podex. These last-mentioned parts have not hitherto been observed in some species of fish; whence authors too hastily denied them in all. These creatures have a *membranous diaphragm*, that forms a sac in which the heart is contained. It is very tense, and almost perpendicular to the vertebræ.

The *heart* is of a triangular form, with its base downwards and its apex uppermost; which situation it has because of the *branchiæ*. The heart has but one auricle, one ventricle, and one great artery. The size of the auricle and that of the ventricle are much the same; the artery sends out numerous branches to the branchiæ or gills. And, what is rather curious, this artery, instead of supporting all parts as in the frog, is distributed entirely upon the gills, every branch terminating there, and becoming so extremely small as at last to escape the naked eye. The *branchiæ* lie in two large slits at each side of the head, and seem to be all that bears any analogy to lungs. Their form is semicircular; they have a vast number of red fibrillæ standing out on each side of them like a fringe, and very much resemble the vane of a feather. These branchiæ are perpetually subject to an alternate motion and pressure from the water; and we may here remark, that we have not found any red blood but in places subject to this alternate pressure. This observation will help us in explaining the action of the lungs upon the blood. Over these gills there is a large flap, allowing a communication externally; by which the water they are obliged to take into their mouths with their food finds an exit without passing into their stomach; it is owing to these flaps coming so far

down, that the heart is said commonly to be situated in their heads. The blood is collected again from the gills by a vast number of small veins, somewhat in the same manner as in our pulmonary vein; but, instead of going back to the heart a second time, they immediately unite and form an aorta descendens without the intervention of an auricle and ventricle. Hence a young anatomist may be puzzled to find out the power by which the blood is propelled from the gills to the different parts of the body; but the difficulty will be considerably lessened when we consider the manner in which the blood is carried through the liver from the intestines in man and quadrupeds. The aorta in fishes sends off branches which supply all the parts of the body excepting the gills. From the extremity of those branches the blood returns to the heart somewhat in the same manner as in the former class of animals; only there are two inferior venæ cavæ, whereas the former has but one.

In the *absorbent system* in fishes, we shall take the haddock as a general example: for the other fishes, particularly those of the same shape, will be found in general to agree with it. On the middle of the belly of a haddock, immediately below the outer skin, a lymphatic vessel runs upwards from the anus, and receives branches from the parietes of the belly, and from the fin below the anus; near the head this lymphatic passes between the two pectoral fins; and, having got above them, it receives their lymphatics. It then goes under the symphysis of the two bones which form the thorax, where it opens into a network of very large lymphatics, which lie close to the pericardium, and almost entirely surrounds the heart. This net-work, besides that part of it behind the heart, has a large lymphatic on each side, which receives lymphatics from the kidney, runs upon the bone of the thorax backwards, and, when it has got as far as the middle of that bone, it sends off a large branch from its inside to join the thoracic duct. After detaching this branch, it is joined by the lymphatics of the thoracic fins, and soon after by a lymphatic which runs upon the side of the fish. It is formed of branches, which give it a beautiful penniform appearance.

The lacteals run on each side of the mesenteric arteries, anastomosing frequently across those vessels. The receptaculum into which they enter is very large, in proportion to them; and consists at its lower part of two branches, of which one lies between the duodenum and stomach, and runs a little way upon the pancreas, receiving the lymphatics of the liver, pancreas, those of the lower part of the stomach, and the lacteals from the greatest part of the small intestines. The other branch of the receptaculum receives the lymphatics from the rest of the alimentary canal. The receptaculum formed by these two branches lies on the right side of the upper part of the stomach, and is joined by some lymphatics in that part, and also by some from the sound and gall-bladder, which in this fish adheres to the receptaculum. This thoracic duct takes its rise from the receptaculum, and lies on the right side of the œsophagus, receiving lymphatics from that part; and, running up about half an inch, it divides into two ducts, one of which passes over the œsophagus to the left side, and the other goes straight upon the right side, passes by the upper part of the kidney, from which it receives some small branches, and soon afterwards is joined by a branch from the large lymphatic that lies above the bone of the thorax; near this part it likewise sends off a branch to join the duct of the opposite side; and then, a little higher, is joined by those large lymphatics from the upper part of the gills, and from the fauces.

The thoracic duct, after being joined by these vessels communicates with the net-work near the orbit, where its lymph is mixed with that of the lymphatics from the posterior part of the gills, and from the superior fins, belly, &c. and then, from this net-work, a vessel goes into the jugular vein just below the orbit. This last vessel, which may be called the termination of the whole system, is very small in proportion to the net-work from which it rises;

and indeed the lymphatics of the part are so large, as to exceed by far the size of the sanguiferous vessels. The thoracic duct, having passed under the œsophagus from the right, runs on the inside of the vena cava of the left side, receives a branch from its fellow of the opposite side, and joins the large lymphatics which lie on the left side of the pericardium, and a part of those which lie behind the heart; and afterwards makes, together with the lymphatics from the gills, upper fins, and side, of the fish, a network, from which a vessel passes into the jugular vein of this side. In a word, the lymphatics of the left side agree exactly with those of the right side above described. Another part of the system is deeper seated, lying between the roots of the spinal processes of the back-bone. This part consists of a large trunk that begins from the lower part of the fish, and, as it ascends, receives branches from the dorsal fins and adjacent parts of the body. It goes up near the head, and sends a branch to each thoracic duct, near its origin.

The brain, in fishes is formed nearly in the same way as that of fowls; only we may observe, that the posterior lobes bear a greater proportion to the anterior. Their organ of *smelling* is large; and they have a power of contracting and dilating the entry into their nose as they have occasion. It seems to be mostly by their acute smell that they discover their food; for their tongue seems not to have been designed for a very nice sensation, being of a firm cartilaginous substance; and common experience evinces, that their sight is not of so much use to them as their smell in searching for their nourishment. If you throw a fresh worm into the water, a fish will distinguish it at a considerable distance; and that this is not done by the eye, is plain from observing, that after the same worm has been a considerable time in the water, and lost its odour, no fishes will come near it: but if you take out the bait, and make several little incisions into it, so as to let out more of the odoriferous effluvia, it will have the same effect as formerly. Now it is certain, had the creatures discovered this bait with their eyes, they would have come equally to it in both cases. In consequence of their smell being the principal means of discovering their food, we may frequently observe their allowing themselves to be carried down with the stream, that they may ascend again leisurely against the current of the water; thus the odoriferous particles, swimming in that medium, being applied more forcibly to their smelling organs, produce a stronger sensation.

The *optic nerves* in these animals are not confounded with one another in their middle progress between their origin and the orbit, but the one passes over the other without any communication; so that the nerve that comes from the left side of the brain goes distinctly to the right eye, and *vice versa*. Indeed it would seem not to be necessary for the optic nerves of fishes to have the same kind of connection with each other as those of man have; for their eyes are not placed in the fore-part, but in the sides, of their head, and of consequence, they cannot so conveniently look at any object with both eyes at the same time. The *lens crystallina* is here a complete sphere, and more dense than in terrestrial animals, that the rays of light coming from the water might be sufficiently refracted.

As fishes are continually exposed to injuries in the uncertain element they live in, and as they are in perpetual danger of becoming a prey to the larger ones, it was necessary that their eyes should never be shut; and, as the cornea is sufficiently washed by the element they live in, they are not provided with palpebræ; but then, as in the current the eye must be exposed to several injuries, there was a necessity that it should be sufficiently defended; which in effect it is by a firm pellucid membrane, that seems to be a continuation of the cuticula, being stretched over here. The epidermis is very proper for this purpose, as being insensible, and destitute of vessels, and consequently not liable to obstructions, or, by that means, of becoming opaque. In the eye of the skate tribe, there is

a digitated curtain which hangs over the pupil, and may shut out the light when the animal rests, and it is similar to the tunica adna of other animals.

Although it was formerly much doubted whether fishes possessed a sense of hearing, yet there can be little doubt of it now; since it is found that they have a complete organ of hearing as well as other animals; and likewise, as the water in which they live is proved to be a good medium for the propagation of sound. Fishes, particularly those of the skate kind, have a bag at some distance behind the eyes; which contains a fluid and a soft cretaceous substance, and supplies the place of vestibule and cochlea. There is a nerve distributed upon it, similar to the portio mollis in man. They have semicircular canals, which are filled with a fluid, and communicate with the bag: they have likewise a meatus externus, which leads to the internal ear. The cod fish, and others of the same shape, have an organ of hearing somewhat similar to the former; but, instead of a soft substance contained in the bag, there is a hard cretaceous stone. In this kind of fish no meatus externus has been yet observed.

ANATOMY of INSECTS.

With respect to insects and worms, they are so exceedingly numerous, that it would be endless to examine all the different kinds, nor would it serve any useful purpose in this enquiry. We shall therefore be content with making a few general observations, and these chiefly on the structure of their body. Insects differ from the former classes, by their bodies being covered with a hard crust or scale, by their having feelers or antennæ arising from their head, and many of them breathing the air through lateral pores. As to the shape of their bodies, though it somewhat differs from that of birds, being in general not so sharp before, to cut, and make way through, the air, yet it is well adapted to their manner of life. The base of their bodies is not formed of bone, as in many other animals, but the hard external covering serves them for skin and bone at the same time. Their feelers, beside the use of cleaning their eyes, are a guard to them in their walk or flight. Their legs and wings are well fitted for their intended service; but the latter vary so much in different insects, that from them naturalists have given names to the several orders of the class. As, first, the *Coleoptera*, or beetle tribe, which have a crustaceous elytra or shell, that shuts together, and forms a longitudinal future down their back. *Hemiptera*: as in cicada, cockroach, bug, &c. which have the upper wings half crustaceous, and half membranaceous; not divided by a longitudinal future, but incumbent on each other. *Lepidoptera*: as the butterfly, have four wings covered with fine scales in the form of powder. *Neuroptera*: as the dragon-fly, spring-fly, &c. have four membranaceous transparent naked wings, generally reticulated. *Hymenoptera*: as wasps, bees, &c. have four membranaceous wings, and a tail furnished with a sting. *Diptera*: as the common house-fly, have only two wings. *Aptera*: as the lobster, crab, scorpion, spider, &c. have no wings.

The structure of the *eye* in many insects is a most curious piece of mechanism. The outer part is remarkably hard, to guard against injuries; and has commonly a reticular appearance, or the whole may be considered as an assemblage of smaller eyes; but whether they see objects multiplied before them, has not yet been determined.

Linnaeus, and several others following him, deny the existence of a *brain* in these creatures. But it is certain, that at least a number of the larger kinds, as the lobster, crab, &c. have a soft substance similar to the brain, from which the optic and other nerves take their rise; besides, when this substance is irritated, the animal is thrown into convulsions: hence we should conclude, that insects have a brain as well as the former classes, although this is smaller in proportion to their bodies. Their ear has been lately discovered to be placed at the root of their antennæ or feelers, and can be distinctly seen in some of the larger kinds,

kinds, as the lobster. They have a *stomach*, and other organs of digestion; and it is curious, that in some, as the lobster, the teeth are found in the stomach. They have a *heart* and *blood-vessels*, and circulation is carried on in them somewhat as in the former class; but the blood is without red globules; or, as naturalists speak, is colourless. In the lobster, and others of the larger kind, when a piece of the shell is broken, the pulsation of the heart is seen distinctly, and that sometimes for several hours after it has been laid bare. The existence of *lungs* has been denied by some authors. But late experiments and observations shew, that no species want them, or at least something similar to them; and, in many insects, they are larger in proportion than in other animals; in most of them, they lie on or near the surface of their body; and send out lateral pores or tracheæ, by which, if the animal is besmeared with oil, it is instantly suffocated.

The same difference in sex exists in insects as in other animals, and they even appear more disposed to increase their species, many of them, when become perfect, seeming to be created for no other purpose but to propagate. Thus the silk-worm, when it arrives at its perfect or moth state, is incapable of eating, and can hardly fly; it endeavours only to propagate its species: after which the male immediately dies; as does the female as soon as she has deposited her eggs. Besides those of the male and female, a third sex exists in some insects which we call *neuter*. As these have not the distinguishing parts of either sex, they may be considered as eunuchs or infertile. We know of no instance of this kind in any other class of animals; and it is only found among those insects which form themselves into societies, as bees, wasps, and ants; and here these eunuchs are real slaves, as on them lies the whole business of the œconomy. No hermaphrodites as yet have been discovered among insects.

Many have imagined that the generality of insects were merely the production of putrefaction, because they have been observed to arise from putrefied substances: but a contrary opinion is now more generally adopted; and it is certain, that, if putrid bodies be shut up in a close vessel, no insects are ever generated unless their ova have been originally deposited there. They are oviparous animals, and lay their eggs in places most convenient for the nourishment of their young; some in water, others in flesh; some in fruit and leaves; while others make nests in the earth or in wood, and sometimes even in the hardest stone.

The eggs of all insects first become caterpillar or maggot. From which they are changed into chrysalis or aurelia, so named from their being inclosed in a case; and these dying, or seeming to die, the fly, or butterfly, or perfect state, succeeds; and during each of these changes their appearance differs wonderfully.

With respect to Worms, they have characters corresponding with those of the former tribe, but are distinguished from them by having no antennæ, and in being furnished with tentacula. Many of them, particularly those without shells, are remarkably tenacious of life, sometimes capable of being new-formed from a part which may have been separated. By much the greater number of them are destitute of head, ears, nose, eyes, and feet. Some of those in the first order, as the common round worms, have a vascular and nervous system, with the parts of generation, which can be distinctly seen. Some, as the cuttle-fish, form a kind of connection between fishes and worms, in possessing gills but wanting fins, &c. while others, as those of the lowest order, or zoophyta, join the properties of the animal and vegetable kingdom together. The class is divided into the following orders, viz. *Intestina*: as the earth-worm, leech, &c. which are the most simple animals, being perfectly naked, and without limbs of any kind. *Mollusca*: as the naked snail, sea-slug, cuttle-fish; which are likewise simple animals without any shell, but they are brachiated or furnished with a kind of limbs. *Testacea*: as the snail, oyster, &c. which have the same characters as the former order, but are covered with a shell, and include the greater part of what we commonly call shell-fish. *Lithophyta*: as corals, madrepores, &c. which are compound animals fixed upon a calcareous base, constructed by the creatures themselves. *Zoophyta*: as the sponge, polypus, &c. These are likewise compound animals, furnished with a kind of flowers, and having a vegetating root and stem.

Some of these creatures inhabit the earth, others live on the rest of the animal or on the vegetable kingdom, and many are found in the hardest stones; while an innumerable tribe of them live in the waters. In general, they are said to be of the hermaphrodite and oviparous kind; while the lowest class, as the polypi, in a great measure resemble the vegetable kingdom in their manner of growth; but for the propagation of these animals, as well as the others of this class, we refer the reader to the various particulars under their respective heads.

A N A

A N A

A'NATRON, *f*. The scum which swims upon molten glass in the furnace, which, when taken off, melts in the air, and then coagulates into common salt. It is likewise that salt which gathers upon the walls of vaults.

A'NAX, a son of Cœlus and Terra, from whom Miletus was formerly called Anactoria. This name was anciently given to several remarkable persons, it having been of the greatest honour.

ANAXA'GORAS, one of the most celebrated philosophers among the ancients. He was born at Clazomene in Ionia, about the 70th Olympiad. He was a disciple of Anaximenes; and he gave up his patrimony, to be more at leisure for the study of philosophy, giving lectures in that science at Athens. Being persecuted in this place, and at last banished from it, he opened a school at Lampacum, where he was greatly honoured during his life, and still more after his death, statues having been erected to his memory. It is said he made some predictions relative to the phenomena of nature, as earthquakes, &c. upon which he wrote some treatises. His principal tenets may be reduced to the following: All things were in the beginning confusedly mixed together, without order and without

motion. The principle of things is at the same time one and multiplex, which had the name of *homemeries*, or similar particles, deprived of life. But there is beside this, from all eternity, another principle, an infinite and incorporeal spirit, who gave motion to these particles; in virtue of which, such as are homogeneous united, and such as were heterogeneous separated according to their different kinds. All things being thus put in motion by the spirit, and every thing being united to such as are similar, those that had a circular motion produced heavenly bodies, the lighter particles ascending, while those that were heavier descended. The rocks of the earth, being drawn up by the whirling force of the air, took fire, and became stars, beneath which the sun and moon took their stations. It was said he also wrote upon the Quadrature of the Circle; the treatise upon which, Plutarch says, he composed during his imprisonment at Athens.

ANAXAR'CHUS, a philosopher of Abdera, highly esteemed by Alexander the Great. His end was peculiarly tragical: having the misfortune to fall into the hands of the enemy, they pounded him alive in a mortar.

ANAXA'RETE, in fabulous history, a nymph of the island

island of Cyprus, for whose unkindness her lover Iphigene hanged himself at her door; and, looking on this sad spectacle without emotion or pity, she was turned into a stone.

ANAXIMANDER, a very celebrated Greek philosopher, was born at Miletus in the 42d Olympiad; for, according to Apollodorus, he was sixty-four years of age in the second year of the 58th Olympiad. He was one of the first who publicly taught philosophy, and wrote upon philosophical subjects. He was the kinsman, companion, and disciple, of Thales. He wrote also upon the sphere and geometry, &c. And he carried his researches into nature very far, for the time in which he lived. It is said that he discovered the obliquity of the zodiac; that he first published a geographical table; that he invented the gnomon, and set up the first sundial in an open place at Lacedæmon. He taught, that infinity of things was the principal and universal element; that this infinite always preserved its unity, but that its parts underwent changes; that all things came from it; and that all were about to return to it. By this obscure and indeterminate principle he probably meant the chaos of other philosophers. He held that the worlds are infinite; that the stars are composed of air and fire, which are carried about in their spheres, and that these spheres are gods; and that the earth is placed in the midst of the universe, as in a common centre. Farther, that infinite worlds were the produce of infinity; and that corruption proceeded from separation.

ANAXIMENES, an eminent Greek philosopher, born at Miletus, the friend, scholar, and successor, of Anaximander. He diffused some degree of light upon the obscurity of his master's system. He made the first principle of things to consist in the air, which he considered as infinite or immense, and to which he ascribed a perpetual motion; that this air was the same as spirit or God, since the divine power resided in it, and agitated it. The stars were as fiery nails in the heavens; the sun a flat plate of fire; the earth an extended flat surface, &c.

ANAXIMENES, the son of Aristocles of Lampfacus, an orator, the disciple of Diogenes the Cynic, and of Zoilus the railer against Homer. He was preceptor to Alexander of Macedon, and followed him to the wars. Alexander being incensed against the people of Lampfacus, they sent this philosopher to intercede for them. Alexander, knowing the cause of his coming, swore that he would do the very reverse of whatever he desired of him. Anaximenes begged of him to destroy Lampfacus. Alexander, unwilling to break his oath, and not able to elude this stratagem, pardoned Lampfacus much against his will.

ANAZAR'BUS, or **ANAZAR'BA**, a town of Cilicia, on the river Pyramus, the birth-place of Dioscorides, and of the poet Oppian. It was sometimes called *Cæsarea*, in honour either of Augustus or of Tiberius. It was destroyed by a dreadful earthquake in the year 525, along with several other important cities: but they were all repaired at a vast expence by the emperor Justin; who was so much affected with their misfortune, that, putting off the diadem, &c. he appeared for several days in sackcloth.

ANBLATUM, *f.* in botany. See **LATHRÆA**.

AN'BERTKEND, in the eastern language, a celebrated book of the Brachmans, wherein the Indian philosophy and religion are contained. The word in its literal sense denotes the cistern wherein is the water of life. The Anbertkend is divided into fifty beths or discourses, each of which consists of ten chapters. It has been translated from the original Indian into Arabic, under the title of *Morat al Maani*, q. d. "the marrow of intelligence."

ANCE'US, the son of Neptune and Astypalæa, who went with the Argonauts, and succeeded Tiphis as pilot of the ship Argo. He reigned in Ionia, and was once told by a slave, whom he pressed with hard labour in his vineyard, that he never would taste of the produce of his vines. Anceus laughed at this prediction, caused a cup of it to be brought immediately, and told him he was a false prophet. Not yet, replied the slave, for many things fall out be-

tween the cup and the lip. Just then he was informed that a wild boar had entered his vineyard; upon which he threw down the cup, and ran to drive away the animal, but was slain in the attempt.

ANCARA'NO, a town of Italy, in the march of Ancona, situated in Lat. 42. 48. N. lon. 14. 54. E.

AN'CASTER, [*of an, and cafter, Sax. a castle,*] Is a town in Lincolnshire of great antiquity, which is taken by some to be the *Crococolana* of Antoninus. At the south end of it are the remains of a castle, encompassed by a ditch and rampart. The area against the east end of the church, where the castle once stood, is large; and on the highest ground of the area stand the ruins of a chapel, dedicated to St. Mary, adjoining which is an hermitage. The townlet is divided into two lordships: the east side, whereon stood the castle, is in the township of Wilsford; the west side is in the township of Ancaster, whereon stands the church, which was built by the Romans; it is a neat building, with a lofty spire, dedicated to St. Martin, and is a vicarage. The town consists chiefly of one street, leading from north to south. On the west side of the town is a road, which was formerly designed for the use of such as travelled after the gates were shut. To the south of the castle is a fine running spring, called Lady's Well; it was never known to rise more than an inch, or to fail of water; it takes its course towards the castle, where emptying itself into a pool, it is no more seen. It is said there is no other spring from hence to Lincoln, which is fifteen miles. There have been vast quantities of human bones found in the town and adjacent villages, some not more than a foot below the surface of the earth, and others at the depth of seven. This town abounds with the remnants of antiquity; the sale of which has, for many years, been carried on by the inhabitants; for, after a hasty shower, the shepherds and school-boys go to seek them in the neighbouring declivities and quarries. This town gives the title of duke to the noble family of Bertie. Ancaster is distant from Sleaford six miles, Boston twenty-three, Grantham eight, Newark fifteen, Folkingham ten, Nottingham thirty-two, Stamford twenty-six, and London 115. Lat. 52. 30. N. lon. 30. 0. W.

ANCE'NIS, a town seated on the river Loire, in the department of Lower Loire, twenty miles east of Nantes.

AN'CESTOR, *f.* [*ancestor, Lat. anceſtre, Fr.*] One from whom a person descends, either by the father or the mother. It is distinguished from *predecessor*; which is not, like *anceſtor*, a natural, but civil, denomination. An hereditary monarch succeeds to his *anceſtors*; an elective, to his *predecessors*.

Most nations have paid honours to their ancestors. It was properly the departed souls of their forefathers that the Romans worshipped under the denominations of *lares*, *lemures*, and *household gods*. Hence the ancient tombs were a kind of temples, or rather altars, wherein oblations were made by the kindred of the deceased. The Chinese seem to have distinguished themselves above all other nations in the veneration they bear their ancestors. By the laws of Confucius, part of the duty which children owe their parents consists in worshipping them when dead. This service, which makes a considerable part of the natural religion of the Chinese, is said to have been instituted by the emperor Kun, the fifth in order from the foundation of that ancient empire.

ANCESTOR, in law, is one from whom an inheritance is derived. No person can be properly such an ancestor as that an inheritance in lands or tenements can be derived from him, unless he hath had actual seisin of such lands, either by his own entry, or by the possession of his own or his ancestor's lessee for years, or by receiving rent from the lessee of the freehold; or unless he hath had what is equivalent to corporal seisin in hereditaments that are incorporeal; such as the receipt of rent, the presentation to a church, and such like. 2 *Blackst.* 209.

AN'CESTREL, *adj.* Claimed from ancestors; relating to ancestors.

AN'CESTRY,

ANCESTRY, *f.* Lineage; a series of ancestors, or progenitors; the persons who compose the lineage.—A tenacious adherence to the rights and liberties transmitted from a wife and virtuous *ancestry*, public spirit, and a love of one's country, are the support and ornaments of government. *Addison*. The honour of descent; birth.—Title and *ancestry* render a good man more illustrious, but an ill one more contemptible. *Addison*.

ANCHENTRY, *f.* [from *ancient*, and therefore properly to be written *ancientry*.] Antiquity of a family; ancient dignity; appearance or proof of antiquity.

ANCHILOPS, *f.* [*αγκυλον*, contraction, and *αψ*, eye.] In medicine, denotes an abscess, or collection of matter, between the great angle of the eye and the nose. If suffered to remain too long, or unskilfully managed, it degenerates, the stagnating humours corrupt, and an ulcer is produced. When the tumour is broke, and the tears flow involuntarily, whilst the os lacrymale is not carious, it is an *aglyops*; but when the ulcer is of a long standing, deep, fetid, and the os lacrymale becomes carious, it is a *stypula*. The cure is by restriction and excision, tying it at the root on the glandula lacrymalis, and, when ready, cutting it off. See *SURGERY Index*.

ANCHISES, a Trojan prince, son of Capys, and father of Æneas, by the goddess Venus. In his youth he fed cattle at the foot of mount Ida. After the burning of Troy, he could not fly from the city on account of his age; and therefore Æneas carried him on his back. He bore his household gods along with him, and died in Sicily, where his son erected a magnificent tomb to his memory.

ANCHOR, *f.* [*anchora*, Lat. of *αγκυρα*, Gr.] A heavy iron, composed of a long shank, having a ring at one end to which the cable is fastened, and at the other branching out into two arms or flocks, tending upwards, with barbs on each side. Its use is to hold the ship, by being fixed to the ground. It is used, by a metaphor, for any thing which confers stability or security.—Which hope we have as an *anchor* of the soul, both sure and steadfast, and which entereth into that within the veil. *Hebrews*. The forms of speech in which it is most used are, to *cast anchor*, to *lie* or *ride* at anchor.

The most ancient anchors are said to have been of stone; and sometimes of wood, to which a great quantity of lead was usually fixed. In some places, baskets full of stones, and sacks filled with sand, were employed for the same use. All these were let down by cords into the sea; and by their weight stayed the course of the ship. Afterwards they were composed of iron, and furnished with teeth, which, being fastened to the bottom of the sea, preserved the vessel immovable; whence *odortes*, and *dentes*, are frequently taken for anchors in the Greek and Latin poets. At first there was only one tooth, whence anchors were called *ἑποστόμοι*; but in a short time the second was added by Eupalamus, or Anacharis, the Scythian philosopher. The anchors with two teeth were called *αμφιβολοι* or *αμφιστομοι*; and from ancient monuments appear to have been much the same with those used in our days, only the transverse piece of wood upon their handles, the stock, is wanting in all of them. Every ship had several anchors; one of which, surpassing all the rest in bigness and strength, was particularly termed *ῥεγα*, or *sacra*; and was never used but in extreme danger; whence *sacram anchoram solvere*, is proverbially applied to such as are forced to their last refuge.

The anchors now made are contrived so as to sink into the ground as soon as they reach it, and to hold a great strain before they can be loosened or dislodged from their station. They are composed of a shank, a stock, a ring, and two arms with their flocks. The stock serves to guide the flocks in a direction perpendicular to the surface of the ground; so that one of them sinks into it by its own weight as soon as it falls, and is still preserved steadily in that position by the stock, which, together with the shank, lies flat on the bottom. In this situation it must necessarily sustain a great effort before it can be dragged through the

earth horizontally. Indeed this can only be effected by the violence of the wind or tide, or both of them, sometimes increased by the turbulence of the sea, and acting upon the ship so as to stretch the cable to its utmost tension, which accordingly may dislodge the anchor from its bed, especially if the ground be soft and oozy, or rocky. When the anchor is thus displaced, it is said, in the sea-phrases, to *come home*. Every ship has, or ought to have, three principal anchors, with a cable to each, viz. the sheet, *maitresse-ancre* (which is the *anchora sacra* of the ancients); the best bower, *second ancre*; and small bower, *ancre d'affourche*, so called from their usual situation on the ship's bows. There are besides smaller anchors, for removing a ship from place to place in a harbour or river, where there may not be room or wind for sailing; these are the stream anchor, *ancre de toue*; the kedge and grappling, *grapin*: this last, however, is chiefly designed for boats.

In England, France, and Holland, anchors are made of forged iron; but in Spain they are sometimes made of copper, and likewise in several parts of the South Sea. M. Bouguer, in his *Traité de Navire*, directs to take the length of the shank in inches, and to divide the cube of it by 1160 for the weight. The reason is obvious; because the quotient of the cube of 201 inches, which is the length of an anchor weighing 7000 lb. divided by the weight, is 1160; and therefore, by the rule of three, this will be a common divisor for the cube of any length, and a single operation will suffice. The same author gives the following dimensions of the several parts of an anchor. The two arms generally form the arch of a circle, whose centre is three-eighths of the shank from the vertex, or point where it is fixed to the shank; and each arm is equal to the same length, or the radius; so that the two arms together make an arch of 120 degrees: the flocks are half the length of the arms, and their breadth two-fifths of the said length. With respect to the thickness, the circumference at the throat, or vertex of the shank, is generally made about a fifth part of its length, and the small end two-thirds of the throat; the small end of the arms of the flocks, three-fourths of the circumference of the shank at the throat. These dimensions should be enlarged when the iron is of a bad quality, especially if cast iron is used instead of forged iron.

ANCHOR of Brandy, in Holland, ten English wine gallons.

To ANCHOR, *v. n.* To cast anchor; to lie at anchor. To stop at; to rest on:

My intention, hearing not my tongue,
Anchors on Isabel.

Shakespeare.

To ANCHOR, *v. a.* To place at anchor; as, he *anchored* his ship. To fix on:

My tongue should to my ears not name my boys,
Till that my nails were *anchor'd* in thine eyes. *Shakespeare.*

ANCHOR-HOLD, *f.* The hold or fastness of the anchor; and, figuratively, security.—The old English could express most aptly all the conceits of the mind in their own tongue, without borrowing from any; as for example: the holy service of God, which the Latins called *religion*, because it knitted the minds of men together, and most people of Europe have borrowed the same from them, they called most significantly *ean-fastness*, as the one and only assurance and fast *anchor-hold* of our souls health. *Camden*.

ANCHOR-SMITH, *f.* The maker or forger of anchors.—Smithing comprehends all trades which use either forge or file, from the *anchor-smith* to the watch-maker; they all working by the same rules, though not with equal exactness; and all using the same tools, though of several sizes. *Moxon*.

ANCHORAGE, *f.* The hold of the anchor.—Let me resolve whether there be indeed such efficacy in nurture and first production; for, if that supposal should fail us, all our *anchorage* were loose, and we should but wander in

a wild sea. *Wotton*. The set of anchors belonging to a ship. The duty paid for the liberty of anchoring in a port.

ANCHORED, *part. adj.* Held by the anchor :—

Like a well-twisted cable, holding fast
The anchor'd vessel in the loudest blast.

Waller.

ANCHORESS, *f.* A nun.

ANCHORET, *f.* [*anchorette*, Fr. *anchoreta*, Lat. of *αγκυρητης*, of *αγκυρα*, and *χωρεω*, to retire.] A recluse; a hermit; one that retires to the more severe duties of religion.

ANCHOVY, *f.* in ichthyology, the English name of the clupea encrasicolus. See CLUPEA.

ANCHOVY-PEAR, *f.* in botany. See GRIAS.

ANCHURUS, in fabulous history, a son of Midas, king of Phrygia, who sacrificed himself for the good of his country. The earth having opened and swallowed up many buildings, the oracle was consulted, which gave for answer, that the gulf would never close, if Midas did not throw into it whatever he had most precious. The king parted with many things of immense value, yet the earth continued open, till Anchurus, thinking himself the most precious of his father's possessions, leaped into the gulf, which closed immediately. Midas erected there an altar of stones to Jupiter, and that altar was the first object which he turned into gold, when he had received his fatal gift from the gods. This unpolished lump of gold existed in the age of Plutarch.

ANCHUSA, *f.* [*αγκυσα*, *παρε το αγκυρι*, Gr. from its supposed constringent quality; or, as others say, because it strangles serpents.] In botany, a genus of the pentandria monogynia class, ranking in the natural order of asperifoliae. The generic characters are—Calyx: perianthium five-parted, oblong, round, acute, permanent. Corolla: monopetalous, funnel-shaped; tube cylindrical, the length of the calyx; limb semiquinquefid, from erect, expanding, obtuse; throat closed with five small scales; convex, prominent, oblong, converging. Stamens: filaments very short, in the throat of the corolla; antheræ oblong, incumbent, covered. Pistillum: germs four; style filiform, the length of the stamens; stigma obtuse, emarginate. Pericarpium: none; but the calyx enlarged, and erect, contains the seeds in its bosom. Seeds: four; oblongish, obtuse, gibbose.—*Essential Character.* Corolla, funnel-shaped, the throat enclosed with an arch of scales. Seeds engraved at the base.

Species. 1. *Anchusa officinalis*, or officinal or garden alkanet or bugloss: leaves lanceolate, spikes imbricate, pointing one way. Stems from a foot to eighteen inches in height, and more, the thickness of a finger, slightly angular, hairy, and rough. Leaves seven inches long, above an inch broad, hairy, and rough. This plant flowers in June, July, and August; and the seeds ripen in a month. It grows wild in Italy, Spain, France, Germany, Sweden, Denmark, and Siberia, by road sides, and in corn fields. When tender in the spring, it is eaten boiled in Upland. The tube of the corolla is melliferous, and the bees are very fond of it. This is not the *anchusa*, but the *bugloss*, of the officinal writers. It appears to be nearly similar to borage; the leaves being less juicy, and the roots more mucilaginous; these, with the leaves and flowers, are ranked among the articles of the materia medica, but they are very seldom made use of. In China, this plant is in great esteem, for gently promoting the eruption in the small-pox.

2. *Anchusa angustifolia*, or narrow-leaved alkanet: racemes almost naked in pairs. Grows to the height of two feet when cultivated in gardens, but, in the places where it grows wild, is rarely more than a foot. The leaves are narrow, and less hairy than those of the first; the spikes of flowers come out double, and have no leaves about them; the flowers are small, and of a red colour. The roots will continue three or four years in poor land. Haller thinks that this is not a distinct species from the first; Linnæus acknowledges that they are very much alike; but, according to Retzius, most authors have mista-

ken the three first species. It is found wild in Italy, Germany, and Switzerland; flowering in July and August, by way-sides, and the borders of ploughed fields. Boerhaave recommended the juice in the pleurisy, and in maniacal cases.

3. *Anchusa Italica*, or Italian alkanet: leaves lucid, strigose; racemes two-parted, two-leaved, flowers somewhat unequal, bearded at the throat. This differs from the first species in size; in that the flowers are equal and funnel-shaped; in this they are salver-shaped; they are much more imbricate in that, the segments of the calyx broader and shorter; those of the corolla ovate; with the scales of the throat only slightly tomentose.

4. *Anchusa undulata*, or waved alkanet: strigose, leaves linear toothed, pedicels less than the bracteæ, fruit-bearing calyxes inflated. Height three feet, with many strong lateral branches, produced from the main stem near the ground. Leaves stiff, rough, six or seven inches long, and about half an inch broad at the top, closely embracing the branches at the base, where they are two inches broad; indented and waved on their edges; the upper surface beset with hairs, and very rough to the touch. The root commonly decays after the seeds are perfected; though sometimes, when it grows upon gravel, or in the joints of stone walls, it will live three or four years. Such plants are seldom more than a foot high, and have small narrow leaves; so that they appear like a different species. It is a native of Spain and Portugal. Gmelin also found it in Siberia.

5. *Anchusa tinctoria*, or dyer's alkanet: downy, leaves lanceolate, obtuse, stamens shorter than the corollas. This species rises near as high as the first, to which it bears great resemblance in its leaves and branches, only that they are more woolly; the stamens are also shorter than the corolla. The root is red. It much resembles the seventh species, and is entirely clothed with a white down. It grows about Montpellier, in Silesia, Spain, and Italy. Cultivated here in 1683, by Mr. James Sutherland. This plant is cultivated in the south of France, for the deep purplish red colour of the roots. It imparts a fine deep red to oils, wax, and all unctuous substances, as well as to spirit of wine. The spirituous tincture, on being inspissated, changes to a dark brown. Its chief use is for colouring plasters, lip-salves, &c. Roots of bugloss boiled in Brazil wood are substituted for those of alkanet; but these will not die oils red.

6. *Anchusa Virginica*, or Virginian alkanet: flowers scattered, stem smooth. This seldom rises a foot high in good ground, but not above half that height where the soil is poor. The flowers grow in loose spikes, upon a smooth stalk. It is perennial, and a native of North America, where it grows in the woods; and, being an early plant, generally flowers before the trees are in leaf; so that, where it abounds, the earth seems covered with bright yellow flowers. It is known in that country by the name of Puccoon.

7. *Anchusa lanata*, or woolly alkanet: leaves villose, calyxes shaggy, stamens longer than the corollas. Found by Brander near Algiers; and very like the fifth species.

8. *Anchusa sempervirens*, or evergreen alkanet: leaves ovate, peduncles two-leaved, racemed. It is found wild in Spain and Italy. With us it has crept out of gardens, and has been remarked growing spontaneously near Rochester, Haddiscoe in Suffolk, Cambridge, Birmingham, Worcester, and London; by road-sides, among rubbish, and from the joints of old walls. It flowers from May through a great part of the summer, and is perennial. Kine, horses, sheep, and goats, are said to eat it: and it has the same qualities with the first and second species.

9. *Anchusa Barrelieri*, or Barrelier's alkanet: leaves ovate-lanceolate; stem erect, peduncles racemed, pointing one way. Found in Piedmont by Bellardi.

10. *Anchusa paniculata*, or panicled alkanet or bugloss: leaves lanceolate strigose quite entire, panicle dichotomous divaricate, flowers peduncled, calyxes five-parted, with subulate

subulate segments. This is biennial; flowers in May and June, and is a native of Madeira.

Propagation and Culture. The roots seldom continue longer than two years, except when they grow in rubbish, or out of a wall. They may all easily be propagated by seeds, sown in the autumn, upon a bed of light sandy earth; and in the spring, when the plants are strong enough to remove, they should be planted in beds, at two feet distance; observing, if the season prove dry, to water them till they have taken root, after which they will require no farther care, but to keep them clear from weeds. If the seeds of the common sorts be permitted to scatter, the plants will rise in plenty. See BARLERIA, BORAGO, LITHOSPERMUM, MYOSOTIS, ONOSMA, and PULMONARIA.

ANCIENT, *adj.* [*ancien*, Fr. *antiquus*, Lat.] Old; that happened long since; of old time; not modern. *Ancient* and *old* are distinguished; *old* relates to the duration of the thing itself, as, An *old* coat, a coat much worn; and *ancient*, to time in general, as, An *ancient* dress, a habit used in former times. But this is not always observed, for we mention *old* customs; but though *old* be sometimes opposed to *modern*, *ancient* is seldom opposed to *new*, but when *new* means *modern*. Old; that has been of long duration.—With the *ancient* is wisdom, and in length of days understanding. *Job*, xii. 12. Past; former.

ANCIENT, *f.* Those that lived in old time were called *ancients*, opposed to the moderns:

And though the *ancients* thus their rules invade,
As kings dispense with laws themselves have made;
Moderns, beware! or, if you must offend
Against the precept, ne'er transgress its end. *Pope.*

ANCIENT, *f.* The flag or streamer of a ship, and, formerly, of a regiment. The bearer of a flag, as was *Ancient Pistol*; whence, in present use, ensign:

This is Othello's *ancient*, as I take it.
The same, indeed, a very valiant fellow. *Shakespeare.*

ANCIENT DEMESNE, in law, a tenure whereby all manors belonging to the crown in William the Conqueror's and Edward the Confessor's time were held. The numbers, names, &c. hereof were entered by the Conqueror, in a book called *Domesday Book*, still remaining in the Exchequer; so that such lands as by that book appeared to have belonged to the crown at that time, are called *ancient demesne*. The tenants of ancient demesne are of two sorts; one who hold their lands frankly by charter; the other by copy of court-roll, or by the verge, at the will of the lord, according to the custom of the manor. The advantages of this tenure are, 1. That tenants holding by charter cannot be rightfully impleaded out of their manor; and, when they are, they may abate the writ, by pleading the tenure. 2. They are free from toll for all things relating to their livelihood and husbandry; nor can be impannelled on any inquest. These tenants held originally by ploughing the king's land, ploughing his hedges, and the like service, for the maintenance of his household; and it was on this account that such liberties were given them, for which they may have writs of *monstraverunt* to such as take the duties of toll, &c. No lands are to be accounted ancient demesne, but such as are held in socage. Whether land be ancient demesne or not, shall be tried by the book of *Domesday*.

ANCIENTLY, *adv.* In old times.—The colewort is not an enemy, though that were *anciently* received, to the vine only, but to any other plant, because it draweth strongly the fattest juice of the earth. *Bacon.*

ANCIENTNESS, *f.* Antiquity; existence from old times.—The Fescenine and Saturnian were the same; they were called Saturnian from their *ancientness*, when Saturn reigned in Italy. *Dryden.*

ANCIENTRY, *f.* The honour of ancient lineage; the dignity of birth.—Of all nations under heaven, the Spaniard is the most mingled and most uncertain. Wherefore, most foolishly do the Irish think to ennoble themselves, by

wresting their *ancientry* from the Spaniard, who is unable to derive himself from any in certain. *Spenser.*

ANCIL'IA, *f.* See ANCYLE.

ANCIL'LON (David), a minister of the reformed church at Metz, where he was born on the 17th of March 1617. He went to Geneva in 1623; and studied divinity under Spanheim, Diodati, and Tronchin, who conceived a very great esteem for him. He left Geneva in April 1641, and offered himself to the synod of Charenton, in order to take upon him the office of a minister: his abilities were greatly admired by the examiners, and the whole assembly were so highly pleased with him, that they gave him the church of Meaux, the most considerable then unprovided for. He returned to his own country in the year 1653, where he remained till the revocation of the edict of Nantes in 1685. He retired to Francfort after this fatal blow; and, having preached at the French church at Hanau, the professors of divinity, and the German and Dutch ministers, attended his sermons frequently: the count of Hanau himself, who had never before been seen in the French church, came hither to hear Mr. Ancillon. This occasioned a great jealousy in the two other ministers; which tended to make his situation uneasy. He therefore went to Berlin; where he met with a kind reception from the elector, and was made minister of the city. Here he had the pleasure of seeing his eldest son made judge and director of the French in the same city, and his other son rewarded with a pension, and entertained at the university of Francfort upon the Oder. He had likewise the satisfaction of seeing his brother made judge of all the French in the states of Brandenburg; and his son-in-law, engineer to his electoral highness. He enjoyed these agreeable circumstances, and several others, till his death, which happened at Berlin the 3d of September, 1692, when he was seventy-five years of age. He published a book, in quarto, in which the whole dispute concerning Traditions is fully examined: he also wrote an apology for Luther, Zuinglius, Calvin, and Beza, and several other pieces.

ANCIS'TRUM, *f.* [*αγκιστρον*, Gr. a hook.] In botany, a genus of the diandria monogynia class, ranking in the natural order of rosaceæ. The generic characters are—Calyx: perianthium one-leaved, turbinate, truncate, four-toothed; teeth cylindrical-awned, erect, terminating in four reversed hooks. Corolla: superior, one-petalled, funnel-shaped with a very short tube, and a spreading quadrifid border; the divisions nearly equal, obtuse, the length of the tube. Stamina: filaments fastened to the base of the tube, longer than the corolla, capillary; anthers roundish. Pistillum: germ oblong; style filiform, the length of the corolla; stigma pencil-shaped. Pericarpium: none, but the calyx; in the bottom of which is the fruit. Seed: single, oblong.—*Essential Character.* Calyx, four-leaved. Corolla, none. Stigma, many-parted. Drupe, dry, hispid, one-celled.

Species. 1. *Ancistrum decumbens*: stems decumbent, peduncle scape-form solitary, flowers in a globular head, leaflets wedge-form deeply serrate hoary beneath, seed covered with the thickened calyx. It resembles burnet in the herb and manner of flowering; and is a native of New Zealand.

2. *Ancistrum lucidum*, or shining *ancistrum*: stems subdemerged, peduncles scape-form, spikes ovate, leaflets oblong quite entire acute subsaccicled. Native of Falkland Islands; flowers in May and June.

3. *Ancistrum latebrosum*, or hairy *ancistrum*: stems demerged, peduncles scape-form, spikes elongate, leaflets oblong gashed villose, fruits armed on every side. The structure of the fruit in this species is somewhat different from that in the first; but the difference is not considerable, and the structure of the other parts is nearly the same in both.

AN'CLAM, a town of the Western, Swedish, or Royal, Pomerania, in Upper Saxony. It made a good figure once among the Hanse-towns, and has an advantageous site among good corn lands and excellent pastures, with the convenience,

convenience of fishing and exporting their commodities, by means of the river Pene, on which it is seated. Formerly it was called Tanglim, and some have supposed it to have been the seat of the Angli, mentioned by Tacitus; some of whom removed from thence to the Elbe, and from that to England. Anclam is 20 miles S. of Gripswald. Lat. 53. 52. N. lon. 14. 2. E.

AN'CLE. See ANKLE.

AN'CLIFF, a village, two miles from Wigan in Lancashire, famous for a spring called the *burning-well*, which, upon the approach of a lighted candle, takes fire, and burns like spirit of wine for a whole day.

AN'COBER, or RIO CORBE, a territory on the gold coast of Guinea, with a river of the same name flowing through it; the banks of which are adorned with fine lofty trees, affording a very agreeable shade, and on the western bank there is a populous village.

AN'CON, *f.* [αγκων, Gr.] The top or point of the elbow; the backward and greater shooting part of the cubit, called *ulna*.

ANCO'NA (marquise of), a province in the pope's territories in Italy. It lies between the gulph of Venice and mount Appenine, which bound it on the north; Abruzzo on the east; the duchy of Spoleto, and that of Urbino, on the west. The air is indifferent; but the soil is fruitful, particularly in hemp and flax; and there is great plenty of wax and honey. It contains several large towns, as Fermo, Loretto, Recanati, Macerata, Jesi, Tolentino, Ascoli, Osimo, St. Severino, Monte Alto, Camerino, and Ripatransone, which are all archiepiscopal or episcopal sees.

ANCONA, a sea-port on the Adriatic sea, the capital of the marquise of that name, and the see of a bishop. Commerce has rapidly increased here of late years, through the patronage of Clement XII. who made it a free port, and built a mole to render the harbour safe. It is erected on the ruins of the ancient mole, raised by the emperor Trajan, and is above 1000 feet in length, 100 in breadth, and about 60 in depth, from the surface of the sea. Near this stands the Triumphal Arch of Trajan, which, next to the Maison Quarree, at Nismes, is the most beautiful and entire monument of Roman magnificence existing. Here, likewise, Clement erected a lazaretto, which advances a little way into the sea, in the form of a pentagon, and is an elegant, as well as useful, edifice. The Jews have a synagogue here, and are established in great numbers. Ancona is 116 miles N. by E. of Rome. Lat. 43. 38. N. lon. 13. 35. E.

ANCO'NES, *f.* in architecture, the corners or quoins of walls, cross-beams, or rafters. Vitruvius calls the *console* by the same name.

AN'CONY, *f.* in the iron-works, a piece of half-wrought iron, of the shape of a bar in the middle, but rude and unwrought at the ends. The process for bringing the iron to this state is this: they first melt off a piece from a sow of cast iron, of the proper size; this they hammer at the forge into a mass of two feet long, and of a square shape, which they call a *bloom*; when this is done, they send it to the finery; where, after two or three heats and workings, they bring it to this figure, and call it an *ancony*. The middle part, beat out at the finery, is about three feet long, and of the shape and thickness the whole is to be; this is then sent to the chafery, and there the ends are wrought to the shape of the middle, and the whole made into a bar.

ANCORA'RUM URBS, [Αγκυρων Πολις, Gr.] A city in the Nomos Aphroditopolites, towards the Red Sea; so called because there was in the neighbourhood a stone quarry, in which they hewed stone anchors before iron ones were invented. The gentilitious name is *Ancropolites*.

AN'COURT (Florent-Carton d'), an eminent French actor and dramatic writer, born at Fontainebleau, October 1661. He studied in the Jesuits college at Paris under father de la Rue. After he had gone through a course of philosophy, he applied himself to the civil law, and was admitted an advocate at seventeen years of age. But fall-

ing in love with an actress, he was induced to go upon the stage, and he married her. As he had all the qualifications necessary for the theatre, he soon greatly distinguished himself: and, not being satisfied with the applause only of an actor, he began to write pieces for the stage. His merit in this way procured him a very favourable reception at court; and Lewis XIV. shewed him many marks of his favour. His sprightly conversation and polite behaviour made his company agreeable to all the men of figure both at court and in the city, and the most considerable persons were extremely pleased to have him at their houses. Having taken a journey to Dunkirk, he took the opportunity of paying his compliments to the elector of Bavaria, who received him with the utmost civility; and, having detained him a considerable time, dismissed him with a present of a diamond valued at 1000 pistoles: he likewise rewarded him in a very generous manner, when, upon his coming to Paris, Ancourt composed an entertainment for his diversion. Ancourt began at length to grow weary of the theatre, which he quitted in 1718, and retired to his estate of Courcelles le Roy, in Berry, where he applied himself wholly to devotion, and composed a translation of David's Psalms in verse, and a sacred tragedy, which were never printed. He died the 6th of December 1726, being sixty-five years of age. The plays which he wrote are fifty-two in all; most of which were printed separately at the time when they were first represented: they were afterwards collected into five volumes, then into seven, and at last into nine. This last edition is the most complete.

AN'CRE, a small town of France, in the late province of Picardy, with the title of a marquise, seated on a little river of the same name. Lat. 49. 59. N. lon. 2. 45. E.

ANCUS MAR'TIUS, the fourth king of the Romans, succeeded by Tullius Hostilius, 639 years before Christ. He defeated the Latins, subdued the Fidenates, conquered the Sabines, Volscii, and Veientes, enlarged Rome by joining to it mount Janicula, and made the harbour of Ostia. He died about 615 years before the Christian era.

AN'CYLE, *f.* in antiquity, a kind of shield that fell, as was pretended, from heaven, in the reign of Numa Pompilius; at which time, likewise, a voice was heard, declaring that Rome should be mistress of the world as long as she should preserve this holy buckler. It was kept with great care in the temple of Mars, under the direction of twelve priests; and, lest any should attempt to steal it, eleven others were made so like, as not to be distinguished from the sacred one. These ancylia were carried in procession every year round the city of Rome.

ANCYLOBLE'PHARON, *f.* [αγκυλοφθαλμος, bent, and βλεφαρον, an eye-lid, Gr.] A disease of the eye, which closes the eye-lids. Sometimes the eye-lids grow together, and also to the tunica albuginea of the eye, from carelessness when there is an ulcer in these parts. Both these cases are called *ancycloblepharon* by the Greeks. This disorder must be distinguished from that coalition of the eye-lids which happens from viscid matter gluing them together. If the cohesion is on the cornea, the sight is inevitably lost. This hath sometimes happened in the small-pox. If there is only a growing together of the eye-lids, they may be separated with the specillum, and pledgets kept between them to prevent their re-union. If the eye-lids adhere to the eye, they are to be separated by a fine-edged knife; and their re-union is to be prevented by a proper use of injections, and lint placed between them, after dipping it in some proper liniment.

ANCYLOGLOSSUS, *f.* [αγκυλογλωσσος, αγκυλη, a contraction, and γλωσσα, the tongue, Gr.] A contraction of the ligaments of the tongue. Some have this imperfection from their birth, others from disease. In the first case, the membrane which supports the tongue is too short or too hard: in the latter, an ulcer under the tongue, healing and forming a cicatrix, is sometimes the cause: these speak with some difficulty. The ancycloglossi by nature are late before they speak; but, when they begin, they soon speak properly. These we call *tongue-tied*. Mauri-

ceau says, that in this case it is a small membranous production, which extends from the frænulum to the tip of the tongue, that hinders the child from sucking, &c. He advises to snip it with scissars in two or three places, taking care not to extend the points of the scissars so far as the frænulum. The instances rarely occur which require any kind of assistance; for, if the child can thrust the tip of its tongue to the outer edge of its lip, this disease does not exist; and, if the tongue is not greatly restrained, the frænulum will stretch by the child's sucking and crying.

ANCYLOS'SIS, *f.* in surgery, a distortion or stiffness of the joints, caused by a settlement of the humours, or a distension of the nerves, and therefore remedies of a mollifying and relaxing nature are required.

ANCY'RA, the capital of Galatia, at no great distance from the river Halys, said to be built by Midas, king of Phrygia, and to take its name from an anchor found there. It was greatly improved by Augustus, deemed the second founder of it, as appears from the *Marmor Ancyranum*. It is now called *Angura*, or *Angora*. Lat. 39. 30. lon. 32. 5. E.

ANCYROIDES, *f.* [*αγκυροειδης*, Gr.] The shooting forth of the shoulder-bone in the form of a peak.

ANCYS'TRUM, *f.* in botany. See ANCISTRUM.

AND, *conj.* The particle by which sentences or terms are joined, which it is not easy to explain by any synonymous word.—It shall ever be my study to make discoveries of this nature in human life, *and* to settle the proper distinctions between the virtues and perfections of mankind, *and* those false colours and resemblances of them that shine alike in the eye of the vulgar. *Addison*.—*And* sometimes signifies *though*, and seems a contraction of *and if*.—It is the nature of extreme self-lovers, as they will set an house on fire, *and* it were but to roast their eggs. *Bacon*.—In *and if*, the *and* is redundant, and is omitted by all later writers.—I pray thee, Launce, *an' if* thou see'st my boy, bid him make haste. *Shakespeare*.

ANDABA'TÆ, *f.* in antiquity, a sort of gladiators, who, mounted on horseback or in chariots, fought hood-winked, having a helmet that covered their eyes.

ANDALUSIA, [it is now become a fashion to pronounce it ANDALUSIA.] The most western province of Spain, having Estremadura and La Mancha on the north; the kingdom of Granada, the straits of Gibraltar, and the ocean, on the south; and, on the west, the kingdom of Algarva in Portugal, from which it is separated by the river Guadiana. It is about 250 miles long, and 150 broad. The chief cities and towns are Seville the capital, Baeza, Gibraltar, Corduba, Cadiz, Medina Sidonia, Jaen, Port St. Mary, &c. It is the best, most fruitful, and the richest, part of all Spain. There is a good air, a serene sky, a fertile soil, and an extent of sea-coast fit for commerce.

New ANDALUSIA, a division of the province of Terra Firma in South America, whose boundaries cannot be well ascertained, as the Spaniards pretend a right to countries in which they have never established any settlements. According to the most reasonable limits, it extends in length 500 miles from north to south, and about 270 in breadth from east to west. The interior country is woody and mountainous, variegated with fine valleys that yield corn and pasturage. The produce of the country consists chiefly in dyeing-drugs, gums, medicinal-roots, brazil-wood, sugar, tobacco, and some valuable timber. To this province also belonged five valuable pearl-fisheries. The capital of New Andalusia is Comana, Cumana, or New Corduba, situated in lat. 9. 55. N. about nine miles from the north sea. Here the Spaniards laid the foundation of a town in the year 1520. The place is strong by nature, and fortified by a castle capable of making a vigorous defence; as appeared in the year 1670, when it was assaulted by the buccaners, who were repulsed with great slaughter.

ANDAMAN or ANDE'MAN Islands, in the East Indies, situated on the east side of the entrance of the bay of Bengal, about eighty leagues distance from Tanaserim on the coast of Siam. The East-India ships sometimes

touch at them, and are supplied by the natives with rice, herbs, and fruits. Lat. from 10° to 15° N. lon. 92. 0. E.

ANDANAGAR, a beautiful, rich, and populous town, of the province of Deccan.

ANDAN'TE, in music, signifies a movement moderately slow, between *largo* and *allegro*.

ANDAY'E, a town in the department of the Lower Pyrenees, famous for its brandy. It is situated at the mouth of the river Bidassoa, opposite Fontarabia in Spain, eighteen miles from Bayonne. Lat. 43. 25. N. lon. 1. 45. W.

AN'DE, a river of Hampshire, that rises in the forest of Chute.

AN'DELY, a town in the department of Eure, and late province of Normandy, in France, is divided by a paved road into two little towns, Great and Little Andely; the former on the river Gambons, the latter on the Seine. The cloths manufactured here are very fine. It is twenty miles south-east of Rouen, and sixty north-west of Paris. Lat. 49. 20 N. lon. 1. 30. E.

ANDE'NA, in old writers, denotes the swarth made in mowing of hay, or as much ground as a man could stride over at once.

AN'DERAB, the most southern city of the province of Balkh, possessed by the Usbeck Tartars. It is very rich and populous, but a place of no great strength. The neighbouring mountains yield excellent quarries of lapis lazuli, in which the Bukhars drive a great trade with Persia and India. This city is situated at the foot of the mountains dividing the dominions of the Great Mogul and Persia from Great Bukharia. As there is no other way of crossing these mountains but by the road through this city, all travellers with goods must pay 4 per cent. On this account the khan of Balkh maintains a great number of soldiers in the place.

AN'DERNACHT, a small town of Cologne, seated on the Rhine, and near it there are some excellent mineral waters. There is some trade carried on here in large timber, which is floated down to this place, and hence to Holland. It is ten miles north-west of Coblenz. Lat. 50. 29. N. lon. 7. 22. E.

ANDE'RO (St.) a sea-port town in the bay of Biscay, in Old Castile, seated on a small peninsula. It is a trading-town, and contains about 700 houses, two parish-churches, and four monasteries. Here the Spaniards build and lay up some of their men of war. Lat. 43. 20. N. lon. 4. 30. W.

AN'DERSON (Sir Edmund), a younger son of an ancient Scotch family settled in Lincolnshire. He was some time a student of Lincoln-college, Oxford; and removed from thence to the Inner Temple, where he applied himself diligently to the study of the law, and became a barrister. In the nineteenth year of the reign of queen Elizabeth he was appointed her majesty's serjeant at law; and, some time after, one of the justices of the assize. In 1582 he was made lord chief justice of the common pleas, and in the year following was knighted. He held his office to the end of his life, died in the year 1605, and was buried at Eyworth in Bedfordshire. His works are, 1. Reports of many Principal Cases argued and adjudged in the time of Queen Elizabeth in the Common Bench. Lond. 1644, fol. 2. Resolutions and Judgments on the Cases and Matters agitated in all the Courts of Westminster, in the latter end of the reign of Queen Elizabeth; published by John Goldborough, Esq. Lond. 1653, 4to. Besides these, there is a manuscript copy of his Readings still in being.

AN'DERSON (Alexander), one of the brightest ornaments of the mathematical world, who flourished about 200 years ago. He was born at Aberdeen in Scotland, towards the latter part of the 16th century, and was professor of mathematics at Paris in the early part of the 17th, where he published several ingenious works in geometry and algebra, both of his own, and of his friend Vieta's. Alexander was cousin-german to a Mr. David Anderson,

of Finshaugh, a gentleman who also possessed a singular turn for mathematical and mechanical knowledge. This mathematical genius was hereditary in the family of the Andersons, and from them it seems to have been transmitted to their descendants of the name of Gregory in the same country: the daughter of the said David Anderson having been the mother of the celebrated mathematician James Gregory, and who herself first instructed her son James in the elements of the mathematics, upon her observing in him, while yet a child, a strong propensity to those sciences.

ANDES, or CORDILLERAS, a huge chain of mountains, or rather two ridges or cordilleras, running almost the whole length of South America, from the isthmus of Darien to the straits of Magellan, through Peru and Chili, a distance of 4300 miles; and in a line parallel to, and but a little distance from, the Pacific ocean. They are also the loftiest, as well as the most extensive, range of hills in the whole world. Even the plain of Quito, which may be considered as a base of the Andes, is elevated farther above the sea than the top of the Pyrenees; and, in different places, they rise more than one-third higher than the Pike of Teneriffe, heretofore accounted the highest part of the whole earth. The Andes may literally be said to hide their heads in the clouds: the storms often roll, and and the thunders burst, below their summits; which, tho' exposed to the rays of the sun, in the centre of the torrid zone, are covered with everlasting snows. From experiments made with a barometer, on the mountain of Cotopaxi, it appeared, that its summit was elevated 6252 yards, which is something more than three geographical miles, above the surface of the sea. These mountains give rise to the largest rivers in the world; and, when the volcanoes, which are numerous here, break out among the snows, the sudden thaws produce such torrents of water, as to deluge the plains, and carry off the inhabitants, both man and beast.

ANDES, a hamlet of Mantua in Italy, celebrated as the birth-place of Virgil. It is now called *Pietola*, two miles to the west of Mantua.

ANDETRIUM, or ANDRECIUM, an inland town of Dalmatia. It is described as situated near Salonæ, on a naturally strong and inaccessible rock, surrounded with deep valleys, and rapid torrents; from which it appears to be the citadel now called *Cissa*. Lat. 43. 20. lon. 17. 46. E.

ANDEUSE, a city of the late province of Languedoc in France, situated in Lat. 43. 45. N. lon. 3. 40. E.

ANDIRON, *f.* [supposed by Skinner to be corrupted from *hand-iron*; an iron that may be moved by the hand, or may supply the place of a hand.] Irons at the end of a fire-grate, in which the spit turns; or iron in which wood is laid to burn.—If you strike an entire body, as an *andiron* of brass, at the top, it maketh a more treble sound, and at the bottom a baser. *Bacon*.

ANDOMADUNUM, a city of Gallia Belgica; now *Langres* in Champagne, situated on an eminence on the borders of Burgundy, at the springs of the Marne. Lat. 48. 0. N. lon. 5. 22. E.

ANDOVER, [*andefaran*, Sax. i. e. the ferry of the river Anton,] is a borough-town in Hampshire, and stands on the river Ande, being a great thoroughfare on the direct western road, as well from Newbury to Salisbury, as from London to Exeter, Taunton, and all the manufacturing towns of Wiltshire, Somersetshire, &c. whereby it is greatly enriched, and is become a handsome, thriving, well-built, populous, place. It is said to have had its first charter from king John; but was last incorporated by queen Elizabeth; being governed by a bailiff, high-steward, recorder, ten approved men, (out of whom are chosen two justices,) and twenty-two capital burgesses, who annually chuse the bailiff, and he elects two sergeants at mace to attend him. Here is an hospital for six poor men, built and endowed by Mr. Pollen, formerly one of its representatives. Here is likewise a free grammar-school, founded in 1569, by John Hanford, Esq. for educating thirty poor

boys. The church is an ancient edifice, but stands high, and is very neat. In a large open square stands the market-house; a handsome spacious modern building, with a council-room over, where the business of the corporation is transacted, and where the public entertainments and assemblies are held. The market, which is pretty considerable, is held on Saturdays; and here are three fairs annually, viz. on Midlent Saturday, 12th of May, and 6th of November; exclusive of Weyhill fair, which is held on the 9th of October, and following days, on a fine open down, contiguous to the village of Weyhill, three miles distant from Andover; and is the greatest fair in this kingdom for hops and sheep. The whole west of England is supplied with hops from it, which are the produce of Farnham, Alton, Crondall, Froyle, and all the Surry and Hampshire growth; and with ewes for store sheep, it supplies the farmers of the counties of Berks, Oxford, Bucks, Bedford, Hertford, Middlesex, Kent, Surry, and Sussex; who depend almost entirely on this fair for their supply.

A considerable trade is carried on at Andover in the malting; as also in a manufacture of shalloons. The town is admirably situated on the margin of the fine open Wiltshire down, and at the edge of an extensive woodland country, which forms the north-western side of the opulent county of Hants. Andover was a place well known to the Romans; and near it they had camps, both on Quarley-hill, and at Brehill, where their sites may be still traced, many of the trenches not being filled up. A navigable canal is now completed from this town through Stockbridge and Romsey, to the sea at Southampton. A junction between this canal, and that at Basingstoke, as also betwixt Salisbury and Bristol, is now going on.

Andover is fourteen miles north by west of Winchester, and sixty-five west by south of London. Lat. 51. 14. N. lon. 1. 20. W.

ANDRA'DA (Diego de Payva d'), or ANDRA'DIUS, a learned Portuguese, born at Conimbrã, who distinguished himself at the council of Trent, where king Sebastian sent him as one of his divines. There is scarcely any Catholic author who has been more quoted by the Protestants than he, because he maintained some opinions a little extravagant concerning the salvation of the heathens. Andrada was esteemed an excellent preacher. His sermons were published in three parts, the second of which was translated into Spanish by Benedict de Alcoran. Many encomiums have been bestowed upon Andrada. Oforius, in his preface to the "Orthodox Explanations of Andradus," gives him the character of a man of wit, vast application, great knowledge in the languages, with all the zeal and eloquence necessary to a good preacher; and Roswedius says, that he brought to the council of Trent the understanding of a most profound divine, and the eloquence of a consummate orator.

ANDRACH'NE, *f.* [*αχνα*, Gr. glume or chaff.] In botany, a genus of the monoecia gynandria class, ranking in the natural order of tricoccæ. The generic characters are—*I. Male.* Calyx: perianthium five-leaved, equal, marcescent. Corolla: petals five, emarginate, slender, shorter than the calyx; nectary, leaflets five, semibifid, herbaceous, one within each petal, and less than it. Stamina: filaments five, small, inserted into the rudiment of each style; antheræ simple. *II. Female.* Calyx: perianthium five-leaved, equal permanent. Corolla: petals none; nectary as in the male. Pistillum: germ superior, globose; styles three, filiform, two-parted; stigmas globose. Pericarpium: capsule globose-trilobate, three-celled; cells bivalved, the size of the calyx. Seeds: in pairs, rounded on one side, triangular and obtuse on the other.—*Essential Character.* Male. Calyx, five-leaved; corolla, five-petalled; stamina, five, inserted into the rudiment of the style. Female. Calyx, five-leaved; corolla, none; styles, three; capsule, three-celled; seeds, two.

Species. 1. *Andrachne telephoides*: procumbent and herbaceous. This is a low plant, whose branches trail on the ground. The leaves are small, of an oval shape, smooth,

smooth, and of a sea-green colour. It is found wild in some parts of Italy, and in the Archipelago, from whence Tournefort sent the seeds to the royal garden at Paris: but, being a plant of no great beauty, it is seldom cultivated, except in botanic gardens for variety.

2. *Andrachne fruticosa*: erect, shrubby. This sort rises twelve or fourteen feet high; the branches have spear-shaped, pointed, smooth, leaves; the flowers are small, of an herbaceous white colour, some of which are male, and others female, but, when the latter are situated at too great a distance from the former, there are rarely any seeds within their covers; though they seem very fair to fight; whereby several persons have been deceived, who have found them without raising a single plant. Native of the East Indies and China, also of La Vera Cruz in New Spain.

3. *Andrachne arborea*: stem aborescent; leaves ovate, obtuse, hoary underneath. It has a strong woody stem, which rises more than twenty feet high, sending out branches on every side, which have oval blunt leaves, hoary on their under side, and having pretty deep furrows on their upper, placed alternately on the branches. It was discovered by the late Dr. William Houston growing naturally at Campeachy. There is also another sort raised from seeds, sent from Jamaica; the whole form of the seeds agrees with those of the third sort, as do also the plants, but the leaves are somewhat like those of the laurel, only much larger; this has not as yet flowered in Europe.

Propagation and Culture. If the seeds of the first sort are sown on a moderate hot-bed in March, they will arise in about a month after, when they may be transplanted each into a small pot, and plunged into another very moderate hot-bed to bring the plants forward, but in mild weather they should have plenty of air admitted to them, and be often refreshed with water: in June they will produce flowers, and the seeds will ripen in August and September, soon after which the plants will decay. The second and third sorts are very tender-plants, so that, when good seeds can be obtained, they should be sown in pots, plunging them in a hot-bed of tanner's bark, observing to water them as the earth becomes dry in the pots; and when the plants come up, and are fit to remove, they should each be planted in a small pot, plunged into a tan-bed, shading them until they have taken fresh root, after which they should have free air admitted to them in warm weather, but must constantly be kept in the bark-stove. See *ARBUTUS*.

ANDRAGH'RA, a river of Sumatra, on which the Dutch have a factory.

ANDRAPODIS'MUS, *f.* in ancient writers, the selling of persons for slaves. Hence also *andrapodistes*, a dealer in slaves, more particularly a kidnapper, who steals men or children to sell them; a crime for which the Thesallians were noted.

ANDRAPODOCA'PELI, *f.* in antiquity, a kind of dealers in slaves. The *andrapodocapeli* had a particular process for taking off moles and the like disfigurements on the faces of the slaves they kept for sale, by rubbing them with bran. At Athens, several places in the forum were appointed for the sale of slaves. Upon the first day of every month, the merchants called *ανδραποδοκαπηλοι* brought them into the market, and exposed them to sale; the crier, standing upon a stone erected for that purpose, called the people together.

ANDRA'RUM, a town of South Gothland, three miles south of Christianstad; here is the greatest alum-work in Sweden.

ANDRE'A (St.) a small village on the Malabar coast in the East Indies, founded originally by the Portuguese. It takes its name from a church dedicated to St. Andrew. On the shore of St. Andrea, about half a league out in the sea, lies Mud-bay, a place which few in the world can parallel. It is open to the wide ocean, and has neither island nor bank to break the force of the billows, which come rolling with great violence from all parts in the south-west monsoons: but on this bank of mud they lose

themselves in a moment; and ships lie on it as secure as in the best harbour, without motion or disturbance. It reaches about a mile under shore, and has been observed to shift its place from the northward about three miles in thirty years.

ANDRE'AS (John), a celebrated canonist in the 14th century, was born at Mugello, near Florence; and was professor of canon-law at Padua, Pisa, and afterwards at Bologna. It is said that he macerated his body with fasting; and lay upon the ground every night for twenty years together, covered only with the skin of a bear. Andreas had a beautiful daughter, named *Novella*, whom he loved extremely: and he is said to have instructed her so well in all parts of learning, that, when he was engaged in any affair which hindered him from reading lectures to his scholars, he sent his daughter in his room; and, lest her beauty should prevent the attention of the hearers, she had a little curtain drawn before her. To perpetuate the memory of this daughter, he intitled his commentary upon the Decretals of Gregory IX. the *Novellæ*. He married her to John Calderinus, a learned canonist. The first work of Andreas was his Gloss upon the Sixth Book of the Decretals, which he wrote when he was very young. He wrote also Glosses upon the Clementines; and a commentary in *regulas Sexti*, which he intitled *Mercuriales*, because he either engaged in it on Wednesdays (*diebus Mercurii*), or because he inserted his Wednesdays disputes in it. He enlarged the *Speculum* of Durant, in the year 1347. This is all which Mr. Bayle mentions of his writings, though he wrote many more. Andreas died of the plague at Bologna, in 1348, after he had been a professor forty-five years; and was buried in the church of the Dominicans.

ANDREAS (John), was born a Mahometan, at Xativa in the kingdom of Valencia, and succeeded his father in the dignity of alfaqui of that city. He was enlightened with the knowledge of the Christian religion by being present at a sermon in the great church of Valencia on the day of Assumption of the blessed Virgin, in the year 1487. Upon this he desired to be baptized; and, in memory of the calling of St. John and St. Andrew, he received the name of John Andreas. At the desire of Martin Garcia, bishop of Barcelona, he undertook to translate from the Arabic, into the language of Arragon, the whole law of the Moors; and, after having finished this undertaking, he composed his famous work of *The Confusion of the Sect of Mahumed*: it contains twelve chapters, wherein he has collected the fabulous stories, impostures, forgeries, brutalities, follies, obscenities, absurdities, impossibilities, and contradictions, which Mahomet, in order to deceive the simple people, has dispersed in the writings of that sect, and especially in the Alcoran, which, as he says, was revealed to him in one night by an angel, in the city of Meke; though in another place he contradicts himself, and affirms that he was twenty years in composing it. Andreas tells us, he wrote this work, that not only the learned amongst Christians, but even the common people, might know the different belief and doctrine of the Moors; and on the one hand might laugh at and ridicule such insolent and brutal notions, and on the other might lament their blindness and dangerous condition. This book, which was published at first in Spanish, has been translated into several languages; and all those who write against the Mahometans quote it very much.

ANDRE'NI (Isabella), a native of Padua, was an excellent poetess, and one of the best comedians in Italy, towards the beginning of the 17th century. The Intenti of Pavia thought they did their society an honour by admitting her a member of it; and she, in acknowledgment of this honour, never forgot to mention amongst her titles that of *academica infanta*: her titles were these, "Isabella Andreini, comica gelosa, academica infanta, detta l'accessa." She was also a woman of extraordinary beauty; which, added to a fine voice, made her charin both the eyes and ears of the audience. She died of a miscarriage, at Lyons, the 10th of June 1604, in the 42d year

of her age. Her death being a matter of general concern and lamentation, there were many Latin and Italian elegies printed to her memory: several of these pieces were placed before her poems in the edition of Milan, in 1605. Besides her sonnets, madrigals, songs, and eclogues, there is a pastoral of hers intitled *Myrtilla*, and letters, printed at Venice in 1610. She sung extremely well, played admirably on several instruments, understood the French and Spanish languages, and was not unacquainted with philosophy.

ANDRE/LINUS (*Publius Faustus*), born at Forli in Italy. He was a long time professor of poetry and philosophy in the university of Paris. Louis XII. made him his poet laureat; and Erasmus tells us he was likewise poet to the queen. His pen was not wholly employed in making verses; for he wrote also moral and proverbial letters in prose, which were printed several times. His poems, which are chiefly in Latin, are inserted in Vol. I. of the *Delicæ Poetarum Italicorum*. Mr. de la Monnoie tells us, "that Andrelinus, when he was but twenty-two years old, received the crown of laurel. That his love-verses, divided into four books, intitled *Livia*, from the name of his mistress, were esteemed so fine by the Roman Academy, that they adjudged the prize of the Latin elegy to the author." He died in 1518.

ANDREW, [*ανδρειας*, Gr. manly or courageous.] A man's name.

ANDREW (St.) the apostle, born at Bethsaida in Galilee, brother to Simon Peter. He had been a disciple of John the Baptist, and followed Jesus upon the testimony given of him by the Baptist: John i. 30, 37, &c. He followed our Saviour with another of John's disciples, and went into the house where Jesus lodged; here he continued from about four o'clock in the afternoon till it was night. This was the first disciple whom our Saviour received into his train. Andrew introduced his brother Simon, and they passed a day with Christ, after which they went to the marriage in Cana, and at last returned to their ordinary occupation. Some months after, Jesus, meeting them while they were both fishing together, called them to him, and promised to make them fishers of men. Immediately they left their nets, followed him, and never afterwards separated from him. After our Saviour's ascension, his apostles having determined by lot what parts of the world they should severally taste, Scythia and the neighbouring countries fell to St. Andrew, who, according to Eusebius, after he had planted the gospel in several places, came to Patræ in Achaia, where, endeavouring to convert the proconsul Ægeas, he was by that governor's orders scourged, and then crucified. The particular time of his suffering martyrdom is not known; but all the ancient and modern martyrologies, both of the Greeks and Latins, agree in celebrating his festival upon the 30th of November. His body was embalmed, and decently interred at Patræ by Maximilla, a lady of great quality and estate. Afterwards it was removed to Constantinople by Constantine the Great, and buried in the great church, which he had built to the honour of the apostles. There was a cross to be seen lately in the church of St. Victor at Marseilles, which was believed by the Romanists to be the same that St. Andrew was fastened to. It is in the shape of the letter X, and is inclosed in a silver shrine.

ANDREW, or *Knights of St. Andrew*, an order of knights, more usually called the order of the thistle. See **THISTLE**.

Knights of St. Andrew, is also an order instituted by Peter the Great of Muscovy, in 1693; the badge of which is a golden medal; on one side whereof is represented St. Andrew's cross, with these words, *Cazar Pierre monarque de tout le Russie*. This medal, being fastened to a blue ribbon, is suspended from the right shoulder.

St. Andrew's Day, a festival of the Christian church, celebrated on the 30th of November, in honour of the apostle St. Andrew.

ANDREW'S (St.) a town of Fifeshire in Scotland, once

the metropolis of the Pictish kingdom, lying in lat. 56. 18. N. lon. 2. 25. W. If we may credit legend, St. Andrew's owes its origin to a singular accident. St. Regulus, a Greek of Achaia, was warned by a vision to leave his native country, and visit Albion, an isle placed in the remotest part of the world; and to take with him the arm-bone, three fingers, and three toes, of St. Andrew. He obeyed, and set sail with his companions, but had a very tempestuous passage. After being tossed for some time on a stormy sea, he was at last shipwrecked on the coasts of Otholonia, in the territories of Hergustus king of the Picts, in the year 370. On hearing of the arrival of the strangers, with their precious relics, the king immediately gave orders for their reception, afterwards presenting the saint with his own palace, and building near it the church, which still bears the name of St. Regulus.

The town of St. Andrew's was erected into a royal borough by David I. in the year 1140, and their privileges afterwards confirmed. The charter of Malcolm II. is preserved in the tolbooth; and appears written on a bit of parchment, but the contents equally valid with what would at this time require whole skins. Here also are kept the silver keys of the city; which, for form's sake, are delivered to the king, if he should visit the place, or to a victorious enemy, in token of submission. In this place, likewise, is to be seen the monstrous ax which, in 1646, took off the heads of Sir Robert Spotswood and other distinguished loyalists. The town underwent a siege in 1337; at which time it was possessed by the English and other partizans of Baliol; but the loyalists, under the earls of March and Fife, made themselves masters of it in three weeks, by the help of their battering machines.

St. Andrew's is now greatly reduced. It is a mile in circuit, and contains three principal streets. On entering the west port, a well-built street, of great length and breadth, appears; but so grass-grown, and presenting such a dreary solitude, that it forms the perfect idea of having been laid waste by the pestilence. The cathedral was founded by bishop Arnold in 1161, but did not attain its full magnificence till 1318. Its length from east to west was 370 feet; that of the transept, 322. But, though this vast pile was 157 years in building, John Knox, in June 1559, effected its demolition in a single day; and so effectually has it been destroyed, that nothing now remains but part of the east and west ends, and of the south side. Near the east end is the chapel of St. Regulus; the tower of which is a lofty equilateral triangle, of twenty feet each side, and 103 feet high; the body of the chapel remains, but the two side-chapels are ruined. The arches of the windows and doors are round, and some even more than semicircles; an undoubted proof of their antiquity.

On the east side of the city are the poor remains of the castle, on a rock overlooking the sea. This fortress was founded, in 1401, by bishop Trail, who was buried near the high altar of the cathedral.

The celebrated university of this city was founded in 1411, by bishop Wardlaw. It consisted once of three colleges. 1. St. Salvator's, founded in 1458 by bishop Kennedy. This is a handsome building, with a court or quadrangle within: on one side is the church, on another the library; the third contains apartments for students: the fourth is unfinished. 2. St. Leonard's college was founded by prior Hepburn, in 1522. This is now united with the last, and the buildings sold, and converted into private houses. 3. The new, or St. Mary's, college, was established by archbishop Hamilton in 1553; but the house was built by James and David Bethune, or Beaton, who did not live to complete it. This is said to have been the site of a *schola illustris* long before the establishment even of the university; where several eminent clergymen taught, gratis, the sciences and languages. But it was called the new college, because of its late erection into a divinity college by the archbishop. The university is governed by a chancellor, an office originally designed to be perpetually vested in the archbishops of St. Andrew's; but since

the reformation, he is elected by the two principals, and the professors of both the colleges. The colleges have their rectors, and professors of different sciences, who are indefatigable in their attention to the instructions of the students, and to that essential article their morals. This place possesses several very great advantages respecting the education of youth. The air is pure and salubrious; the place for exercise dry and extensive; the exercises themselves are healthy and innocent. The university is fixed in a peninsulated country; remote from all commerce with the world, the haunt of dissipation.

The trade of St. Andrew's was once very considerable. So late as the reign of Charles I. this place had thirty or forty trading vessels, and carried on a considerable herring and white fishery, by means of buoys, in deep water; which fisheries had for ages been the grand source of their commerce and splendour. The harbour is artificial, guarded by piers, with a narrow entrance, to give shelter to vessels from the violence of a very heavy sea, by the encroachments of which it has suffered much. The manufactures this city might in former times possess are now reduced to one, that of golf-balls; which, trifling as it may seem, maintains a great number of people. It is, however, commonly fatal to the artists; for the balls are made by stuffing a great quantity of feathers into a leathern case, by help of an iron rod, with a wooden handle, pressed against the breast, which seldom fails to bring on a consumption.

ANDREWS (Lancelot), bishop of Winchester, was born at London in 1555, and educated at Cambridge. After several preferments, he was made bishop, first of Chichester, then of Ely, and, in 1618, was raised to the see of Winchester. This very learned prelate, who was distinguished by his piety, charity, and integrity, may be justly ranked with the best preachers and completest scholars of his age; he appeared to much greater advantage in the pulpit than he does now in his works, which abound with Latin quotations and trivial witticisms. His sermons, though full of puns, were suited to the taste of the times in which he lived, and were consequently greatly admired. He was a man of polite manners and lively conversation; and could quote Greek and Latin authors, or even pun, with king James. There is a pleasant story related of him in the Life of Waller the Poet. When that gentleman was young, he had the curiosity to go to court, and stood in the circle to see king James dine; where, among other company, there sat at table two bishops, Neale and Andrews. The king proposed aloud this question, Whether he might not take his subjects money when he needed it, without all this formality of parliament? Neale replied, "God forbid you should not; for you are the breath of our nostrils." Whereupon the king turned, and said to the bishop of Winchester, "Well, my lord, what say you?" "Sir (replied the bishop), I have no skill to judge of parliamentary cases." The king answered, "No put-offs, my lord; answer me presently." "Then, sir (said he), I think it lawful for you to take my brother Neale's money, for he offers it." He died at Winchester-house in Southwark, September 27, 1626, in the seventy-first year of his age; and was buried in the parish-church of St. Saviour's. Bishop Andrews had, 1. A share in the translation of the Pentateuch, and the historical books from Joshua to the first book of Chronicles exclusively. He also wrote, 2. *Tortura Torti*, in answer to a work of cardinal Bellarmine, in which that cardinal assumes the name of Matthew Tortus. 3. A manual of Private Devotions; and, 4. A manual of Directions for the Visitation of the Sick; besides the Sermons and Tracts, in English and Latin, published after his death.

ANDRIA, in Grecian antiquity, public entertainments first instituted by Minos of Crete, and, after his example, appointed by Lycurgus at Sparta, at which a whole city or a tribe assisted. They were managed with the utmost frugality, and persons of all ages were admitted, the

younger sort being obliged by the law-giver to repair thither as to schools of temperance and sobriety.

ANDRIA, is a city and a bishop's see in the territory of Bari, in the kingdom of Naples. It is pretty large, well peopled, and seated in a spacious plain, four miles from the Adriatic coast. Lat. 41. 15. N. lon. 17. 4. E.

ANDRIS'CUS, a man of mean extraction, who, pretending to be the son of Perseus, last king of Macedonia, took upon him the name of *Philip*, for which reason he was called *Pseudo-Philippus*, the *False Philip*. After a complete victory over Juventus, the Roman prætor sent against him, he assumed kingly power, but exercised it with vast cruelty. At last, the Romans obliged him to fly into Thrace, where he was betrayed and delivered into the hands of Metellus. This victory gained Macedonia once more into the power of the Romans, and to Metellus the name of *Macedonicus*, but cost the Romans 25,000 men. Andriscus adorned the triumph of Metellus, walking in chains before the general's chariot.

ANDRO'AS, or ANDRO'DAMAS, among ancient naturalists, a kind of pyritæ, to which they attributed certain magical virtues.

ANDROCLE'A, a daughter of Antipænus of Thebes, who with her sister Alcida, sacrificed their lives for the service of their country, when the oracle had promised a victory to the Thebans, who were engaged in a war against Orchomenos, if any one of noble birth devoted himself to the service of the nation. They received great honours after death; and Hercules, who fought on the side of Thebes, dedicated to them the image of a lion in the temple of Diana.

ANDROGE'US, in fabulous history, the son of Minos king of Crete, was murdered by the Athenian youth and those of Megara, who envied his being always victor at the Attic games. But Minos, having taken Athens and Megara, obliged the inhabitants to send him an annual tribute of seven young men and as many virgins to be devoured by the Minotaur; but Theseus delivered them from that tribute.

ANDRO'GYNAL, *adj.* [*ανρ and γυν, Gr.*] Having two sexes; hermaphroditical.

ANDRO'GYNALLY, *adv.* in the form of hermaphrodites; with two sexes.—The examples hereof have undergone no real or new transfection, but were *androgynally* born, and under some kind of hermaphrodites. *Brown.*

AN'DROGYNE, *f.* [*ανδρoγυνος, of ανρ, a man, and γυν, a woman, Gr.*] An hermaphrodite, or one that is both male and female, or that is castrated and effeminate. See under ANATOMY, p. 623.

ANDRO'GYNOUS, *f.* An appellation given, by astrologers, to such of the planets as are sometimes hot and sometimes cold; as Mercury, which is accounted hot and dry when near the sun, and cold and moist when near the moon. In zoology, an appellation given to animals which have both the male and female sex in the same individual. In botany, the term is applied to such plants as bear both male and female flowers on the same root.

ANDROI'DES, in mechanics. See AUTOMATON.

AN'DROLEPSY, *f.* in Grecian antiquity, an action allowed by the Athenians against such as protected persons guilty of murder. The relations of the deceased were empowered to seize three men in the city or house where the malefactor had fled, till he were either surrendered, or satisfaction made for the murder.

ANDRO'MACHE, the wife of the valiant Hector, the mother of Astyanax, and daughter of Eton king of Thebes in Cilicia. After the death of Hector, and the destruction of Troy, she married Pyrrhus; and afterwards Helenus the son of Priam, with whom she reigned over part of Epirus.

ANDRO'MEDA, in fabulous history, the daughter of Cepheus and Cassiope, king and queen of Ethiopia, whose mother was so rash as to think herself and daughters more beautiful than Juno and the Nereides. Juno, by way of

punishment, condemned Andromeda to be chained to a rock by the Nereides, and exposed naked, in order to be devoured by a sea-monster; but Perseus, mounted on the horse Pegasus, as he was passing by, saw Andromeda in this condition; and the monster appearing, he shewed him the head of Medusa, which turned him to stone; upon which the princess was rendered back to her father, who married her to Perseus. Andromeda was made a constellation in heaven after her death.

ANDROMEDA, in astronomy, a constellation of the northern hemisphere, representing the figure of Andromeda, almost naked, her feet at a distance from each other, and her arms extended and chained, as stated above; being one of the original forty-eight asterisms, or figures under which the ancients comprehended the stars, as derived to us from the Greeks, who probably had them from the Egyptians, or Indians. The Arabians, whose religion did not permit them to draw the figure of the human body on any occasion whatever, have changed this constellation into the figure of a sea-calf. Schickard has changed the name for that of the scripture-name *Abigail*. And Schiller has also changed the figure of the constellation for that of a sepulchre, and calls it the *Holy Sepulchre*. This constellation contains about twenty-seven stars that are visible to the naked eye; of which the principal are, α , *Andromeda's head*; β , in the girdle, and called *mirach* or *mizar*; γ , on the south foot, and named *alamah*, and sometimes *alhames*. The number of stars placed in this constellation by the catalogue of Ptolemy is twenty-three; by that of Tycho Brahe also twenty-three; by that of Hevelius forty-seven; and by that of Flamsteed sixty-six.

ANDROMEDA, *f.* [from the daughter of Cepheus and Cassiope, rescued from the sea-monster by Perseus.] In botany, a genus of the decandria monogynia class, ranking in the natural order of bicornes. The generic characters are—Calyx: perianthium five-parted, acute, very small, coloured, permanent. Corolla: monopetalous, campanulate, quinquefid; clefts reflex. Stamina: filaments subulate, shorter than the corolla, and scarcely fixed to it; anthers two-horned, nodding. Pistillum: germ roundish; style cylindric, longer than the stamens, permanent; stigma obtuse. Pericarpium: capsule roundish, five-cornered, five-celled, five-valved, opening at the corners; partitions contrary. Seeds: very many, roundish, shining.—*Essential Character*. Calyx, five-parted. Corolla, ovate, or campanulate, quinquefid at the edge. Capsule, superior, five-celled, with the partitions from the middle of the valves.

Species. 1. *Andromeda tetragona*: peduncles solitary, lateral; corollas bell-shaped; leaves opposite, imbricate, obtuse, revolute. This is like the *passerina filiformis*, but the flowers are very different, resembling those of the lily of the valley. The leaves are generally four-fold; whence it has the square appearance which acquired it the name of tetragona. Linnaeus first observed it growing very sparingly in Lapland, in the year 1732. Gmelin also found it on the mountains of Siberia.

2. *Andromeda hypnoides*: peduncles solitary, terminal; corollas bell-shaped; leaves crowded, awl-shaped. This little plant has the appearance of a moss, spreads over great tracts of ground in the Lapland Alps, and adorns them with its beautiful red flowers; it is found also in Denmark and Siberia.

3. *Andromeda cerea*: peduncles axillary, two-leaved, one-flowered; leaves alternate, ovate, serrate. Resembles the fourteenth species, but is smooth. This is from the island of Otaheite.

4. *Andromeda cærulea*: peduncles aggregate; corollas ovate; leaves scattered, linear, obtuse, flat. It grows wild on the mountains of Lapland; but more plentifully on those of Dalecarlia and Jemtia; and is found also in Denmark and Siberia.

5. *Andromeda mariana*, or Maryland andromeda: peduncles aggregate, branched; corollas ovate-cylindrical; leaves oblong-ovate, quite entire, deciduous. A native of North America. Of this there are two varieties: i. With

oval leaves; ii. With oblong leaves. They appear in June and July, and sometimes are succeeded by fruit, which seldom ripens in England.

6. *Andromeda ferruginea*, or rusty andromeda: peduncles aggregate, axillary; corolla subglobose; leaves elliptic, quite entire, beneath scaly-scariose. This is also a native of North America. It flowers in July and August.

7. *Andromeda polifolia*, or marsh andromeda: peduncles aggregate, corollas ovate, leaves alternate, lanceolate, revolute. This elegant little shrub is from six or eight inches to a foot in height, erect and branched. The calyx is red, and the corolla is of a pink colour. Native of America, and the northern countries of Europe, on turf-bogs; in Russia, Sweden, Denmark, Germany, Switzerland; and in Britain, on the moor of Cheshire, Lancashire, Westmoreland, Cumberland, Yorkshire, and Scotland, as on Brigflour-moss near Kendal, Middleton-moss by Lancaster, on Blackstone-edge between Hallifax and Rochdale, upon Solway-moss abundantly, and not unfrequent in peat-bogs in the low-lands of Scotland. It flowers about the end of May; and is called *mars chistus*, *wild rosemary*, *peley mountain*, *moorwort*, and *marsh holy rose*. There is some difference between the varieties of this species, as found in North America, in Europe, and in Newfoundland and Labrador.

8. *Andromeda bryantha*: flowers corymbed, leaves elliptic, stem prostrate. The antheræ adhere perpendicularly to the back of the filaments. Peduncles many-flowered. It comes up in thick clumps, like wild thyme, on the rocks of Kamtschatka.

9. *Andromeda dabocia*, or Irish whorts, or cantabrian heath, or trailing andromeda: racemes pointing one way, flowers quadrifid ovate, leaves alternate, lanceolate, revolute. This species has been observed to grow only in the Irish bogs, and flowers in June and July.

10. *Andromeda droseroides*, or clammy andromeda: racemes pointing one way; leaves linear, hairy, viscid. This is a native of the Cape of Good Hope.

11. *Andromeda paniculata*, or panicked andromeda: racemes terminal paniced; corollas roundish; leaves ovate rather entire. Stem about four feet high; the flowers grow in loose spikes from the ends of the branches; they appear in July, but do not produce seeds in this country. A native of Virginia.

12. *Andromeda japonica*: racemes paniced, cylindric, bracted; leaves elliptic, reflex, serrate at the tip. This is a tree. Branches coming out by threes or more in a sort of umbel, striated and angular, smooth, purplish, erect, knobbed from the fall of the leaves, and subdivided. Nao of Japan, near Nagasaki; flowering in December.

13. *Andromeda arborea*, or tree andromeda, or forrel-tree: panicles terminal, corollas rather downy, leaves elliptic, pointed, toothletted. In Virginia it is a shrub growing ten or twelve feet high; but in Carolina it rises twenty feet. The branches are very slender, bending downward. The flowers grow in long naked spikes from the sides of the branches; they are of an herbaceous colour, and ranged on one side of the stalk.

14. *Andromeda racemosa*, or branching or Pennsylvania andromeda: racemes terminal, simple, bracted; corollas cylindric; leaves oblong-lanceolate, serrate. This was found in Pennsylvania, by Kalm. It flowers in July.

15. *Andromeda axillaris*, or notch-leaved andromeda: racemes axillary, simple; corollas oblong; leaves ovate, acute, serrulate. Native of Carolina; and flowers from May to August.

16. *Andromeda coriacea*, or thick-leaved andromeda: racemes axillary, simple; leaves ovate, very entire, very shining; branchlets three-cornered. Found in North America; and flowers in July and August.

17. *Andromeda acuminata*, or acute-leaved andromeda: racemes axillary, simple; leaves ovate-lanceolate, acuminate, serrate. This is a shrub about four feet in height, upright, and the whole of it smooth, with round branches, which are leafy to a considerable extent. It flowers in

July and August. It is a native of North America, and was introduced in 1765.

18. *Andromeda calyculata*, or calyced andromeda: peduncles solitary, axillary, pointing one way; bracts two; leaves oval, scaly-dotted, obsoletely serrulate. It is a low shrub: the leaves shaped like those of the box-tree, and of the same consistence, with small punctures on them. The flowers grow in short spikes from the extremities of the branches; they are produced single, between two leaves, and are white. It grows in Sweden, Ingria, Siberia; and also in North America, on mossy land. There is some difference in the varieties from Russia, Newfoundland, and North America and Siberia.

19. *Andromeda anastomozans*: racemes crowded, leafy; leaves ovate slightly serrate, anastomosing underneath and dotted. A shrub with hairy branches; found by Mutis, in New Granada.

20. *Andromeda rupestris*: leaves oblong, alternate, serrulate. A native of New Zealand.

21. *Andromeda falcifolia*, or willow-leaved andromeda: racemes pointing one way, naked; corollas subcylindrical; leaves lanceolate, acute, quite entire. It was found by Commerfon, in the island of Mauritius.

22. *Andromeda buxifolia*, or box-leaved andromeda: racemes pointing one way, naked; corollas subcylindrical; leaves cordate-ovate, quite entire, with a little dagger point. It is a native of the isle of Bourbon, where it was found by Commerfon.

23. *Andromeda fasciculata*: peduncles aggregate, leaves alternate ovate-lanceolate, obtuse slightly crenulate, coriaceous.

24. *Andromeda jamaicensis*: peduncles aggregate, corollas ovate transparent, leaves alternate broad-lanceolate obtuse entire, beneath ash-coloured membranaceous.

25. *Andromeda octandra*: peduncles aggregate, corollas cylindric quadrifid, leaves alternate ovate-lanceolate entire membranaceous. Natives of Jamaica.

Propagation and Culture. Most of the sorts are hardy deciduous shrubs, delighting in moist ground. They may be increased by their creeping roots, which put up suckers at a distance, which may be taken off with roots, and transplanted where they are designed to remain; for they do not bear to be often removed. Such also as are imported from America by the seedmen may be propagated by seed, which must be sown in the spring, in a bed of moist earth. They may also be increased by layers, in autumn. The 13th sort requires to be sheltered from hard frost in winter, but in the summer should be frequently watered. It is a difficult plant to keep in gardens, as it grows naturally on boggy places, and requires a greater heat than that of this climate.

ANDRON, *f.* in Grecian antiquity, denotes the apartment in houses designed for the use of men; in which sense it stands opposed to *Gynæceum*. The Greeks also gave their dining-rooms the title of *andron*, because the women had no admittance to feasts with the men.

ANDRONA, *f.* in ancient writers, denotes a street, or public place, where people met and conversed together. In some writers, *androna* is more expressly used for the space between two houses; in which sense, the Greeks also use the term *andronas*, for the way or passage between two apartments. *Androna* is also used, in ecclesiastical writers, for that part in churches destined for the men. Anciently it was the custom for the men and women to have separate apartments in places of worship, where they performed their devotions asunder; which method is still religiously observed in the Greek church. The *andron*, or *androna*, was in the southern side of the church, and the women's apartment on the northern.

ANDRONICUS I. emperor of the East, caused Alexius II. who had been put under his care, to be strangled; and then took possession of the throne of Constantinople in 1183: but the people, becoming exasperated at his cruelties, proclaimed Isaac Angelus emperor, and put Andronicus in irons: they then thrust out his eyes; and, having

led him through the city in an ignominious manner, hanged him.

ANDRONICUS of CYRRHUS, built at Athens an octagon tower, with figures carved on each side, representing the eight principal winds. A brass triton at the summit, with a rod in its hand, turned round by the wind, pointed to the quarter from whence it blew. From this model is derived the custom of placing weather-cocks on steeples.

ANDROPHA'GI, in ancient history, the name of a nation whose country, according to Herodotus, was adjacent to Seythia. Their name, compounded of two Greek words, signifies *man-eaters*. Herodotus does not inform us whether their manner of subsisting corresponded with their name; whether they were so savage as to eat human flesh. See the article *ANTHROPOPHAGI*. They are represented, however, as the most barbarous and fierce of all nations. They were not governed by laws: the care of their cattle was their chief employment. Their dress was like that of the Scythians; and they had a language peculiar to themselves.

ANDROPO'GON, *f.* [*ανδροπωγων*, Gr. signifying man's beard.]. In botany, a genus of the polygamia monoecia class, of the natural order of gramina or grasses. The generic characters are—Hermaphrodite flowers sessile. Calyx: a glume, one-flowered, two-valved, oblong, obtuse, cartilaginous, awnless; the outer valve concave, flattish at the back, embracing the inner, which is narrower, with its edges. Corolla: a two-valved glume, less and more slender than the calyx; outer valve smaller, frequently very small, within the inner valve of the calyx, sharp or bifid at the end, in most of the species awned; awn terminating, or from the cleft of the glume, long, with a bent joint, and twisted at bottom; the inner valve lanceolate, doubled at the edges; nectary two-leaved; leaflets thickish, diaphanous. Stamina: filaments three, capillary, very tender; antheræ oblong, forked at both ends, incumbent. Pistillum: germ oblong; styles two, capillary; stigmas oblong, feathered. Pericarpium: none, glumes of the corolla and calyx involving and inclosing the seed. Seed: solitary, oblong, covered; armed with the awn of the corolla, which easily falls off. Male flowers peduncled, single, or in pairs to each hermaphrodite. Calyx, corolla, and stamina, as in the others; only that the corolla has no awn.—*Essential Character.* Hermaphrodite. Calyx, glume one-flowered; corolla, glume awned at the base; stamina, three; styles, two; seed, one. Male. Calyx and corolla the same; stamina, three.

Species. 1. *Andropogon caricofum*: spike solitary, imbricate; seeds shaggy; awns naked, contorted. A native of Amboyna and Japan.

2. *Andropogon contortum*: spike solitary; male flowers awnless on the back of the spike; female flowers on the belly of it, twice as long as the males, with twisted approximating awns, longer than the whole spike. A native of the East Indies.

3. *Andropogon crinitum*: spike solitary, shaggy; awns naked, jointed, very long. A native of Japan; found by Thunberg.

4. *Andropogon divaricatum*: spike oblong; flowers woolly, remote, divaricate; awn flexuose, naked. Native of Virginia.

5. *Andropogon gryllus*: peduncles of the panicle entirely simple, three-flowered; the hermaphrodite floccule sessile, awned, ciliate, bearded at the base. A native of Piedmont, Verona, Montpellier, Carniola, the Grisons, and Switzerland.

6. *Andropogon saccharoides*: branches of the panicle simple, florets in pairs, hermaphrodite awned sessile, the other awnless pedicelled withering, pedicel and rachis woolly. Native of Jamaica.

7. *Andropogon nutans*: panicle nodding; awns twisted, polished; glumes of the calyx shaggy. A native of Virginia and Jamaica.

8. *Andropogon ciliatum*: panicle nodding; outer calyx many-

many-flowered, ciliate; awns contorted, hairy. Found by Thunberg on the mountains of Nagasaki in Japan; flowering in September.

9. *Andropogon ferratum*: panicle loose; one floscule sessile, villose at the base; the other pedicelled, with the pedicel villose, and shorter than the calyx. 10. *Andropogon cotuliferum*: panicle spreading, villose; awn twisted, naked; pedicels clubbed or swelling at top, and hollowed like a saucer or dish. Natives of Japan.

11. *Andropogon cymbarium*: panicle scattered; bractes boat-form; flowers transverse, awned, three-fold. A native of the East Indies.

12. *Andropogon squarrosus*: panicle crowded, glumes awl-shaped, rugged. Koenig observed it in Ceylon, swimming on deep pools. It is used by the natives for its pleasant smell: they also make fans of it.

13. *Andropogon prostratus*: peduncles in five-flowered umbels without calyces, the hermaphrodite floscule awned. A native of the East Indies.

14. *Andropogon fastigiatum*: spikes of the panicle solitary, peduncles elongate subfastigiate, rachis woolly, floscules awned, male fertile. Native of Jamaica.

15. *Andropogon alopecuroides*: panicle loose, rachis woolly, a twisted awn to each floscule. A native of Jamaica and Virginia.

16. *Andropogon distachyum*: spikes two, terminal: culm undivided. This species is above a foot high, with flat leaves and solitary flowers. Linnæus says, from Burser, that it grows wild in Switzerland. Scheucher had it from Smyrna.

17. *Andropogon schænanthus*, or sweet rush, or camel's hay: spike of the panicle conjugate, ovate-oblong; rachis pubescent, floscules sessile with a twisted awn. Native of Arabia and India. Cultivated in the gardens of China and Cochinchina, where the inhabitants use it to season their meat. This is brought over from Turkey in bundles, about a foot long. When in perfection, it has an agreeable smell, with a warm, bitterish, not unpleasant, taste. It was formerly employed as a warm stomachic and deobstruent; but, in this country, more common aromatic vegetables have now superseded its use. Perennial.

18. *Andropogon virginicus*: spikes of the panicle conjugate, peduncles simple, rachis woolly, floscules awnless, the male one wasting. A native of America.

19. *Andropogon bicornis*: spikes of the panicle conjugate, peduncles branching very much, rachis woolly, awn caducous, male floscule wanting. Native of the East Indies, on dry hills, and there called by the English *fox-tail grass*.

20. *Andropogon hirtum*: spikes of the panicle conjugate, calyces shaggy. A native of Portugal, Italy, Sicily, and Smyrna.

21. *Andropogon insulare*: panicle loose, smooth; floscules double, awnless; one pedicel shorter, calyces woolly. A native of Jamaica.

22. *Andropogon barbatus*: spikes digitate, calyces permanent, corollas ciliate. A native of the East Indies.

23. *Andropogon pubescens*: spikes digitate, calyces subtriflorous, outer petals awned; keel and edge of the hermaphrodite flower ciliate. This is a native of Jamaica, from whence it was sent by Mr. Gilbert Alexander. It was introduced at Kew, in 1779; and flowers from July to September. It is perennial.

24. *Andropogon nardus*: branches of the panicle superdecapound, proliferous. Indian nard, or spikenard, as brought to us, is a congeries of small tough reddish-brown fibres, forming a bunch about the size of a finger. It was kept in the shops only as an article in *mithridate* and *theriaca*, and is said to be used among the orientals as a spice. It is moderately warm and pungent, accompanied with a flavour not disagreeable. There is an account of the true *Nardus Indica*, in the Philosophical Transactions, by Dr. Blane. It was discovered in India by his brother, in December 1786, after crossing the river Rapti, about twenty miles from the foot of the northern mountains; where,

perceiving the air to be perfumed by an aromatic smell, and asking the cause, he was told that it proceeded from the roots of the grass trodden out of the ground by the elephants and horses. The country was wild and uncultivated, and this was the common grass which covered the surface of it, growing in large tufts close to each other, very rank, and in general from three to four feet in length. Transplanted into a garden at Lucknow, it thrived exceedingly, and in the rainy season shot up spikes about six feet high. The whole plant has a strong aromatic odour; but both the smell and the virtues reside principally in the husky roots, or lower parts of the stalks, which in chewing have a bitter, warm, pungent, taste, accompanied with some degree of that kind of glow in the mouth which cardamoms occasion. It is remarkable, that the circumstance of the discovery corresponds, in a striking manner, with an occurrence related by Arrian: that, during the march of Alexander the Great through the deserts of Gedrosia, the air was perfumed by the spikenard, which was trampled under foot by the army; and that the Phœnicians collected large quantities of it, as well as of myrrh, in order to carry them into their own country, as articles of merchandize. Gedrosia, or Gedrosia, answers to the modern Mackran, or Kedge-Mackran, a maritime province of Persia, situated between Kerman (the ancient Carmania) and the river Indus, being of course the frontier of Persia towards India; and this desert lies in the middle of the tract of country between the river Indus and the Persian gulph, and within a few days march of the Arabian or Erythrean sea; which is the northern part of the Ethiopic ocean, and not the Red Sea. It should seem that the nard was found towards the eastern part of it; for Alexander was then directing his route to the westward, and the length of march through the desert afterwards was very great. Garcias ab Horto, a Portuguese, who resided many years at Goa in the sixteenth century, has given a figure of the roots, or rather the lower part of the stalks, which corresponds with Dr. Blane's specimens; he says, that there is but one species of nardus known in India, either for the consumption of the natives, or for exportation to Persia and Arabia. It is remarkable, that he is perhaps the only author who speaks of it in its recent state from his own observation. Rumphius mentions having seen a dried specimen, of which the leaves were almost five feet long; and that Mackran was one of the countries from whence it was brought. It is probable that the nardus of Pliny, and great part of what is now imported from the Levant, and found under that name in the shops, is a plant growing in the countries on the Euphrates, or in Syria, where the great emporiums of the eastern and western commerce were situated. There is a *Nardus Assyria* mentioned by Horace; and Dioscorides speaks of the *Nardus Syriaca* as different from the *Indica*, which certainly was brought from some of the remote parts of India; for both Dioscorides and Galen, by way of fixing more precisely the country from whence it comes, call it also *Nardus Gangites*. It is called by the natives *terankus*, which means literally, in the Hindoo language, fever-restrainer, from the virtues they attribute to it in that disease. They infuse about a drachm of it in half a pint of hot water, with a small quantity of black pepper. This infusion serves for one dose, and is repeated three times a day. It is esteemed a powerful medicine in all kinds of fevers, whether continued or intermittent. It was highly valued anciently as an article of luxury as well as medicine. The favourite perfume which was used at the ancient baths and feasts was the *unguentum nardinum*; and it appears, from a passage in Horace, that it was so valuable, that as much of it as could be contained in a small box of precious stone, was considered as a sort of equivalent for a large vessel of wine, and a handsome quota for a guest to contribute at an entertainment, according to the custom of antiquity. It may here be remarked, that as its sensible qualities do not depend on a principle so volatile as essential oil, like most other aromatic vegetables, this would be a great recommendation

commendation to the ancients, as its virtues would thereby be more durable; and they were not acquainted with the method of collecting essential oils, being ignorant of the art of distillation. The fragrance and aromatic warmth of the nardus depends on a fixed principle, like that of cardamoms, ginger, and some other spices. I tried, says Dr. Blane, to extract the virtues of the nardus by boiling water, by maceration in wine, and proof spirits, but it yielded them sparingly and with difficulty to all these menstrua. It had a high character among the ancients as a remedy both external and internal. It is one in the list of ingredients in all the antidotes, from those of Hippocrates, as given on the authority of Myrepsus, and Nicolaus Alexandrinus, to the officinals which have kept their ground till modern times, under the name of *mithridate* and *Venice treacle*. It is recommended by Galen and Alexander Trallian in the dropsy and gravel. Celsus and Galen recommend it both externally and internally in pains of the stomach and bowels. The first occasion on which the latter was called to attend Marcus Aurelius was, when that emperor was severely afflicted with an acute complaint in the bowels, answering by the description to that we now call the *cholera morbus*; and the first remedy he applied was warm *oleum nardinum* on wool to the stomach. He was so successful in the treatment of this illness, that he ever afterwards enjoyed the highest favour and confidence of the emperor. It appears that the natives of India consider it as an efficacious remedy in fevers, and its sensible qualities promise virtues similar to those of other simples now in use among us in such cases. Besides a strong aromatic flavour, it possesses a pungency to the taste little inferior to the *serpentaria*, and much more considerable than the *contrayerva*. It is mentioned in a work attributed to Galen, that a medicine composed of this, and some other aromatics, was found useful in long protracted fevers, which are the cases in which medicines of this class are employed in modern practice.

25. *Andropogon nuticum*: spikes digitate, mostly three; floscules alternate, sessile awnless. A native of the Cape of Good Hope.

26. *Andropogon ischaemum*: many digitate spikes, floscules sessile, awned and awnless, pedicels woolly. A native of the southern parts of Europe, growing on mountains, hills, and other dry situations.

27. *Andropogon fasciculatum*, or many-spiked andropogon: spikes fascicled, very many, smooth; calyxes two-flowered; valves acute, smooth, and even, the outer like petals and awned, the inner floscule barren. A native of Jamaica; and flowers from July to September.

28. *Andropogon polydactylon*: spikes fascicled, outer petals awned, those of the lower floscule ciliate-bearded. A native of Jamaica.

29. *Andropogon glaucum*: panicle leafy, involuclers and calyxes two-flowered, calyxes of the sessile flowers three-valved, of the peduncled ones two-valved. Native of the East Indies; from whence it was sent by Koenig.

30. *Andropogon ferratum*: spike simple imbricate with two rows of awned sessile flowers, and two of awnless pedicelled ones, calyxes one-valved. Native of Bengal; found there by Koenig.

31. *Andropogon incurvatum*: spikes filiform subdigitate, flowers twin, the female pedicelled and awned, the male sessile and awnless, calyxes one-valved. Found by Koenig in Tranquebar, near rivers.

32. *Andropogon binatum*: spikes twin, woolly, one valve of the calyxes acuminate, the other truncate three-toothed, the larger petal awned. Observed in the East Indies by Koenig.

33. *Andropogon aciculatum*: panicle contracted upright, peduncles three-flowered, male flowers two pedicelled acuminate, female sessile awned. Native of the East Indies, in barren places.

34. *Andropogon Bladhii*: spikes about eight, hermaphrodite floscule sessile awned, neuter peduncled ciliate awnless. Native of China, and sent from thence by Bladh.

35. *Andropogon provinciale*: spikes fascicled smooth, floscules alternate subsessile, directed one way, awned. Native of the south of France; from whence the seeds were sent by Dahl.

Propagation and Culture. Few of these grasses have been propagated in European gardens. The greater part of them would require the protection of a stove, since they are natives of the East or West Indies. See *SACCHARUM* and *STIPA*.

AN'DROS, one of the ancient Cyclades, lying between Tenedos and Eubœa; being one mile distant from the former, and ten from the latter. The ancients gave it various names, viz. Cauros, Lafia, Nonagria, Epagris, Antandros, and Hydrusia. The name of Andros it received from Andreus, appointed, according to Diodorus Siculus, by Rhadamanthus, one of the generals, to govern the Cyclades, after they had of their own accord submitted to him. As to the name of *Antandros*, the same author tells us, that Ascanius the son of Æneas, being taken prisoner by the Pelasgians, gave them this island for his ransom, which on that account was called *Antandros*, or "delivered for one man." The name of *Hydrusia* it obtained in common with other places well supplied with water. It had formerly a city of great note, bearing the same name, and situated very advantageously on the brow of a hill, which commanded the whole coast. In this city, according to Strabo and Pliny, stood a famous temple, dedicated to Bacchus. Near this temple, Mutianus, as quoted by Pliny, tells us, there was a spring called the *gift of Jupiter*; the water of which had the taste of wine in the month of January, during the feasts of Bacchus, which lasted seven days. The same author adds, that the waters, if carried to a place whence the temple could not be seen, lost their miraculous taste. Pausanias makes no mention of this spring; but says, that, during the feast of Bacchus, wine flowed, or was at least by the Andrians believed to flow, from the temple of that god. The priests, no doubt, found their account in keeping up this belief, by conveying, through secret conduits, a great quantity of wine into the temple.

The Andrians were the first of all the islanders who joined the Persians at the time Xerxes invaded Greece; and therefore Themistocles, after the victory at Salamis, resolved to attack the city of Andros, and oblige the inhabitants to pay large contributions for the maintenance of his fleet. Having landed his men on the island, he sent heralds to the magistrates, acquainting them, that the Athenians were coming against them with two powerful divinities, *persuasion* and *force*; and therefore they must part with their money by fair means or foul. The Andrians replied, that they had likewise two mighty deities who were very fond of their island, viz. *poverty* and *impossibility*; and therefore could give no money. Themistocles, not satisfied with this answer, laid siege to the town; which he probably made himself master of and destroyed, as we are informed by Plutarch, that Pericles, a few years after, sent thither a colony of 250 Athenians. It was, however, soon retaken by the Persians; and, on the overthrow of that empire by Alexander the Great, submitted to him, along with the other islands. On his death it sided with Antigonus, who was driven out by Ptolemy. The successors of the last-mentioned prince held it to the times of the Romans; when Attalus, king of Pergamos, besieged the metropolis at the head of a Roman army; and, having taken it, was by them put in possession of the whole island. Upon the death of Attalus, the republic claimed this island, as well as his other dominions, in virtue of his last will.

Andros is now subject to the Turks; and contains a town of the same name, with a great many villages. It is the most fruitful island in all the Archipelago, and yields a great quantity of silk. There are said to be about 6000 inhabitants, besides those of the villages Arni and Amoldeos, who are about 200, have a different language and customs, and are called *Albanois*. There are seven monasteries,

naderies, a great number of churches, and a cathedral for the bishops of the Roman catholic persuasion; but most of the inhabitants are of the Greek communion. The Jesuits had a house and a church in this island; but they were forced to quit them long ago. Here are some delightful valleys; but the air is bad, and the water of the city worse. A cadi, assisted by a few of the principal persons of the island, has the management of civil affairs, and his residence is in the castle; an aga, who presides over the military force, lives in a tower without the city. About two miles from the present town are still to be seen the ruins of a strong wall, with the fragments of many columns, chapiters, bases, broken statues, and several inscriptions, some of which mention the senate and people of Andros, and the priests of Bacchus; from which it is probable that this was the site of the ancient city. Lat. 37. 50. N. lon. 25. 30. E.

ANDROS, an island in the Irish sea, called Hedros by Ptolemy. Now Bardsey, distant about a mile from the coast of North Wales.

ANDROSACE, *f.* [*ανδρος σανος*, Gr. the shield of a man, from the form of the calyx, in the common species.] In botany, a genus of the pentandria monogynia class, ranking in the natural order of præciæ. The generic characters are—Calyx: involucre many-leaved, many-flowered, very small; perianthium one-leaved, five-cornered, semiquinquefid, acute, erect, permanent. Corolla: monopetalous, salver-shaped; tube ovate, involved in the calyx; border flat, five-parted; divisions ovate-oblong, obtuse, entire; throat beset with glands. Stamina: filaments very short, within the tube; antheræ oblong, erect, included. Pistillum: germ globose; style filiform, very short; stigma globose, included. Pericarpium: capsule globose, sitting on a flat calyx, one-celled, opening into five parts at the top. Seeds: very many, roundish, gibbous on one side, flat on the other. Receptaculum: erect, free.—*Essential Character.* An involucre to the umbel; tube of the corolla ovate, with a glandulous mouth; capsule one-celled, globose.

Species. 1. *Androsace maxima*, or oval-leaved androsace: perianthiums of the fruit very large. There are six or more seeds in a capsule; they are dark brown or blackish, and slightly pubescent. The flowers appear in April, or the beginning of May; the seeds ripen in June, and the plants soon after perish. It grows naturally among corn, in Austria, Bohemia, and other parts of Germany, in the Valais, Piedmont, Carniola, and Hungary. Annual.

2. *Androsace elongata*, or cluster-flowered androsace: leaves lanceolate-toothed, fruiting umbel elongate, corollas shorter than the angular calyx. Native of Austria, near Vienna, up to the very suburbs. It flowers in April, and perfects its seeds in June.

3. *Androsace septentrionalis*, or tooth-leaved androsace: leaves lanceolate-toothed, smooth; perianthiums angular, shorter than the corollas. Root annual, (according to Miller biennial.) Native of Lapland, Sweden, Denmark, Switzerland, Germany, Russia, in mountainous situations.

4. *Androsace villosa*, or hairy androsace: leaves hairy, perianthiums shaggy. Root perennial. Common in the Swiss Alps, Jura, &c. in the mountains of Austria and Carniola, in the Pyrenees, &c.

5. *Androsace lactea*, or grass-leaved androsace: leaves lanceolate, smooth; umbel many times larger than the involucre. Root perennial. Native of the mountains of Switzerland, Austria, and Carniola. Flowering, as does the foregoing, in July and August.

6. *Androsace carnea*, or awl-leaved androsace: leaves awl-shaped, smooth; umbel equalling the involucre. Native of the Alps and Pyrenees.

7. *Androsace filiformis*: leaves ovate-toothed petioled, rays of the umbel capillary, corollas exceeding the bell-shaped calyx. It is a native of Siberia.

Propagation and Culture. These, being low plants, with small flowers, making no great appearance, are only preserved in botanic gardens. All the sorts, except the first,

require a shady situation. The seeds should be sown soon after they are ripe; otherwise they seldom grow the same year. If permitted to scatter, they will come up of themselves, and often succeed better than those which are sown. The annual sorts perish as soon as the seeds are ripe; but the others will live in an open border for several years, and require no other care, but to keep them clean from weeds. See *ARETIA*.

ANDROSÆMUM, *f.* in botany. See *HYPERICUM*.

ANDRO'TOMY, *f.* [of *ανηρ* and *τεμνω*, Gr. to cut.] A dissection of human bodies.

AN'DRUM, *f.* a kind of hydrocele, to which the people of Malabar are very subject. Its origin is derived from the vicious quality of the country waters, impregnated with corrosive muriatic salts, the source of most other diseases that affect the Malabrians. Its signs or symptoms are an erysipelas of the scrotum, returning every new moon, by which the lymphatics, being eroded, pour a serous saline humour into the cavity of the scrotum. The andrum is incurable; those once seized with it have it for life: but it is not dangerous, nor very troublesome to those used to it; though sometimes it degenerates into an hydroscrocele. The method of prevention is by a heap of sand fetched from a river of the province Mangatti, and strewed in the wells. This is practised by the rich. As to the cure, they have only a palliative one; which is by incision, or tapping, and drawing off the water from the scrotum once in a month or two.

ANDRY'ALA, *f.* [*ανδρος αλη*, *viri erratio, anxietas animi*.] In botany, a genus of the syngenesia polygamia æqualis class, ranking in the natural order of compositæ semisculosæ. The generic characters are—Calyx: common, many-parted, short, rounded, villose; scales very many, subequal, subulate. Corolla: compound imbricate, uniform; corollules hermaphrodite, numerous, equal; each ligulate, linear, truncate, five-toothed. Stamina: filaments five, capillary, very short; anthera cylindrical, tubulose. Pistillum: germ ovate; style filiform, the length of the stamens; stigmas two, reflex. Pericarpium: none; calyx converging, globose. Seeds: solitary, ovate; downy capillary, the length of the calyx. Receptaculum: villose, flattish.—*Essential Character.* Receptaculum villose; calyx many-parted, subequal, rounded; down simple, sessile.

Species. 1. *Andryala integrifolia*, or hoary andryala: lower leaves runcinate; upper ovate-oblong, tomentose. Near a foot and a half in height, with woolly branching stems, having leaves scatteringly set on them, which are oblong and downy. The flowers are yellow, and are produced in small clusters at the top of the stalks. It flowers in July, and the seeds ripen in September. This species is annual, growing naturally in the south of France, Spain, Italy, and Sicily.

2. *Andryala cheiranthifolia*, or various-leaved andryala: leaves runcinate; upper ones lanceolate, entire; down glanduliferous. Native of the island of Madeira. Observed there by Mr. Francis Masson, and introduced in 1777. It is perennial, three feet high, and full of milk.

3. *Andryala pinnatifida*, or pinnatifid-leaved andryala: leaves tomentose, pinnatifid; calyxes tomentose, hairy; hairs rather stiff. A native of Madeira, and of the Canary islands; and was found there by Mr. Francis Masson. It is biennial, and flowers in July and August.

4. *Andryala crithmifolia*, or samphire-leaved andryala: leaves pinnate, linear, tomentose. Native of Madeira. It is biennial, and flowers from June to August.

5. *Andryala ragulina*, or downy andryala: leaves lanceolate, undivided, denticulate, acute, tomentose, flowers solitary. One yellow flower terminates every branch in June and July. This plant, being very hoary, makes a pretty appearance, intermixed with others whose leaves are green. It will not live abroad, except in a dry soil and warm situation. Robert More, Esq. sent it from Spain; it has also been received from the Cape and Algiers. Linnæus says it is a native of the islands of the Archipelago.

6. *Andryala lanata*, or woolly andryala: leaves oblong-ovate,

ovate, slightly-toothed, woolly; peduncles branching. This flowers in June, and the seeds ripen in August. The whole plant is white: and a native of the south of Europe.

Propagation and Culture. All these plants may be propagated from seeds; those of the hardy sorts should be sown in the spring, in the place where the plants are to remain. They require no other culture, but to thin them when they are too close, and too keep them clean from weeds. The second, third, fourth, and fifth, require the protection of a green-house, where they flower all the summer, till late in the autumn, frequently perfecting their seeds, by which they may be propagated. The perennial sorts may also be propagated by their creeping roots. See LEONTODON.

ANDUX'AR, an ancient, large, and populous, city, of Andalusia. It has several fine buildings, a strong castle, and is seated on the Guadalquivir, over which there is a stately bridge. It vends great quantities of silk, and the country abounds in corn, wine, oil, honey, &c. It is twenty-five miles east of Corduba. Lat. 37. 55. N. lon. 3. 34. W.

ANEAU' (Bartholomew), a native of Bourges in France, a man of eminent learning in the 16th century, educated under Melchior Volmar. He was professor at Lyons, where he propagated the doctrines of the reformation secretly for a long time: but, on the festival of the holy sacrament 1565, as the procession was passing on towards the college, there was a large stone thrown from one of the windows upon the host and priest who carried it. The people, enraged at this, broke into the college, and assassinated M. Aneau, whom they imagined to have been the occasion, and the college itself was shut up next day by order of the city.

AN'ECDOTE, *f.* [ἀνέκδοτος, Gr. of ἀ priv. and ἐκδίδωμι, published.] A term used by some authors for the titles of *secret histories*; but it more properly denotes a relation of detached and interesting particulars. Procopius gives this title to a book which he published against Justinian and his wife Theodora; and he seems to be the only person among the ancients who has represented princes such as they are in their domestic relation. Varillas has published *Anecdotes of the House of Medicis*.

ANEC'DOTES is also an appellation given to such works of the ancients as have not yet been published. In which sense, M. Muratori gives the name *Anecdota Græca* to several writings of the Greek fathers, found in the libraries, and first published by him. F. Martene has given a *The-saurus Anecdotarum Novus*, in folio, 5 vols.

ANE'E, *f.* in commerce, a measure for grain, used in some provinces of France. At Lyons, it signifies also a certain quantity of wine, which is the load an ass can carry at once, and which is fixed at eighty English quarts, wine-measure.

ANEMO'GRAPHY, *f.* [ἀνέμος and γραφω, Gr.] The description of the winds.

ANEMO'METER, *f.* [of ἀνέμος, the wind, and μέτρον, Gr. measure.] A machine for measuring the force and velocity of the wind. Various machines of this kind have been invented at different times, and by different persons. The following by Mr. Martin has been often experienced, and found to answer the intention. An open frame of wood, ABCDEFGHI, is supported by the shaft or arbour I. In the two cross-pieces HK, LM, is moved an horizontal axis QM, by means of the four sails, ab, cm, Of, gh, exposed to the wind in a proper manner. Upon this axis is fitted a cone of wood, MNO; upon which, as the sails move round, a weight R, or S, is raised by a string round its superficies, proceeding from the smaller to the larger end NO. Upon this larger end or base of the cone, is fixed a rocket wheel k, in whose teeth the click X falls, to prevent any retrograde motion from the depending weight. The structure of this machine sufficiently shews that it may be accommodated to estimate the variable force of the wind; because the force of the weight will continually increase as the string advances on the conical sur-

face, by acting at a greater distance from the axis of motion; consequently, if such a weight be added on the smaller part M, as will just keep the machine in equilibrium in the weakest wind, the weight to be raised, as the wind becomes stronger, will be increased in proportion, and the diameter of the cone NO may be so large in comparison to that of the smaller end at M, that the strongest wind shall but just raise the weight at the greater end. If, for example, the diameter of the axis be to that of the base of the cone NO as 1 to 28; then, if S be a weight of one pound at M on the axis, it will be equivalent to twenty-eight pounds when raised to the greater end: if, therefore, when the wind is weakest, it supports one pound on the axis, it must be twenty-eight times as strong to raise the weight to the base of the cone. If therefore a line or scale of twenty-eight equal parts be drawn on the side of the cone, the strength of the wind will be indicated by that number on which the string rests.

ANE'MONE, *f.* [from ἀνέμος, Gr. the wind: because the flower is supposed not to open except the wind blows; or rather, because it grows in situations much exposed to the wind.] In botany, a genus of the polyandria polygynia class, ranking in the natural order of multifloræ. The generic characters are—Calyx: none. Corolla: petals in two or three rows, three in a row, somewhat oblong. Stamina: filaments numerous, capillary, half the length of the corolla; antheræ twin, erect. Pistillum: germ numerous, in a head; styles acuminate; stigmas obtuse. Pericarpium: none; receptacle globular or oblong, hollowed and dotted. Seeds: very many, acuminate, retaining the style.—*Essential Character.* Calyx none; petals six or nine; feeds many.

Species. 1. *Hepatica*, with a subcalyculate flower. 1. *Anemone hepatica*, or *hepatica*: leaves three-lobed, quite entire. The leaves of the year before remain; they are heart-shaped, three-lobed, obtuse, smooth, beneath veined in net-work. The bud has generally four outer scales, ovate and membranaceous; three inner, concealing the leaves and flowers. The flower lies a year complete in all its parts within the bud. This plant is asfringent, but not in use. It is found wild in Sweden abundantly, in Denmark, Switzerland, France, Spain, Italy, and other parts of Europe; in woods and among bushes; with blue, red, and white, flowers, single. It flowers in March. There are many varieties of *hepatica* common in gardens; as, 1. Single and double blue. 2. Single and double red or peach-coloured. 3. Single and double white. 4. Single and double variegated red and white. 5. Single and double violet-coloured. 6. With striped leaves. Parkinson mentions a white with red stamens. These are some of the greatest ornaments of the spring; the flowers are produced in February and March in great plenty, before the green leaves appear, and make a very beautiful figure in the borders of the pleasure-garden, especially the double sorts, which commonly continue a fortnight longer in flower than the single ones, and the flowers are much fairer.

11. *Pulsatilla*, with the peduncle involucred, and the seeds tailed. 2. *Anemone patens*, or woolly-leaved *anemone*:

mone: peduncles involucred, leaves digitate, multifid. Root perennial. A native of Siberia about Tobolski, and of Lower Lusatia. It was cultivated in 1759 by Miller.

3. *Anemone sulphurea*: peduncle involucred; leaves triply-pinnate, hairy, flat, acutely-gashed, seeds tailed. Differs from the vernal in having sharper petals, yellow within.

4. *Anemone baldensis*: leaves biternate, shaggy. Unknown to latter writers. The fruit resembles that of the garden anemone. It grows wild about Aigle, &c. in Switzerland, Monte Baldo, Monte Cenis, &c.

5. *Anemone vernalis*: peduncle involucred, leaves pinnate, flowers erect. Flower red without, white within; leaves approaching those of meadow-rue; stem half a foot high. When the flower is young it is white, with a bluish or purple on the outside, where it is hairy: these hairs afterwards become yellow. It grows in the woods bordering on the mountains, in barren sands, in Sweden, Germany, and on the high Alps of Switzerland.

6. *Anemone cernua*: peduncle involucred, leaves pinnate, flowers nodding. Differs from the last in the nodding of the flower, and in the leaves having more pinnas, finely cut. Thunberg found it in Japan near Jeddo, flowering early in spring.

7. *Anemone pulsatilla*, or pasque-flower: peduncle involucred, petals straight, leaves bipinnate. This is acrid, and will raise blisters; the distilled water will vomit; it cannot therefore be safe to give it in disorders of the lungs. It grows wild on open hills in dry soils, in Sweden, Denmark, Switzerland, France, Italy, Germany, Carniola, Siberia, &c. and in England, on chalky downs; as Gogmagog-hills; Barnack-heath, near Stamford; about Leadstone-hall, near Pontefract; near Charlbury, in Oxfordshire; Lexham, Bury, Newmarket, &c. flowering in April. It has the Italian name *pulsatilla* from the downy seed being beaten about by the wind. There is a variety with double, and another with white, flowers.

8. *Anemone pratensis*, or meadow anemone: peduncle involucred, petals reflex at the tip, leaves bipinnate. The flower of this is less than that of the former, and of a darker colour; it hangs down like that, but the tips of the petals are bent back. It is very common in the barren stony fields of Oeland and Scania, also in Denmark, Germany, and Piedmont. The leaves are shorter, the stalks do not rise so high, and the flowers do not expand so wide, as in the former.

9. *Anemone Alpina*, or Alpine anemone: stem-leaves ternate, connate, superdecompound, multifid; seeds shaggy, tailed. Flower almost as big as a tulip, white, with a tinge of purple. It grows wild on the Alps, Jura, and in Austria.

10. *Anemone apiifolia*: stem-leaves ternate, connate, superdecompound, multifid, very slender, extremely hairy underneath. It has no smell, and is a native of the Leontine Alps. It may be doubted whether this be really distinct from the ninth species.

III. *Anemones* with a leafy stem and tailed seeds. 11. *Anemone coronaria*, or narrow-leaved garden anemone: radical leaves ternate-decompound, involucre leafy. It grows naturally in the Levant, particularly in the islands of the Archipelago, where the borders of the fields are covered with it of all colours: but the flowers are single, though rendered double by culture. In France it was long cultivated, before it was much known in Holland or England. We find it however in our gardens so early as 1596. Parkinson, in 1629, says that some reckoned up thirty sorts with single flowers, of which he mentions only the watchet or pale blue, the ordinary purple, and the scarlet, with some of their intermediate varieties. Of those with double flowers he gives twelve varieties: 1. Common double red or scarlet. 2. Party-coloured crimson. 3. Crimson velvet. 4. Great double bluish. 5. White. 6. Lesser bluish. 7. Purple. 8. Blue. 9. Rose-coloured. 10. Carnation. 11. Purple velvet. 12. Purple velvet of three colours. He observes, that the art of raising them

from seed was not then familiarly known to our nation, although it was very frequent in the Low Countries; and he gives directions for that purpose. Mr. Ray, in his history, enumerates near three hundred varieties of this and the broad-leaved sort. Mr. Rea, in his *Flora* or *Complete Florilege*, specifies the following varieties of the narrow-leaved, or soft-leaved, anemone, as it was called by the Walloons, who brought them over out of France and Flanders to sell: 1. Common double red. 2. Variable. 3. Elegant red. 4. Scarlet. 5. Variegated scarlet. 6. White with a scarlet thrum. 7. Nacara or yellowish scarlet. 8. Double brimstone. 9. Green. 10. Great white. 11. Greatest or white of Bourdeaux. 12. Blush, called *columbina*. 13. Rose-coloured. 14. Variegated rose. 15. Spotted bluish. 16. Purple. 17. Lavender-coloured. 18. Blue. 19. White with a purple thrum or plush, called *perfect in beauty*. 20. Red with a dark or murrey purple thrum, called *amarant*. 21. Variegated amarant. 22. Five-coloured. 23. Dark purple striped with white. Besides these, he gives a list of seventy-four varieties raised from seed in France and Flanders, all fine, different, and many rare: and another, translated out of French, by the accomplished Sir Thomas Hanmer, containing forty-seven sorts. The catalogues of our modern seedsmen have usually about 150 or 200. The principal colours in anemones, according to Mr. Miller, are white, red, blue, and purple; and these in some are curiously intermixed: but the most prevailing colours amongst our English-raised anemones are white and red; though we have received from France great variety of blues and purples, which are exceeding fine flowers, and being intermixed with those of English growth, make a beautiful variety. The plain colours in the modern catalogues are, red, crimson, rose-coloured, purple, lilac, clear and pale blue, ash-coloured, and white. The principal variegated ones are, red and white striped, rose and white, blue and white, red white and purple: but there are innumerable shades of these and the other colours. A double anemone, in order to be a fine one, should have a strong upright stem, about nine inches high; the flower should be from two to near three inches in diameter, the outer petals should be firm, horizontal except that they turn up a little at the end, and the smaller petals within these should lie over each other gracefully, so as to form an elegant whole. The plain colours should be brilliant and striking; the variegated ones should be clear and distinct.

12. *Anemone hortensis*, or broad-leaved garden anemone: leaves digitate, seeds woolly. Broad-leaved garden anemone; or *hard-leaved* anemone, as it was formerly called by the Walloons who imported the roots; or *star* anemone, as the single varieties are sometimes named: is found wild, with single flowers, in Italy, Provence, and Germany. Clusius discovered it near the Rhine, with red, and with purple, flowers; Ray also remarked it with these colours, in many parts of Italy; and Haller in Switzerland. Clusius found it with white flowers in Germany; and it has been seen of the same colour in Austria. Parkinson enumerates several varieties of this also, both with single and double flowers: as single and double yellow; purple starre anemone, darker and paler; violet purple; purple striped; carnation; gredeline, between a peach-colour and a violet; cochenille, of a fine reddish violet or purple; cardinal, of a rich crimson red; blood-red, of a deeper, but not so lively, a red; crimson; flamell, near unto a scarlet; incarnadine, of a fine delayed red or flesh-colour; Spanish incarnate, of a lively flesh-colour, shadowed with yellow; bluish, of a fair whitish red; nutmegge, of a dark whitish colour, striped with veins of a bluish-colour; monk's-gray, pale whitish tending to a gray, such as the monks and friers were wont to wear with us; great orange tawny; lesser orange tawny. Of double flowers the most remarkable are, the great double anemone of Constantinople, or Spanish marigold; great double orange tawny; double anemone of Cyprus; double Persian anemone. Rea mentions, the common great double

ble variable anemone; common double and variegated scarlet; red and purple; and variegated of these colours; besides single of divers sorts and colours. He says, that the best star-anemones come from Brittany, where they raise yearly many fine sorts. This species also was cultivated here by Gerard in 1597.

13. *Anemone palmata*: leaves heart-shaped, sublobate; calyx six-leaved, coloured. This, having a six-parted calyx, connects the hepaticas with the anemones. Clusius found it in Portugal by the Tagus. The leaves are large; the corolla consists of ten or more petals, yellow without and orange within.

IV. *Anemonoides* with a naked flower, and tailless seeds.

14. *Anemone Sibirica*: stem one-flowered, involucre leafy, obtuse. Found in Siberia by Gmelin.

15. *Anemone sylvestris*, or large white-flowered wood anemone: peduncle naked; seeds roundish, shaggy, awnless. This approaches near to our wood anemone, but the seeds of it are round and hairy; the flower is large and white, but having little beauty is seldom planted in gardens; yet there is in the flowers, especially before they expand, a simple elegance, somewhat like that of the snow-drop, which affords a pleasing contrast to the more showy flowers of the garden. Parkinson notices its creeping roots, its large white flowers standing on the tops of the flower-stalks, which sometimes grow two together, but most commonly single; the leaves on the stalk, he observes, are more finely divided than those of the root, and its seeds are woolly. It is a native of many parts of Germany. Linnæus observed it once in Sweden; it is found also in Alsace and Siberia. It flowers in May, and ripens its seeds in June.

16. *Anemone fragifera*: peduncle naked; seeds roundish, woolly, awnless, gashes of the leaves acute, lanceolate. Native of Carinthia.

17. *Anemone Virginiana*, or Virginian anemone: peduncles alternate, very long; fruit cylindric; seeds shaggy, awnless. It is a native of North America, and flowers in May and June.

18. *Anemone capetala*, or ten-petalled anemone: stem one-flowered, flower ten-petalled, leaves ternate, lobate, radical. Native of Brazil.

19. *Anemone Pennsylvanica*, or Pennsylvanian anemone: stem dichotomous, leaves sessile stem-clasping, the lowest ternate, trifid, gashed. This is so like the *dichotoma*, that a person might easily be deceived: but the leaves at the first dichotomy of the stem are not two, but three: sessile, more veined, less horizontal. It is a native of Canada and Pennsylvania, and was cultivated in 1766 by Mr. Jas. Gordon.

20. *Anemone dichotoma*: stem dichotomous; leaves sessile, all opposite, stem-clasping, trifid, gashed. It flowers about Midsummer, and ripens its seeds. It is a native of Canada, and Siberia; from whence it was sent growing, by David de Gorter, physician in ordinary to the empress of Russia, into Sweden, in the year 1760.

21. *Anemone trifolia*: leaves ternate, ovate, entire, ferrate; stem one-flowered. A native of France, Carniola, and Siberia; growing in woods, and flowering at the end of April.

22. *Anemone quinquefolia*: leaves quinate, oval, serrate; stem one-flowered. Native of Virginia and Canada.

23. *Anemone nemorosa*, or wood anemone: seeds acute, leaflets gashed, stem one-flowered. The root of the wood anemone is perennial; the height of the whole plant from five to ten inches. It grows in woods, among bushes, and in hedges, in most parts of Europe, and sometimes in pastures. In many of our woods the ground is almost covered with the flowers in March, April, and May. In fine clear weather the blossoms are expanded, and become so erect as to face the sun; but, in the evening, and in wet weather, they are closed and hang down. It is acrid, and in some degree poisonous; according to Linnæus, cattle brought from open to woody pastures, and eating of this plant, have been affected with the bloody flux, and have

made bloody urine. The paper in which dried specimens of this plant are preserved being stained brown, it is probable that it may be employed as a dye. When the flowers become double, the wood anemone is cultivated by the gardeners; and, were the same pains taken with it as with the foreign anemones, it might probably be much improved in the eye of the florist. The leaves have frequently a parasitical plant growing on their backs, which deceived Bobart and the great Dillenius, who took it for a fern, and figured it as such in the third edition of Ray's Synopsis. This error, though detected more than sixty years since, has been lately revived, and has given occasion to Mr. Relhan to ascertain that this appearance is occasioned, not by eggs of an insect as some supposed, but by the *acidium fuscum*.

24. *Anemone Apennina*, or mountain wood anemone: seeds acute, leaflets gashed, petals lanceolate, numerous. It flowers in April, at the same time as the wood anemone, with which it has some affinity in its foliage; but the root is much thicker and more knobby, the petals much narrower, more than twice as many, and of a light pleasant purplish blue: when they first expand, the outside has a rich purplish tint, which is lost when the flowers have been some time exposed to the sun. Native of the Apennines, near Rome; and of some few places in England; as Lord Spencer's park at Wimbledon, near Harrow-on-the-Hill, in a wood by Luton Hoe in Bedfordshire, and near Berkhamstead in Hertfordshire. It is a very ornamental plant, suitable to the flower-garden or plantation; and loves a light loamy soil.

25. *Anemone ranunculoides*, or yellow wood anemone: seeds acute, leaflets gashed, petals roundish, stem mostly one-flowered. This differs from the wood anemone in having a yellow corolla, two petals alternately outer, and two inner, and one having one side within and the other side without the next petal; whereas that has three outer and three inner petals; it differs also in the peduncles being accompanied with two leaflets, the latter of which is furnished with three at the base. It flowers a day or two earlier than the other. This sometimes has two flowers on a stem, the peduncles villose, short, so that the flower scarcely rises above the leaves. It grows wild in Sweden, Denmark, Switzerland, France, Germany, Austria, Carniola, Italy, Siberia, and Geneva; flowers in April. With us it has been found near King's Langley in Hertfordshire, and near Wrotham in Kent.

26. *Anemone narcissiflora*, or narcissus-flowered anemone: flowers umbelled; seeds oval-depressed, naked. It grows wild on the mountains of Italy, Switzerland, Austria, and Siberia. Introduced in 1773 by John earl of Bute.

27. *Anemone fasciculata*: flowers umbelled, collected, leaves multifid. This very much resembles the last, so that Linnæus doubts whether it be a distinct species, and Haller thinks that it is only a variety. It was first observed by Tournefort in the Levant, and is found in the mountains about the lake Baikal.

28. *Anemone thalictroides*, or meadow-rue-leaved anemone: flowers umbelled; stem-leaves simple, verticillate; radical leaves biternate. It grows wild in Virginia and Canada.

Propagation and Culture. The plants of this genus are mostly hardy perennials, and may be increased both by seeds and by the roots.

The *hepaticas* are some of the greatest beauties of the spring. The flowers are produced in February and March in great plenty, before the green leaves appear, and make a handsome figure in the borders of the pleasure-garden, especially the double sorts, which commonly continue a fortnight longer in flower than the single ones, and the flowers are much fairer. The single sorts produce seeds every year, whereby they are easily propagated, and also new flowers may be that way obtained. The best season for sowing the seeds is in the beginning of August, either in pots or boxes of light earth, which should be placed so

as to have only the morning sun until October, when they should be removed into the full sun, to remain during the winter season; but, in March, when the young plants will begin to appear, they must be removed again to a shady situation, and in dry weather frequently watered, and about the beginning of August they will be fit to be transplanted; at which time you should prepare a border facing the east, of good fresh loamy earth, into which you should remove the plants, placing them about six inches distance each way, closing the earth pretty fast to their roots, to prevent the worms from drawing them out of the ground, which they are very apt to do at that season; and, in the spring following, they will begin to shew their flowers; but it will be three years before they flower strong, and till then you cannot judge of their goodness; when, if you find any double flowers, or any of a different colour from the common sorts, they should be taken up, and transplanted into the borders of the flower-garden, where they should continue at least two years before they are taken up, or parted; for it is remarkable in this plant, that, where they are often removed and parted, they are very subject to die; whereas, when they are permitted to remain undisturbed for many years, they will thrive exceedingly, and become very large roots. The double flowers, which never produce seeds, are propagated by parting their roots, which should be done in March, at the time when they are in flower; but you should be careful not to separate them into very small heads, nor should they be parted oftener than every third or fourth year, if you intend to have them thrive, for the reason before given. They delight in a strong loamy soil, and in an eastern position, where they may have only the morning sun, though they will grow in almost any aspect, not too warm, and are never injured by cold. Mr. Bradley relates a remarkable change that was made in the colours of these flowers. Some roots of the double blue hepatica were sent to Mr. Harrison, of Henley-upon-Thames, from Mr. Keys's garden in Tottenham-fields, whose soil was so different from the ground they were planted in at Henley, that when they came to blossom there they produced white flowers, and were therefore returned back to their first station, where they retook the blue colour they had at first.

The *pulsatillas* (2—10) may be propagated by seeds, which should be sown in boxes or pots filled with very light sandy earth, observing not to cover the seeds too deep with mould, which will prevent their rising, for they require no more than just to be covered. These boxes should be placed where they may have the morning sun until ten o'clock, but must be screened from it in the heat of the day; and, if the season proves dry, the earth should be often refreshed with water. The best time for sowing these seeds is in July or August, soon after they are ripe, for, if they are kept till spring, they seldom grow. These boxes or pots, in which the seeds are sown, should remain in this shady situation until the beginning of October, when they should be moved where they may enjoy the full sun during the winter season. About the beginning of March, the plants will begin to appear, at which time the boxes should be again removed where they may have only the forenoon sun; for, if they are too much exposed to the heat, the young plants will soon be destroyed. They should also be carefully kept clean from weeds, which, if suffered to grow among them, will in a short time overbear them. When the leaves are entirely decayed (which is commonly in July), you should then take up all the roots, which, being nearly of the colour of the ground, will be difficult to find while small; therefore you should pass the earth through a fine wire sieve, which is the best method to separate the roots from the earth. The roots, being taken up, should be immediately planted again on beds of light fresh sandy earth, about three or four inches asunder, covering them about three inches thick with the same light earth. The spring following most of these plants will produce flowers, but they will not be so large and fair as in the succeeding years, when the roots

are larger. The roots of these plants generally run down deep, and, being of a fleshy substance somewhat like carrots, will not bear to be kept long out of the ground; therefore, when they are removed, it should be done early in the autumn, that they may take fresh root before the frost comes on; for, if they are transplanted in the spring, they will not produce strong flowers. These plants thrive best in a loamy soil, for in very light dry ground they are apt to decay in summer.

The *garden anemones* (11, 12) are natives of the east, from whence their roots were brought originally; but have been so greatly improved by culture, as to render them some of the chief ornaments to our gardens in the spring. We shall therefore proceed to give ample directions for their culture; by which, if duly observed, every person may have these flowers in perfection. Take a quantity of fresh untried earth (from a common, or some other pasture land) that is of a light sandy loam, or hazel mould, observing not to take it above ten inches deep below the surface; and, if the turf be taken with it the better, provided it has time to rot thoroughly before it is used: mix this with a third part of rotten cow-dung, and lay it in a heap, keeping it turned over at least once a month for eight or ten months, the better to mix it, and rot the dung and turf, and to let it have the advantages of the free air: in doing this be careful to rake out all great stones, and break the clods, but by no means sift or screen the earth, which is found very hurtful to many sorts of roots; for, when the earth is made very fine, upon the first great rains of winter or spring, the small particles thereof join closely together, and form one solid mass, so that the roots often perish for want of some small stones to keep the particles asunder, and make way for the tender fibres to draw nourishment for the support of the root. This earth should be mixed twelve months before it is used, if possible; but, if you are constrained to use it sooner, you must turn it over the oftener, to mellow and break the clods; and observe to rake out all the parts of the greed-sward that are not quite rotten before you use it, which would be prejudicial to your roots if suffered to remain. The beginning of September is a proper season to prepare the beds for planting, which, if in a wet soil, should be raised with this sort of earth six or eight inches above the surface of the ground, laying at the bottom some of the rakings of your heap to drain off the moisture; but, in a dry soil, three inches above the surface will be sufficient: this compost should be laid at least two feet and a half thick, and in the bottom there should be about four or five inches of rotten neat-dung, or the rotten dung of an old melon or cucumber bed, so that you must take out the former soil of the beds to make room for it. And observe, in preparing your beds, to lay them, if in a wet soil, a little round, to shoot off the water; but, in a dry one, let it be nearer to a level; in wet land, where the beds are raised above the surface, it will be proper to fill up the paths between them in winter, either with rotten tan or dung, to prevent the frost from penetrating into the sides of the beds, which often destroys the roots. The earth should be laid in the beds at least a fortnight or three weeks before you plant the roots, that it may settle; and, when you plant them, stir the upper part of the soil about six inches deep with a spade; then rake it even and smooth, and with a stick draw lines each way of the bed at six inches distance, so that the whole may be in squares, that the roots may be planted regularly: then with three fingers make a hole in the center of each square, about three inches deep, laying therein a root with the eye uppermost; and, when you have finished your bed, with the head of a rake draw the earth smooth, so as to cover the crown of the roots about two inches. The best season for planting these roots, if for forward flowers, is about the latter end of September; and, for those of a middle season, any time in October; but observe to perform this work, if possible, at or near the time of some gentle showers; for, if the roots are planted when the ground is perfectly dry,

and

and there should no rain fall for three weeks or a month after, they will be very apt to grow mouldy upon the crown, and, if they once get this distemper, they seldom come to good after. You may also reserve some of your anemone-roots till after Christmas, before you plant them, left by the severity of the winter your early-planted roots should be destroyed; which sometimes happens in very hard winters, especially where they are not covered to protect them from the frost. These late-planted roots will flower a fortnight or three weeks after those which were planted in autumn, and many times blow equally as fair, especially if it prove a moist spring, or that care be taken to refresh them gently with water. In the beginning of April your first planted roots will begin to flower, which will continue for three weeks or more, according to the heat of the weather, or the care taken in covering them, during the heat of the day, with mats or cloths: after these are past flowering, the second planted sorts will come to succeed them, and these will be followed by those planted in the spring; so that you may have these beauties continued for near two months together, or sometimes longer, if the season prove favourable, or proper care be taken to shade them in the heat of the day. The beginning of June, the leaves of your first blown roots will begin to decay; soon after which time you must take them out of the ground, clearing them from decayed stalks, and washing them, to take the earth clean from the root; then spread them on a mat in a dry shady place till they are perfectly dried, when you may put them up in bags, and hang them out of the reach of mice, or other vermin, which will destroy many of the roots if they can come at them. Observe also to take up the latter planted roots as soon as their leaves decay; for if they are suffered to remain long after in the ground, and there should fall some showers of rain, they would soon put forth fresh fibres, and make new shoots, when it would be too late to remove them. At the time when you take up the roots, is the proper season for breaking or parting them, which may be done by separating those that you would choose to make all possible increase from, into as many parts as you can conveniently, provided each one of them has a good eye or bud; but, those you intend to blow strong, should by no means be parted too small, which greatly weakens their flowering. You should observe, in planting the roots, to distribute the different colours, so as to make an agreeable mixture of each in every bed, which will greatly add to their beauty.

ANEMONE PUSILLA, *f.* in botany. See DRYAS.

Sea-ANEMONE. See ANIMAL-FLOWER.

ANEMONIDES, *f.* in botany. See ANEMONE.

ANEMONOSPERMOS, *f.* in botany. See ARCTOTIS and GORTERIA.

ANEMOSCOPE, *f.* [of *ανέμος*, the wind, and *σκοπεω*, Gr. to view.] A machine invented to foretell the changes of the wind, or weather; and sometimes for an instrument shewing by an index what the present direction or course of the wind is. Of this latter sort was that used by the ancients, and described by Vitruvius; and we have many of them at present in large or public buildings, where an index within a room or hall points to the name of the quarter from whence the wind blows without; which is simply effected by connecting an index to the lower end of the spindle of a weather-cock. Of this kind is the anemoscope in one of the turrets of the Queen's Palace, in St. James's Park. But the best machine for shewing the course and velocity of the wind, was invented by the late Mr. Pickering, and published in the Philosophical Transactions, No. 473. His anemoscope is four feet and a quarter high, consisting of a broad and weighty pedestal, a pillar fastened into it, and an iron axis of about half an inch diameter fastened into the pillar. Upon this axis turns a wooden tube; at the top of which is placed a vane, of the same materials, twenty-one inches long, consisting of a quadrant, graduated, and shod with an iron rim, notched to each degree; and a counter-

poise of wood, as in the figure, on the other. Through the centre of the quadrant runs an iron pin, upon which are fastened two small round pieces of wood, which serve as moveable radii to describe the degrees upon the quadrant, and as handles to a velum or sail, whose pane is one foot square, made of canvas, stretched upon four battens, and painted. On the upper batten, next to the shod rim of the quadrant, is a small spring which catches at every notch corresponding to each degree, as the wind shall, by pressing against the sail, raise it up; and prevents the falling back of the sail, upon lessening of the force of the wind. At the bottom of the wooden tube is an iron index, which moves round a circular piece of wood fastened to the top of the pillar on the pedestal, on which are described the 32 points of the compass.

In the above figure of this machine, *a* is the pedestal; *b*, the pillar on which the iron axis is fitted; *c*, the circle of wood, on which are described the thirty-two points of the compass; *e*, the wooden tube upon its axis; *f*, the velum; *g*, the graduated quadrant; *h*, the counterpoise of the vane. The adjoining figure represents the velum, which takes off: *a* is the plane of the velum; *b*, the spring; *c*, the wooden radii; *dd*, the holes through which the pin in the centre of the quadrant goes. Its uses are the following: 1. Having a circular motion round the iron axis, and being furnished with a vane at top, and index at the bottom, when once you have fixed the artificial cardinal points, described on the round piece of wood on the pillar, to the same quarters of the heavens, it gives a faithful account of that quarter from which the wind blows. 2. By having a velum or sail elevated by the wind along the arch of the quadrant to an height proportionable to the power of the column of wind pressing against it, the relative force of the wind, and its comparative power, at any two times of examination, may be accurately taken. 3. By having a spring fitted to the notches of the iron with which the quadrant is shod, the velum is prevented from returning back upon the fall of the wind; and the machine gives the force to the highest blast, since the last time of examination, without the trouble of watching it.

ANE'NT, *prep.* [a word used in the Scotch dialect.] Concerning; about; as, He said nothing *anent* this particular. Over against; opposite to; as, He lives *anent* the market-house.

ANES or Awns, *f.* The spires or beards of corn.

ANETHIFOLIUS, *f.* in botany. See PROTEA.

ANE'THUM, *f.* [*ανέθον*, Gr. from its running up quick or straight.] In botany, a genus of the pentandria digynia class, ranking in the natural order of umbellatæ, or umbelliferæ. The generic characters are—Calyx: umbel universal and partial manifold; involucre, neither universal nor partial; perianthium proper obsolete. Corolla: universal uniform; floscules all fertile, proper; petals five, involute, entire, very short. Stamina: filaments capillary; antheræ roundish. Pistillum: germ inferior; styles approximating, obsolete; stigmas obtuse. Pericarpium: none; fruit subovate, compressed, striated, bipartite. Seeds: two; subovate, margined, convex, and striated on one side, flat on the other.—*Essential Character.* Fruit subovate, compressed, striated; petals involuted entire.

Species. 1. *Anethum graveolens*, or common dill: fruit compressed. Dill differs from fennel, which it otherwise resembles very much, in having an annual root, a smaller and lower stem, seldom exceeding three quarters of a yard; the leaves more glaucous, and of a less pleasant smell; the seeds broader, flatter, surrounded with a membranaceous rim, and of a less pleasant flavour than fennel seeds; the umbels of flowers yellow, but smaller than those of fennel. This plant has a peculiar strong smell, but aromatic. The bruised herb is anodyne and resolvent. The seeds are aromatic, and contain an ethereal oil; are useful therefore in flatulencies; for this purpose they rub the bellies of children with the oil prepared by infusion: the essential oil is also good in the cholic. A distilled water, drawn off to the quantity of a gallon from a pound of the seeds, was ordered in the London Pharmacopœia; and occasionally made the basis of carminative draughts and juleps: its flavour is more agreeable than that of the seeds in substance. Along with the water arises a considerable quantity of essential oil, which is given from one to three or four drops, or more, as a carminative; and in hiccoughs. No mention is made of this in the last edition of the London Pharmacopœia. It grows wild among the corn in Spain and Portugal; also in Italy on the coast. It is annual, and was cultivated in 1597.

2. *Anethum segetum*: three stem-leaves, fruits oval. Annual. A native of Portugal.

3. *Anethum fœniculum*, or fennel or finckle: fruit ovate. Native of Germany, Spain, Italy, Madeira, China, &c. It flowers in July, and the seeds ripen in autumn. Height five or six feet. Of this species there are three varieties: i. *Fœniculum vulgare*, or common fennel: Has a strong fleshy root, which penetrates deep into the ground, and will continue several years. It flowers in July, and the seeds ripen in autumn. It has sown itself in many places where it has been introduced in such plenty, as to appear as if it were a native in England; but it is no where found at a great distance from gardens. It is however enumerated among our native plants, by Hudson, Withering, &c. though certainly not originally so: and is now common on chalk-cliffs, as about Marazion in Cornwall, in Sussex, about Gravesend, and other parts of Kent; and in many inland places, as Nottingham castle, near Spetchly in Worcestershire, Burwell, and other places in Cambridgeshire. ii. *Fœniculum dulce*, or sweet fennel: The sweet fennel has been by many supposed only a variety of the common sort. The leaves of it are very long and slender, growing more sparsely, and do not end in so many points as those of the common sort; the stalks do not rise so high, and the seeds are longer, narrower, and of a lighter colour. These seeds are generally imported from Germany or Italy, and are by some preferred to those of the common sort for use, being much sweeter. The tender buds of fennel are eaten in salads. The leaves boiled are used as sauce for fish, and they are eaten raw with pickled fish. In Spain they put them up with olives and pickled pork. A pound of sweet fennel seeds impregnates a gallon of water strongly with their flavour, in distillation. A great quantity of yellowish essential oil floats on the surface of the water, mild and sweetish like oil of aniseeds, and, like it also, congealing by a slight cold into a white mass like butter. These seeds contain likewise a considerable quantity of gross expressed oil, which is extracted, along with the aromatic matter of the fennel, by digestion in rectified spirit, but rises to the surface upon inspissating the filtered tincture: the concentrated extract retains much the greatest part of both taste and finell. The seeds of common fennel are warmer and more pungent, but less sweet, and of a less grateful flavour. There is the same difference in the preparations from them: the spirituous tincture of sweet fennel is yellowish; of this, greenish. The leaves impregnate water by distillation with a grateful flavour, and yield a considerable portion of essential oil. An extract made from them by rectified spirit, is likewise no inelegant aromatic. The

roots, taken up early in the spring, have a pleasant sweetish taste, with a slight aromatic warmth. They are ranked among the aperient roots, and supposed by some to be equivalent in virtue to the *ginseng*; from which however they differ considerably in their sensible qualities. iii. *Fœniculum Azoricum*, or Azorian fennel or finocchio: The finocchio is supposed to have been originally brought from the Azorian islands; it has been long cultivated in Italy as a salad-herb; and there are some few gardens in England, where it is now cultivated, but in small quantities, for there are not many English palates which relish it, nor is it easy to be furnished with good seeds; those which are annually brought from Italy seldom prove good; and it is difficult to save it in England, because the winter frequently kills those plants which are left for seeds, and, when any good plants of the early sowing are left for seeds, they do not ripen, unless the winter should prove very favourable. This sort has very short stalks, which swell just above the surface of the ground to four or five inches in breadth, and almost two thick, being fleshy and tender: this is the part which is eaten when blanched, with oil, vinegar, and pepper, as a cold salad. When the plants are permitted to run for seeds, the stalks do not rise more than a foot and a half high, having a large spreading umbel standing on the top. The seeds of this sort are narrow, crooked, and of a bright yellow colour; they have a very strong smell like anise-seed, and are very sweet to the taste.

Propagation and Culture. Dill is propagated by sowing the seeds, which should be done in autumn soon after they are ripe; for, if they are kept out of the ground till spring, they frequently miscarry; or, if any of the plants come up, they often decay before they have perfected their seeds. They love a light soil, and will not bear to be transplanted, but must be sown where they are to remain, and should be allowed eight or ten inches room to grow, otherwise they will draw up very weak, and produce few lateral branches, whereby their leaves will decay, and be rendered useless, nor will they produce so good seeds; therefore the best way is, when the plants are come up, to hoe them out, as is practised for onions, carrots, &c. leaving the plants about eight or ten inches asunder every way, observing to keep them clear from weeds; and, when the seeds begin to be formed, you should cut up those that are intended to be put into the pickle for cucumbers, leaving those that are intended for the use of the seeds until they are ripe; at which time they should be cut, and spread upon a cloth to dry, and then beat out for use. If you let the seeds fall upon the ground, the plants will rise the next spring without any care.

The best time to sow the seeds for fennel is, soon after they are ripe; the plants will come up in the autumn, or the following spring, and require no other care but to keep them clear from weeds, and thin the plants where they are too close; it will grow in any soil or situation.

For the cultivation of finocchio, your first care must be to procure good seeds from some person who has been careful in the choice of the plants, otherwise there will be little hope of having it good; for the plants will run up to seed before they swell to any size, and thus not be fit for use: then make choice of a good spot of light rich earth, not dry nor very wet, for in either extreme this plant will not thrive. The first crop may be sown about a fortnight in March, which, if it succeeds, will be fit for use in July; and, by sowing at several times, there may be a supply for the table till the frost puts a stop to it. After having well dug and levelled the ground, you must make a shallow drill by a line, into which you must scatter your seeds pretty thin; for, if your plants are six inches asunder in the rows, it will be full near enough; however, you must expect some of your seeds to fail, and therefore you should scatter them about two inches distance; then cover the seeds about half an inch thick with earth, laying it smooth: these drills should be made eighteen inches asunder, or more, that there may be room to clean

the ground, as also to earth up the plants when they are full grown. When the plants come up, which will be in about three weeks or a month after sowing, you must with a small hoe cut up all the weeds between them, and, where the plants are too close; they should be thinned to about three inches distance; and as they advance, and the weeds spring again, they should, from time to time, be hoed; and, at the last time of thinning them, they should be left seven or eight inches asunder at least. If your kind be good, the stems of the plants will increase to a considerable bulk just above the surface of the ground; which part should be earthed up in the manner of celery, to blanch, about a fortnight or three weeks before it is used, and this will cause it to be very tender and crisp. Your second crop should be sown about three weeks after the first, and so continue sowing every three weeks or a month till the end of July, after which time it will be too late for the plants to come to any perfection. But you should observe to sow in April, May, and June, on a moister soil than that which you sowed the first on; as also what you sow in the latter part of July, should be sown on a drier soil, and in a warmer situation; because this crop will not be fit for use till late in autumn, and therefore will be subject to injuries from too much wet or cold weather, if on a moist soil. But as the ground is often extremely dry in June and July, and the seeds more apt to miscarry and not come up, you should therefore observe to water and shade the beds where this seed is sown at that season, until the plants come up. And, if the season should prove dry, the plants must be duly watered, otherwise they will run up to seed before they are of any size; therefore there should be a channel made where every row of plants grows, to detain the water which is poured on them. In the autumn, if there should happen sharp frosts, it will be very proper to cover the plants with some pease-haulm, or other light covering, to prevent their being pinched; by which method they may be continued for use till the middle of winter. A small bed of this plant will be sufficient at each sowing for a middling family; and, for a large family, a bed of about twenty feet long, and four feet broad, will be full enough at a time.

A'NEURISM, *f.* [from *ανευρνω*, Gr. to dilate much; of *ανα*, asunder, and *ευρος*, broad.] A disease of the arteries, in which, either by a preternatural weakness of any part of them they become excessively dilated; or, by a wound through their coats, the blood is extravasated amongst the adjacent cavities. See **SURGERY**.

ANE'W, *adv.* [from *a* and *new*.] Over again; another time; repeatedly. This is the most common use:

That, as in birth, in beauty you excel,
The muse might dictate, and the poet tell:
Your art no other art can speak; and you,
To shew how well you play, must play *anew*. *Prior*.

Newly; in a new manner.—He who begins late, is obliged to form *anew* the whole disposition of his soul, to acquire new habits of life, to practise duties to which he is utterly a stranger. *Rogers*.

ANFRAC'TUOUS, *adj.* [from *anfractus*, Lat.] Winding; mazy; full of turnings and winding passages.—Behind the drum are several vaults and *anfractuous* cavities in the ear-bone, so to intend the least sound imaginable, that the sense might be affected with it; as we see, in subterraneous caves and vaults, how the sound is redoubled. *Ray*.

ANFRAC'TUOUSNESS, *f.* Fullness of windings and turnings.

ANFRAC'TURE, *f.* [from *anfractus*, Lat.] A turning; a mazy winding and turning.

ANGA'RI, or **ANGA'RIL**, *f.* in antiquity, denote public couriers, appointed for the carrying of messages. The ancient Persians, Budæus observes, had their *αγγελιστον εφορνια*; which was a set of couriers on horseback, posted at certain stages or distances, always in readiness to receive the dispatches from one, and forward them to another, with wonderful celerity, answering to what the moderns

call *posts*, *q. d. positi*, as being posted at certain places or stages. The angari were also called by the Persians *ajlandæ*; by the Greeks *ημεροδρομοι*, on account of the long journeys they made in one day, which according to Suidas amounted to no less than 1500 stadia.

ANGA'RIA, *f.* in Roman antiquity, a kind of public service imposed upon the provincials, which consisted in providing horses and carriages for the conveyance of military stores, and other public burdens. It is sometimes also used for a guard of soldiers, posted for the defence of a place. In a more general sense, it is used for any kind of oppression or services performed through compulsion, such as pressing horses, men, ships, &c. for the public service.

ANGA'ZYA, one of the Comorra islands, lying between the north end of Madagascar and the coast of Zanguebar in Africa, from lat. 10° to 15° S. It is inhabited by Moors, who trade with divers parts of the continent, in cattle, fruits, and other commodities of the island, which they exchange for calicoes and other cotton cloths. The houses here are built of stone, and lime made of calcined oyster-shells; with which the walls and roof are plastered in a very elegant manner. The government of Angazya is pure aristocracy; the island being subject to ten lords, who have all the title of *sultan*. The people are very careful of their women; never permitting strangers to see them, without permission from a sultan, or an order which the stranger brings with him. Many of them read and write Arabic with great facility; and some even understand Portuguese, which they learn from their intercourse with Mosambique, whither they trade in vessels of forty tons burthen.

ANGEIO'GRAPHY, *f.* [of *αγγειον*, a vessel; and *γραφη*, a description, from *γραφω*, Gr. to write or describe.] A description of vessels in the human body; nerves, veins, arteries, and lymphatics.

ANGEIO'LOGY, *f.* [from *αγγειον* and *λογος*, Gr.] A treatise or discourse of the vessels of a human body.

ANGEIOMONOSPER'MOUS, *f.* [of *αγγειον*, a vessel, *μονος*, alone or single, and *σπερμα*, Gr. seed.] Such plants as have but one single seed in the seed-pods.

ANGEIO'TOMIST, *f.* A person skilled in the course of the blood-vessels, or who can dissect them readily.

ANGEIO'TOMY, *f.* [from *αγγειον*, a vessel, and *τομή*, Gr. to cut.] An opening of the vessels as in arteriotomy and phlebotomy. It also signifies a particular dissection of the vessels for anatomical purposes.

A'NGEL, *f.* a spiritual intelligent substance, the first in rank and dignity among created beings. The word *angel* is Greek (*αγγελος*), and signifies a messenger; the Hebrew *מלאך* signifies the same thing. The angels are in Daniel, chap. iv. ver. 13, &c. called *כְּשִׁיפִים* or watchers, from their vigilance: for the same reason they are, in the remains we have of the prophecy attributed to Enoch, named *egregori*; which word imports the same in Greek.

Angels, therefore, in the proper signification of the word, do not import the nature of any being, but only the office, to which they are appointed, especially by way of message, or intercourse between God and his creatures; in which sense they are called the *ministers of God*, who do his pleasure, and *ministering spirits* sent forth to minister for them who shall be heirs of salvation. That there are such beings as we call angels, that is, certain permanent substances, invisible, and imperceptible to our senses, endued with understanding and power superior to that of human nature, created by God, and subject to him as a supreme Being; ministering to his divine providence in the government of the world by his appointment, and more especially attending the affairs of mankind; is a truth so fully attested by Scripture, that it cannot be doubted. Nay, the existence of such invisible beings was generally acknowledged by the ancient heathens, though under different appellations: the Greeks called them *demons*; and the Romans *genii*, or *lares*. Epicurus seems to have been the only one among the old philosophers who absolutely rejected

rejected them. Indeed, the belief of middle intelligences influencing the affairs of the world, and serving as ministers or interpreters between God and man, is as extensive as the belief of a God; having never, so far as we know, been called in question by those who had any religion at all.

The creation of angels is not indeed expressly mentioned by Moses in the first of Genesis, yet it is generally considered by judicious expositors as implied. The reason why the sacred historian is silent on this subject, is supposed by Berrington to be the natural proneness of the Gentile world, and even of the Jews, to idolatry. And it is thought, if they worshipped mere material elements, which was the case, much more might they be inclined to worship such superior and sublime beings as angels. But a better reason is perhaps given by other writers, viz. that this first history was purposely and principally for information concerning the visible world; the invisible, of which we know but in part, being reserved for a better life.

On what day they were created has been matter of conjecture. It is a point on which learned men have differed. The Socinians, indeed, hold, says bishop Hopkins, that it was long before the account given by Moses, but it must have been within the six days creation; because, as we are informed, that within this space God made heaven and earth, and all things that are therein. All the writers that we have seen on this subject, think they were included in the first day's work, when the heavens were framed.

It has been thought by some persons, that the words of Job, "When the morning stars sang together, and all the sons of God shouted for joy," militate against the creation of angels within the six days. About the meaning of these words, however, expositors are not agreed; but, admitting that they refer literally to angels, Dr. Lightfoot, Caryl, and others, see no difficulty in the passage. The doctor thinks they were created on the first day, with the heavens; and that they were spectators of God's works in the other parts of creation, and praised and magnified the Lord for his works all along; singing and shouting when God laid the foundation of the earth, as the Jews did at the laying the foundation of the temple, Ezra iii.

On a subject of this nature, it would be imprudent to indulge a spirit of conjecture. Scripture is the only standard by which truth and error can be tried, and to this we must ultimately appeal. It is acknowledged that Moses has not expressly mentioned angels by name; yet, as we have remarked, their creation is undoubtedly implied: for the heavens must include all that are in them; and therefore it is that the divine penman says, in the conclusion of his narrative, "Thus the heavens and the earth were finished, and all the host of them." Of the *hosts* of heaven, the angels must form a considerable part; they are expressly called the *heavenly host*, and the *armies of heaven*, Dan. iv. 35. Luke ii. 13. And, if divine authority be admitted as decisive, the reasons adduced by Jehovah for the sanctification of a sabbath, demonstrate that they did not exist previous to the creation of the heavens. It is, surely, asserted with propriety, that in *six days* the Lord made heaven and earth, the sea, and ALL that *in them is*. Similar to which is a declaration of the divine historian relating to the same fact: "And God blessed the seventh day and sanctified it; *because* that in it he had rested from ALL his work which God created and made," Gen. ii. 3. Now, if angels existed prior to the six days of the creation, the language of Moses is far from being accurate and intelligible; and especially when it is considered that the obscurity might have been removed by adding, "from all the work which God had *then* created and made."

But, if angels were created before the heavens, where could they exist? For, as the learned Gill has remarked, "though angels have no bodies, and so are not in place circumscriptively; yet as they are creatures they must have an *ubi*, a somewhere in which they are definitively; so that they are here, and not there, and much less every where. Now where was there an *ubi*, a somewhere, for

them to exist in, before the heavens and the earth were made? It is most reasonable, therefore, to conclude, that as God prepared an habitation for all the living creatures before he made them; as the sea for the fishes, the expanse, or air, for the fowls, and the earth for men and beasts; so he made the heavens first, and then the angels to dwell in them."

That this was the fact, will appear very evident, if the words of Moses be impartially considered. "In the beginning (says he), God created the heavens and the earth;" which words must refer to either the beginning of *creation* or of *time*: if to the former, and angels previously existed, the language is neither *intelligible* nor conformable to *truth*: if to the latter, the difficulty remains; for what is time but the measure of created existence. "Time (says the judicious Charnock) began with the foundation of the world: before the beginning of the creation and the beginning of time, there could be nothing but eternity; nothing but what was uncreated, that is, nothing but what was without beginning." But, if angels were in a pre-existent state, the historian's language is unaccountably strange and inaccurate: for if the phrase *in the beginning*, which is remarkably emphatical, refer to the creation of the heavens and the earth *only*, they are unhappily expressed; so expressed, indeed, as to convey no meaning to those who consider words as the vehicle of thought, and as intended to express clearly to others the meaning of the writer. For the *natural obvious* sense is as follows: "In the beginning of the creation of the heavens and the earth, God created the heavens and the earth;" which language is not only a departure from that perspicuity and precision which distinguish all his narrations, but entirely irrational and absurd.

That the words *in the beginning* refer to the first creation, cannot be doubted, if it be remembered that JEHOVAH himself founds a claim to *eternity* on this very ground: "Before the day was, I am he." "Before the mountains were brought forth, or ever thou hadst formed the earth and the world, even from everlasting to everlasting, thou art God." Isa. xliii. 13. Ps. ix. 2. See also Prov. viii. 22, 23, &c. Now there could be no propriety in this kind of reasoning, if angels or any other creature existed before the creation of the world, because all claims to eternity from such premises would apply even to Gabriel as well as to JEHOVAH. "Before the world was," is, in Scripture language, a phrase always expressive of eternity; and on this principle the evangelist John asserts the divinity of Jesus Christ in the first chapter of his history. For this purpose he alludes to the words of Moses, and introduces his divine master to notice by celebrating the first act of his creative power. "In the beginning (says he) was the Word;" that is, Dr. Doddridge remarks, before the foundation of the world, or the first production of any creature: and Dr. Sherlock is of opinion, that the words, in their most common and usual acceptation, signify the first creation of all things, and are a demonstration of the divinity of Christ. Of the same mind was Dr. Owen. He says, that, if the phrase *beginning* does not absolutely and formally express *eternity*, yet it doth a pre-existence to the whole creation, which amounts to the same thing; for no thing can pre-exist before all creatures but the nature of God, which is eternal, unless we suppose a creature before the creation of any. But what is meant by this expression is fully declared by other passages of Scripture: "I was set up from everlasting, before the *beginning*, or ever the earth was;" "Glorify thou me with thine own self, with the glory which I had with thee before the world was;" both which passages not only explain the text, but undeniably prove the pre-existence of Christ the son of God.

If, therefore, the words of Moses be impartially viewed in their obvious and natural meaning, and compared with other passages of Scripture that relate to the same subject, we have no doubt but every unprejudiced mind will perceive, that as he intended to give a summary history of the creation of all things both in heaven and earth,

earth, he has done it in language intelligible and accurate, and in terms sufficiently explicit.

As to the nature of these beings, we are told, that they are spirits: but whether pure spirits divested of all matter, or united to some thin bodies, or corporeal vehicles, has been a controversy of long standing. Not only the ancient philosophers, but some of the Christian fathers, were of opinion, that angels were clothed with ethereal, or fiery, bodies, of the same nature with those which we shall one day have when we come to be equal to them. But the more general opinion, especially of later times, has been, that they are substances entirely spiritual, tho' they can at any time assume bodies, and appear in human or other shapes.

That the angelical powers and abilities vastly excel those of man, cannot be denied, if we consider, that their faculties are not clogged or impeded, as ours are, by any of those imperfections which are inseparable from corporeal beings: so that their understandings are always in perfect vigour; their inclinations regular; their motions strong and quick; their actions irresistible by material bodies, whose natural qualities they can controul, or manage to their purposes, and occasion either blessings or calamities, public or private, here below; instances of which are too numerous to mention.

Besides their attendance on God, and their waiting and executing his commands, they are also presumed to be employed in taking care of mankind and their concerns: and that every man had such a tutelar or guardian angel, even from his birth, was a firm belief and tradition among the Jews; and our Saviour himself seems to have been of the same sentiment. The heathens were also of the same persuasion, and thought it a crime to neglect the admonitions of so divine a guide. Socrates publicly confessed himself to be under the direction of such an angel, or demon, as several others have since done. And in this tutelar genius of each person they believed his happiness and fortune depended. Every genius did his best for the interest of his client; and, if a man came by the worst, it was a sign the strength of his genius was inferior to that of his opponent, that is, of an inferior order; and this was governed by chance. There were some genii, whose ascendant was so great over others, that their very presence entirely disconcerted them; which was the case of that of Augustus in respect of that of Marc Antony; and, likewise, for the same reason, perhaps, some persons seem to have wit, and to speak well, when others are absent, in whose presence they are confounded, and out of countenance. The Romans thought the tutelar genii of those who attained the empire to be of an eminent order; on which account they had great honours shewn them. Nations and cities also had their several genii. The ancient Persians so firmly believed the ministry of angels, and their superintendence over human affairs, that they gave their names to their months, and the days of their month; and assigned them distinct offices and provinces: and it is from them the Jews confess to have received the names of the months and angels, which they brought with them when they returned from the Babylonish captivity. After which, we find, they also assigned charges to the angels, and in particular the patronage of empires and nations; Michael being the prince of the Jews, as Raphael is supposed to have been of the Persians.

The Mahometans have so great a respect for the angels, that they account a man an infidel who either denies their existence, or loves them not. They believe them to be free from sin, enjoying the presence of God, to whom they are never disobedient: that they have subtle pure bodies, being created of light; and have no distinction of sexes, nor do they need the refreshment of food or sleep. They suppose them to have different forms and offices: that some adore God in several postures; others sing his praises, and intercede for men; some carry and encompass his throne; others write the actions of men, and are assigned guardians to them. As the numbers of these celestial spi-

rits are very great, it is likewise reasonable to believe that there are several orders and degrees among them; which is also confirmed by Scripture; whence some speculative men have distributed them into nine orders, according to the different names by which they are there called; and reduced those orders into three *hierarchies*: to the first of which belong seraphim, cherubim, and thrones; to the second, dominions, virtues, and powers; and to the third, principalities, arch-angels, and angels. They imagine farther, that there are some who constantly reside in heaven; others who are ministers, and sent forth, as there is occasion, to execute the orders they receive from God by the former. The Jews reckon but four orders or companies of angels, each headed by an arch-angel; the first order being that of Michael, the second of Gabriel, the third of Uriel, and the fourth of Raphael; but, though the Jews believe them to be four, yet it seems there were rather seven. The Persians also held, there were subordinate degrees among the angels.

Although the angels were originally created perfect, good, and obedient to their Master's will, yet some of them sinned, and kept not their first estate, but left their habitation; and so, of the most blessed and glorious, became the most vile and miserable, of all God's creatures. They were expelled the regions of light, and cast down to hell, to be reserved in everlasting chains under darkness, until the day of judgment. With heaven they lost their heavenly disposition, which delighted once in doing good and praising God; and fell into a settled rancour against him, and malice against men: their inward peace was gone; all desire of doing good departed from them; and, instead thereof, revengeful thoughts and despair took possession of them, and created an eternal hell within them. When, and for what offence these apostate angels fell from heaven, and plunged themselves into such an abyss of wickedness and woe, are questions very hard, if not impossible, to be determined by any clear evidence of scripture. As to the time, we are certain that it could not be before the sixth day of creation; because on that day it is said, "God saw every thing that he had made, and behold it was very good;" but that it was not long after is very probable, as it must have preceded the fall of our first parents. Some have imagined it to have been after; and that carnality, or lust to converse with women upon earth, was the sin that ruined them. Lactantius supposes the angels, who were guilty of this enormity, had been sent down by God to guard and take care of mankind; and, being endued with free-will, were charged by him not to forfeit the dignity of their celestial nature, by defiling themselves with the corruptions of the earth; but that the devil at length enticed them to debauch themselves with women. He adds, that, being not admitted into heaven by reason of the wickedness into which they had plunged themselves, they fell down to the earth, and became the devil's ministers; but that those who were begotten by them, being neither angels nor men, but of a middle nature, were not received into hell, no more than their parents were into heaven. Hence arose two kinds of demons, celestial and terrestrial. These are unclean spirits, the authors of whatever evils are committed, and whose prince is the devil. From hence very probably proceeded the notions of *Incubi*, or demons who are supposed to have carnal knowledge of women. Others have supposed, that the angels, being informed of God's intention to create man after his own image, and to dignify his nature by Christ's assuming of it, and thinking their glory to be eclipsed thereby, envied man's happiness, and so revolted: and with this opinion that of the Mahometans has some affinity; who are taught, that the devil, who was once one of those angels who are nearest to God's presence, and named *Azazel*, forfeited paradise for refusing to pay homage to Adam at the command of God. But, on what occasion soever it first shewed itself, pride seems to have been the leading sin of the angels; who, admiring and valuing themselves too much on the excellence of their nature

ture and the height of their station, came at length to entertain so little respect for their Creator, as to be guilty of downright rebellion and apostasy. 'Tis certain from scripture, that these fallen angels were in great numbers, and that there was also some order and subordination preserved among them; one especially being considered as their prince, and called by several names, *Belzebub*, *Satan*, or *Sammael*, by the Jews; *Ahrimam* by the Persians; and *Eblis* by the Mahometans. Their constant employment is not only doing evil themselves, but endeavouring by all arts and means to seduce and pervert mankind, by tempting them to all kinds of sin, and thereby bringing them into the same desperate state with themselves.

ANGEL is likewise a title given to bishops of several churches. In this sense is St. Paul understood by some authors, where he says, "Women ought to be covered in the church, because of the angels." The learned Dr. Prideaux observes, that the minister of the synagogue, who officiated in offering up the public prayers, being the mouth of the congregation, delegated by them as their representative, messenger, or angel, to speak to God in prayer for them, was therefore, in the Hebrew language, called the *angel* of the church; and from thence the bishops of the seven churches of Asia are, by a name borrowed from the synagogue, called the *angels* of those churches.

ANGEL, in commerce, the name of a gold coin formerly current in England. It had its name from the figure of an angel represented upon it, weighed four pennyweights, and was twenty-three and a half carats fine. It had different values in different reigns; but is at present only an imaginary sum, or money of account, implying ten shillings.

ANGEL, *adj.* Resembling angels; angelical:

I have mark'd

A thousand blushing apparitions

Start into her face; a thousand innocent shames

In *angel* whiteness bear away those blushes. *Shakespeare.*

Or virgins visited by *angel* powers,

With golden crowns, and wreaths of heav'nly flow'rs. *Pope.*

ANGEL FISH, *f.* in ichthyology, a species of *squalus*. See *SQUALUS*.

ANGEL-LIKE, *adj.* Resembling an angel:

In heav'n itself thou sure wert drest

With that *angel-like* disguise.

Waller.

ANGEL-SHOT, *f.* [perhaps properly *angle-shot*, being folded together with a hinge.] Chain-shot, being a cannon bullet cut in two, and the halves being joined together by a chain.

ANGE'LIC, *adj.* [*angelicus*, Lat.] Partaking of the nature of angels; angelical; above human:

My fancy form'd thee of *angelic* kind,

Some emanation of th' all-beauteous mind.

Pope.

ANGELIC GARMENT (*angelica vestis*), among our ancestors, was a monkish garment, which laymen put on a little before their death, that they might have the benefit of the prayers of the monks. It was from them called *angelical*, because they were called *angeli* who by these prayers *animæ salutis succurrebant*. Hence, where we read the phrase *monachus ad succurrendum* in our old books, it must be understood of one who had put on the habit when he was at the point of death.

ANGE'LICA, *f.* [from the angelic or supposed super-excellent qualities of the roots and seeds.] In botany, a genus of the pentandria digynia class, ranking in the natural order of umbellatæ or umbellifere. The generic characters are—Calyx: universal umbel manifold, roundish; partial, when flowering exactly globular; universal involucre three or five leaved, small; partial eight-leaved, small; proper perianthium five-toothed, scarcely observable. Corolla: universal uniform; floscules all fertile, partial, petals five, equal, lanceolate, flattish, incurved, caducous. Stamina: filaments simple, longer than the corolla; antheræ simple. Pistillum: germ inferior; styles

reflex; stigmas obtuse. Pericarpium: none; fruit roundish, angular, solid, bipartite. Seeds: two, ovate; flat on one side, and margin'd; convex on the other, scored with three lines.—*Essential Character.* Fruit roundish, angular, solid, with reflex styles. Corollas equal, with petals bent inwards.

Species. 1. *Angelica archangelica*, or garden angelica: the odd leaflet of the leaves lobed. Root thick, branched, very long, brown on the outside, white within. Fruit elliptic, swelling, lens-shaped, slightly emarginate at both ends, grooved and winged, whitish or pale straw-colour; splitting into two seeds, which are convex on one side, with a stiff marginal wing, and three on the back similar to it; flat on the other side, with a single raised longitudinal streak. This is the structure of the seeds in the garden plant; the wild one has no dorsal wings, but only three curved risings, and those very low ones. Scopoli remarks, that, in this species, the back of the seed is more convex than in the *sylvestris*, and truly furrowed; so that it cannot be said to be marked with lines, but to be really angular. Native of the northern parts of Europe. It flowers with us from June to August; and was cultivated here in 1568. Mr. Miller makes a distinct species of the angelica which grows naturally in Hungary and some parts of Germany. He affirms, that, from many years experience in the culture of this plant, he could never observe any alteration in it; for all the plants which he raised from seeds proved exactly the same as the parent plant; and, when planted in the same soil with the common sort, they were twice their size. The leaves were also much larger, and deeper sawed on the edges, the umbels much larger, and the flowers were yellow. The stalks of garden angelica were formerly blanched, and eaten as celeri. The young shoots are in great esteem among the Laplanders. In Norway bread is sometimes made of the roots. The gardeners near London, who have ditches of water running through their gardens, propagate great quantities of this plant, for which they have a large demand from the confectioners, who make a sweetmeat with the tender stalks of it cut in May. The roots are one of the principal aromatics of European growth, though not much regarded in the present practice. The other parts of the plant have the same flavour, but their active principles are far more perishable. The seeds, which come nearest to the roots, can scarcely be kept till the spring after they are gathered. These, however, are the only part of the plant which is ordered by the London college, and that only in compound spirit of aniseed. The college formerly directed the roots brought from Spain to be kept in the shops; but they are probably more efficacious on their native northern mountains; and accordingly that direction is now dropped.

2. *Angelica sylvestris*, or wild angelica: leaflets equal, ovate-lanceolate, ferrate. Our wild angelica grows to the height of six feet, with a smooth stem. The fruit has four wings, and three ridges on each side. It is perennial, and is found common in moist woods and hedges, and by the sides of rivers, flowering in July and August. This, possessing only the same properties with garden angelica in a far lower degree, has been long neglected. The herb, however, dyes a good yellow.

3. *Angelica verticillaris*: leaves very much divaricate, leaflets ovate, ferrate, stem verticilled with peduncles. Height of the stem six feet and more, with a glaucous bloom on it. Flowers green. A native of Italy and Silesia.

4. *Angelica atropurpurea*, or purple angelica: the outermost pair of leaves coadjoined; the terminal leaf petioled. A native of North-America.

5. *Angelica lucida*, or shining angelica: leaflets equal, ovate, gaih-ferrate. It flowers in June, and the seeds ripen in August. Native of Canada.

6. *Angelica Razulii*: leaves bipinnate, leaflets lanceolate, ferrate, decurrent. Native of the Apennines and Piedmontese mountains. It was found on the former by M. Rafouls, an apothecary at Perpignan, whence the trivial name.

Propagation

Propagation and Culture. All the sorts may be increased by seeds. The common angelica delights to grow in a very moist soil; the seeds of this plant should be sown soon after they are ripe; for, if they are kept until the spring, seldom one seed in forty will grow. When the plants are come up about six inches high, they should be transplanted at a great distance, for their leaves extend very wide. The best place for this plant is upon the sides of ditches, or pools of water; where, being planted about three feet asunder, they will thrive exceedingly. The second year after sowing, they will shoot up to flower; therefore, if you have a mind to continue their roots, you should cut down these stems in May, which will occasion their putting out heads from the sides of the roots, whereby they may be continued for three or four years; whereas, if they had been permitted to seed, their roots would perish soon after; where it is cultivated for the seeds, there should be new plantations annually made to supply the places of those which die, for, when they are permitted to seed, they last but two years. See *ÆGROPODIUM*, *CHÆROPHYLLUM*, *CICUTA*, *LASERPITIUM*, *SELINUM*, and *SMYRNIUM*.

ANGELICA-TREE. See *ARALIA*.

ANGELICAL, *adj.* [*angelicus*, Lat.] Resembling angels.—It discovereth unto us the glorious works of God, and carrieth up, with an *angelical* swiftness, our eyes, that our mind, being informed of his visible marvels, may continually travel upward. *Raleigh*. Partaking of the nature of angels:

Others, more mild,
Retreated in a silent valley, sing
With notes *angelical* to many a hap
Their own heroic deeds, and hapless fall
By doom of battle.

Milton.

Belonging to angels; suiting the nature or dignity of angels.—It may be encouragement to consider the pleasure of speculations, which do ravish and sublime the thoughts with more clear *angelical* contentments. *Wilkins*.

ANGELICALNESS, *f.* The quality of being angelical; resemblance of angels; excellence more than human.

ANGE'LICS, or **ANGELICI**, in church-history, an ancient sect of heretics, supposed by some to have got this appellation for their excessive veneration of angels; and by others, from their maintaining that the world was created by angels.

ANGELICS is also the name of an order of knights, instituted in 1191, by Angelus Flavius Comnenus, emperor of Constantinople.

ANGELICS is also a congregation of nuns, founded at Milan, in 1534, by Louisa Torelli, countess of Guastalla. They observe the rule of St. Augustine.

ANGELITES, in ecclesiastical history, a sect of Christian heretics, in the reign of the emperor Anastasius, and the pontificate of Symmachus, about the year 494, so called from Angelium, a place in the city of Alexandria, where they held their first meetings. They were called likewise *Severites*, from one Severus, who was the head of their sect; as also *Theodosians*, from one among them named Theodosius, whom they made pope at Alexandria. They held that the persons of the Trinity are not the same; that none of them exists of himself, and of his own nature; but that there is a common god or deity existing in them all, and that each is God by a participation of this deity.

AN'GELO (Michael). There were five celebrated Italian painters of this name, who flourished in the 16th and 17th centuries; but the two most distinguished of them are these. First, **MICHAEL ANGELO BUONAROTI**, who was a most incomparable painter, sculptor, and architect, born in 1474, in the territory of Arezzi, in Tuscany. He was the disciple of Dominico Ghirlandajo; and erected an academy of painting and sculpture in Florence, under the protection of Lorenzo di Medicis; which, upon the troubles of that house, was obliged to remove to Bologna.

VOL. I. No. 44.

About this time he made an image of Cupid, which he carried to Rome, broke off one of its arms, and buried the image in a place he knew would soon be dug up, keeping the arm by him. It was accordingly found, and sold to cardinal St. Gregory for an antique; until Michael, to their confusion and his own credit, discovered his artifice, and confirmed it by the deficient arm which he produced. His reputation was so great at Rome, that he was employed by pope Sixtus to paint his chapel; and by the command of pope Paul III. executed his most celebrated piece *The last Judgment*. He has the character of being the greatest designer that ever lived; and it is universally allowed that no painter ever understood anatomy so well. He died immensely rich at Rome, in 1564. In the beginning of the present century, the senator Buonaroti caused the vault to be opened at Florence in which his body was deposited; it was found perfect; and the dress of green velvet, and even the cap and slippers, in which he was buried, were entire. He appeared to have been a small well-set man, with a countenance of great severity.

The late president of the Royal Academy carried his veneration for this great man so far, that he used to seal his letters with his head; and, in the picture which he painted of himself for the Royal Academy, has represented himself standing near a bust of Michael Angelo. So impressed was Sir Joshua Reynolds with the transcendent powers of Michael Angelo, that in the last speech, which, unfortunately for the lovers of art, he delivered as president of the Royal Academy, he thus concludes: "Gentlemen, I reflect, not without vanity, that these discourses bear testimony of my admiration of this truly divine man; and I should desire, that the last words which I should pronounce in this academy, and from this place, might be the name of Michael Angelo, Michael Angelo!"

One of the great ornaments of the present English school of painting, who has studied the works of this sublime artist with the greatest attention, and who has imitated them with the greatest success, (Mr. Fuseli,) gives the following character of his master and his model. "Sublimity of conception, grandeur of form, and breadth of manner, are the elements of Michael Angelo's style. By these principles he selected or rejected the objects of imitation. As painter, as sculptor, as architect, he attempted, and above any other man succeeded, to unite magnificence of plan and endless variety of subordinate parts with the utmost simplicity and breadth. His line is uniformly grand. Character and beauty were admitted only as far as they could be made subservient to grandeur. The child, the female, meanness, deformity, were by him indiscriminately stamped with grandeur. A beggar rose from his hand the patriarch of poverty; the hump of his dwarf is impressed with dignity; his women are moulds of generation; his infants teem with the man; his men are a race of giants. This is the '*terribilis via*' hinted at by Agostino Caracci, but perhaps as little understood by him as by Vafari, his blind adorer. To give the appearance of perfect ease to the most perplexing difficulty, was the exclusive power of Michael Angelo. He has embodied sentiment in the movements of St. Lorenzo, and in the chapel of Sixtus traced the characteristic line of every passion that sways the human race, without descending to individual features, the face of Biagio Cefena only excepted. The fabric of St. Peter, scattered into an infinity of jarring parts by Bramante and his followers, he concentrated, suspended the cupola, and to the most complex gave the air of the most simple of all edifices. Though as a sculptor he expressed the character of flesh more perfectly than all that went before or came after him, yet he never submitted to copy an individual; whilst in painting he contented himself with a negative colour, and as the painter of mankind rejected all meretricious ornament. Such was Michael Angelo as an artist. Sometimes he no doubt deviated from his principles, but it has been his fate to have had beauties and faults ascribed to him which belonged only to his servile copyists or unskilful imitators."

S P

Secondly,

Secondly, MICHAEL ANGELO DE CARAVAGGIO, born at that village in Milan, in 1569. He was at first no more than a bricklayer's labourer; but he was so charmed at seeing some painters at work, that he immediately applied himself to the art; and made such a progress in a few years, that he was admired as the author of a new style in painting. It was observed of Michael Angelo Buonaroti, that he was incomparable in designing, but knew little of colouring; and of Caravaggio, that he had as good a goût in colouring as he had a bad one in designing. There is one picture of his in the Dominican church at Antwerp, which Rubens used to call his master. It is said of this painter, that he was so strangely contentious, that the pencil was no sooner out of his hand but his sword was in it. He died in 1609.

ANGELO (St.) a small but strong town of Italy, in the Capitanata. There are several other towns and castles of the same name in Italy, and particularly the castle of St. Angelo at Rome. Lat. 41. 43. N. lon. 15. 56. E.

ANGÉLOS (Los), a province of Mexico, the ancient republic of Tlascala, of which a city called *Tlascala* was once the capital. That city is now reduced to an inconsiderable village, and has given place to another, called *Puebla des los Angeles*, or the City of Angels. It is situated in lat. 19. 13. N. and lon. 103. 12. W. It was formerly an Indian town; but in 1530 was entirely abandoned by the natives, on account of the cruelties of the Spaniards. A succeeding viceroy of Mexico, by a milder treatment, recalled them; and the town is now exceedingly rich and populous, so as even to vie with Mexico itself in magnificence. It is situated on the river Zacatula, in a fine valley, about twenty-five leagues to the eastward of Mexico. In the middle is a beautiful and spacious square, from whence run the principal streets in direct lines, which are crossed by others at right angles. One side is almost entirely occupied by the magnificent front of the cathedral; while the other three consists of piazzas, under which are the shops of tradesmen. The city is the see of a bishop, suffragan to the archbishop of Mexico; and we may form a judgment of the wealth of the place by the revenue of the cathedral and chapter, which amounts to 300,000 pieces of eight annually. It must be remembered, however, that in all popish countries the wealth of the laity by no means bears the same proportion to that of the clergy as in Britain. What contributes greatly to encrease the riches of this province is, that here is situated the city of Vera Cruz, the natural centre of all the American treasures belonging to Spain.

ANGÉLOT, *f.* in commerce, a small, fat, rich sort of cheese, brought from Normandy. It is made chiefly in the Pays de Bray, whence it is also denominated *angelot de Bray*. It is commonly made in vats, either square or shaped like a heart.

ANGELOT, *f.* A musical instrument somewhat resembling a lute.

ANG'ER, *f.* [A word of no certain etymology, but, with most probability, derived by Skinner from *ange*, Sax. vexed; which, however, seems to come originally from the Latin *ango*.]—*Anger* is uneasiness or discomposure of the mind, upon the receipt of any injury, with a present purpose of revenge. *Locke*.

Anger is like

A full hot horse, who being allow'd his way,
Self-mettle tires him. *Shakespeare.*

Anger is, according to some, a transient hatred, or at least very like it. *South*. Pain, or smart, of a sore or swelling. In this sense it seems plainly deducible from *angor*.—I made the experiment, setting the moxa where the first violence of my pain began, and where the greatest *anger* and soreness still continued, notwithstanding the swelling of my foot. *Temple*.

Anger is either deliberate or instinctive; and the latter kind is rash and ungovernable, because it operates blindly, without affording time for deliberation and foresight.

Bishop Butler very justly observes, that anger is far from being a selfish passion, since it is naturally excited by injuries offered to others as well as to ourselves; and was designed by the Author of nature not only to excite us to act vigorously in defending ourselves from evil, but to interest us in the defence or rescue of the injured and helpless, and to raise us above the fear of the proud and mighty oppressor.

Neither, therefore, is all anger sinful: hence the precept, "Be ye angry and sin not." It becomes sinful, however, and contradicts the rule of scripture, when it is conceived upon slight and inadequate provocations; and when it continues long. It is then contrary to the amiable spirit of charity, which "suffereth long, and is not easily provoked." Hence these other precepts, "Let every man be slow to anger;" and, "Let not the sun go down upon your wrath." These precepts, and all reasoning indeed upon the subject, suppose the passion of anger to be within our power; and this power consists not so much in any faculty we have of appealing our wrath at the time, (for we are passive under the smart which an injury or affront occasions, and all we can then do is to prevent its breaking out into action,) as in so mollifying our minds by habits of just reflection, as to be less irritated by impressions of injury, and to be sooner pacified. Add to this, the indecency of extravagant anger; how it renders us, whilst it lasts, the scorn and sport of all about us, and leaves us, when it ceases, sensible and ashamed; the inconveniences and irretrievable misconduct into which our irascibility has sometimes betrayed us; the friendships it has lost us; the distresses and embarrassments in which we have been involved by it, and the fore repentance which on one account or other it always costs us.

Physicians and naturalists have recorded many instances of very extraordinary effects produced by the passion of anger. Bórrichius cured a woman of an inveterate tertian ague, which had baffled the art of physic, by putting the patient in a furious fit of anger. Valeriola made use of the same means, with like success, in a quartan ague. The same passion has been equally salutary to paralytic, gouty, and even dumb, persons; to which last it has sometimes given the use of speech. Etmüller gives divers instances of very singular cures wrought by anger; among others, he mentions a person laid up in the gout, who, being provoked by his physician, flew upon him, and was cured. It is true, the remedy is somewhat dangerous in the application, when a patient does not know how to use it with moderation. We meet with several instances of persons to whom it has proved suddenly mortal. There are also instances wherein it has produced the epilepsy, jaundice, cholera morbus, diarrhoea, &c. In fact, this passion throws the whole nervous system into preternatural commotions, and surprisingly augments the systole of the heart and contiguous vessels. It also injures the tone of the whole machine. By the spasmodic effect it produces on the stomach and intestines, very dangerous consequences are liable to ensue. Its effect on the biliary and hepatic ducts is also very surprising; since, by an intense constriction of these parts, a sudden and universal jaundice has frequently been produced. The liver is sometimes also rendered schirrhous, and stones are generated in the gall-bladder and biliary ducts, in consequence of an obstruction of the bile. Besides these effects, it is evident from experience, that anger has a great tendency to excite enormous hæmorrhages, either from the nose, the lungs, the veins of the anus, or, in women, from the uterus, especially in those previously disposed to such evacuations.

To ANGER, *v. a.* To make angry; to provoke; to enrage.—Who would *anger* the meanest artisan, which carrieth a good mind? *Hooker*.—There are some late taxes and impositions introduced, which rather *anger* than grieve the people. *Clarendon*. To make painful.—He turneth the humours back, and maketh the wound bleed inwards, and *angereth* malign ulcers and pernicious imposthumations. *Bacon*.

ANG'ERLY,

AN'GERLY, *adv.* In an angry manner; like one offended; it is now written *angrily*.

Why, how now, Hecate? you look *angrily*. *Shakespeare*.

Such jesters' dishonest indiscretion is rather charitably to be pitied, than their exception either *angrily* to be grieved at, or seriously to be confuted. *Carew*.

ANGERMAN'NIA, a province in the kingdom of Sweden, bounded on the N. by Lapland and Bothnia, on the E. by the gulph of Bothnia and Medelpadia, and on the W. by Jemti and Herndel. It is full of rocks, mountains, and forests; and there is one very high mountain called *Scull*. It has excellent iron-works, and lakes abounding with fish.

AN'GERMOND, a town of the duchy of Berg, in Germany, on the E. side of the Rhine, subject to the Elector Palatine. Lat. 51. 10. N. lon. 6. 20. E.

ANGERO'NIA, a goddess of silence, whom the Romans invoked to obtain the art of being silent at proper times. She is said to have presided over councils, because secrecy is required therein. She is represented under the figure of a woman holding her finger to her mouth.

ANGERONA'LIA, *f.* in antiquity, solemn feasts held by the Romans the 21st of December, in honour of Angeronia, the goddess of patience and silence. Festus and Julius Modestus, quoted by Macrobius, Saturn. lib. i. c. 10. derive the name from *angina*, "quinzy;" and suppose the goddess to have been thus denominated, because she presided over that disease. Others suppose it formed from *angor*, "grief, pain;" to intimate that she gave relief to those afflicted therewith. Others deduce it from *ango*, "I press, I close;" as being reputed the goddess of silence, &c.

AN'GERS, a city of France, and capital of the duchy of Anjou, in the department of Maine and Loire. It is seated a little above the place where the Sarthe and the Loire lose themselves in the Maine. This last river divides the city into two equal parts, called the High and the Low Town. There are twelve parishes in the city, and four in the suburbs, which contain upwards of 36,000 inhabitants. Its greatest extent is along the declivity of a hill, which reaches quite down to the river side. The castle was built by St. Louis, about the middle of the 13th century. The walls, fosses, and numerous towers, of the castle, which yet subsist, evince its former magnificence; and its situation in the centre of the city, on a rock overhanging the river, conduces to give it an air of grandeur, though at present in decay. It was the principal residence of the kings of Sicily, as dukes of Anjou, but is now in a state of total ruin. The cathedral of Angers is a venerable structure; and, although it has undergone many alterations in the course of ages since its construction, yet the architecture is singular, and deserves attention. Here lies interred with her ancestors the renowned Margaret, daughter of René, king of Sicily, and queen of Henry VI. of England. She expired, after her many intrepid, but ineffectual, efforts, to replace her husband on the throne, in the year 1482, at the castle of Dampierre, in Anjou. The university of Angers was founded in 1398, and the academy of belles lettres in 1685. This last consists of thirty academicians. At the end of the suburbs of Bressigny are the quarries of Angers, so famous for the fine slate which is got from thence. The pieces are of the thickness of a crown piece, and a foot square. All the houses in Angers are covered with this slate, which has gained it the appellation of the *Black City*. The walls with which king John of England surrounded it, in 1214, remain nearly entire, and are of very great circumference. Lat. 47. 28. N. lon. 0. 30. W.

ANGHIE'RA, a town of Italy, in the duchy of Milan, and capital of a county of the same name. It is seated on the eastern side of the lake Maggiore, in lat. 45. 42. N. long. 9. 5. E.

AN'GILD, *f.* [*ane*, one, and *gild*, Sax.] A tribute or fine; was a single compensation for an offence. So *anthlote* and *anfcot*, was a single payment of scot and lot.

ANGINA, *f.* in medicine, a violent inflammation of the throat, otherwise called *quinzy*. See *MEDICINE*.

ANGIO'GRAPHY, &c. See *ANGEOGRAPHY*, &c.

ANGIOPTERIS, *f.* in botany. See *ONOCLEA*.

ANGIO'SPERMIA, *f.* in the Linnæan system of botany, the second order in the class didynamia. It consists of those plants, of that class, whose seeds are inclosed in a pericarpium. In this order the stigma is generally obtuse. These are the *personati* of Tournefort.

ANGIT'IE (*LUCUS* or *NEMUS*), situated on the west side of the Lacus Fucinus. The inhabitants are called *Lucenses*, by Pliny. Angitia was sister of Medea, who taught antidotes against poison and serpents, according to Sil. Italicus. But Servius on Virgil says, that the inhabitants called Medea by this name for the same reason. The town is now called *Luco*.

AN'GLE, *f.* [*angle*, Fr. *angulus*, Lat.] The inclination of two lines meeting one another in a point. See *GEOMETRY*.

ANGLE OF INCIDENCE, in optics, the angle which a ray of light makes with a perpendicular to that point of the surface of any medium on which it falls; though it is sometimes understood of the angle which it makes with the surface itself.

ANGLE OF REFRACTION, generally means the angle which a ray of light, refracted by any medium, makes with a perpendicular to that point of the surface on which it was incident; but has sometimes been understood of the angle which it makes with the surface of the refracting medium itself.

ANGLE, *f.* [*angel*, Ger. and Dut.] An instrument to take fish, consisting of a rod, a line, and a hook:

The patient fisher takes his silent stand,
Intent, his *angle* trembling in his hand;
With looks unmov'd, he hopes the scaly breed,
And eyes the dancing cork and bending reed. *Pope*.

To **ANGLE**, *v. n.* To fish with a rod and hook. To try to gain by some insinuating artifices, as fishes are caught by a bait:

The pleasant'st angling is to see the fish
Cut with her golden oars the silver stream,
And greedily devour the treacherous bait;
So *angle* we for Beatrice. *Shakespeare*.

ANGLE-ROD, *f.* [*angel-rode*, Dut.] The stick to which the line and hook are hung.

AN'GLER, *f.* He that fishes with an angle.—Neither do birds alone, but many sorts of fishes, feed upon insects; as it is well known to *anglers*, who bait their hooks with them. *Ray*.

ANGLER, *f.* in ichthyology, the English name of a species of lophus. See *LOPHUS*.

AN'GLES, an ancient German nation, originally a branch of the Suevi; who, after various migrations, settled in that part of Denmark, and duchy of Sleswick, which to this day is called *Angel*, and of which the city of Flensburg is the capital. Here they were known, even in the time of Tacitus, by the name of *Angli*. The origin of this name is variously accounted for. According to Saxo-Grammaticus, they were called *Angli* from Angulus, son to Humblus, king of Denmark. Widschind, a Saxon writer, will have them to be called *Angli*, from an island in the corner or angle of the sea, which they conquered. Goropius derives their name from the Saxon word *Angel*, or *Engel*, signifying a fish-hook; the Angles, like the other Saxon nations, being greatly addicted to piracy, and on that account being so named by the neighbouring nations; as if, like hooks, they caught all that was in the sea. To this nation the British ambassadors are said to have applied when soliciting succours against the Scots and Picts. The Angles, therefore, came over in greater numbers than any other Saxon nation; and accordingly had the honour of giving the name of *Anglia* to England.

AN'GLESEY (Isle of), is the most western county of North Wales. It is twenty-four miles in length, eighteen in breadth, and sends one member to parliament. It is separated from Caernarvonshire by a strait called *Menai*, and on every other side is surrounded by the sea. It is a fertile spot, and abounds in corn, cattle, flesh, fish, and fowls. At Port Aethwy, the most general ferry into the island, there is a great passage of cattle. It is computed that the island sends forth annually from 12,000 to 15,000 heads, and multitudes of sheep and hogs. It is also computed that the remaining stock of cattle is 30,000. In 1770, upwards of 90,000 bushels of corn were exported, exclusive of wheat. The improvement in husbandry has greatly increased since the suppression of smuggling from the Isle of Man; before that time every farmer was mounted on some high promontory, expecting the vessel with illicit trade; but, since that period, he applies in earnest to industry and cultivation. Not but that the island was in a most remote time famous for its fertility: Mon, Mam Gymry, the Nursing-mother of Wales, was a title it assumed even in the 12th century.

This island is divided into seventy-four parishes, of which most of the churches are situated near the shores. By an account given on the 13th of August, 1563, there were 2010 households, or families, in Anglesey; allowing five to a family, the whole number of inhabitants in that period was 10,050. In 1776; the number of houses in Anglesey was about 3,956: allowing five persons to a family, the whole number of inhabitants was at that time 19,780; which wants only 340 of doubling the number of inhabitants in the intervening space. The chief town is Beaumaris.

In ancient times this island was called *Mon*, *Mona*, or *Moneg*. It was the great nursery of the religion of the Druids; being the residence of the Grand Druid, or chief pontiff, and consequently of all the learned doctors in that religion. Many ancient monuments of Druidism still remain in the island. At Tre'r Dryw, or the habitation of the arch druid, are several mutilated remains, which have been described by Mr. Rowlands. His *Bryn Gwyn*, or royal tribunal, is a circular hollow of 180 feet in diameter, surrounded by an immense agger of earth and stones, evidently brought from some other place, as there is not the least mark of their being taken from the spot. It has only a single entrance. This is supposed to have been the grand consistory of the druidical administration. Not far from it was one of the *Gorffedlau*, now in a manner dispersed, but which once consisted of a great copped heap of stones, on which sat a druid, instructing the surrounding people *multa de Deorum immortalium vi et potestate disputare, et juventuti tradunt*. Cæf. lib. vi. Here were also the relics of a circle of stones, with the *cromlech* in the midst; but all extremely imperfect. Two of the stones are very large; one, which serves at present as part of the end of a house, is twelve feet seven inches high, and eight feet broad; and another eleven feet high, and twenty-three feet in girth. Some smaller stones yet remain. This circle, when complete, was one of the temples of the druids, in which their religious rites were performed. It is the conjecture of Mr. Rowlands, that the whole of these remains were surrounded with a circle of oaks, and formed a deep and sacred grove: *Jam per se roborum elegunt lucos, neque ulla sacra sine ea fronde consuevit*. Plin. Hist. Nat. xv. 44. Near this is *Caer Leb*, or the moated entrenchment; of a square form, with a double rampart, and broad ditch intervening, and a smaller one on the outside. Within are foundations of circular and of square buildings. This Mr. Rowland supposes to have been the residence of the arch druid, and to have given the name, *Tre'r Dryw*, to the township in which it stands. At Tre'r Wry are several faint traces of circles of stones, and other vestiges of buildings; but all so dilapidated, or hid in weeds, as to become almost formless. *Bod-drudan*, or the habitation of the druids, *Tre'r-Beirdd*, or that of the bard, and *Bodowyr*, or that of the priests, are all of them hamlets, nearly surrounding the seat of the

chief druid, composing the essential part of his suite. At the last is a thick cromlech, resting on three stones.

The shore near Porthamel, not far from hence, is famed for being the place where Suetonius landed, and put an end in this island to the Druid reign. His infantry passed over in flat-bottom boats, perhaps at the spot still called *Pant yr Yscrappie*, or the valley of *skiffs*. His cavalry crossed partly by fording, partly by swimming. Of the conflict on this occasion we have the following animated description by Tacitus: *Stat pro litore diversa acies, densa armis virisque, intercurfantibus fœminis in modum furarum, veste ferali, crinibus dejectis, facies, preforebant; druidæque circum, preces diras sublati ad cælum manibus fundentes. Novitate aspectus percutere militem, ut quasi hærentibus membris, immobile corpus vulneribus præberent. Dein cohortationibus ducti, et se ipsæ stimulant, ne muliebri et fanaticum agmen pavescerent, inferunt signa, sternuntque obvios et igni suo involvunt. Præsidium posthac impositum vicis, excisq; luci, sævis superstitionibus sacri. Nam cruore captivo dolere aras, et hominum fibris consulere deos fas habebant.* Thus Englished: "On the shore stood a motley army in close array, and well armed; with women running wildly about in black attire with dishevelled hair, and like the furies brandishing their torches; surrounded by the druids, lifting up their hands to heaven, and pouring forth the most dreadful imprecations. The soldier stood astonished with the novelty of the sight. His limbs grew torpid, and his body remaining motionless resigned to every wound. At length, animated by their leader, and rousing one another not to be intimidated with a womanly and fanatic band, they displayed their ensigns, overthrew all who opposed them, and flung them into their own fires. After the battle, they placed garbisons in the towns, and cut down the groves consecrated to the most horrible superstitions: for the Britons held it right to sacrifice on their altars with the blood of their enemies, and to consult the gods by the inspection of their entrails." There are no traces of any Roman works left in this country. Their stay was so short, that they had not time to form any thing permanent.

Near the ferry of Moel y Don appear the fine woods of Sir Nicholas Bayley, skirting the Menai for a considerable way. The wooded part of the island is on this side. It commences at Llanidan, and recalls the ancient British name of Anglesey, *Ynys Dywyll*, or the Dark Island, on account of the deep shade of its groves: but at present it is (except in this part) entirely divested of trees; and the climate so averse to their growth, that in most parts it is with great difficulty the gentry can raise a plantation round their houses. Plas Newydd, the seat of Sir Nicholas Bayley, lies close upon the water, protected on three sides by venerable oaks and ashes. The view up and down this magnificent river-like strait is extremely fine. The shores are rocky; those on the opposite side covered with woods; and beyond soar a long range of Snowdonian alps. Here stood a house built by Gwennllian, a descendant of Cadrod Hardd. The mansion has been improved, and altered to a castellated form by the present owner.

In the woods are some very remarkable druidical antiquities. Behind the house are to be seen two vast cromlechs. The upper stone of one is twelve feet seven inches long, twelve broad, and four thick, supported by five tall stones. The other is but barely separated from the first: is almost a square, of five feet and a half, and supported by four stones. The number of supporters to cromlechs are merely accidental, and depend on the size or form of the incumbent stone. These are the most magnificent we have, and the highest from the ground; for a middle-sized horse may easily pass under the largest. In the lands of Llugwy, indeed, there is a most stupendous one of a rhomboidal form. The greatest diagonal is seventeen feet and a half, the smaller fifteen, and the thickness three feet nine inches; but its height from the ground is only two feet: it was supported by several stones. The Welsh, who ascribe every thing stupendous to our famous British king,

king, call it *Arthur's Quoit*. In the woods at this place are some druidical circles nearly contiguous to each other.

At a small distance from Beaumaris, on the shore, stand the remains of Llanvaes, or the Friars. It was founded by prince Llewelyn ap Ierwerth, and according to the general tradition of the country, over the grave of his wife Joan, daughter of king John, who died in 1237, and was interred on the spot. Here also were interred a son of a Danish king, lord Clifford, and many barons and knights who fell in the Welsh wars. It was dedicated to St. Francis, and consecrated by Howell bishop of Bangor, a prelate who died in 1240. The religious were Franciscans, or minor friars. Their church and house were destroyed, and their lands wasted, in the insurrection made soon after the death of Llewelyn, last Welsh prince, by his relation Madoc. Edward II. in consideration of their misfortunes, remitted to them the payment of the taxes due to him, which before the war were levied at the rate of 12l. 10s. These friars were strong favourers of Owen Glendwr. Henry IV. in his first march against Owen, plundered the convent, put several of the friars to the sword, and carried away the rest; but afterwards set them at liberty, made restitution to the place, but peopled it with English recluses. It possibly was again reduced to ruin: for Henry V. by patent, establishes here eight friars, but directs that two only should be Welsh. At the dissolution, Henry VIII. sold the convent and its possessions to one of his courtiers. They became in later days the property of a family of the name of *White* (now extinct), who built here a good mansion. It of late became the property of lord Bulkeley. The church is turned into a barn, and the coffin of the princess Joan now serves for a watering-trough. A little farther is Castle Aber Llienawg, a small square fort, with the remains of a little round tower at each corner. In the middle one stood a square tower. A foss surrounds the whole. A hollow way is carried quite to the shore, and at its extremity is a large mound of earth, designed to cover the landing. This castle was founded by Hugh Lupus earl of Chester, and Hugh the Red earl of Shrewsbury, in 1098, when they made an invasion, and committed more savage barbarities on the natives, especially on one Kenred a priest, than ever stained the annals of any country. Providence sent Magnus king of Norway to revenge the cruelties. His coming was to all appearance casual. He offered to land, but was opposed by the earls. Magnus stood in the prow of his ship, and calling to him a most expert Bowman, they at once directed their arrows at the earl of Shrewsbury, who stood all armed on the shore. An arrow pierced his brain through one of his eyes, the only defenceless part. The victor, seeing him spring up in the agonies of death, insultingly cried out in his own language, *Leit loupe*, "Let him dance." This fort was garrisoned so lately as the time of Charles I. when it was kept for the parliament by Sir Thomas Cheadle; but was taken by colonel Robinson in 1645.

Above Llanddona is a high hill, called *Bardd Arthur*; the true name was probably *Din*, or *Dinas Sulwy*: for a church immediately beneath bears that of *Llanvihangle Din-Sulwy*. On the top of it is a great British post, surrounded by a double row of rude stones with their sharp points uppermost; and in some parts the ramparts are formed of small stones. In the area are vestiges of oval buildings: the largest is formed with two rows of flat stones set on end. There had been the temporary habitations of the possessors. It had been a place of vast strength: for, besides the artificial defence, the hill slopes steeply on all sides, and the brink next to the ramparts is mostly precipitous. It is worth the attention of the traveller to ascend this hill for the sake of the vast prospect; an intermixture of sea, rock, and alps, most elegantly great.

About two miles south of Plas Gwyn, the seat of Paul Panton, Esq. was situated Penmynydd, once the residence of the ancestors of Owen Tudor, second husband to Catherine of France, queen dowager of Henry V. "who, being (as honest Halle informs us) young and lusty, follow-

ing more her own appetite than friendly consail, and regarding more her private affection than her open honour, took to husband privily (in 1428) a goodly gentylman, and a beautiful person, garnished with manye godlye gyftes both of nature and of grace, called *Owen Teuther*, a man brought furth and come of the noble lignage and ancient lyne of Cadwaladar, the last kynge of the Britonnes." The match, important in its consequences, restored the British race of princes to this kingdom. These reigned long, under the title of the House of Tudor; the mixed race having ceased on the accession of Henry VII. grandson to our illustrious countryman. The remains of the residence of the Tudors are, the door of the gateway: part of the house, and the great chimney-piece of the hall, are to be seen in the present farm-house. The Tudors, for a considerable space before the extinction of their race, assumed the name of *Owen*. Richard was the last male of the family, and was sheriff of the county in 1657. Margaret, heiress of the house, married Coningsby Williams, Esq. of Glan y gors, in this island, who possessed it during his life. It was afterwards sold to lord Bulkeley, in whose descendant it still continues. In the church of Penmynydd is a most magnificent monument of white alabaster, removed at the dissolution from the abbey of Llanvaes to this place; probably erected in memory of one of the house of Tudor, who had been interred there.

On the western point of the bay is a small cape, flat at top, called *Castell mawr*, joined to the land by a low isthmus. It is composed of lime-stone, which is carried to distant parts in small vessels, which lie in a small channel near the rock, and by their numbers frequently enliven the view. Roman coins have been found in this neighbourhood; but there are no vestiges of there having been any station. Beyond Castell mawr, on the shore, are vast blocks of black marble filled with shells, coralloids, and fungites.

At Tryselwyn mountain is the most considerable body of copper-ore perhaps ever known. The part of Tryselwyn which contains it is called *Parys mountain*. Of this mountain, and the works there carried on, we have the following very curious and interesting account by Mr. Pennant: "The external aspect of the hill is extremely rude, and rises into enormous rocks of coarse white quartz. The ore is lodged in a basin, or hollow, and has on one side a small lake, on whose waters, distasteful as those of Avernus, no bird is known to alight. The whole aspect of this tract has, by the mineral operations, assumed a most savage appearance. Suffocating fumes of the burning heaps of copper arise in all parts, and extend their baneful influence for miles around. In the adjacent parts vegetation is nearly destroyed: even the mosses and lichens of the rocks have perished; and nothing seems capable of resisting the fumes but the purple melic grass, which flourishes in abundance. It is thought that the ore had been worked in a very distant period. Vestiges of the ancient operations appear in several parts, carried on by trenching, and by heating the rocks intensely, then suddenly pouring on water, to as to cause them to crack or scale; thus awkwardly supplying the use of gunpowder. Pieces of charcoal were also found, which proves that wood was made use of for that purpose. As the Britons imported all works in brass, it is certain that the Romans were the undertakers of these mines; and it is very probable that they sent the ore to Caerhên to be smelted, the place where the famous cake of copper was discovered. They might likewise have had a smelting hearth in this island; for a round cake of copper was discovered at Llanvaethlle, a few miles from this place. Its weight was fifty pounds, and it had on it a mark resembling an L.

"In the year 1762, Alexander Frazier came into Anglesey in search of mines. He visited Parys mountain; called on Sir Nicholas Bayley, and gave him so flattering an account of the prospect, as induced him to make a trial, and sink shafts. Ore was discovered; but, before any quantity could be gotten, the mines were overpowered with water. In about two years after, Messrs. Roe and

Co. of Macclesfield, applied to Sir Nicholas for a lease of Penrhyn ddu mine in Caernarvonshire; with which they were, much against their wills, compelled to take a lease of part of this mountain, and to carry on a level, and make a fair trial. The trial was accordingly made; ore was discovered; but the expences overbalanced the profits. They continued working to great loss; and at length determined to give the affair up. They gave their agent orders for that purpose; but he, as a final attempt, divided his men into ten several companies, of three or four in a partnership, and let them sink shafts in various places, about 800 yards eastward of a place called the *Golden Venture*, on a presumption that a spring, which issued from near the place, must come from a body of mineral. His conjecture was right; for in less than two days they met with, at the depth of seven feet from the surface, the solid mineral, which proved to be that vast body which has since been worked to such advantage. The day that this discovery was made was March 2, 1768: which has ever since been observed as a festival by the miners. Soon after this discovery, another adventure was begun by the Rev. Mr. Edward Hughes, owner of part of the mountain, in right of his wife Mary Lewis, of Llys Dulas; so that the whole of the treasure is the property of Sir Nicholas Bayley and himself. The body of copper-ore is of unknown extent. The thickness has been ascertained in some places by the driving of a level under it, several years ago, and it was found to be in some places twenty-four yards. The ore is mostly of the kind called by Cronstedt *Pyrites cupri flavo viridescens*, and contains vast quantities of sulphur. There are other species of copper-ore found here. Of late a vein of the *Pyrites cupri griseus* of Cronstedt, about seven yards wide, has been discovered near the west end of the mountain: some is of an iron grey, some quite black; the first contains 16lb. of copper per cwt. the last forty. An ore has been lately found, in form of loose earth, of a dark purplish colour; and the best of it has produced better than eight in twenty. Some years ago, above thirty pounds of native copper was found in driving a level through a turbery; some was in form of moss, some in very thin leaves.

"It is quarried out of the bed in vast masses; is broken into small pieces; and the most pure part is sold raw, at the rate of about 3l. to 6l. per ton, or sent to the smelting-houses of the respective companies to be melted into metal. The more impure ore is also broken to about the size of hens eggs; but, in order to clear it from the quantity of sulphur with which it abounds, as well as other adventitious matter, it must undergo the operation of burning. For that purpose it is placed between two parallel walls of vast length: some kilns are twenty, others forty and fifty, yards in length; some ten, others twenty, feet wide; and above four feet in height. The space between is not only filled, but the ore is piled many feet higher, in a convex form, from end to end. The whole is then covered with flat stones, closely luted with clay; and above is placed a general integument of clay, and small rubbish of the work, in order to prevent any of the fumes from evaporating. Of late, some kilns have been constructed with brick arches over the ore, which is found to be the best method of burning. Within these few years, attempts are made to preserve the sulphur from flying away; and that is done by flues made of brick, whose tops are in form of a Gothic arch, many scores of feet in length. One end of these opens into the beds of copper which are to be burnt. Those beds are set on fire by a very small quantity of coal, for all the rest is effected by its own phlogiston. The volatile part is confined, and directed to the flues; in its course the sulphureous particles strike against their roofs, and fall to the bottom in form of the finest brimstone; which is collected and carried to adjacent houses, where it is melted into what is called in the shops *stone brimstone*.

"The beds of copper, thus piled for burning, are of vast extent. Some contain 400 tons of ore, others 2000.

The first require four months to be completely burnt, the last near ten. Thus burnt, it is carried to proper places to be dressed, or washed, and made merchantable. By this process the ore is reduced to a fourth part in quantity, but considerably improved in quality: and by this means the water is strongly or richly impregnated with copper, which is dissolved by the acid quality of the sulphur; and is collected or precipitated again by iron in the above described pits. The iron is all dissolved.

"But a far richer produce of copper is discovered from the water lodged in the bottom of the bed of ore, which is highly saturated with the precious metal. This is drawn up, either by means of whimsies or windmills, to the surface, and then distributed into numbers of rectangular pits thirty-six feet long, some pits more some less, twelve to fifteen feet broad, and twenty inches deep. To speak in the language of the adept, Venus must make an assignation with Mars, or this solution will have no effect. In plain English, a quantity of iron must be immersed in the water. The kind of iron is of no moment; old pots, hoops, anchors, or any refuse, will suffice; but of late, for the convenience of management, the adventurers procure new plates, four feet long, one and a half broad, and three-quarters of an inch thick. These they immerse into the pits. The particles of copper instantly are precipitated by the iron, and the iron is gradually dissolved into a yellow ochre. Great part of it floats off by the water, and sinks to the bottom. The plates, or the old iron (as it happens), are frequently taken out, and the copper scraped off; and this is repeated till the whole of the iron is consumed. The copper thus procured differs little from native copper, and is prized accordingly, and sold for prices of 25l. to 45l. a ton. This discovery is far from new: it has been practised long in the Wicklow mines in Ireland; and above a century in those of Hern-grundt in Hungary, where it is called *ziment copper*. The waters of the Hungarian mines are much more strongly impregnated with copper than those of Parys mountain. The first effects its operation in twelve or about twenty days, the last requires two months. Horse-shoes, iron made in the shape of hearts, and other forms, are put into the foreign waters; and, when perfectly transmuted, are given as presents to curious strangers.

"Nature hath been profuse in bestowing her mineral favours on this spot: for above the copper-ore, and not more than three quarters of a yard beneath the common soil, is a bed of yellowish greasy clay, from one to four yards thick, containing lead-ore, and yielding from 600 to 1000 pounds weight of lead from one ton; and one ton of the metal yields not less than fifty-seven ounces of silver. This place has been worked for lead-ore in very distant times. In the bottom of the pool was found an ancient smelting-hearth of grit-stone, and several bits of smelted lead, of about four inches in length, two in breadth, and half an inch thick. These works have added greatly to the population of the island; for about 1500 persons are employed; who, with their families, are supposed to make near 8000 persons, getting their bread from these mines."

Near Kemlyn Bay is a quarry of marble, common to this place, some parts of Italy, and to Corsica, and known in the shops by the name of *Verde di Corsica*. Its colours are green, black, white, and dull purple, irregularly disposed. In different blocks one or other of the colours are frequently wanting; but among the green parts are often found narrow veins of a most elegant and silky white asbestos. It is a compound species of marble: part is calcareous, and may be acted upon by aqua-fortis. The green parts partake of the nature of jasper. It is apt to be intersected by small cracks, or by asbestos veins, therefore incapable of taking a high polish. This quarry lies on the lands of Monachty, in the parish of Llan-Fair-Ynghornwy; and it is found again in the isle of Skerries, off this parish. In Rhoscolyn parish, a green amianthus, or brittle asbestos, is met with in great plenty in a green marble

marble similar to the above; but by reason of the inflexible quality of its fibres not applicable to the same use.

AN'GLICISM, *f.* [from *Anglus*, Lat.] A form of speech peculiar to the English language; an English idiom.—They corrupt their stile with untutored *anglicisms*. *Milton*.

AN'GLING, *f.* the art of fishing with a rod, hook, and line; for which see FISHING.

AN'GLO-CALVINISTS, *f.* a name given by some writers to the members of the church of England, as agreeing with the other Calvinists in most points except church-government.

ANGLO-SAXON, *f.* an appellation given to the language spoken by the English Saxons; in contradistinction from the true Saxon, as well as from the modern English.

AN'GLUS (Thomas), an English priest, well known for the singularity of his opinions, and several little tracts which he wrote in the 17th century. He went by several names. Mr. Baillet says his true name was *White*; but that he used to disguise it under that of *Candidus*, *Albus*, *Bianchi*, and *Richworth*; but he was most known in France by the name of *Thomas Anglus*. Des Cartes generally called him Mr. *Vitus*. He passed some time in most countries of Europe; but his longest stay was at Rome and Paris. When he was in England, he lived a considerable time in the family of Sir Kenelm Digby; and seems to have had a great esteem for the opinions of this gentleman, as may be seen in his writings, particularly in the preface to his Latin work concerning the Institutions of the Peripatetic Philosophy, according to the hypothesis of Sir Kenelm. He was a great advocate for the peripatetic philosophy. He attempted even to make the principles of Aristotle subservient to the explaining the most impenetrable mysteries of religion; and with this view he engaged in the discussion of predestination, free-will, and grace. Mr. Baillet says, "What he wrote upon this subject resembles the ancient oracles for obscurity." He died some time after the restoration of Charles II. but in what year is uncertain.

AN'GOL, a pleasant well-watered city of Chili, situated on a fertile and beautiful plain, 125 miles north of Baldivia. Lat. 37. 56. S. lon. 72. 59. W.

ANGO'LA, a kingdom on the western coast of Africa, lying, according to the most probable accounts, between lat. 8. 30. and 16. 21. S. forming a coast of upwards of 480 miles; but how far it extends from west to east has never been exactly determined. Angola Proper is bounded on the north by the river Danda, which separates it from Congo; and on the south by the Coanza, by which it is separated from Benguela. This last, however, is now included in the kingdom of Angola, having been conquered by its monarchs, though it still retains the name of kingdom, and is included in the dimensions just now given. The air here is very hot and unwholesome, and the country mountainous: there being but few plains to be met with in it, except on the sea-coast, and between the huge ridges of mountains. That part of the kingdom distinguished by the name of Angola Proper, was subject to the kings of Congo in the year 1484, when the Portuguese first discovered the country: but how long it had been so before that time, is not known; the inhabitants being utterly destitute of chronology, and having no other way of distinguishing past events, but by saying they happened in such a king's reign. Neither, though Angola became a distinct kingdom since its discovery by the Portuguese, is it known with more certainty at what time that revolution happened; or whether the Portuguese were not concerned in assisting the viceroy of the king of Congo, who governed the province of Angola, to set up for himself.

All accounts agree, that this kingdom was founded by one *Ngola* or *Angola*, from whom it took its name. According to the tradition of the country, this Ngola was a smith, and the inventor of that trade, in which he had been instructed by the demons of the country. In consequence of this, he became exceedingly rich, not in gold, silver, or shell-money, which were not at that time in use, but in corn, cattle, and fruits, which were then exchanged in traf-

fic. The country being not long after visited by a grievous famine, Ngola generously relieved his distressed countrymen, and saved the lives of some thousands. In gratitude for this generosity, he was unanimously chosen king; and hence the smith's trade is reckoned among the royal arts of Angola.

According to other accounts which can be more depended upon, Ngola was the king of Congo's viceroy; who, having become powerful by the reduction of several of the neighbouring states, was induced to set up for himself. Dreading, nevertheless, the power of his old master, he chose to send him the usual tribute and presents annually, till he reckoned himself firmly seated on the throne, and had secured it to his descendants. His measures were greatly facilitated by the wars which the king of Congo was then engaged in with the *Giagas*, a barbarous nation in the neighbourhood. These made such a powerful inroad into his dominions, that he was glad to ask the assistance of Ngola; not as a subject, but as a friend and ally. This was readily granted; and the two monarchs continued ever after sending presents and assistance to each other, and encouraging a mutual commerce between all their subjects.

Ngola lived to a great age, highly respected by his subjects, and in alliance with the king of Congo and the Portuguese, whose numerous settlements on the coast had made them become very powerful. According to the custom of the country, he had many wives and concubines. By his chief favourite he had three daughters, *Zunda Ri-angola*, *Tumba Ri-angola*, and another whose name is unknown. Towards the latter part of his life, the king's chief care was to secure the crown to the eldest of these; for which purpose he consulted his queen, who encouraged him in the design with all the eloquence in her power. By her advice, he sent for his lieutenant-general, a favourite slave, whom he had created viceroy over the whole kingdom, to acquaint him with his resolution. The artful minister did not fail to applaud his design, though his intention was to defraud the princefs, and seize the throne for himself. He accordingly took the opportunity, one day, when that princefs and the whole court were employed in sowing their lands, to spread a report that the Angolic enemies had entered the kingdom, and were destroying every thing with fire and sword. In this confusion, the treacherous viceroy conducted the three princefses to the royal palace; and, acquainting Ngola with the pretended danger, urged him to betake himself to a speedy flight. The frightened monarch, unable to stir with age, desired his minister to take the most proper means for his safety: whereupon, being a stout young fellow, he took his majesty on his back, and carried him into a neighbouring wood, where he stabbed him with a dagger. This stratagem was too shallow to remain long concealed; the murderer was quickly discovered, and many of the nobles rose in arms against him; but, finding his party too strong to be opposed, they were at last obliged to submit, and suffer him quietly to ascend the throne, upon his publicly declaring that he had not seized it for himself, but with a view of securing it to the princefs Zunda Ri-angola.

To this princefs the usurper palliated his conduct in the best manner he could; and she had art enough to disguise her resentment so effectually, that he never discovered the smallest occasion for jealousy. At last, his sudden death gave Zunda an opportunity of ascending the throne peaceably; when she behaved with such moderation and justice, as to gain the love and affection of all her subjects. Her jealous temper prevented her from marrying; and, by giving too much way to it, she came at last to dread as rivals the two sons of her younger sister Tumba, and to form designs against their life. To accomplish her purposes, she ordered them to be brought to court, pretending to have them educated under her own eye. This was declined for some time; but at length the queen prevailed so far as to have the eldest sent to her; whom she no sooner got into her power, than she caused him to be massacred,

massacred, with all his attendants; only one escaping, all covered with wounds; to carry the dreadful news to the prince's and her husband.

On hearing of this bloody act, the afflicted parents immediately sallied forth at the head of all their vassals. They were waited for by queen Zunda at the head of a numerous army; but no sooner did her soldiers perceive the parents of the deceased prince, than they immediately abandoned the queen to their resentment. Tumba then rushed upon her sister, and stabbed her to the heart; after which, she commanded her entrails to be taken out, and thrown into the hole in which her son's body had been cast. Upon this Tumba was crowned queen of Angola, and invited her husband to participate with her in the management of public affairs. This offer he was too wise to accept; and Tumba, upon his refusal, resigned the crown into the hands of her surviving son, named *Angola Chilvagni*. He proved a great and wise prince, gaining the love of his subjects by the moderation and equity of his government. He was succeeded by one of his younger sons, named *Dambi Angola*; who no sooner ascended the throne, than he put all his brethren to death, lest they should unite in favour of the eldest. The rest of his reign proved conformable to such a beginning. He was a monster of cruelty, avarice, lewdness, and perfidy. Death, however, in a short time, happily delivered his subjects from this tyrant; who, notwithstanding his infamous life, was buried with the greatest magnificence; and a mount was erected over his grave, consisting, according to the custom of the country, of a prodigious number of human victims which had been sacrificed to his ghost. *Dambi Angola* was succeeded by *Ngola Chilivagni*, a warlike and cruel prince. He conquered many nations, and made the most dreadful inroads into the kingdom of Congo, along the rivers of Danda, Lucalla, Zanda, and Coanza; whose waters were often tinged with the blood of thousands whom he massacred in his excursions. Notwithstanding these butcheries, *Ngola Chilivagni* shewed such generosity to those who readily submitted to him, that he was sure to conquer, not only wherever he came, but wherever he seemed to direct his forces. At last, as if weary of conquest, he planted a tree on the banks of the Coanza, about eight leagues from Loanda San Paulo, as a boundary to his ravages. This tree the Portuguese called *Ifanda*, or *Ifandaura*; and afterwards erected a fortress near it.

The same folly and insolence which took place in the breast of Alexander the Great, on account of his rapid conquests, soon puffed up the mind of this petty African tyrant. Because he had conquered and ravaged some of the neighbouring countries, and brought under his subjection a few cowardly barbarians, he first fancied himself invincible, and then that he was a god. He demanded the same respect and adoration that was paid to their other deities; and with this demand his subjects were servile enough to comply. This pretended deity, however, was forced to submit to the fate of other mortals, and died without leaving a successor behind him.

On the decease of *Ngola Chilivagni*, the states elected *Ngingha-Angola-Chilombo-Kickafanda*, great-nephew to queen Tumba's husband, as his successor. He proved such a rapacious and cruel tyrant, that his subjects universally wished for his death; which, luckily for them, soon happened. He was interred with the usual pomp and solemnities, particularly that of having a whole hecatomb of human victims sacrificed upon his grave. His son *Bandi Angola*, who succeeded him, proved yet a greater tyrant than his father; so that he soon became intolerable to his subjects. A general revolt ensued, in which his subjects called in the cannibal *Glagas* to their assistance. These immediately poured in like a torrent, and, having defeated the forces of the tyrant, besieged him in an inaccessible mountain; where, not being able to come at him, they resolved to reduce him by famine. *Bandi Angola* applied to the king of Congo for assistance. As it was the interest of that prince to hinder the ravenous *Glagas* from en-

tering into the Angolic dominions, he did not hesitate at granting his request; and ordered a strong reinforcement of the Portuguese, of whose valour he had a high opinion, and of whom he entertained a great number at his court, to march to the assistance of the king of Angola. The command of the army was given to one of the most experienced Portuguese officers; who, depending more on the handful of Europeans he had under his command than on the Congoe, attacked the rebels, though greatly superior in number; and, having utterly defeated them, restored the king of Angola to the throne.

This essential service so endeared the Portuguese to *Bandi Angola*, that he took them into his service, and even into his council. Their general became a great favourite of the king, but much more so of his daughter, who conceived a violent passion for him. Unfortunately for them both, the amour was carried on with so little precaution on her part, that the king quickly discovered it; and immediately formed a resolution of exterminating the Portuguese all at once. Such violent measures, however, could not be concerted so privately but the prince's got intelligence of it; and, having apprised her lover of his danger, he immediately withdrew into Congo, taking with him as many of his countrymen as he conveniently could. The king of Congo expressed such strong resentment against *Bandi Angola* for his ingratitude, that the Portuguese general would have probably prevailed upon him to declare war against Angola, had he not been obliged to defend his own dominions against a neighbouring prince who then made an invasion. This afforded that general a fair pretence of asking leave to return home; promising to come with such reinforcements as would enable the king of Congo to revenge himself for the affront put upon him by the Angolic monarch. His real intention, however, was, to give the king of Portugal an opportunity of seizing upon the kingdom of Angola.

On his return to Lisbon, the Portuguese general having laid his plan before the king, it was so well relished, that an armament was ordered to be fitted out, well furnished with every necessary for building fortresses, &c. and a sufficient number of men. The wind proving favourable all the way back, the Portuguese soon arrived safe at Loanda San Paulo; whence the general dispatched a messenger to acquaint the king of Congo with his arrival, and to make him some rich presents. These were no sooner gone than the admiral sailed up the Coanza; and, landing without opposition in the kingdom of Angola, set about erecting a fortress in a convenient situation, which was completed in a few days. The king being informed of the return of the Portuguese, and of their fortifying themselves, gathered together a numerous army: but his forces, though upwards of 100,000 in number, were utterly defeated by the Portuguese; vast numbers were killed, and many more carried into slavery. The admiral now ravaged the whole country, putting all to fire and sword, and making himself master of every advantageous spot of ground. The king, however, had still the good luck to escape all the stratagems that were laid for him; and once more got safe to his inaccessible fortress.

All this time *Bandi Angola* had himself tyrannized, and allowed his favourites to tyrannize, in such a manner, that his subjects were become no less weary of his government than when they formerly revolted. Being now exasperated beyond measure at the calamitous war of which he had been the occasion, they formed a design of putting an end to his life; and, in order to draw him out of his retreat, where he wallowed in all manner of debauchery, they had recourse to the following stratagem: A deputation was sent, acquainting him with the revolt of one *Cuculo Cabazzo*; who, at the head of a numerous band, committed the most cruel ravages. They besought his majesty, either to levy a sufficient number of troops, and march in person against him, or to allow them to arm themselves against him. The credulous king complied with this last proposal; and granted them leave to raise what forces might be thought

thought necessary. Four days after, notice was sent to the king, that his subjects had attacked the rebels, and had been repulsed with loss; but that, if his majesty would but condescend to animate them with his presence, the sight of him would inspire them with such courage, that they would assuredly prove victorious. This had the desired effect; and the king set out a few days after, without any other precaution than his own guards, to head his army, which was encamped on the banks of the Lucalla. He no sooner appeared in view, than the chief officers came out to meet him; and having, under pretence of paying their respects, gradually separated him from his guards, they fell upon him and dispatched him at once.

Bandi Angola was succeeded by his son Ngola Bandi, whose mother had been a slave, and whose title to the crown was consequently disputable, according to the laws of the country. Of this the new king being well apprised, thought proper to begin his reign by murdering every person who had opposed his election. He began with the *ten-dula*, or commander of the king's rear-guard; who, by his office, is the chief of the electors, and the person who governs the kingdom during the interregnum. Him he ordered to be put to death, with all his family. These were followed by the principal officers of his father's court; all his concubines, together with their parents and near relations, whom he caused to be butchered; together with his half-brother, his father's son by a favourite concubine, and then but an infant. He did not spare even the son of his sister Zingha Bandi, whom she had by one of her paramours. The interest of his sister had contributed greatly to raise this tyrant to the throne; and his ingratitude, with the murder of her son, so exasperated her, that she swore to be revenged on him in the same way.

The Portuguese were the next objects of his resentment. These he so much dreaded on account of their valour and policy, that he immediately declared war, resolving not to lay down his arms till he had exterminated them to the last man, or driven them totally out of his dominions. His rashness, however, cost him dear. Myriads of the Angolic troops were overthrown by a handful of Portuguese; and the king himself was forced to fly, first into the island of Chiconda, in the river Coanza, and then into the deserts of Oacco. Here his conquerors, out of great clemency, allowed him to live among the wild beasts, without any other sustenance than what the deserts afforded. He had the misfortune also to lose his queen, and two sisters, Cambi and Fungi, who were taken prisoners by the Portuguese. The king, being informed of this, sent an embassy to treat of their ransom, and an exchange of prisoners. The proposal was readily agreed to; and the princesses were sent back laden with presents. The king, however, refused to perform his part of the agreement, and thereby plunged himself into still greater difficulties. A new Portuguese viceroy being arrived about this time, Ngola was quite at a loss how to excuse the non-performance of his part of the treaty. At last he had recourse to his exasperated sister Zingha; and having excused, as well as he could, the murder of her son, proposed to send her on a splendid embassy to the viceroy. Having consented, but without forgetting her resentment, she set out, as plenipotentiary for the king of Angola, with a magnificent retinue, was received with all the honour due to her rank, and lodged in a splendid palace prepared for her.

At the first audience Zingha had of Don John (the Portuguese viceroy), she was surprised to find a stately elbow-chair prepared for him to sit upon, and for herself only a rich tapestry spread on the floor, with a velvet cushion embroidered with gold, and placed over against the chair of state. Dissembling her displeasure, however, she beckoned to one of the ladies of her retinue, commanded her to lay herself down on her elbows and knees upon the carpet, and sat herself upon her back during the whole time of the audience. She behaved with such address and dignity, as to gain the admiration of the whole council. A proposal was made of entering into an alliance offensive and defensive

with the king of Angola, provided he acknowledged himself the vassal of the king of Portugal, and submitted to pay a yearly tribute. To this Zingha replied, that such conditions were indeed fit to be imposed upon those who had been conquered by the sword; but not upon a great and powerful monarch, who only sought their friendship and alliance: upon which the treaty was concluded on both sides, without any other conditions than the exchange of prisoners.

Zingha was so taken with the honours done her by the Portuguese, and so intent upon observing the order, dress, arms, &c. of their troops, that she staid at Loanda a considerable time; during which she was instructed in the Christian religion, and consented to be baptised. Don John and his spouse were the sponsors; who dismissed her soon after, with all possible honours, and highly satisfied with her reception and success. At her return, she took care to have the articles ratified by her brother, who expressed his approbation of them, and the highest obligations to her. He even went so far as to desire the viceroy to send him some proper persons to instruct him in the Christian religion, which he said he was very desirous of embracing. This request was immediately granted; and Don Denis de Faria, a negro priest, a native of Angola, was dispatched, with an officer of distinction, to stand godfather to the king. These met at first with a gracious reception; but, when they came to talk of baptism, Ngola altered his mind, and told them it was too much below his dignity to receive it from the son of one of his slaves, and sent them both back.

As no experience seems to have been a sufficient antidote against the innate folly of Ngola Bandi, he soon after took it into his head to make war on the Portuguese, and invaded some of their territories. This last action proved his ruin: his troops were all cut off, and himself forced to swim for his life to a small island in the Coanza, whither the Portuguese pursued and surrounded him; so that he had no other chance, but either to fall into their hands, or be devoured by wild beasts, with which the place swarmed. From both these dangers he was relieved by a dose of poison, given him, as was supposed, by his sister Zingha. Before this time, however, he had taken care to send his eldest son to the country of the Giagas, and put him under the care of one of their chiefs, called *Giaga Caza*, whom he besought to take care of him, and protect him from his aunt Zingha, as he rightly imagined she would not fail of attempting his life, in order to secure herself on the throne. Zingha Bandi was crowned queen of Angola in 1627. She was a very artful woman, endowed with great presence of mind, firm in her resolutions, of an intrepid courage, and a great mistress in the art of dissimulation. She inherited a jealous and cruel temper, to which she would not hesitate to sacrifice her nearest relations, if they gave her the least umbrage. To this jealousy, therefore, she resolved to sacrifice her nephew, because he had a better title to the crown than herself. She made use of the most solemn oaths to draw him out of the hands of his guardian, protesting that she had accepted of the throne with no other view than to preserve it for him. But Giaga, her brother, being well acquainted with her temper, was proof against all her oaths and fair speeches. Zingha, finding this method ineffectual, pretended a desire of resigning the crown to her nephew, to which she said she had no other objection, than that she was afraid he was yet incapable of assuming the reins of government. She therefore desired an interview with him, though ever so short, that she might satisfy herself in this particular, and promised to detain him no longer than Giaga should think necessary. Giaga thought there could be no danger in consenting to a short interview; and therefore sent the unfortunate prince to her, attended by a magnificent retinue. The cruel queen no sooner got him in her power, than she murdered him with her own hand, and caused his body to be thrown into the Coanza, ridding herself, by that inhuman act, of a dangerous rival, as well as revenging herself on her brother,

as she had sworn to do, for the murder of her son. Zingha's next scheme was to rid herself of the Portuguese, who had established themselves in such a manner as to be almost entire masters of Angola. They had built fortresses on every convenient spot that suited them, especially near her principal towns, which they could level with the ground with the greatest ease. They had engrossed all her commerce, were become very wealthy, and their numbers increased daily; so that they were dreaded not only by her subjects, but by all the neighbouring nations. As Zingha was of a martial temper, she did not long hesitate. She quickly made all necessary provisions, strengthened herself by alliances with the Giagas, and other idolatrous nations, and even with the Dutch, and the king of Congo. With this combined force she attacked the Portuguese so suddenly and unexpectedly, that she gained some advantages over them; and the Dutch made themselves masters of San Paulo de Loando, and soon after of some of the best provinces in the kingdom.

Zingha's successes, however, proved but short lived. Her allies, the Congoes, were so completely overthrown, that they were forced to sue for peace; which the Portuguese did not grant till they had obtained a sufficient number of hostages, and obliged the Congoes to deliver up to them some considerable posts, upon which they immediately erected fortresses. Zingha's troops were now defeated in every quarter; and these defeats followed one another so close, that she was soon abandoned, not only by her allies, but by her own troops. She was also constrained to abandon her dominions, and retire to some of the eastern deserts, whither the Portuguese did not think it worth while to follow her. Zingha being reduced to this distress, the Portuguese, after giving her some time to ruminate on her situation, sent her proposals of peace, upon condition that she should become tributary to the crown of Portugal. This proposal she rejected with scorn; and let them know, that, however her dastardly subjects might sullenly and shamefully behave towards them, their queen disdained subjection to any foreign power. On this haughty answer the Portuguese, to mortify her still more, set up a king in her place. The person they pitched upon was named *Angola Oarij*, or *Aaru*, who was of the royal family. Before he was crowned, the Portuguese obliged him to turn Christian; and he was accordingly baptised by the name of John. The new king, however, soon died of grief, at seeing himself so hardly treated by his masters the Portuguese. They quickly set up another, named Philip; who bore the yoke with more patience, and lived to the year 1660.

In the mean time Zingha, exasperated at seeing herself deprived of eleven of the best provinces in her dominions, and her authority in the remaining six greatly weakened, renounced the Christian religion, to which she had become a profelyte, and embraced all the horrid customs of the Giagas, whom she outdid even in their own barbarity. In eating human flesh, Zingha not only joined them, but took pleasure in devouring the raw flesh of human victims, and drinking the blood while warm, both at her sacrifices and at her public meals. She affected a martial and heroic spirit, together with an utter aversion to the male sex; but, according to the Portuguese, maintained a number of the strongest and lustiest youths, in whose embraces she sometimes indulged her inclinations, and managed matters with such secrecy that her intrigues could not easily be discovered. At the same time she ordered many of her own sex to be ripped up, when their incontinency was manifested by their pregnancy; and their bodies, with those of the infants, to be cast to wild beasts. But what made her most admired, as well as dreaded, by her subjects, was a notion that she had by various stratagems inculcated among them, of her being able to penetrate into the most secret thoughts. To keep up their apprehension, she ordered the bones of her deceased brother to be brought from the island where he was poisoned, locked up in a

chest covered with coarse plates of silver, and laid on a fine carpet upon a pedestal. A number of singhillos, or priests, were ordered to offer sacrifices to the bones, and to keep lamps continually burning before them. To this place she herself frequently repaired, to assist at those rites, which, as she gave out, and every body believed, engaged the spirit of the deceased to inform her of every thing that was done, said, or even designed, either in the kingdom or out of it. To procure, however, as much real intelligence as possible, she kept vast numbers of spies all over the kingdom, who constantly gave her notice of what happened in their respective circles; and this she so cunningly improved to her own ends, that her subjects looked upon her as a kind of deity from whom nothing could be concealed.

By these means, Zingha gained such authority over the Giagas, that they were ready, at the very first indication of her will, to follow her through the most dreadful dangers, and to engage in the most desperate enterprizes. She now made many strenuous and daring efforts to drive out the Portuguese; but though she had, in all probability, more valour and skill than her enemies, the fire-arms gave them such an advantage, that she was always defeated with great loss. Perceiving, therefore, the folly of attempts of this kind, she contented herself with making continual inroads into their country, carrying off or destroying every thing that fell in her way. Though she spared neither Europeans nor blacks, who were subjects of the mock-monarchs set up by the Portuguese, yet the case of the former was peculiarly dreadful when they happened to be taken prisoners. They were either roasted by a slow fire, or had their flesh cut off in pieces, and devoured before their faces, in the manner related by Dr. Bruce of the Abyssinian oxen. In this manner she infested the Portuguese territories for twenty-eight years, scarce ever allowing them a moment's cessation of arms. Their mock-kings were often obliged to shelter themselves from her fury in an inaccessible rock, called *Maopongo*; and they themselves could never hope to enjoy their dominions with any kind of peace so long as this furious queen continued alive. They in vain attempted either to reduce her by force, or to mollify her by presents. The one she rejected with disdain, and always found means to baffle the other. Nor would she hearken to any terms, unless they consented to resign all their conquests. The refusal of this demand was so commonly followed by some marks of her resentment, that it was with the utmost difficulty the Portuguese could prevail on any body to carry their proposals to her; and, as for Zingha, she disdained to make any to them, except those of the hostile kind. The terror of her arms procured her a free passage wherever she directed her course; all the inhabitants of a province making no less haste to abandon than she to invade it. Thus she continued to advance, till she reached the small island of Dangii, in the river Coanza. The Portuguese now found themselves under a necessity of raising an army of negroes to oppose her. Accordingly they surrounded the island, and intrenched themselves along the banks on both sides of the river; but, while they were busy at their work, Zingha attacked them with such advantage, that she killed and wounded several hundreds of the blacks, and some of the white men. Elated with this advantage, she was preparing for another attack; when she perceived, to her surprise, that the Portuguese had drawn their lines so close, and raised them to such a height, that they overlooked her whole camp, and could fire upon her at pleasure. Thus great numbers of her men were cut off, particularly her chief officers. The queen, perceiving the danger of her situation, amused the Portuguese with proposals of an accommodation; and, having obtained a truce for three days, crossed the river in the dead of the night, and led her forces to the province of Oacco. The next morning, the Portuguese, seeing no human creature upon the island, began to apprehend some new stratagem; but, upon land-

ing some of their troops, they perceived themselves overreached, and deprived of the fairest opportunity they ever had of forcing her to surrender at discretion.

Zingha staid no longer in the province whither she had retired than till she was assured that the Portuguese had quitted the Coanza; and then, crossing the river once more, she marched directly to the kingdom of Metamba, which had been invaded by some of the neighbouring princes. The speed with which she led her forces hither, and recruited her army with multitudes of Giagas, who were all emulous of fighting under her banner, quickly enabled her to recover some of her territories in that kingdom. Beginning now to think herself successful, she again attacked the Portuguese; but was defeated with great loss, so as to be obliged to send for fresh troops. To complete her misfortune, she received news that the Giaga Cassangi had taken the advantage of her absence, to enter her kingdom with a numerous army, had carried off the greatest part of the inhabitants, destroyed the fruits of the earth, plundered the towns of all that was valuable, and set fire to the rest, leaving that kingdom in a manner desolate. To add to all this, her troops, exasperated at the loss of their wives, children, and goods, which were carried to the farthest corner of Benguela, were all on the point of revolting.

Notwithstanding these disasters, Zingha behaved with such resolution and address, that the Portuguese, who, according to character, had probably instigated the Giaga against her, were so much afraid of her joining with him in alliance against them, that they dispatched Anthony Coglio, a learned priest and an excellent negotiator, with Don Gaspar Borgia, an eminent officer, under pretence of negotiating a peace between them, first to the Giaga, and afterwards to the queen. They met with a very civil reception from the first, who told them, that he was very willing to live at peace with that prince, and even to let her enjoy the kingdom of Metamba, though he was the rightful heir to it, provided she would lay down her arms. This answer encouraged the priest to try whether he could prevail on him to embrace the Christian religion; but this was declined by the Giaga in such strong terms, that the priest thought proper to desist, and set out for Zingha's camp. The ambassadors, at their first arrival, met with such a polite reception, as made them hope for success; but, after she had heard their proposals, she assumed a haughty tone, and told them, in the conclusion of her speech, "That it did not become her dignity to lay down her arms till she had brought the war to an honourable conclusion; that, as to the Giagas, whose sect she had embraced some years before, and who had furnished her with such a prodigious number of forces to fight in her defence, her honour and interest required that she should still keep them in her service, and under her protection; and lastly, that, as to herself, she remembered, indeed, that she had formerly embraced Christianity; but that it was not now a proper season to propose her returning to it; and they ought to remember, that they themselves were the cause of her abandoning it."

Borgia, perceiving that she was not to be wrought upon by religious motives, shifted his plan, and told her, that she had gained honour enough in war, and that it was now high time to think of granting peace and tranquillity to the subjects of two such powerful kingdoms, and accept of the favour and friendship of the king of Portugal, which was offered her by his viceroy. To this the queen made answer, that she was perfectly well acquainted with the valour and strength of the Portuguese, and should esteem it an honour to be allied to that monarch; but that she thought it just, that their respective claims to the dominions which she inherited from her ancestors, and of which he had unjustly deprived her, should first of all be decided, either by the sword, or by some equitable judges. Borgia, vainly imagining that he had now obtained enough, set off immediately for Loanda San Paulo; but left the priest, on some pretence or other, to see whether, in the time of sickness, he could make any impression on the inflexible

mind of Zingha, who now laboured under a lingering disease. Coglio, however, found all his arts to no purpose; and, upon the queen's recovery, she recommenced the war with more fury than ever. Hostilities were carried on with various success; Zingha being sometimes victorious, and sometimes defeated. In one attempt of the latter kind, before the fortrefs of Massangana, she not only lost a great number of men, but had her two sisters, Cambi and Fungi, taken prisoners, she herself escaping with the utmost difficulty. Exasperated by this loss, she led her troops into some of the best provinces of the Portuguese, and reduced them to a mere wilderness. Still, however, she had the mortification to find her losses vastly greater than what she gained; and she had also the additional misfortune of losing her sister Fungi, who was put to death by the Portuguese for treachery, and seeing her allies, the Dutch, totally expelled out of Angola.

Zingha, being thus oppressed with a complication of misfortunes, and conscious of the crimes she had committed, began seriously to consider whether such a continued series of disasters was not owing to the displeasure of the God of the Christians. To this opinion she seemed to have inclined; and therefore began to treat with more lenity such Christians as fell into her hands, especially if they were priests or monks. To these she now began to listen with some attention; and ordered them, under severe penalties, to be treated with all possible respect; yet without losing in the least that invincible hatred she had conceived against those who had stripped her of her dominions, or dropping her resolution never to make peace till she had recovered them. The viceroy, Don Salvador Correo, who had driven out the Dutch, being apprised of the regard shewn to the clergy by Zingha, thought proper to send some capuchins to her, in hopes that they might now find her more tractable. But Zingha was still proof against her utmost art; observing, however, that, if they would consent to restore what they had unjustly taken from her, she would not only return to the Christian religion, but encourage it to the utmost of her power.

The viceroy, afraid that Zingha might make an alliance against him with the king of Congo, first raised a powerful army, and then acquainted that monarch, that, if he designed to prevent the total ruin of his dominions, he must immediately make reparation for all the damage he had caused to the Portuguese by his alliance with the Dutch. The fame of the Portuguese valour so intimidated the king, that he submitted to a treaty almost on the viceroy's own terms; and, as soon as this treaty was concluded, Don Ruy Pegado, an old experienced officer, was dispatched to Zingha, offering a firm and lasting alliance with her, provided she renounced the Giagan sect, and returned to the bosom of the church. To this embassy she returned the old answer, namely, that the Portuguese themselves had been the occasion of all that had happened; as they had not only stripped her of her hereditary dominions, but dared to proclaim one of her vassals king of Angola; but, provided these dominions were restored, she would immediately embrace Christianity.

All this time the furious Zingha went on with her ravages, notwithstanding the viceroy importuned her with letters for near three years. At last he had recourse to the artifice of taking advantage of the remorse of her crimes with which Zingha was sometimes affected, in order to procure the peaceable enjoyment of his own ill-gotten conquests. It is easy to see, that had this viceroy, or the priests he employed, really intended to convert Zingha to Christianity, they ought to have so far set her an example, as at least to abandon part of the countries of which they had robbed her. But, instead of this, they impiously made use of the sacred name of religion, in order to deter a poor savage African from recovering what justly belonged to her. Zingha, however, at last became so much inclined to return to the Christian religion, that a general murmur ran through her army. But having, by various artifices, reconciled the minds of her subjects to this event, she ex-
plained

plained her design in an animated speech; offering at the same time liberty to those who chose to abandon her on this account to go where they would: and such was their attachment to her, that even in such a sudden and important change in her resolutions they expressed no uneasiness, but on the contrary applauded her to the highest degree.

The Portuguese, after having been harrassed in a terrible manner for twenty-eight years, began now freely to enjoy the fruits of their conquests. A treaty was set on foot between the viceroy and Zingha; which, however, was not easily concluded. She demanded the release of her sister Cambi, whose Christian name was Donna Barbara. This princess was received by Zingha in a very affectionate manner: and, some time after, the queen was not only thoroughly reconciled to the Portuguese, but looked upon them as her best friends. She encouraged the Christian religion; had a church built in her capital; made several laws against Paganism; and, to encourage marriage, she herself wedded a handsome young fellow in the seventy-fifth year of her age.

The Portuguese now proposed to her the following terms, as the basis of a lasting treaty between the two nations: 1. That they should yield to her, *as a present*, some of the countries of which they had already robbed her. 2. That in consideration of the said present, which should in no wise be interpreted as an investiture, the queen should pay yearly a certain acknowledgment to the king of Portugal, who should be at liberty to withdraw the said present whenever she failed of making the said acknowledgment. 3. That a free commerce should be opened between those two states, as well for slaves as for other merchandizes. 4. That the queen should molest none of the lords that were feudatory to the Portuguese, whatever damages and ravages they might have committed during the late wars between them. 5. That she should restore all the Portuguese slaves that had taken refuge in her dominions. 6. That she should deliver up the Giaga Colanda, who had revolted from the Portuguese, upon condition that his crime should go unpunished.

The queen, having now a thorough view of the avarice and ambition of those with whom she had to do, conceived such displeasure against the Portuguese, that she fell sick. During this sickness, father Anthony, her chief confidant, and a creature of the viceroy, never ceased from soliciting her to make her peace with God, and to accept the terms offered her by the Portuguese; but Zingha, though worn out with age and sickness, had still the good sense to perceive, that there was no connection between making her peace with God and complying with such infamous terms; and therefore gave the following answer, which under such circumstances, shews a magnanimity scarcely equalled in any age or in any country: 1. That, as to her conversion, as it was neither owing to any desire of obtaining a peace, or other worldly motives, but the Divine Grace by which she was recalled, she was resolved to persevere in it to her last breath. 2. That, as to her going over to the Giagan sect, she had in a great measure been forced to it by the Portuguese viceroy. 3. That the king of Portugal would do a generous act in restoring some of her Angolic dominions; but it would be more so, were he to restore them all. 4. That, as to her paying homage to him, neither her mind nor heart were base enough to consent to it; and that, as she had refused the proposal while she lived among the Giagas, much more did she think herself above it now she was a Christian queen, and owed neither tribute nor homage to any but to the Supreme Power, from whom she had received both her being and her kingdom. That, nevertheless, if she could be convinced that there was any thing in her dominions that would be acceptable to his Portuguese majesty, she would voluntarily make him a present of it; and, as to the rest of the articles, such was her desire of making a firm and lasting peace with them, that she should make no difficulty of consenting to them.

This answer was not altogether satisfactory to the viceroy; but the priest, finding it impossible to make any impression upon her mind, easily prevailed upon him to consent to the following terms: 1. That the river Lucalla should be the boundary between the dominions of the Portuguese and of queen Zingha. 2. That neither side should thenceforth give any reception to the fugitive slaves of the other, but send them back without delay, together with the prisoners which had been taken during the last war. 3. That the queen should remain wholly free and exempt from all tribute and homage whatever, provided she agreed to the other articles.

These terms were at last signed by the queen, and ratified by the king of Portugal. The only difficulty the queen had concerning this treaty was with regard to the Giaga Colanda: and the manner in which she extricated herself from it, with her subsequent behaviour, cannot fail to give us an high idea of the mental abilities of this African heroine.

This Giagan chief, weary of the Portuguese yoke, had retired at the head of 1000 soldiers, and a much greater number of slaves, some leagues beyond the river Lucalla, and put himself under the queen's protection. This she readily granted, as he was very able to be serviceable to her in case the perfidious conduct of the Portuguese should oblige her to renew the war. She could not therefore but look upon it as unjust and dishonourable, to deliver up a brave chief who had devoted himself to her service, and whom she had taken under her special protection, to a nation with whose perfidy she was so well acquainted. To save her honour, therefore, some time before the ratification of the treaty, she sent privately for the Giaga, and acquainted him with the demand of the Portuguese; telling him, at the same time, that though she doubted not of the viceroy's keeping his word, and forgiving his offence, yet she advised him to go out of her dominions, and settle in some distant country from the Portuguese frontiers; but forbade him, on pain of her highest displeasure, to commit the least outrage or hostility within their dominions. The Giaga thanked her, and seemed to acquiesce with her advice, but did not follow it. On the contrary, he had no sooner reached his fortrefs, than he set himself about fortifying it in such a manner as looked rather like defence than defence; and, having gathered a considerable army, soon spread a general terror around him. Of this the Portuguese failed not to complain to the queen; who immediately marched against him, surprised and defeated his army; and, he himself being killed in the action, his head was cut off and sent to the Portuguese.

This was among the last memorable actions performed by this famous queen; who, now finding herself unfit for the fatigues of war, contented herself (in 1658) with dispatching an old experienced general against a neighbouring prince who had invaded her territories. He proved no less successful than herself, and quickly forced the aggressor to submit to her terms. She now gave herself up to study the best method of propagating Christianity among her subjects; and for this purpose sent a solemn embassy to Rome, to pay homage to the pope in her name, and to request a fresh supply of missionaries. To this letter she received an answer from his holiness in 1662; and it was read in the church, that same year, in the most public and solemn manner. The day appointed was the 15th of July; on which she repaired to the church at the head of a numerous retinue, and having the letter hanging about her neck in a purse made of cloth of gold. The concourse was so great, that the church could not contain one half of the people. The father, having finished the mass, read the letter at the altar in the Portuguese language; and the secretary interpreted it in that of the country. The queen, who had stood all the while it was reading, went towards the altar, and on her knees received it from the father: and having kissed it, and sworn afresh upon the gospel to continue in obedience to the church of Rome, kissed the letter again, put it into the purse, and returned to the palace.

lace amidst the shouts and acclamations of many thousands of her subjects. On that day she gave a magnificent entertainment to the Portuguese resident, and to all her court, in two great porticos, and she herself vouchsafed to eat after the European manner; that is, sitting on a stately elbow chair, with a high table before her, covered with the finest linen, and with dishes, plates, knives, and forks, all of silver gilt. She bestowed some largesses upon her chief officers, released a number of slaves, and at night appeared at the head of her ladies of honour, dressed in the Amazonian manner. They performed a kind of combat, in which the queen, though upwards of eighty years of age, behaved with the great vigour and activity of a woman of thirty. Her life, however, was not lengthened in proportion to her vigour and activity: for in the month of September, she was seized with an inflammation in her throat; which, in December, having seized her breast and lungs, she expired on the 17th of that month, and was succeeded by her sister Barbara.

The deceased queen was buried with extraordinary pomp; and, out of regard to her, Barbara was inaugurated a second and third time, with the greatest pomp, and the most joyful acclamations. She was a very zealous Christian, but wanted her sister's abilities, and had the misfortune of being in the decline of life, lame, and almost blind. Besides this, she had been married to a proud ill-natured husband, named *Mona Zingha*; who, though to her he owed all his fortune and advancement, being himself no more than the son of a slave, used her with such cruelty, even in the late queen's life, that she was obliged to take refuge in the palace.

The queen's infirmities, augmented by his cruelty, and daily increasing, soon brought on her death, which happened on the 24th of March, 1666. Upon this, *Mona Zingha* made all possible haste to get himself elected king; and immediately renounced the Christian religion, raising a persecution at the same time against its professors. He even wrote to the Portuguese viceroy, acquainting him with his having renounced Christianity, and with his design to revive the *Giagan* rites. To shew that he meant to be as good as his word, he ordered all the children under six years of age, that could be found, to be sacrificed in honour of their infernal deities. He also recalled the *singhillos*, and heaped many favours upon them; so that they became entirely devoted to his purposes. He likewise caused many of his subjects to be privately poisoned; and then gave out, that their unaccountable deaths were owing to their having abandoned the religion of their ancestors, and embraced Christianity; which he styled the religion of a parcel of famished strangers, who, through their extreme misery, had been forced to leave their native country, and seek for a livelihood in the richest provinces of Africa.

By these and such-like stratagems he almost entirely extirpated Christianity, with every appearance of civilization which had been introduced among his subjects. His career, however, was stopped by Don John the prince's Barbara's first husband, from whom she had been divorced on account of his having another wife. He soon compelled the usurper to fly into an island in the *Coanza*; but, not having the precaution to reduce him entirely, *Mona Zingha* found means to retrieve his affairs, and at last defeated and killed Don John himself, by which he again became master of the throne without any farther opposition. He was no sooner re-established, than he began to pursue his ravages with more fury than ever: when, on a sudden, Don Francisco, the son of Don John, appeared at the head of an army in opposition to the usurper; and, in the first engagement *Mona Zingha* being defeated and killed, Don Francisco became sole master of the empire.

It is not known whether this prince kept to the terms of alliance made by *Zingha* with the Portuguese or not. These, however, have preserved their conquests, and for some time they allowed the natives to choose a king for themselves. These kings enjoy only a mere shadow of

royalty: their whole grandeur consisting in being allowed to breed peacocks, and adorn themselves with their feathers, which was forbidden to their subjects under pain of perpetual slavery. The last of these kings was named *Ngola Sedesio*, who, disliking an empty name of royalty, revolted from the Portuguese, and carried on a long war with them; but, being at last defeated and killed, his head was cut off, salted, and sent to Lisbon in pickle. After this the Portuguese seem not to have thought it safe to trust their Angolic subjects even with the name of a king of their own, but have vested the power entirely in their viceroy; but as to the extent of his dominions, and how matters stand between him and that race of Angolic princes who have preserved their liberty, we are in the dark.

When in its greatest splendour, the kingdom of Angola contained the seventeen following provinces: *Cheffama*, *Sumbi*, *Benguela*, *Rimba*, *Sietta*, *High and Low Bembea*, *Temba*, *Oacco*, *Cabezzo*, *Lubolo*, *Loanda*, *Bengo*, *Danda*, *Mofiche*, *Higher and Lower Ilamba*, *Oraij*, and *Embacca*. The provinces conquered by the Portuguese during the wars above-mentioned were, *Danda*, *Mofiche*, *Bengo*, the *Higher and Lower Ilamba*, *Oraij*, *Embacca*, *Benguela*, *Sietta*, *Cabezzo*, *Lubolo*, and *Oacco*. The principal rivers are the *Danda* and *Coanza*. The *Coanza* is large, deep, and rapid. It empties itself into the Atlantic ocean about lat. 9. 20. S. twelve leagues south of *Loando* the capital of the kingdom. It is navigable for 150 miles, and abounds with a variety of fish. It forms several islands, has some cataracts, and one in particular which bears its name. As for its source, and the length of ground it crosses from east to west before it comes to the Portuguese settlement, it is absolutely unknown, as well as the countries through which it runs. Its mouth, which runs between the capes *Palmerino* and *Lego*, is above a league wide; the northern shore is the deepest, and along which the vessels sail. The fall of this river into the ocean is so rapid, that the sea appears quite muddy for two or three leagues below it. Its mouth is not easily perceived from the open sea, by reason of an island quite covered with high trees which lies just before it. The two principal islands formed by this river are called *Maffander* and *Motchiamia*. The one is six leagues long, and about two miles broad: it is very fertile in maize, millet, and some other grains, which are reaped at three different seasons of the year. It produces likewise vast quantities of manioc, a root, of which they make a coarse kind of meal, which serves instead of bread. Here also grow great numbers of palm and other fruit trees of various kinds. The island of *Motchiamia* is four or five miles long, and one in breadth, mostly plain, and producing a variety of roots and herbs. It likewise abounds in cattle; and there were formerly five or six Portuguese families settled upon it, who carried on a considerable trade in these commodities, and likewise in slaves.

AN'GON, *f.* in the ancient military art, a kind of javelin used by the French. They darted it at a considerable distance. The iron head of this weapon resembled a flower-de-luce. It is the opinion of some writers, that the arms of France are not flowers-de-luce, but the iron point of the angon or javelin of the ancient French.

ANGO'NE, *f.* A nervous sort of quinsy. Vogel defines it to be an acute stopping up of the fauces, without inflammation. He says that the convulsive quinsy, and hyseric suffocation, are its species.

AN'GOR, *f.* A concentration of the natural heat of the body, causing a palpitation of the heart, and anxiety. In the beginning of a fever it is a bad prognostic.

AN'GOT, a province or kingdom of Abyssinia, formerly rich and fertile, but almost ruined by the Gallas, a wandering nation in the internal parts of Africa.

ANGOULE'SME, a town in the department of Charente. It stands on a mountain surrounded with rocks, the river Charente running at the foot of it. It is twenty miles west of Limoges, and 250 south-by-west of Paris. Lat. 45. 39. N. lon. 0. 14. E.

ANGOUMO'IS, late a province of France, now included in the department of Charente. It is hilly, but fertile, has good iron-mines, and excellent paper manufactures.

ANGOU'RA, or ANGORA, anciently ANCY'RA, a town of Naxos, in Asiatic Turkey, remarkable for its remains of antiquity, as inscriptions, pillars, ruins of temples, &c. of porphyry and old marble. The castle, which is as large as a small town, and well inhabited, both by the Christians and Turks, is built of white marble, and stone resembling porphyry, and, throughout the walls of the town, which are low, and those of the houses, which are generally built of unburnt brick, antique fragments are interspersed. The city of Angora is computed to have 100,000 inhabitants in it, 90,000 of whom are Turks; and about 1000 of these are janizaries. Greeks, Armenians, &c. compose the remaining 10,000. The country produces very good red wine, and they have excellent rice on some of the rivers. They have the finest breed of goats here in the world; their hair or wool is quite white, and almost as fine as silk; a great trade is carried on in this article, and the finest stuffs, especially camblets, are made of it. The exports of Angora to Holland, France, and England, are about 1600 camel-loads yearly. It is 212 miles south-east of Constantinople. Lat. 39. 30. N. lon. 32. 5. E.

ANGO'Y, a kingdom of Loango in Africa, bounded on the north by Cacongo, and on the south by Congo; from the former of which it is separated by the river Cabinda, and from the latter by the river Zaire. The country is full of woods and thickets; and has no towns of any note, except one called Bomangoy, situated on the north banks of the Zaire, and not far from its mouth. Its chief port is Cabinda, called also *Kabenda*, or *Cubenda*, situated on the mouth of a river of the same name, about five leagues north of cape Palmerino, on the north side of the Zaire's mouth. The bay is very commodious for trade, or wooding and watering along the shore. It is flat and marshy in some places; but ascends gradually about three miles inland, and then forms itself into a ridge of hills. The town stands on the round point of the bay looking to the westward; and the English have a factory on the south-west of the road. The country round the bay is mostly barren; owing chiefly to the indolence of the inhabitants, which often occasions a scarcity of provisions. The wild beasts swarm in the woods, and destroy all the tame kinds; so that there are no cattle bred here but hogs. The coasts abound so much with oysters, that the sailors quickly load their boats with them. The natives follow the occupation of fishing more than any other. The dress of the inhabitants is the same with that of the Congolese. They allow polygamy, and the best beloved wife hath the command of the rest; but is no less liable to be turned out, if she proves unfaithful.

AN'GRA, a city of Tercera, one of the Azores; the capital, not only of that island, but of all the rest, and the residence of the governor. It is seated on the south side, near the middle of the longest diameter of the island, on the edge of the sea. The harbour is the best in the whole island, being equally secured against storms and the efforts of an enemy. It is of the form of a crescent; the extremities of which are defended by two high rocks, that run so far into the sea as to render the entrance narrow, and easily covered by the batteries on each side. From this harbour the town is said to derive its name, the word *Angra* signifying a creek, bay, or station, for shipping; and this is the only convenient one among all the Azores.

The town is well built and populous, is the see of a bishop, under the jurisdiction of the archbishop of Lisbon. It hath five parishes, a cathedral, four monasteries, as many nunneries, besides an inquisition and bishop's court, which extends its jurisdiction over all the Azores, Flores, and Corvo. It is surrounded by a good wall, a dry ditch of great depth and breadth, and defended by a strong castle, rendered famous by the imprisonment of king Alphonso by his brother Peter in 1668. At Angra are kept

magazines for anchors, cables, sails, and other stores, for the royal navy, or occasionally for merchantmen in distress. All maritime affairs are under the inspection of an officer called *desembargador*, who hath subordinate officers and pilots for conducting ships into the harbour, or to proper watering-places. The English, French, and Dutch, have each a consul residing here, though the commerce of any of these nations with the Azores is very inconsiderable.

ANGRÆ'CUM, *f.* in botany. See EPIDENDRUM.

AN'GRILY, *adv.* In an angry manner; furiously; peevishly.

ANGRIVA'RII, anciently a people of Germany, situated between the Weser and the Ems, and eastward reaching beyond the Weser, as far as the Cherusci, on which side they raised a rampart; to the south, having the Tubantes on the Ems, and on the Weser where it bends to the forest Bacenis; to the west, the Ems and the confines of the Bructeri; and, to the north, the territory of the Angrivarii lay between the Chamavi and Anfibarii. Ptolemy places them between the Canchi and Suevi or Catti. Supposed now to contain a part of the county of Schaumburg, the half of the bishopric or principality of Minden: to the south, the greatest part of the bishopric of Osnabrug, the north part of the county of Teclenburg, and a part of the county of Ravensberg. A trace of the name of the people still remains in the appellation *Engern*; a small town in the county of Ravensberg.

ANGROG'NE, or ANGROG'NA, a mountainous, yet fruitful, community, parish, or township, of Piedmont, through which runs a little river of the same name. It is accessible only at two places from the south and east, and there are retreats among the rocks, where, during the most violent persecutions against the poor Vaudois, their old *bards* (bards), as they are called, or valley-ministers, preached without interruption. Sometimes the valleys of Piedmont are called by the name of Angrogne. The town of Angrogna is seven miles west of Pignerol. Lat. 45. 0. N. lon. 7. 15. E.

AN'GRY, *adj.* Touched with anger; provoked.—Oh let not the Lord be *angry*, and I will speak: peradventure there shall be thirty found there. *Gen.* xviii. 30.—It seems properly to require, when the object of anger is mentioned, the particle *at* before a thing, and *with* before a person; but this is not always observed.—Now, therefore, be not grieved, nor *angry with yourselves*, that ye told me hither: for God did send me before you to preserve life. *Gen.* xlv. 5.—I think it a vast pleasure, that, whenever two people of merit regard one another, so many scoundrels envy and are *angry at them*. *Swift*.—Having the appearance of anger; having the effect of anger.—The north wind driveth away rain: so doth an *angry* countenance a backbiting tongue. *Prov.* xxv. 23.—In chirurgery, painful; inflamed; smarting.—This serum, being accompanied by the thinner parts of the blood, grows red and *angry*; and, wanting its due regrefs into the mass, first gathers into a hard swelling, and, in a few days, ripens into matter, and so dischargeth. *Wiscman*.

ANGUED, a province of Algiers, or rather a desert of Tremecen. Hords or clans of Arabs, and others, live here mostly on plunder, obliging travellers to pay them money for their passports, which are a kind of snail flag at the end of a lance. They have but little corn, and they feed principally on dates, milk, and what wild game they kill. They all ramble or range about the country, without acknowledging any but their own chief, or paying any tribute to the Algerines.

ANGUIL'LA, one of the West-India or Caribbee islands, lying in about 15° N. lat. It has its name from its snake-like form; and is about ten leagues in length and three in breadth. It was first discovered by the English in 1650, when it was filled with alligators and other noxious animals; but they, finding the soil fruitful, and proper for raising tobacco and corn, settled a colony on it, and imported live cattle, which have since multiplied exceedingly. But, the colony not being settled under any public encouragement,

encouragement, each planter laboured for himself, and the island became a prey to every rapacious invader, which disheartened the inhabitants so much, that all industry was lost among them. Their chief suffering was from a party of wild Irish, who landed here after the revolution, and treated them worse than any of the French pirates who had attacked them before. The people of Barbadoes, and other English Caribbees, knowing the value of the soil, several of them removed to Anguilla, where they remained for many years, and even carried on a profitable trade, though without any government, either civil or ecclesiastical. In 1745, their militia, though not exceeding 100 men, defended a breast-work against 1000 French who came to attack them; and at last obliged them to retire with the loss of 150 men, besides carrying off some of their arms and colours as trophies of their victory. Since that time the inhabitants have subsisted mostly by farming; though they still plant sugar, and the island is said to be capable of great improvements.

ANGUILLA'RIA, *f.* in botany. See ARDISIA.

ANGUILIFORM, *f.* an appellation given by zoologists, not only to the different species of eels, but to other animals resembling them in shape.

ANGUINA, *f.* in botany. See CALLA and TRICHOSANTHES.

ANGUINUM OVUM, *f.* a fabulous kind of egg, said to be produced by the saliva of a cluster of serpents, and possessed of certain magical virtues. The superstition in respect to these was very prevalent among the ancient Britons; and there still remains a strong tradition of it in Wales. This wondrous egg seems to have been nothing more than a bead of glass, used by the druids as a charm to impose on the vulgar, whom they taught to believe, that the possessor would be fortunate in all his attempts, and that it would gain him the favour of the great. Our modern druidesses (says Mr. Pennant) give much the same account of the *ovum anguinum*, *glain neidr* as the Welsh call it, or the *adder gem*, as the Roman philosopher does; but seem not to have so exalted an opinion of its powers, using it only to assist children in cutting their teeth, or to cure the chin-cough, or to drive away an ague. These beads are of a very rich blue colour; some plain, others streaked.

AN'GUIS, or SNAKE, in zoology, a genus belonging to the order of amphibia serpentes. The characters of the anguis are these: they are squamous or scaly in the belly and under the tail; without any scuta. There are a number of different species of the anguis:

1. The eryx, a native of Britain and likewise of America, is about a span in length, and about the thickness of a man's finger. One from Scotland, described by Mr. Pennant, was fifteen inches long; tongue broad and forked; nostrils small, round, and placed near the tip of the nose; eyes lodged in oblong fissures above the angle of the mouth; belly of a bluish lead-colour, marked with small white spots irregularly disposed. The rest of the body is of a greyish brown, with three longitudinal dusky lines; one extending from the head along the back to the point of the tail; the others broader, and extending the whole length of the sides. It was entirely covered with small scales; largest on the upper part of the head.

2. The fragilis, blind-worm, or slow-worm: grows to about a foot in length, and to the thickness of a man's little finger; the irides are red, the head is small, and the neck still more slender; from that part the body grows suddenly, and continues of an equal bulk to the tail, which ends quite blunt. The colour of the back is cinerous, marked with very small lines composed of minute black specks: the sides are of a reddish cast; the belly dusky; both marked like the back. The tongue is broad and forked; the teeth are minute, but numerous; the scales small. The motion of this serpent is slow, from which, and from the smallness of the eyes, are derived its name. It resembles the viper in the manner of producing its young, which are put forth alive. It is frequent with us in gar-

dens and pastures, where it lives principally under ground, feeding on worms. Like others of the genus, they lie torpid during winter, and are sometimes found in vast quantities twisted together.

3. The ventralis, or glass-snake of Catesby: has 127 squamæ on the belly, and 223 on the tail. The head is very small, and the tongue of a singular form. The upper part of the body is of a colour blended brown and green, most regularly and elegantly spotted with yellow, the undermost part of which is brightest. The skin is very smooth and shining; with small scales, more closely connected, and of a different structure from those of other serpents. A small blow with a stick will cause the body to separate, not only at the place struck, but at two or three other places, the muscles being articulated in a singular manner quite through to the vertebra. They appear earlier in the spring than any other serpent, and are numerous in the sandy woods of Virginia and Carolina. They are generally said to be harmless.

4. The jaculus, or dart-snake: is about three hand-breadths long, and about the thickness of one's little finger. Its colour is a milky grey on the back, variegated with small black spots like so many eyes; and on the belly it is perfectly white. The neck is wholly black; and from that two milk-white streaks run all the way along the back to the tail: the black spots also are each surrounded with a small circle of white. It has its name from its vibrating its body in the manner of a dart. It is a native of Egypt, Libya, and the islands of the Mediterranean.

5. The quadrupes: the body of this species is cylindrical, with fourteen or fifteen longitudinal ash-coloured streaks; the teeth are extremely small; it has no ears: the feet are at a great distance from each other, very short, with five toes and small nails; but the toes are so minute, that they can hardly be numbered. Native of Java.

6. The meleagris: is a native of the Indies; it has small teeth, but no ears.

7. The colubrina: an inhabitant of Egypt, is beautifully variegated with pale and yellow colours.

8. The maculata: a native of America, is yellow, and interspersed with ash-coloured lines on the back; the head is small in proportion to the body.

9. The reticulata: a native of America, has brownish scales, with a white margin.

10. The cerasus: with 200 squamæ on the belly and fifteen on the tail, is a native of Egypt.

11. The lumbricalis: a native of America, has 250 squamæ on the belly and seven on the tail; its colour is a yellowish white.

12. The platyura: the head is oblong and without teeth; the body is about a foot and a half long, black above and white below; the tail is about one ninth of the length of the animal, much compressed or flattened, and variegated with black and white; the scales are roundish, small, not imbricated, but they cannot be numbered.

13. The laticauda: a native of Surinam; the tail is compressed, acute, pale, with brownish belts.

14. The scytale: a native of the Indies, with 220 squamæ on the belly and thirteen on the tail. The head is small and oval, and the eyes are little: the body is cylindrical, about a foot and a half long, covered with oval obtuse scales: the tail is thick and obtuse like the head; its colour is white, interspersed with brownish rings; the margins of the scales are of an iron colour; and the top of the head is blue. According to Linnæus, none of this genus are poisonous.

ANGUEL'LES, *f.* with falconers, small worms cast up by sick hawks.

ANGUISH, *f.* [*angoisse*, Fr. *angor*, Lat.] Excessive pain either of mind or body; applied to the mind, it means the pain of sorrow, and is seldom used to signify other passions:

Perpetual *anguish* fills his anxious breast,
Not slopt by business, nor compos'd by rest;

No mule cheers him, nor no feat can please. *Dryden.*

ANGUISHED,

AN'GUISHED, *adj.* Seized with anguish; tortured; excruciatingly pained. Not in use.

AN'GUILUM SENECTÆ, *f.* called also *exuvie*. The skins of serpents that are cast in spring; the slough or cast skin of a snake is as good. A decoction of it boiled in wine is said to cure deafness, pain in the ears, &c.

AN'GULAR, *adj.* Having angles or corners; cornered. Consisting of an angle.—As for the figure of crystal, it is for the most part hexagonal, or six-cornered, being built upon a confused matter, from whence, as it were from a root, *angular* figures arise, even as in the amethyst and baltates. *Brown*.

ANGULARITY, *f.* The quality of being angular, or having corners.

ANGULARLY, *adv.* With angles or corners.—Another part of the same solution afforded us an ice *angularly* figured. *Boyle*.

AN'GULARNESS, *f.* The quality of being angular.

AN'GULATED, *adj.* Formed with angles or corners.—Topazes, amethysts, or emeralds, which grow in fissures, are ordinarily crystallized, or shot into *angulated* figures; whereas, in the strata, they are found in rude lumps, like yellow, purple, and green, pebbles. *Woodward*.

ANGULO'SITY, *f.* Angularity; cornered form.

AN'GULOUS, *adj.* Hooked; angular.—Nor can it be a difference, that the parts of solid bodies are held together by hooks, and *angulus* involutions; since the coherence of the parts of these will be of as difficult a conception. *Glanville*.

ANGU'RIA, *f.* [*αγγύριον*, Gr. a vessel.] In botany, a genus of the monoeceia diandria class, and ranking in the natural order of cucurbitaceæ. The generic characters are—*I.* Male flowers. Calyx: monophyllous, quinquefid, swelling at the base; divisions lanceolate, short. Corolla: pentapetalous, spreading, growing to the border of the calyx. Stamina: filaments two, opposite, inserted into the calyx; anthera creeping up and down. *II.* Female flowers. Calyx and corolla: as in the male. Stamina: filaments as in the male, but no antheræ. Pistillum: germ inferior oblong; style semibifid; stigmas bifid, acute. Pericarpium: a pome oblong, quadrangular, bilocular. Seeds: very many, oval, compressed, nestling.—*Essential Character.* Male. Calyx, five-cleft; corolla five-petalled. Female. Calyx, five-cleft; corolla, five-petalled; pome inferior, two-celled, many-seeded.

Species. 1. *Anguria trilobata*: leaves three-lobed. This plant has a very shining appearance. The leaves are alternate, large, and three-lobed; the lobes oblong, acuminate, flat, entire, except that they have a few toothlets on the edge; the outer ones usually have a blunt appendicle with a terminating toothlet, resembling the rudiment of a fourth and fifth lobe. Tendrils the length of the leaves. Peduncles of the male flowers solitary from the axils, long, and bearing at the end about twenty subaggregate, sessile, inodorous, beautiful, vermilion-coloured, flowers, opening successively. They are perfectly those of the next species, except that the petals are more round. Jacquin had not an opportunity of observing the female flowers. Native of Carthage in South America, and flowers in June.

2. *Anguria pedata*: leaves pedate, serrate. This is a perennial plant, climbing trees by means of long tendrils to the height of twenty feet. Flowers inodorous, with orange-coloured petals. Fruits an inch in length, the thickness of the middle finger, green with longitudinal white streaks, and shining. Seeds white. Plumier's figure has male and female flowers on the same plant. Jacquin has always found them on different plants: and yet, from the analogy which this genus bears to cucumbers, he suspects that the *anguria* may sometimes be monoecious, as Plumier has represented it. Native of St. Domingo, and flowers in September. The fruit is ripe in December.

3. *Anguria trifoliata*: leaves ternate, quite entire. This differs, in having the leaves quite entire, and narrower; and several fruits collected together. Native of St. Domingo. See *CUCURBITA*.

AN'GUS, a shire of Scotland, sometimes called Forfar, from the name of the county-town, is bounded on the north by Aberdeenshire, on the north-east by Kincardineshire, on the east by the German ocean, on the south by the frith of Tay, and on the west by Perthshire. Its length and breadth are nearly equal, about thirty-five miles. It has many lakes and hills, with quarries of slate and freestone, mines of lead and iron ore; the lower grounds are fertile in corn and pasture; and, along the coast, the salmon-fishery is very extensively carried on. The principal rivers are the North and South Esk.

ANGU'ST, *adj.* [*angustus*, Lat.] Narrow; strait.

ANGUSTA'TION, *f.* The act of making narrow; straitening: the state of being narrowed.—The cause may be referred either to the grumousness of the blood, or to obstruction of the vein somewhere in its passage, by some *angustation* upon it by part of the tumour. *Wesman*.

ANGUSTICLA'VIA, *f.* in Roman antiquity, a tunica embroidered with little purple studs. It was worn by the Roman knights, as the *laticlavus* was by the senators.

AN'HALT, an island of Denmark, in North Jutland, lying in the Categat, eight miles from the coast of Jutland, ten from Zealand, and seven from Holland. It is dangerous for seamen, for which reason there is a light-house.

ANHALT, a principality of Germany, in the circle of Upper Saxony, is a long narrow tract, situated betwixt the rivers Elbe and Saal, about ninety miles in length from east to west, but of unequal breadth, the greatest being on the east side, which is but thirty-five miles. The house of Anhalt, from whence the electors of Saxony and Brandenburg are said to derive their original, is a very ancient and honourable family. The best genealogists deduce their origin from Berenthobaldus, who made war upon the Thuringians in the sixth century: it has produced many princes who make a great figure in the German history. Joachim Ernest, who died in 1586, left five sons, who divided the principality among them. All of them having children, and being of equal authority, they unanimously agreed to submit to the eldest of the family, who has the supreme government, which is *Anhalt-Deffau*. The others are, *Anhalt-Bernburg*, *Anhalt-Schaumburg*, *Anhalt-Coethen*, and *Anhalt-Zerbst*. The Saxons acknowledge that the inhabitants of these little independent sovereignties live in the land of milk and honey. These petty princes possess lands sufficient for their expences, the revenues being reckoned at about half a million of dollars. The tax on lands is four per cent. which, rating them at twenty years purchase, is not quite one shilling in the pound. Upon an emergency the subjects are able to raise half a million extraordinary. The towns in these little states are not so numerous in proportion to the extent of country as Saxony, but they are better peopled. It is bounded on the S. by the county of Mansfeld, on the W. by the duchy of Halberstadt, on the E. by the duchy of Saxony, and on the N. by the duchy of Magdeburg. It abounds in corn, and is watered by the Salde and Mulda; its principal trade is in beer.

ANHALT-WATER. It is in the Brandenburg Dispensatory, and is the *sp. vini rect.* distilled from turpentine, and twelve or thirteen other ingredients of the aromatic kind; but a more elegant spirit of this kind may be obtained by mixing a proper quantity of the essential oils of rosemary, lavender, sage, or other such like, with the common oil of turpentine, and then distilling them. This water is an excellent cordial.

ANHELA'TION, *f.* [*anhele*, Lat.] The act of panting; the state of being out of breath. A shortness of breath, or a difficult and small, but quick, respiration, which happens to sound persons, especially fat people, and valetudinarians, after strong exercise. In fevers, dropsies, asthmas, pleurifies, &c. there is always an *anhelitus*. To express this, Hippocrates often uses the word *pneuma*. But this amongst the chemists signifies smoke, and also horse-dung; this last is termed also, when hot, *cancinpericon*.

ANHELO'SE, *adj.* [*anhelus*, Lat.] Out of breath; panting; labouring of being out of breath.

A'NIAN, the name of a strait formerly supposed to lie between the north-east of Asia and the north-west of America; but now found to exist only in imagination.

ANIAN is also the name of a barren sandy desert lying on the east coast of Africa. It is so excessively hot and otherwise inhospitable, that it contains but very few inhabitants, except some wandering Arabs who live in camps.

ANIBA, *f.* in botany. See CEDROTA.

ANICE'TON, *f.* An epithet for a plaster ascribed to Crito, and so called because it was an infallible remedy for the acores.

ANIEN'TED, *adj.* [*ancantir*, Fr.] Frustrated; brought to nothing.

ANIGRI'DES, nymphs, who inhabited the banks of the river Anigrus. They had a cave where those afflicted with a leprosy, or any other cutaneous disease, entered, and sacrificed to those nymphs; after which they swam over the river, and left all their impurities behind them.

ANI'GRUS, a river of Thessaly, where the Centaurs washed the wounds they had received from Hercules, and made the waters unwholesome.

ANJEN'GO, a small town and factory, with a fort, on the coast of Malabar, in the peninsula on this side the Ganges, belonging to the East-India company. The fort is small, but neat and strong: it is a square with four bastions, having eight guns mounted on each, carrying a ball of 18 pounds. Two of these bastions face the sea, the other two the country. Besides these, there is a line of eighteen or twenty guns pointing towards the sea, of 18 and 24 pounders. About pistol-shot from the back of the fort runs a river, which, besides being a security to the factory, adds much to the agreeable situation of the place. This river has its source in some distant mountains; and, descending in a course from the north and east, it afterwards turns in several pleasing meanders so far to the west as to wash the bottom of our factory's garden, and at last, winding to the south, it empties itself into the sea. This settlement supplies our East-India company with pepper: and its situation is also very convenient for giving proper intelligence to our ships touching here from Europe, or from any part of India. Lat. 7. o. N. lon. 76. 1. E.

ANIL, *f.* in botany. See INDIGOFERA.

ANILENESS, or AN'ILITY, *f.* [*anilitas*, Lat.] The state of being an old woman; the old age of women.

ANIMA, *f.* among divines and naturalists, denotes the soul, or principle of life, in animals. See SOUL.

ANIMA, among the old chemists, denoted the volatile or spirituous parts of bodies.

ANIMA HEPATIS, is an obsolete name for the *ferrum vitriolatum*, or salt of iron, on account of its supposed efficacy in diseases of the liver.

ANIMA MUNDI, i. e. the *soul of the world*; a certain pure ethereal substance or spirit, diffused, according to many of the ancient philosophers, through the mass of the world, informing, actuating, and uniting, the divers parts thereof into one great, perfect, organical, and vital, body or animal. They add, that this anima mundi, which more immediately resides in the celestial regions as its proper seat, moves and governs the heavens in such manner, as that the heavens themselves first received their existence from the fecundity of the same spirit; for that this anima, being the primary source of life, every where breathed a spirit like itself, by virtue whereof various kinds of things were framed conformable to the divine ideas.

ANIMA SATURNI, a white powder obtained by pouring distilled vinegar on litharge, of considerable use in enamelling. See ENAMEL.

ANIMABLE, *adj.* That which may be put into life, or receive animation.

ANIMADVER'SION, [*animadversio*, Lat.] Reproof; severe censure, blame.—He dismissed their commissioners

with severe and sharp *animadversions*, Clarendon. Punishment. When the object of *animadversion* is mentioned, it has the particle *on* or *upon* before it.—When a bill is debating in parliament, it is usual to have the controversy handled by pamphlets on both sides; without the least *animadversion upon* the authors. Swift. In law, An ecclesiastical censure, and an ecclesiastical *animadversion*, are different things; for a censure has a relation to a spiritual punishment, but an *animadversion* has only a respect to a temporal one; as, degradation, and the delivering the person over to the secular court. Ayliffe. Perception; power of notice: not in use.—The soul is the sole percipient which hath *animadversion* and sense, properly so called. Glanville.

ANIMADVER'SIVE, *adj.* That has the power of perceiving; percipient: not in use.—The representation of objects to the soul, the only *animadversive* principle, is conveyed by motions made on the immediate organs of sense. Glanville.

ANIMADVER'SIVENESS, *f.* The power of animadverting, or making judgment.

TO ANIMADVERT', *v. n.* [*animadverto*, Lat.] To pass censures upon.—I should not *animadvert* on him, who was a painful observer of the decorum of the stage, if he had not used extreme severity in his judgment of the incomparable Shakespeare. Dryden. To inflict punishments. In both senses with the particle *upon*.—If the Author of the universe *animadverts upon* men here below, how much more will it become him to do it upon their entrance into a higher state of being? Grew.

ANIMADVERTER, *f.* He that passes censures, or inflicts punishments.—God is a strict observer of, and a severe *animadverter upon*, such as presume to partake of those mysteries, without such a preparation. South.

ANIMAL, *f.* [*animal*, Lat.] A living creature corporeal, distinct, on the one side, from pure spirit; on the other, from mere matter. Animals are such beings, which, besides the power of growing, and producing their like, as plants and vegetables have, are endowed also with sensation and spontaneous motion.

ANIMAL, *f.* in natural history, an organized and living body, which is also endowed with sensation: thus, minerals are said to grow or increase, plants to grow and live, but animals alone to have sensation. It is this property of sensation that is deemed the essential characteristic of an animal; and by which the animal and vegetable kingdoms seem to be so materially separated. Those naturalists, who have supposed the distinction between animals and vegetables to consist in any thing else, have found themselves greatly embarrassed; and have generally agreed, that it was extremely difficult, if not impossible, to settle the boundaries between the animal and vegetable kingdoms. But this difficulty will be easily seen to arise from their taking the characteristic marks of the animal kingdom, from something that was evidently common to both. Thus Boerhaave attempted to distinguish an animal from a vegetable, by the former having a mouth, which the latter has not: but here, as the mouth of an animal is only the instrument by which nourishment is conveyed to its body, it is evident that this can be no essential distinction, because vegetables also require nourishment, and have instruments proper for conveying it into their bodies; and, where the end is the same, a difference in the means can never be essential. The fixing the difference in an animal's having a gula, stomach, and intestines, as is done by Dr. Tyson, is as little to the purpose.

The power of moving from one place to another, hath by many been thought to constitute their principal difference; and indeed, in most cases, it is the obvious mark by which we distinguish an animal from a vegetable; but Lord Kames hath given several very curious instances of the locomotive power of plants; some of which, as he says, would do honour to an animal. Upon the slightest touch, the sensitive plant shrinks back, and folds up its leaves, similar to a snail; which, on the slightest touch,

retires within its shell. If a fly perch upon one of its flower-leaves, it closes instantly, and crushes the insect to death!

Plants in general, when forced from their natural position, are endowed with a power to restore themselves. A hop-plant, twisting round a stick, directs its course from south to west, as the sun does. Untwist it, and tie it in the opposite direction, it dies. Leave it loose in the wrong direction, it recovers its natural direction in a single night. Twist a branch of a tree, so as to invert its leaves; if left in any degree loose, it untwists itself gradually, till the leaves be restored to their natural position. What better can an animal do for its welfare? A root of a tree, meeting with a ditch in its progress, is laid open to the air. What follows? It alters its course like a rational being, dips into the ground, undermines the ditch, rises on the opposite side to its wonted distance from the surface, and then proceeds in its original direction. Place a wet sponge near a root laid open to the air, the root will direct its course to the sponge. Change the place of the sponge, the root varies its direction. Thrust a pole into the ground at a moderate distance from a scandent plant, the plant directs its course to the pole, lays hold of it, and rises on to its natural height. A honeysuckle proceeds in its course till it be too long for supporting its weight, and then strengthens itself by shooting into a spiral. If it meets with another plant of the same kind, they coalesce for mutual support; the one screwing to the right, the other to the left. If a honeysuckle twig meets with a dead branch, it screws from the right to the left. The claspers of briony shoot into a spiral, and lay hold of whatever comes in their way for support. If, after completing a spiral of three rounds, they meet with nothing, they try again for further support by altering their course.

M. Buffon, who appears almost to confound the animal and vegetable kingdoms, denies sensation to be any essential distinction. "Sensation," says he, "more essentially distinguishes animals from vegetables: but sensation is a complex idea, and requires some explication. For, if sensation implied no more than motion consequent upon a stroke or an impulse, the sensitive-plant enjoys this power. But if, by sensation, we mean the faculty of perceiving and comparing ideas, it is uncertain whether brute animals are endowed with it. If it should be allowed to dogs, elephants, &c. whose actions seem to proceed from motives similar to those by which men are actuated, it must be denied to many species of animals, particularly to those which appear not to possess the faculty of progressive motion. If the sensation of an oyster, for example, differed only in degree from that of a dog, why do we not ascribe the same sensation to vegetables, though in a degree still inferior? This distinction, therefore, between the animal and vegetable, is neither sufficiently general nor determined. From this investigation, we are led to conclude, that there is no absolute and essential distinction between the animal and vegetable kingdoms; but that nature proceeds, by imperceptible degrees, from the most perfect to the most imperfect animal, and from that to the vegetables; and the fresh-water polypus may be regarded as the last of animals and the first of plants.

It were to be wished, that philosophers would on some occasions consider, that a subject may be dark as well on account of their inability to see, as when it really affords no light. This great author boldly concludes, that there is no essential difference between a plant and an animal; because we ascribe sensation to an oyster, and none to the sensitive-plant: but we ought to remember, that, though we cannot perceive a distinction, it may nevertheless exist. Before M. Buffon, therefore, had concluded in this manner, he ought to have proved that some vegetables were endowed with *sensation*.

It is no doubt, however, as much incumbent on those who take the contrary side of the question, to prove that vegetables are not endowed with sensation, as it was incumbent on M. Buffon to have proved that they are. But

a little attention will shew us, that the difficulty here proceeds entirely from our inability to see the principle of sensation. We perceive this principle in ourselves, but no man can perceive it in another. Why then does every individual of mankind conclude, that his neighbour has the same sensations with himself? It can only be from analogy. Every man perceives his neighbour formed in a manner similar to himself; he acts in a similar manner on similar occasions, &c. Just so it is with brute animals. It is no more doubtful that they have sensations, than that we have them ourselves. If a man is wounded with a knife, for instance, he expresses a sense of pain, and endeavours to avoid a repetition of the injury. Wound a dog in the same manner, he will also express a sense of pain; and, if you offer to strike him again, will endeavour to escape, before he feels the stroke. To conclude here, that the action of the dog proceeded from a principle different from that of the man, would be absurd and unphilosophical to the last degree.

We must farther take notice, that there are sensations essentially distinct from one another; and, in proportion as an animal is endowed with more or fewer of these different species, it is more or less perfect as an animal; but, as long as only one of them remains, it makes not the least approach to the vegetable kingdom; and, when they are all taken away, is so far from becoming a vegetable, that it is only a mass of dead matter. The senses of a perfect animal, for instance, are five in number. Take away one of them, suppose sight, he becomes then a less perfect animal; but is as unlike a vegetable as before. Suppose him next deprived of hearing, his resemblance to a vegetable would be as little as before; because a vegetable can neither feel, taste, nor smell; and we suppose him still to enjoy those three senses. Let us, lastly, suppose him endowed only with the sense of feeling, which, however, seems to include that of taste, and he is no more a vegetable than formerly, but only an imperfect animal. If this sense is then taken away, we connect him not with the vegetable kingdom, but with what M. Buffon calls *brute-matter*. It is to this kingdom, and not to the vegetable, that animals plainly approximate as they descend. Indeed, to suppose an approximation between the vegetable and animal kingdoms, is very absurd; for, at that rate, the most imperfect animal ought to be the most perfect plant; but we observe no such thing. All animals, from the highest to the lowest, are possessed of vegetable life; and that, as far as we can perceive, in an equal degree, whether the animal life is perfect or imperfect: nor doth there seem to be the smallest connection between the highest degree of vegetation and the lowest degree of sensation. Though all animals are possessed of vegetable life, these two seem to be as perfectly distinct and incommensurate to one another, as any two things we can possibly imagine.

The power of vegetation, for instance, is as perfect in an onion or leek, as in a dog, an elephant, or a man; and yet, though you threaten a leek or an onion ever so much, it pays no regard to your words, as a dog would do; nor, though you wound it, does it avoid a second stroke. It is this principle of self-preservation in all animals, which, being the most powerful one in their nature, is generally taken, and with very good reason, as the true characteristic of animal life. This principle is undoubtedly a consequence of sensation; and, as it is never observed to take place in vegetables, we have a right to say that the foundation of it, namely, *sensation*, belongs not to them. There is no animal, which makes any motion in consequence of external impulse where danger is threatened, but what puts itself in a posture of defence; but no vegetable whatever does so. A muscle, when it is touched, immediately shuts its shell; and, as this action puts it in a state of defence, we conclude that it proceeded from the principle of self-preservation. When the sensitive-plant contracts from a touch, it is no more in a state of defence than before; for whatever would have destroyed it in its expanded state will also do it in its contracted state. The motion

tion of the sensitive-plant proceeds only from a certain property called *irritability*; and which, though our bodies possess it in an eminent degree, is a characteristic neither of animal nor vegetable life, but belongs to us in common with brute-matter. It is certain, that an electrified silk-thread shews a much greater variety of motions than any sensitive-plant. If a bit of silk-thread is dropped on an electrified metal-plate, it immediately erects itself, spreads out the small fibres like arms, and, if not detained, will fly off. If a finger is brought near it, the thread seems greedily to catch at it. If a candle approaches, it clasps close to the plate, as if afraid of it. Why do we not conclude that the thread, in this case, is really afraid of the candle? For this plain reason, That its seeming flight is not to get away from the candle, but to get towards the electrified metal; and, if allowed to remain there, will suffer itself to be burnt without offering to stir. The sensitive-plant, in like manner, after it has contracted, will suffer itself to be cut in pieces, without making the least effort to escape. The case is not so with the meanest animal. An hedge-hog, when alarmed, draws its body together, and expands its prickles, thereby putting itself in a posture of defence. Throw it into water, and the same principle of self-preservation prompts it to expand its body and swim. A snail, when touched, withdraws itself into its shell; but, if a little quick-lime be sprinkled upon it, so that its shell is no longer a place of safety, it is thrown into agonies, and endeavours to avail itself of its locomotive power in order to escape the danger. In muscles and oysters, indeed, we cannot observe this principle of self-preservation so strongly as in more perfect animals: but, as we observe them constantly to use the means which nature has given them for self-preservation, we can have no reason to think they are destitute of that principle upon which it is founded.

But there is no need of arguments drawn from the inferior creation. We ourselves are possessed both of the animal and vegetable life, and certainly must know whether there is any connection between vegetation and sensation or not. We are conscious that we exist; that we hear, see, &c. but of our vegetation we are absolutely unconscious. We feel a pleasure, for instance, in gratifying the calls of hunger and thirst; but of the process by which our aliment improves our growth and vigour, we are altogether ignorant. If we, then, who are more perfect than other vegetables, are utterly insensible of our own vegetable life, why should we imagine that the less perfect vegetables are sensible of it?

Thus we may easily give M. Buffon a reason why we ascribe sensation to an oyster, and none to a vegetable, namely, because we perceive the vegetable do nothing but what is also performed in our own bodies, without our having the least sensation of it; whereas an oyster puts itself in a defensive posture on the approach of danger; and, this being an action similar to our own upon a like occasion, we conclude that it proceeds from the same principle of sensation. Here it may also be observed, that, though the inferior animals are deficient in the number, they are by no means so in the acuteness, of their sensations; on the contrary, though a muscle or an oyster is probably endowed with no other sense than that of feeling, yet this sense is so exquisite, that it will contract upon the slightest touch, such as we should be altogether insensible of ourselves.

ANIMAL-FLOWER, in zoology, a name given to several species of animals belonging to the genus *actinia*. The grand argument for animal life in vegetables, was originally inferred from the curious construction of the *actinia* genus; viz. the *sea-anemone*, *sea-sun-flower*, *fresh-water polypus*, &c. which having indeed the external form and figure of vegetables, with scarcely any progressive motion, might easily deceive superficial observers; but, when more minutely examined, the polypus, and all the *actinia* class, turn out to be absolute animals; the heads or mouths of which, when open, resemble a full-blown flower, whence

they are called *flower-fish*. There is one species of them, which the purest white, carmine, and ultramarine, are scarce sufficient to express their brilliancy. The bodies of some of them are hemispherical, of others cylindrical, and of others shaped like a fig. Their substance likewise differs: some are stiff and gelatinous, others fleshy and muscular; but all of them are capable of altering their figure when they extend their bodies and claws in search of food. They are found on many of the rocky coasts of the West-India islands, and on some parts of the coast of England. They have only one opening, which is in the centre of the uppermost part of the animal; round this are placed rows of fleshy claws: this opening is the mouth of the animal, and is capable of great extension. The animals themselves, though exceedingly voracious, will bear long fasting. They may be preserved alive a whole year, or perhaps longer, in a vessel of sea-water, without any visible food; but, when food is presented, one of them will successively devour two muscles in their shells, or even swallow a whole crab as large as a hen's egg. In a day or two the crab-shell is voided at the mouth, perfectly cleared of all the meat. The muscle-shells are likewise discharged whole, with the shells joined together, but entirely empty, so that not the least particle of fish is to be perceived on opening them. An anemone of one species will even swallow an individual of another species; but, after retaining it ten or twelve hours, will throw it up alive and uninjured. Through this opening also it produces its young ones alive, already furnished with little claws, which, as soon as they fix themselves, they begin to extend in search of food. One of the extremities of the sea-anemone exactly resembles the outward leaves of that flower; while its limbs are not unlike the flag or inner part of it. By the other extremity it fixes itself, as by a sucker, to the rocks or stones lying in the sand; but it is not totally deprived of the power of progressive motion, as it can shift its situation, though very slowly.

A peculiar species of animal-flowers, called the *clustered animal-flower*, has been found in some of the West-India islands, an account of which was published in the Philosophical Transactions, vol. 57, by Mr. Ellis, in a letter to Lord Hillsborough. This compound animal, which is of a tender fleshy substance, consists of many tubular bodies, swelling gently towards the upper part, and ending like a bulb or very small onion. On the-top of each is its mouth, surrounded by one or two rows of tentacles, or claws, which when contracted look like circles of beads. The lower part of all these bodies has a communication with a firm fleshy wrinkled tube, which sticks fast to the rocks, and sends forth other fleshy tubes, which creep along them in various directions. These are full of different sizes of these remarkable animals, which rise up irregularly in groups near to one another. This adhering tube, that secures them fast to the rock, or shelly bottom, is worthy of our notice. The knobs are formed into several parts of it by its insinuating itself into the inequalities of the coral rock, or by grasping pieces of shells, part of which still remain in it, with the fleshy substance grown over them. This shews us the instinct of nature, that directs these animals to preserve themselves from the violence of the waves, not unlike the anchoring of muscles, by their fine silken filaments that end in suckers; or rather like the shelly basis of the serpula, or worm-shell, the tree-oyster, and the slipper-barnacle, &c. whose bases conform to the shape of whatever substance they fix themselves to, grasping it fast with their testaceous claws, to withstand the fury of a storm. When we view the inside of this animal dissected lengthwise, we find a little tube leading from the mouth to the stomach, from whence there rise eight wrinkled small guts in a circular order, with a yellowish soft substance in them; these bend over in the form of arches towards the lower part of the bulb, from whence they may be traced downwards, to the narrow part of the upright tube, till they come to the fleshy adhering tube, where some of them may be perceived entering into the papilla,

papilla, or the beginning of an animal of the like kind, most probably to convey it nourishment until it is provided with claws; the remaining parts of these slender guts are continued on in the fleshy tube, without doubt for the same purpose of producing and supporting more young from the same common parent.

The abbé Dicquemarre, by many curious, though cruel, experiments, related in the Philosophical Transactions for 1773, has shewn that these animals possess, in a most extraordinary degree, the power of reproduction; so that scarcely any thing more is necessary to produce as many sea-anemones as we please, than to cut a single one into as many pieces. A sea-anemone being cut in two by a section through the body, that part, where the limbs and mouth are placed, ate a piece of a muscle offered to it soon after the operation, and continued to feed and grow daily for three months after. The food sometimes passed thro' the animal; but was generally thrown up again, considerably changed, as in the perfect sea-anemone. In about two months, two rows of limbs and a mouth were perceived growing out of the part where the incision was made. On offering food to this new mouth, it was laid hold of and eaten; and, the limbs continually increasing, the animal gradually became as perfect as those which had never been cut. In some instances, however, when one of these creatures was cut through, new limbs would be produced from the cut place, those at the mouth remaining as before; so that a monstrous animal was the consequence, having two mouths, and feeding at both ends.

Under a large hollow cliff, in the island of Barbadoes, where the sea flows up, and forms a basin, there is a fixed stone or piece of rock in the middle, which is always under water. Round its sides, at different depths, seldom exceeding eighteen inches, are seen, at all times of the year, issuing out of little holes, certain substances that have the appearance of fine radiated flowers, of a pale yellow, or bright straw colour, slightly tinged with green, having a circular border of thick-set petals, about the size of, and much resembling, those of a single garden-marigold, except that the whole of this seeming flower is narrower at the discus, or setting on of the leaves, than any flower of that kind. Mr. Hughes, in his History of Barbadoes, gives the following curious account of them: "I have attempted to pluck one of these animal-flowers from the rock, to which they are fixed; but never could effect it: for, as soon as my fingers came within two or three inches of it, it would immediately contract its yellow border, and shrink back into the hole of the rock; but, if left undisturbed for about four minutes, it would come gradually in sight, expanding, though at first very cautiously, its seeming leaves, till at last it appeared in its former bloom. However, it would again recoil, with a surprising quickness, when my hand came within a small distance of it. Having tried the same experiment by attempting to touch it with my cane, and a small slender rod, the effect was the same. But, though I could not by any means contrive to take or pluck one of these animals entire, yet I cut off (with a knife which I had held for a long time out of sight, near the mouth of a hole out of which one of these animals appeared) two of these seeming leaves. These, when out of the water, retain their shape and colour; but, being composed of a membrane-like substance, surprisingly thin, they soon shrivelled up, and decayed." The reproductive power of the Barbadoes animal-flower is prodigious. Many people coming to see these strange creatures, and occasioning some inconvenience to a person through whose grounds they were obliged to pass, he resolved to destroy the objects of their curiosity; and, that he might do so more effectually, he caused all the holes out of which they appeared, to be carefully bored and drilled with an iron instrument, so that we cannot suppose but their bodies must have been entirely crushed to a pulp; nevertheless, they again appeared in a few weeks in still greater abundance, from the very same places.

The sea-carnation, or animal-flower, found among the rocks at Hastings in Sussex, is very similar to the animal-flower of Barbadoes. This animal adheres by its tail, or sucker, to the under-part of the projecting rocks opposite the town; and, when the tide is out, has the appearance of a long white fig; which is also the form of it when put into a glass of sea-water.

The *fresh-water polypus* is also of a similar species, and of a cylindrical figure, but variable, with very long tentacula, or claws. There is scarcely an animal in the world more difficult to describe; it varies its whole form at pleasure, and is frequently found beset with young in such a manner, as to appear ramose and divaricated; these young ones adhering to it in such a manner as to appear parts of its body. When simple, and in a moderate state as to contraction or dilatation, it is oblong, slender, pellucid, and of a pale-reddish colour; its body is somewhat smaller towards the tail, by which it affixes itself to some solid body; and larger towards the other extremity, where it has a large opening, called its mouth, around which are the tentacula, or claws, which are eight in number, and are usually extended to about half the length of its body. By means of these tentacula, or arms, as they are commonly called, expanded into a circle of more than half a foot diameter, the creature feels every thing that can serve it for food; and, seizing the prey with one of them, calls in the assistance of the others, if necessary, to conduct it to its mouth. The production of its young is different from the common course of nature in other animals; for the young one issues from the side of its parent in the form of a small pimple, which, lengthening every hour, becomes, in about two days, a perfect animal, and drops from off its parent to shift for itself; but what is still more surprising, is the reproduction of its several parts when cut off; for, when cut into a number of separate pieces, it becomes in a day or two so many distinct and separate animals; each piece having the property of producing a head and tail, and the other organs necessary for life, and all the animal functions.

There is no distinguished place in the body of the polypus, from whence the young are brought forth; for they spring out like shoots or branches of a tree, from all the exterior parts of their bodies. They are always to be found in clear slowly-running waters, adhering by the tail to sticks, stones, and water-plants, and live on small insects. What were originally taken for feet, have since been called its horns, and of late more properly its arms, their office being to catch its prey. With these little arms, which are capable of great extension, it seizes minute worms, and various kinds of water-insects, and brings them to its mouth; and, like the sea-anemone, often swallows bodies larger than itself; having a surprising property of extending its mouth wider, in proportion, than any other animal. After its food is digested in its stomach, it returns the remains of the animals upon which it feeds through its mouth again, having no other observable excretory. In a few days there appear small knobs or papillæ on its sides: as these increase in length, little fibres are seen rising out of the circumference of their heads, as in the parent animal; which fibres they soon begin to use, for the purpose of procuring nourishment, &c. When these are arrived at mature size, they send out other young ones on their sides in the same manner; so that the animal branches out into a numerous offspring, growing out of one common parent. Each of these provides nourishment not only for itself, but for the whole society; an increase of the bulk of one polype by its feeding, tending to an increase in the rest. Thus a polype of the fresh-water kind becomes like a plant branched out, or composed of many bodies, each of which has this singular characteristic, that, if one of them be cut in two in the middle, the separated part becomes a complete animal, and soon adhering to some fixed base, like the parent from which it was separated, produces a circle of arms; a mouth is formed in the centre; it increases in bulk, emits a numerous

merous progeny, and is soon, in every respect, as perfect an animal as that from which it was severed.

In the annexed plate we have given an exact representation of these curious animals. Fig. 1, represents the fresh-water polype, with its tentacula or arms extended upwards. Fig. 2, shews the same animal, with its young branching from it, and putting out their claws for food. Fig. 3, represents the animal carnation-flower of the rocks near Hastings in Suffex, with its tentacles extended in search of food. Fig. 4, is an exact view of the sea-anemone. Fig. 5, shews the head of the animal-flower of Barbadoes. Fig. 6, is a brilliant display of the sea-flower animal, with its innumerable tentacles expanded to catch its prey, which being allured to it by its elegant appearance, they close instantly upon it, and convey it to the interior concavity or mouth. Fig. 7, represents a cluster of the animal-flower described by Mr. Ellis, in the West-India islands, in which *a* shews one of the animals stretching out its tentacles in quest of food. Fig. 8, is a perpendicular dissection of one of the same animals, in order to shew the gullet, intestines, stomach, and fibres or tendons, that move the claws.

ANIMAL-LIFE. See LIFE.

ANIMAL-MAGNETISM. See MAGNETISM.

ANIMAL-OECONOMY. See PHYSIOLOGY.

ANIMAL-SYSTEM, denotes the whole class of beings endowed with animal life, otherwise called ANIMAL-KINGDOMS.

ANIMALS, the preparations of, for collections or museums. See BIRDS, and ZOOLOGY.

Pairing of ANIMALS. See PAIRING.

ANIMAL, *adj.* That which belongs or relates to animals. *Animal-functions*, distinguished from *natural* and *vital*, are the lower powers of the mind, as the will, memory, and imagination. *Animal-life* is opposed, on one side, to *intellectual*, and, on the other, to *vegetable*. *Animal* is used in opposition to *spiritual* or *rational*; as, The *animal* nature.

ANIMALCULE, *f.* A diminutive of the word *animal*; that is, they are such little creatures as require to be viewed through glasses, to discern them distinctly. Rain, as soon as it falls, contains many animalcules, but snow still more; the dew on glass windows is full of them. In boiled water they retain their shape, and sometimes revive. The animalcules get in shoals in the fluid they swim in, and, if disturbed, they separate as fish in a pond, and will be many hours before they are collected together. They follow their liquor in which they swim to the last drop, and then, for want of it, they seem to struggle and die; after their apparent death, put water to them, and they revive. When seemingly dead they are very flat, but, if not past regain, they soon recover their plumpness. Animalcules chuse the surface of liquors, probably for the want of air. Dip a needle-point into the oil of vitriol, then into a drop of liquor in which these animalcules are, and they instantly spread about to evade the acid, and soon drop down dead. If the needle is dipped in a solution of common salt, or in the tincture of salt of tartar, the same is observed to follow. Sugar, urine, and blood, speedily destroy them. Default, and some others, endeavour to prove that all diseases are owing to animalcules; but it does not appear, that any animal substance contains animalcules until it becomes putrid, and then these are the effect rather than the cause of diseases.

These little animals are so different from those of the larger kinds, that scarce any sort of analogy seems to exist between them; and one would almost be tempted to think that they lived in consequence of laws directly opposite to those which preserve ourselves and other visible animals in existence. They have been systematically arranged by O. F. Muller; though it is by no means probable that all the different classes have yet been discovered. Such as have been observed, however, are by this author divided in the following manner; and a few of the most curious of them are represented in the annexed plate, exactly as they appear through the microscope.

VOL. I. No. 45.

I. Such as have no external organs.

1. Monas: Punctiforma. A mere point.
2. Proteus: Mutabilis. Mutable.
3. Volvox: Sphæricum. Spherical.
4. Enchylis: Cylindracea. Cylindrical.
5. Vibrio: Elongatum. Long.
- * Membranaceous.
6. Cyclidium: Ovale. Oval.
7. Paramecium: Oblongum. Oblong.
8. Kolpoda: Sinuatum. Sinuous.
9. Gonium: Angulatum. With angles.
10. Burfaria. Hollow like a purse.

II. Those that have external organs.

* Naked, or not inclosed in a shell.

1. Cercaria: Caudatum. With a tail.
2. Trichoda: Crinitum. Hairy.
3. Kerona: Corniculatum. With horns.
4. Himantopus: Cirratum. Cirrated.
5. Leucopha: Ciliatum undique. Every part ciliated.
6. Vorticella: Ciliatum apice. The apex ciliated.
- * Covered with a shell.
7. Brachionus: Ciliatum apice. The apex ciliated.

I. MONAS. This is defined to be "an invisible (to the naked eye), pellucid, simple, punctiform, worm;" but of which, small as it is, there are several species. 1. The *monas termo*, or *gelatinosa*, is a small jelly-like point, which can be but imperfectly seen by the single microscope, and not at all by the compound one. In a full light they totally disappear, by reason of their transparency. Some infusions are so full of them, that scarce the least empty space can be perceived; the water itself appearing composed of innumerable globular points, in which a motion may be perceived somewhat similar to that which is observed when the sun's rays shine on the water; the whole multitude of animals appearing in commotion like a hive of bees. This animal is very common in ditch-water, and in almost all infusions of animal or vegetable substances. 2. *Monas atomus*, or *albida*; white monas with a variable point: this appears like a white point, which through a high magnifier appears somewhat egg-shaped. The smaller end is generally marked with a black point, the situation of which is variable; sometimes it appears on the large end, and sometimes there are two black spots in the middle. This species was found in sea-water, which had been kept through the whole winter, but was not very fetid. 3. *Monas punctum*, or *nigra*, black monas: this was found in a fetid infusion of pears, and appears in form of a very minute, opaque, and black point, moving with a slow and wavering motion. 4. *Monas ocellus*, transparent like talc, with a point in the middle: this is found in ditches covered with conserva, and sometimes with the cyclidium milium; the margin of it is black, with a black point in the middle. 5. *Monas lens*, or *hyalina*; of a talcy appearance: this is found in all kinds of water; sometimes even in that which is pure, but always in the summer-time in ditch-water. It is found also in all infusions of animal or vegetable substances, whether in fresh or salt water; myriads being contained in a single drop. It is found likewise in the filth of the teeth. It is nearly of a round figure, and so transparent, that it is impossible to discover the least vestige of intestines. They generally appear in clusters, but sometimes singly. These and the animalcules of the first species are so numerous, that they exceed all calculation even in a very small space. 6. *Monas mica*, marked with a circle: this is found in the purest waters, and may be discovered with the third lens of the single microscope when the magnifying power is increased. It appears like a small lucid point, but can assume an oval or spherical shape at pleasure; sometimes the appearance of two kidneys may be perceived in its body. It seems encompassed with a beautiful halo, which is thought to be occasioned by the vibration of fine invisible hairs. It has a variety of motions, and

8 U often

often turns round for a long time in the same place. 7. The *tranquilla*, or egg-shaped transparent monas with a black margin: is found in urine which has been kept for some time. Urine in this state acquires a scum in which the animalcules reside; but, though kept for several months, no other species was found in it. A drop of urine is usually fatal to other animalcules, though this species is to be met with in no other substance. 8. The *lamellula*, or flat transparent monas, is most usually found in salt-water: is of a whitish colour and transparent, more than twice as long as it is broad, with a dark margin, having a vacillatory motion, and frequently appearing as double. 9. The *pulvisculus*, or monas with a green margin: these are generally found in marshy grounds, in the month of March. They appear like small spherical grains of a green colour, sometimes in clusters, from three to seven or more in number, having a wavering kind of motion. 10. The *uva*, or transparent gregarious mona, is found in a variety of infusions, and is of that kind which multiplies by dividing itself. They appear in clusters of four, five, or sometimes many more; the corpuscles being of various sizes, according to the number collected into one group. The smaller particles, when separated from the larger, move about with incredible swiftness.

II. The PROTEUS: an invisible, very simple, pellucid worm, of a variable form. 1. The *diffusus*, branching out in a variety of directions: it is very rare, and only met with in fens; appearing like a grey mucous mass, filled with a number of black globules, and continually changing its figure, pushing out branches of different lengths and breadths. The internal globules divide immediately, and pass into the new-formed parts, always following the various changes of the animalcule; which changes seem to proceed entirely from the internal mechanism of its body, without the aid of any external power. 2. The *tenax*, running out into a point: this is a pellucid gelatinous body, stored with black molecules, and likewise changing its figure, but in a more regular order than the former. It first extends itself in a straight line, the lower part terminating in a bright acute point. It appears to have no intestines; and, when the globules are all collected in the upper part, it next draws the pointed end up towards the middle of the body, which assumes a round form. It is found in river-water, and goes through a vast number of different shapes. When it is alarmed, it suddenly draws in its neck, represented in the plate, fig. 1. and 2. transforming itself into the shape represented at fig. 3. when it becomes more opaque, and moves about very slowly, with the large end foremost. When it has continued some time in this posture, it will often, instead of the head and neck it had formerly, put forth a new one, with a kind of wheel-machinery, represented at fig. 4. the motions of which draw a current of water to it from a considerable distance. Having often pulled in and thrust out this short head, sometimes with and sometimes without the wheel-work, the creature, as if weary, will remain motionless for a while; then its head and long neck will be very slowly protruded, as in fig. 5. and it soon resumes its former agility. Sometimes it disposes of its neck and head, as represented in the plate at fig. 6.

III. VOLVOX: an invisible, very simple, pellucid, spherical, worm. 1. The *punctum*, of a black colour, with a lucid point: this is a small globule, with one hemisphere opaque and black, the other having a crystalline appearance, and a vehement motion is observed in the black part. Many are often seen joined together in their passage thro' the water; sometimes moving as in a little whirlpool, and then separating. They are found in great numbers on the surface of fetid sea-water. 2. The *granulum*, is of a spherical figure and green colour, the circumference being bright and transparent: it is found in marshy places about the month of June, and moves but slowly. It seems to have a green opaque nucleus. 3. The *globulus*, with the hinder part somewhat obscure, sometimes verges a little towards the oval in its shape, having a slow fluttering kind

of motion, but more quick when disturbed: the intestines are but just visible; is found in most vegetable infusions, and is ten times larger than the mona lens. 4. The *pilula*, small and round, with green intestines: this is found in water where the lemna minor grows, in the month of December, and has a kind of rotatory motion, sometimes slow and at others quick. There is a small incision on one of the edges of the sphere, which may possibly be the mouth of the creature. 5. The *grandinella*, with immoveable intestines, is much smaller than the last, and marked with several circular lines. Sometimes it moves about in straight line, at others irregularly, and sometimes keeps in the same spot, with a tremulous motion. 6. The *socialis*, with crystalline molecules placed at equal distances from one another: this is found in water where the chara vulgaris has been kept; and has its molecules disposed in a sphere, filling up the whole body of the animalcule; and its motion is sometimes rotatory and sometimes not. 7. The *sphericula*, with round molecules, appears to consist of pellucid homogeneous points of different sizes. It moves slowly from right to left and back again, about a quarter of a circle each time. 8. The *lunula*, with lunular molecules, is a small roundish transparent body, consisting of an innumerable multitude of homogeneous molecules of the shape of a crescent, without any common margin: it moves continually in a twofold manner, viz. of the molecules among one another, and the whole mass turning slowly round. It is found in marshy places in the beginning of spring. 9. The *globator*, or spherical membranaceous volvox, is found in great numbers in the infusions of hemp and tremella, and in stagnant waters in spring and summer; it was first observed and depicted by Leuwenhoeck, but the descriptions of it given by authors differ considerably from each other. The following is that of Mr. Baker: "There is no appearance of either head, tail, or fins: it moves in every direction, backwards, forwards; up or down, rolling over and over like a bowl, spinning horizontally like a top, or gliding along smoothly without turning itself at all; sometimes its motions are very slow, at other times very swift; and when it pleases can turn round as upon an axis very nimbly, without moving out of its place. The body is transparent, except where the circular spots are placed, which are probably its young." 10. The *morum*, with spherical green globules in the centre: this is found amongst the lemna in the months of October and December, and has a slow rotatory motion. The globules seldom move, though a slow quivering motion may sometimes be perceived among them in the centre. 11. The *alva*, composed of green globules not inclosed in any membrane, is found in the month of August, in water where the lemna polyrrhiza grows. It consists of a congeries of greenish-coloured globules, apparently of an equal size, with a bright spot in the middle; the whole mass is sometimes of a spherical form, sometimes oval, without any common membrane: a kind of halo may be perceived round it, and the mass generally moves from right to left. 12. The *vegetans*, terminating in a little bunch of globules: this is found in river-water, in the month of November. It consists of a number of floccose opaque branches invisible to the naked eye; and at the apex of these is a small congeries of very minute oval pellucid corpuscles.

IV. ENCHELIS: A simple, invisible, cylindric, worm. 1. The *viridis*, or green enchelis, has an obtuse tail, the fore-part terminating in an acute truncated angle; the intestines are more obscure and indistinct; it continually varies its motion, turning from right to left. 2. The *punctifera*, having the fore part obtuse, the hinder part pointed. It is opaque, and of a green colour, with a small pellucid spot on the fore part, in which two black points may be seen; and a kind of double band crosses the middle of the body. The hinder part is pellucid and pointed, with an incision, supposed to be the mouth, at the apex of the fore-part. It is found in marshes. 3. The *deses*, or gelatinous enchelis, is found, though rarely, in an infusion of leince,

lemnae, and moves very slowly. The body is round, of a very dark-green, the fore-part bluntly rounded off, and the hinder-part somewhat tapering, but finished with a round end. 4. The *similis*, with moveable intestines, is found in water that has been kept for several months: it is of an egg-shape, and generally moves very quick, either to the right or left. 5. The *ferotina*, with immoveable intestines, is of an oval figure, partly cylindrical, the fore-part smaller than the hind, with a black margin, full of grey vesicular molecules: it moves very slowly. 6. The *nebulosa*, with visible moveable intestines, is found in the same water with the cyclidium glaucoma, but is much more scarce. The body is egg-shaped, the fore-part narrow, and frequently filled with opaque confused intestines. 7. The *feminitum* is found in water that has been kept for some days, and moves by ascending and descending alternately. It is of a cylindrical figure, twice as long as broad. Sometimes it is observed swimming about with the extremities joined together. 8. The *intermedia*, with a blackish margin, is one of the smallest animalcules: it has a transparent body, without any visible intestines. 9. The *ovulum*, is transparent, round, and egg-shaped. A very strong magnifier discovers some long foldings on the surface, with bright molecules. 10. The *pirum*, with the hinder part transparent, has the fore-part protuberant and filled with molecules. The hinder-part is smaller and empty, with moveable molecular intestines. 11. The *tremula* was found in an infusion with the paramæcia aurelia, and many other animalcules. It is among the least of these minute creatures, and is of a cylindrical figure and gelatinous texture. Two of these creatures may at times be seen to adhere together. 12. The *constricta*, with a stricture in the middle, is found in salt-water, and is of a very small size, and of an oval shape. 13. The *elliptica*, with a congeries of green-intestines, is found among the green matter on the sides of vessels in which water has been kept for some time. They are generated in such numbers, that myriads may sometimes be found in one drop. 14. The *fusus*, with both ends truncated, was found in water called pure, and had a languid motion. The body is round and transparent, with the fore and hind parts somewhat smaller than the rest. 15. The *fritillus*, with the fore-part truncated, is found in an infusion of grafs and hay, and runs backward and forward through the drop with a wavering motion. 16. The *caudata*, with a kind of tail, is but seldom met with. The body is grey and transparent, with globular molecules. 17. The *epistomium*, with the fore-part slender and roundish, is among the smaller animalcules. 18. The *gemmata* is found in ditch-water where the lemna thrives. It moves slowly, and generally in a straight line. 19. The *retrograda* moves commonly sideways, and sometimes in a retrograde manner. It has a gelatinous transparent body, thicker in the middle than at the ends. 20. The *festinans*, with obtuse ends, is found in sea-water, and has a quick vacillatory motion from one side to the other. The body is round, and the fore-part transparent. 21. The *farcimen* was found by Joblot in an infusion of blue bottles, moving very slowly in an undulatory manner. The body is cylindrical, about four times as long as broad, and truncated at both ends. 22. The *index* is found in water with the lemna minor; the body opaque, of a grey colour, and long conical shape: the lower end is obtuse, one side projecting like a finger, with two very small projections from the lower end. 23. The *truncus*, with a kind of head, is the largest of this kind of animalcules. The body is grey, long, and mucous; the fore-part globular, the hinder part obtuse; but it can alter its shape considerably. 24. The *larva* is long, round, and filled with molecules. The fore-part is obtuse and transparent, with a kind of neck or small contraction formed near the end. 25. The *spatula*, with the fore-part transparent, and of the shape of a spatula. It is perfectly cylindrical, and crystalline. It moves in a wavering kind of manner, retaining its general form, but moving the spatula in various ways. 26. The *pupula*, with the

fore-part papillary, is found in dunghill water in November and December: it has a rotatory motion on a longitudinal axis, and moves in an oblique direction through the water. 27. The *pupa*, with a small nipple proceeding from the apex, has a very slow motion, and resembles the former.

V. VIBRIO: A very simple, invisible, round, and rather long, worm. 1. The *lineola* is found in most vegetable infusions in such numbers, that it seems to fill up almost the whole of their substance. It is so small, that with the best magnifiers we can discern little more than an obscure tremulous motion among them. 2. The *rugula* is like a bent line; and sometimes draws itself up in an undulated shape, at others moves without bending the body at all. 3. The *bacillus*, equally truncated at both ends, is found in an infusion of hay. It is from six to ten times longer than the monas lens, but much more slender. 4. The *undula*, is a round, gelatinous, undulating line. This is the animal which Leewenhoeck says is less than the tail of one of the feminal animalcules. It never appears straight; but when at rest it resembles the letter V. and when in motion the letter M. It commonly rests on the top of the water. 5. The *serpens*, with obtuse windings or flexures, is found in river-water, but seldom. It is slender, and resembles a serpentine line. 6. The *spirillum* is exceedingly minute, and twisted in the form of a spiral, which seems to be its natural shape, as it never untwists itself. It was found, in 1782, in an infusion of the sonchus arvensis. 7. The *vermiculus* has a milky appearance, with an obtuse apex, and a languid undulatory motion, like that of the common worm. It is found in marshy water in November. It is thought to be the animal mentioned by Leewenhoeck as found in the dung of the frog and spawn of the male libellula. 8. The *intestinum* is found in marshy waters, and has a slow progressive motion. 9. The *bipunctatus* is found in fetid salt-water, and moves slowly, in a straight line. 10. The *tripunctatus* is also transparent and talsey, with both ends tapering. It moves in a straight line, backwards and forwards. 11. The *pavilifer*, or straw-like vibrio, called the hair-like insect by Mr. Baker, consists of a transparent membrane, with yellow intestines, and two or three visible points. The body or middle part, which is nearly straight, appears in some composed of such rings as the windpipe of land-animals, but in others, seems rather scaled, or made up of rings that obliquely cross one another. Its two ends are hooked, or bent, pretty nearly in the same degree, but in a direction opposite to one another; and, as no eyes can be discerned, it is difficult to judge which is the head or tail. Its progressive motion is very singular, being performed by turning upon one end as a centre, and describing almost a quarter of a circle with the other; its shape and form may be seen in the plate, at fig. 7. Its motions are very slow, and require much patience and attention in the observer. These creatures are found in parcels or clusters, as described in the circle, at fig. 8. They arrange themselves in a variety of forms, but generally assume a quadrangular figure. 12. The *lunula*, or bow-shaped vibrio, resembles the moon at its first quarter; it is of a green colour, and has from seven to ten globules disposed in a longitudinal direction. 13. The *verminus* is found in salt-water kept for some days till it becomes fetid. It moves quickly, and with an undulatory motion, backwards and forwards. These animalcules seem to be joined together in a very singular manner. 14. The *malleus* is found in great plenty in spring-water, and is alternately at rest and in motion every moment. 15. The *acus* is in the shape of a sewing needle; the neck round and partly transparent, and marked in the middle with a red point; the tail resembling a fine bristle. 16. The *flagitta*, with a seraceous tail, and a long and flexible body, is found in salt-water, and seems to move by contracting and extending its neck. 17. The *gordius*, with a tail terminated by a small tubercle, was found in an infusion made with salt water. 18. The *serpentulus*, somewhat pointed at both ends. This is

found in the infusions of vegetables which have been kept for some weeks. Its body is of a whitish colour, frequently convoluted, and drawn into different figures. 19. The *coluber*, is found in river-water; the tail is extremely small; and the mouth, œsophagus, intestines, and the twistings of them, are easily discerned. 20. The *anguillula* is divided into four varieties: 1. The vinegar eel; 2. That in paste; 3. That of fresh water; and, 4. That of salt. Fig. 9, in the annexed plate, represents one of the eels in paste, very considerably magnified. 21. The *linter*, or ventricose oval vibrio, with a short neck, is found among the *lemna*, but not very frequently. It is among the larger kinds of animalcules, egg-shaped, pellucid, and somewhat depressed at top. 22. The *utriculus* resembles a bottle; the belly is full of molecular intestines, the neck bright and clear, the top truncated, and some have a pellucid point at the bottom of the belly. 23. The *fasciola* is found in water just freed from the frost, and not often in any other fluid. It is pellucid, with intestines like points in the middle. Its motion is very quick. 24. The *colymbus* is larger than many of the other species of vibrio, and resembles a bird in shape. 25. The *strichus*, has a linear body, being a bright membranaceous thread; the hinder part somewhat thicker, round, and filled with molecules, excepting at the end, where there is a small, empty, pellucid space. 26. The *anas*, with both ends attenuated, and the neck longer than the tail, is found in salt water; though a kind is likewise found in fresh water with a neck longer than the other. 27. The *cygnus* is a very pellucid line, crooked at top, swelling in the middle, and sharp at the end; the middle full of dark coloured molecules and pellucid intestines. 28. The *anser* is found in water where duckweed grows. The trunk is elliptic, round, and without any inequality on the sides. It is full of molecules: the hind part sharp and bright; the fore part produced into a bending neck, longer than the body. It moves the body slowly, but the neck more briskly. 29. The *olor* is found in water that has been kept for a long time, and is full of vegetable green matter. The body is elliptical and ventricose; the neck is three or four times longer than the body, of an equal size throughout, and is moved very quickly. 30. The *falx*, with a crooked neck, and obtuse hinder part, is pellucid and elliptical; the fore part lessening into a little, round, bright, neck, nearly as long as the trunk. 31. The *intermedius*, appears to be an intermediate species betwixt the *falx* and the *fasciola*: it seems to be a thin membrane, constantly folded, and has all round a distinct bright margin.

VI. CYCLIDIUM: a simple, invisible, flat, pellucid, orbicular or oval, worm. 1. The *bulia*, or orbicular bright cyclidium: this is found occasionally in an infusion of hay; it is very pellucid and white, moves slowly, and in a femicircular direction. 2. The *millium* is very pellucid, and splendid like crystal; of an elliptical figure: and its motion is swift, interrupted, and fluttering. 3. The *fluitans*, is one of the smallest animalcules; the body somewhat of an oval shape, with two small blue spaces at the sides. 4. The *glaucoma* has an oval pellucid body, with both ends plain: the intestines are so transparent, that they can scarcely be discerned when empty; when full they are of a green colour, and, when it seems to be taking in water, the intestines are in a violent commotion: it generates by division. 5. The *nigricans* is very small, pellucid, and flat, with a black margin. 6. The *rostratum* is oval, smooth, and very pellucid, with the fore part running out into an obtuse point, with which it seems to feel and examine the bodies to which it comes. 7. The *nucleus*, resembles a grape-seed, the body being pellucid and depressed, the fore part obtusely convex, and the hind part acute. 8. The *hyalinum*, has a tremulous kind of motion; the body oval, flat, and bright, without any visible intestines. 9. The *pediculus*, is scarcely ever seen but on the hydra pallida, upon which it runs as if it had feet; it is gelatinous and white, and the bottom gibbous over the back. 10. The *dubium*, is of an oval shape, with one side convex, the

other concave; the margin pellucid, and the inner part containing a great number of molecules.

VII. PARAMÆCIUM: an invisible, membranaceous, flat, and pellucid, worm. 1. The *aurelia*, is membranaceous, pellucid, and four times longer than it is broad; the fore part obtuse and transparent; the hind part filled with molecules: it is found in ditches where there is plenty of duckweed. 2. The *chrysalis*, is found in salt water, and differs very little from the former, only the ends are more obtuse, and the margins are filled with black globules. 3. The *versutum*, is found in ditches, and has an oblong, green, and gelatinous, body, filled with molecules: it propagates by division. 4. The *oviferum*, is membranaceous, oval, grey, and pellucid, with many oval corpuscles dispersed through the body. 5. The *marginatum*, is flat, elliptical, and every where filled with molecules; it is surrounded by a broad double margin, and a bright spiral intestine is observable.

VIII. KOLPODA: an invisible, pellucid, flat, and crooked, worm. 1. The *lamella*, is very seldom met with: it resembles a long, narrow, and pellucid, membrane, with the hind part obtuse, narrower, and curved towards the top. 2. The *gallinula*, is found in fetid salt water; and has the apex somewhat bent, the belly oval, convex, and striated. 3. The *rostrum*, is found, though seldom, in water where the *lemna* grows, and has a slow and horizontal motion; the fore part is bent into a kind of hook; the hind part obtuse, and quite filled with black molecules. 4. The *ochrea*, is depressed, membranaceous, and flexible; one edge nearly straight; the other somewhat bent. 5. The *mucronata*, is a dilated bright membrane; the apex an obtuse point, with a broad marked border running quite round it; it is filled with grey molecules, and has a truncated appearance. 6. The *triquetra*, was found in salt water, and appears to consist of two membranes; the upper side flattened, the lower convex, with the apex bent into a kind of shoulder. 7. The *striata*, is likewise found in salt water, and is very pellucid and white, with the upper part rather bent, and terminating in a point. 8. The *nucleus*, is of an oval shape, with the vertex pointed, and of a brilliant transparency, by which the viscera are rendered visible; these consist of a number of round diaphanous vesicles. 9. The *melagris*, has a dilated membrane, with very fine folds, which it varies in a moment; the fore part of the body to the middle is clear and bright; the hind part variously folded in transverse and elevated plaits, and full of molecules. 10. The *affinis*, is found on the sea-coast, and has an elliptic mass in the middle, but is not folded like the former. 11. The *cucullus*, is found in vegetable infusions, and in fetid hay; moving in all directions, and commonly with great vivacity: it is very pellucid, and has a well-defined margin, filled with little bright vesicles differing in size, and of no certain number: from some circumstances it would seem probable that this animalcule casts its skin, as is the case with some insects. 12. The *cucullulus*, is found in an infusion of the *sonchus arvensis*: it is very pellucid and crystalline, and has an oblique incision a little below the apex. 13. The *cuculio*, is elliptical, flat on the upper side, and convex on the under; the fore part is clear, and from the middle to the hinder part is full of silver-like globules. 14. The *ren*, or *crassa*, is found in an infusion of hay, commonly about thirteen hours after the infusion is made, and has a quick and vacillatory motion: its body is yellow, thick, and somewhat opaque; curved a little in the middle, so that it resembles a kidney; and full of molecules. 15. The *pirum*, has an uniform and transparent body, and is of a pale colour, with obscure little globules: it propagates by division. 16. The *cuneus*, is white, gelatinous, and without any distinct viscera; the apex has three or four teeth; and it can bend the hinder part into a spiral form.

IX. GONIUM: an invisible, simple, smooth, and angular, worm. 1. The *pelliculare*, is found in pure water, and moves alternately towards the right and left. It is quadrangular and pellucid, with sixteen sperical molecules

of a greenish colour, "set in a quadrangular membrane, like the jewels in the breast-plate of the high-priest, reflecting light on both sides." 2. The *pulvinatum*, is found in dung-hills; and appears like a little quadrangular membrane, plain on both sides. 3. The *corrugatum*, is found in various kinds of infusions; and is somewhat of a square shape, very small, and in some positions appears as streaked. 4. The *rellangulum*, differs but little from the former: the angle at the base is a right one; the larger vesicle is transparent, the rest green. 5. The *truncatum*, is found chiefly in pure water, and then but seldom: it has a languid motion, and is much larger than the foregoing.

X. BURSARIA: a very simple, hollow, membranaceous, worm. 1. The *truncatella*, is visible to the naked eye; white, oval, and truncated at top, where there is a large aperture descending towards the base: most of them have four or five yellow eggs at the bottom. 2. The *bullina*, is pellucid and crystalline, having splendid globules of different sizes swimming about with it: the under side is convex, the upper hollow, with the fore-part forming a kind of lip. 3. The *hirundinella*, has two small projecting wings, which give it somewhat of the appearance of a bird; and it moves something like a swallow. 4. The *dupletta*, was found among duckweed, and appears like a crystalline membrane folded up, without any visible intestines except a small congeries of points under one of the folds. 5. The *globina*, has a roundish shape, and is hollow; the lower end being furnished with black molecules of different sizes. It moves slowly about from right to left.

XI. CERCARIA: an invisible transparent worm with a tail. 1. The *gyrinus*, greatly resembles the spermatic animalcules: it has a white gelatinous body; the fore part somewhat globular; the hind part round, long, and pointed: when swimming, it keeps its tail in continual vibration like a tadpole. 2. The *gibba*, is found in the infusions of hay and other vegetables; and is small, opaque, gelatinous, white, and without any visible intestines. 3. The *inquieta*, is found in salt water, and is remarkable for changing the shape of its body: sometimes it appears spherical, sometimes like a long cylinder, and sometimes oval. 4. The *lemna*, also varies its form, sometimes appearing of an oblong, sometimes of a triangular, and sometimes of a kidney, shape: the tail is generally short, thick, and annulated; but sometimes long, flexible, cylindrical, and without rings; vibrating, when stretched out, with so much velocity, that it appears double: a small pellucid globule, which Muller supposes to be its mouth, is observable at the apex; and two black points not easily discovered, he thinks, are its eyes. 5. The *turbo*, with a tail like a bristle, is found among duckweed: it is of a tawny appearance, partly oval and partly spherical; and seems to be composed of two globular bodies. 6. The *poduria*, is found in November and December, in marshy places covered with lemna: it is pellucid; and seems to consist of a head, trunk, and tail; the head resembles that of a herring; the trunk is ventricose and full of intestines, of a spiral form and black colour. 7. The *viridis*, is found in the spring in ditches of standing water; and in some of its states has a considerable resemblance to the last, but has a much greater power of changing its shape. 8. The *setifera*, is found in salt water, but seldom: it is small, the body rather opaque, of a round figure, and has a slow rotatory motion. 9. The *hirta*, was likewise found in salt water: it is opaque and cylindrical; and, when in motion, the body appears to be furrowed with rows of small hairs separated from each other. 10. The *crumena*, has a ventricose, cylindrical, thick, and wrinkled, body; the lower part small; the upper part terminating in a small straight neck like that of a pitcher. 11. The *catellus*, has a moveable head fixed to the body by a point: the abdomen is twice as long as the head, full of intestines, and has a tail still narrower, and terminating in two bristles which it can unite and separate at pleasure. 12. The *catelina*, was found in a ditch where there was plenty of duckweed: it is larger than the preceding, and has a thicker and more cylin-

drical body. 13. The *lupus*, is found in water among duckweed, and is larger than most of the genus: the head is larger than the body; the apex turned down into a little hook; sometimes it contracts into one half its common size, and again extends itself as before. 14. The *vermicularis*, is long, cylindrical, fleshy, and capable of changing its shape: it is divided into eight or nine rings or folding plaits; the apex either obtuse, or notched into two points; and it is found in water where there is duckweed. 15. The *forcipata*, is found in marshy places, is cylindrical and wrinkled, with a forked proboscis which it can thrust out or pull in. 16. The *pleuronectes*, is found in water which has been kept for several months: it is membranaceous, roundish, and white, with two blackish points in the fore part, the hinder part being furnished with a slender sharp tail. 17. The *tripos*, is flat, pellucid, triangular, having each angle of the base or fore part bent down into two linear arms: it is found in salt water. 18. The *cyclidium*, is frequently found in pure water, and has an oval, smooth, membranaceous, pellucid, body, with a black margin. 19. The *tenax*, appears like an oval pellucid membrane, something larger than the *monas lens*; the fore edge is thick and truncated; the hinder part acute, and terminating in a short tail: it whirls about in various directions with great velocity. 20. The *discus*, is a small orbicular animalcule, with a bent tail. 21. The *orbis*, is round, and has a tail consisting of two long bristles. 22. The *luna*, is likewise round, and has the fore part hollowed into the form of a crescent.

XII. LEUCOPHRA: an invisible, pellucid, and ciliated, worm. 1. The *conflictor*, with moveable intestines, is perfectly spherical and semitransparent, of a yellow colour, the edges dark: it rolls from right to left, but seldom removes from the spot where it is first found, and is filled with a number of the most minute molecules, which move as if they were in a violent conflict; and in proportion to the number of these little combatants which are accumulated either on one side or other, the whole mass rolls either to the right or left; it then remains for a little time at rest, and the conflict ceases; but it soon becomes more violent, and the sphere moves the contrary way in a spiral line: when the water begins to fail, they assume an oblong, oval, or cylindric, figure; and the molecules shoot into a shapeless mass, which also soon vanishes, and the whole assumes the appearance of crystals of sal ammoniac. 2. The *mamilla*, is of a dark colour, and filled with globular molecules; short hairs are curved inwards: it is found in marshy water. 3. The *virescens*, is a large, pear-shaped, greenish-coloured, animalcule, filled with opaque molecules, and covered with short hairs; generally moving in a straight line: it is found in salt water. 4. The *viridis*, is much smaller than the former; sometimes it appears contracted in the middle, as if it were to be divided in two. 5. The *burstata*, is found in salt water, and is similar in many respects to the former: it is of a long oval shape, bulging in the middle, and filled with green molecules. 6. The *posthuma*, is globular, and covered as it were with a pellucid net; is found in fetid salt water. 7. The *aurea*, is yellow, oval; has both ends equally obtuse; little hairs discovered with difficulty; and has in general a vehement rotatory motion. 8. The *pertusa*, is found in salt water; and is gelatinous and small, without any molecules. 9. The *fracta*, is long, with sinuated angles, white, gelatinous, and granulated, changing its form considerably. 10. The *dilatata*, appears like a gelatinous membrane, with a few grey molecules in the fore-part, and a great number in the hinder part. 11. The *scintillans*, was found in December, among the smaller lemna: it is of a green colour, oval, round, and opaque; and is supposed to be ciliated, from its bright twinkling appearance, which probably arises from the motion it gives the water. 12. The *vesiculifera*, is oval, very pellucid, with a defined dark edge and inside, containing some very bright bladders or vesicles; the middle frequently appears blue, and the vesicles appear as if set in a ground of that colour. 13. The

globulifera,

globulifera, was found in a ditch where the *lemna minor* grew: the body is round, very pellucid, without molecules, and every where set with short hairs. 14. The *pustulata*, is found in marthy waters; and is white, gelatinous, and somewhat granulated; the lower part truncated as if an oblique section were made in an egg near the bottom. 15. The *turbinata*, is found in stinking salt water; and is round, pellucid, somewhat of the shape of an acorn, with a pellucid globule at the lower end. 16. The *acuta*, is found in salt water, and is gelatinous, thick, capable of assuming different shapes; having the apex bright, and the rest of the body filled with little spherules. 17. The *notata*, is oval, round, and has a black point at the edge. 18. The *candida*, is found in salt water; and is membranaceous, flat, very white, with no visible intestines. 19. The *nodulata*, is oblong and oval, with a double row of little nodules. 20. The *signata*, is common in salt water in the months of November and December: it is oblong and subdepressed, with a black margin filled with little molecules. 21. The *trigona*, is found in marshes, but not commonly: it is a yellow triangular mass filled with unequal pellucid vesicles. 22. The *fluida*, is somewhat of a kidney-shape, but ventricose. 23. The *fluxa*, is reniform and sinuated. 24. The *armilla*, is round and annular. 25. The *cornuta*, is of the shape of an inverted cone, opaque, and of a green colour; the body is composed of molecular vesicles; the fore part is wide and truncated, with a little prominent horn or hook on both sides: at one time this animalcule will appear reniform and ciliated on the fore part; but at another time the hairs are concealed: it dissolves into molecular vesicles when the water evaporates. 26. The *heteroclitia*, appears to the naked eye like a white point; in the microscope as a cylindrical body; and wholly ciliated through a large magnifier.

XIII. TRICHODA: an invisible, pellucid, hairy worm. 1. The *grandinella*, is a very small pellucid globule, with the intestines scarcely visible, the top of the surface furnished with several small bristles not easily discoverable. It is found in pure water, as well as in infusions of vegetables. 2. The *cometa*, is a pellucid globule filled with bright intestines, the fore part furnished with hairs. 3. The *granata*, resembles the two former, and has a darkish nucleus in the centre, with short hairs on the edge. 4. The *trochus*, is somewhat of a pear-shape, and pellucid; each side being distinguished by a little bunch of hairs. 5. The *gyrinus*, is one of the smallest of this genus, and is found in salt-water: it is smooth and free from hairs, except at the fore part, where there are a few. 6. The *sol*, is small, globular, and crystalline; beset every where with diverging rays longer than the diameter of the body: it was found with other animalcules in water which had been kept three weeks. 7. The *solaris*, is orbicular, bright, and filled with globular intestines, frequently having in it a moveable substance of the shape of the letter S. 8. The *bomba*, is of a yellow colour, and full of clay-like molecules: it moves with such velocity as to elude the sight, and appears of various shapes, sometimes spherical, sometimes kidney-shaped, &c. 9. The *orbis*, is composed of vesicular molecules; is of a spherical figure, smooth, pellucid, and a little notched in the fore part. 10. The *urnula*, is membranaceous, pellucid, somewhat in the form of a water-pitcher, with the fore part hairy: it moves but slowly. 11. The *diota*, is of a clay-colour, and filled with molecules; the upper part cylindrical and truncated, the lower part spherical, the upper part of the mouth hairy at the edges. 12. The *horrida*, is of a conical shape, the fore part broad and truncated, the lower part obtuse, and the whole covered with radiating bristles. 13. The *urinarium*, is egg-shaped, with a short hairy beak. 14. The *femiluna*, is smooth, pellucid, and shaped like a crescent. 15. The *trigona*, is of a triangular shape, a little convex on both sides, the fore part acute and ciliated, the hind part broader. 16. The *tinea*, is round, not very pellucid, narrow in the fore part, and resembling an inverted club. 17. The *nigra*, was found in salt water, and has an opaque

body; but when at rest one side appears pellucid: when in violent motion, it seems entirely black. 18. The *pubes*, is found in water where duckweed grows, chiefly in December: the apex is furnished with hairs, but they are seldom visible till the creature is in the agonies of death, when it extends and moves them vehemently, attempting as it were to draw in the very last drop of water. 19. The *flocus*, is membranaceous, the fore part rather conical, with three small hairy papillæ projecting from the base. 20. The *sinuata*, is found in river water: it is oblong and depressed, with one margin hollow and hairy, and the lower end obtuse; it is of a yellow colour. 21. The *præceps*, is pellucid, the fore part formed into a kind of neck; one edge rising into a protuberance like a hump-back, the other edge convex. 22. The *proteus*, is found in the slimy matter adhering to the sides of vessels in which vegetables have been infused, or animal substances preserved: the body of this animalcule resembles that of a snail. 23. The *versatilis*, lives in the sea, and has some resemblance to the *proteus*; but the neck is shorter, the apex less spherical, and the hinder part of the trunk acute. 24. The *gibba*, is pellucid; the upper part swelled out, with numerous molecules, and three large globules on the inside. When the water begins to fail, a few minute hairs may be discovered about the head, and at the abdomen. 25. The *foeta*, somewhat resembles a rolling-pin in shape; has both ends obtuse, and one shorter than the other: it can draw in the ends, and swell out so as to appear almost spherical. 26. The *patens*, is found in salt water; and is of a long cylindrical shape, filled with molecules, the fore part bright and clear, and is beset with hairs. 27. The *patula*, is ventricose, rather inclining to an oval figure, with a small tube at the fore part, the upper part of which is hairy. 28. The *foveata*, is oblong, and broad, with three little horns on the fore part. 29. The *striata*, is found in December, in river water: it is a beautiful animalcule, of a fox colour. 30. The *uvula*, is found in the infusion of hay and other vegetables. It is six times longer than broad, with an alimentary canal and lucid globules near the middle; the margin of the fore part is covered with short hairs. 31. The *aurantia*, is of a gold colour, pellucid, and filled with vesicles. 32. The *igniti*, is of a fine purple colour, with something of a reddish cast, pellucid, splendid, with a number of globules of different sizes. 33. The *prisma*, is very small, and so transparent that it cannot easily be delineated: it is of a singular shape; the under part being convex, and the upper compressed into a kind of keel. 34. The *forceps*, is found about the winter solstice in water covered with *lemna*: it is of a yellow colour, large, somewhat transparent, and filled with molecules, with a large opaque globule in the lower part. 35. The *forfex*, is found in river water: it has the fore part formed into a kind of forceps, one of which is twice as long as the other, hooked and ciliated. 36. The *index*, is found in salt water, and has the under part of the front of the margin hairy; the apex is formed by the fore part projecting like a finger on a direction post. 37. The *trichoda*, is of a yellow colour, formed of two pellucid membranes striated longitudinally; the lower end obliquely truncated, and the two extremities bent in opposite directions. 38. The *navicula*, has three corners; the fore part truncated and ciliated, and a kind of longitudinal keel runs down the middle. 39. The *succisa*, is of a flattened oval shape, the edge hairy, and hollowed out in such a manner as to form two unequal legs. 40. The *fulcata*, is ovated and ventricose, the apex acute, with a furrow at the abdomen, and both sides of it ciliated. 41. The *anas*, is found in pure water, and is smooth, five times broader than it is long, filled with darkish molecules. 42. The *barbata*, is round, somewhat linear, with both ends obtuse; the fore part narrower, forming as it were a kind of neck, under which is a row of fluctuating hairs. 43. The *faricimen*, is long, round, pellucid, and covered with very minute hairs, and has a great number of mucous vesicles about the body. 44. The *crinita*, is long, round, every

every where ciliated on the upper part, and the under part likewise hairy. 45. The *angulus*, is long, more convex than most of the genus, and divided by a kind of articulation in the middle; the apex has short waving hair. 46. The *linter*, is found in an infusion of old grafts: it is egg-shaped or oblong; but it is of different shapes at different ages, and sometimes has a rotatory motion. 47. The *paxillus*, is found in salt water, and is long, full of grey molecules; the fore part truncated and hairy. 48. The *vermicularis*, is found in river water; and is pellucid in the fore part, with the hind part filled with molecules. 49. The *melitæa*, is found in salt water, but very rarely: it is oblong, ciliated with a globular apex, and a kind of peristaltic motion perceivable within it. 50. The *fimbriata*, is subovated, the apex hairy, the hinder part obliquely truncated and serrated. 51. The *camelus*, is found but rarely in vegetable infusions, and moves in a languid manner: the back is divided by an incision in the middle into two tubercles. 52. The *augur*, is oblong, depressed, pellucid, and filled with molecules: the vertex is truncated, the fore part forming a small beak, with three-feet underneath. 53. The *pupa*, is roundish, pellucid, and consists of three parts: the head is broad, and appears to be hooded, the top being furnished with very small hairs. 54. The *lunaris*, is round and crystalline; the hinder part smaller than the other: the edge of the back and the part near the tail are bright and clear. 55. The *bilunis*, is arched and flattened with an hairy apex, and two little bristles proceeding from the tail. 56. The *rattus*, is oblong, with a kind of keel; the fore part hairy, and a very long bristle proceeding from the hinder part. 57. The *tigris*, resembles the former, but differs in the form of the tail, which consists of two bristles, and likewise in having a kind of incision in the body a little below the apex. 58. The *perillum*, is frequently found in marshes; it is cylindrical, pellucid, muscular, and capable of being folded up: it appears double; the interior part full of molecules, with an orbicular muscular appendage, which it can open and shut, and which forms the mouth. 59. The *clavus*, has a considerable resemblance to a common nail; the fore part is round and hairy, the hinder part terminating in a sharp tail. 60. The *cornuta*, is membranaceous, elliptical, full of molecules; the fore part lunated, the other round, and terminating in a tail as long as the body. 61. The *gallina*, is found in river water: it is of a grey colour, flat, with seven large molecules and globules within it. 62. The *musculus*, is found in the infusions of hay, which have been kept for some months. It is smooth, egg-shaped, moves slowly, and is furnished with molecular intestines. 63. The *delphis*, is found in river water: it is smooth, pellucid, having the fore part dilated into a semicircle, gradually decreasing in breadth towards the tail; the front is hairy. 64. The *delphinus*, is found in hay that has been infused for some months: it is pellucid, smooth, and egg-shaped; it moves sometimes on its belly and sometimes on its side. 65. The *clava*, or club trichoda, has the fore part thick, but the hinder part narrow; both extremities obtuse, pellucid, and replete with molecules. 66. The *cuniculus*, is oblong, the fore part hairy, the hinder part rather acute, and filled with molecules and black vesicles. 67. The *felis*, is large and curved; the fore part small, the hinder part gradually diminishing into a tail, the under part beset with hairs longitudinally. 68. The *piscis*, is oblong, the fore part hairy, the hinder part terminating in a very slender tail: it is smooth, pellucid, much longer than broad, and filled with yellow molecules. 69. The *larus*, is long, round, beset with hairs, and has the tail divided into two points. 70. The *longicauda*, is cylindrical; the fore part truncated, and beset with hairs; the tail long, furnished with two bristles, and having two joints. 71. The *fixa*, has the circumference set with hairs, and a little solitary pedicle projecting from the body. 72. The *inquilinus*, is sheathed within a cylindrical transparent bag, having a little pedicle bent back within. 73. The *ingenita*, is sheathed in a depressed

bag, broadest at the base. This animalcule is funnel-shaped, and can extend or contract itself within the bag, fixing its tail to the base, without touching the sides: it is found in salt water. 74. The *innata*, is sheathed in a cylindrical bag, with a pedicle passing through and projecting beyond it. 75. The *transfuga*, is broad, the fore part hairy, the hinder part full of bristles; one side sinuated, and the other pointed. 76. The *ciliata*, is ventricose, the hinder part covered with hair. 77. The *bulia*, is membranaceous, the sides bent inwards; the fore and hind parts both covered with hairs. 78. The *pellionella*, is thick in the middle, and pellucid, with a few molecules here and there; the sides obtuse, the fore part ciliated with very fine hairs. 79. The *cyllidium*, has the hinder extremity filled with globules of various sizes: it vacillates upon the edge, commonly advancing on its flat side, and continually drawing in water. 80. The *cursor*, is oval, the fore part hairy; the body is flat, and filled with molecules. 81. The *pulex*, is egg-shaped, with an incision in the fore part; the front and base hairy. 82. The *lynceus*, is nearly square, with a crooked beak and hairy mouth: the intestines are beautiful, and a small bent tube goes from the mouth to them in the middle of the body; there is also another tube between the fore and hind edge, filled with blue liquor. 83. The *erofa*, is orbicular, the fore part notched; one side furnished with hairs, the hinder part with bristles. 84. The *rostrata*, is found in water where duckweed has been kept: it is capable of changing its shape, yellow, with long ciliated hairs; it has four feet tapering to a point, one of them longer than the rest. 85. The *lagena*, is round, ventricose, with a long neck, and the lower end set with bristles. 86. The *charon*, was found in salt water; it is oval, and resembles a boat as well in its motion as shape; the upper part is hollowed, the under part furrowed, and convex; the stern round, with several hairs proceeding from it. 87. The *cimex*, has an oval body, with a convex back: when this animalcule meets with any obstacles in swimming, it makes use of four bristles which appear on the under side as feet. 88. The *cicada*, differs but little from the cimex: it is oval, the fore part covered with hairs, the hinder parts beardless.

XIV. KERONA: an invisible worm with horns. 1. The *rajiellum*, is found in river-water; it has three rows of horns on the back, which occupy almost the whole of it. 2. The *hyncaster*, is square, and its disk furnished with shining horns. 3. The *hystrio*, appears an oblong membrane, pellucid, with four or five black points in the fore part, which are continually changing their situation, thick set with small globules in the middle. 4. The *cypris*, is found in water covered with lemna; it is pear-shaped, compressed, with a broad and blunt fore part, the front furnished with hairs or little vibrating points inserted under the edge, having a retrograde motion. 5. The *haustorium*, is orbicular, with the horns in the middle, the fore part membranaceous and ciliated. 6. The *haustallum*, differs from the preceding only in having the hinder part without any bristles. 7. The *patella*, has an univalve shell, orbicular and crystalline; with horns or hairs of different lengths jutting out beyond the shell, and acting instead of feet and oars. 8. The *vannus*, is oval and rather flat, with one edge bent, the opposite one ciliated; the front furnished with horns, and the hind part with bristles. 9. The *pullaster*, agrees in many respects with the trichoda pulex; the upper part is pellucid, without any black molecules; the whole surface of the head covered with hair, and the fore part sinuous. 10. The *mytilus*, is a large animalcule, very pellucid and white, with black intestines intermixed with a few pellucid vesicles; it has two small horns, with which it agitates the water so as to form a little whirlpool. 11. The *lepus*, is egg-shaped, pellucid, and covered with short waving hairs; the base terminated with bristles. 12. The *stirus*, is oval, with a fascicle of vibrating hair on the fore part; it has a sharp tail furnished with unequal rows of moveable hairs, the back being also ciliated; the hairs produce a rotatory

rotatory motion. 13. The *calvitium*, is found in the infusion of vegetables: the body is broad and flat, filled with black molecules, and a few short bristles. 14. The *pustulata*, is found in salt water: it is convex; one edge of the hinder part sinuated, both ends set with hairs, and horns on the fore part.

XV. HIMANTOPUS: a pellucid, invisible, and ciliated, worm. 1. The *acarus*, is lively, conical, ventricose, full of black molecules, with a bright and transparent fore part. The lower part of the apex has rows of long hairs on the under part set like rays; and it is continually moving these and other hairs in various directions. 2. The *ludio*, is a lively diverting animalcule, full of small points, the fore part clubbed and a little bent, the hinder part narrow. The top of the head and middle of the back are furnished with long and vibrating hairs; and three flexible curls hang down from the side of the head at a distance from each other. 3. The *fannio*, is found in water where the lemna grows. The cilia are longer than the hairs, and are continually vibrating. 4. The *volutor*, is shaped like a crescent; the convex part has a row of hairs longest towards the tail, and underneath are four feet: it is very lively, and often turns round with a swift circular motion. 5. The *lava*, is long and ciliated in the middle; the body is long; the hinder parts acute, and curved, pellucid, and filled with granular molecules. 6. The *charon*, is found in sea-water, but rarely. It is oval, with longitudinal furrows, and several rows of hair below the middle, but none on the hinder part. 7. The *corona*, is a membranous lamina, very thin, pellucid, and semilunar: the edge of the base thick set with molecular intestines; the fore part furnished with a kind of mane; towards the hind part are three equal curved hairs or spines.

XVI. VORTICELLA: a naked worm with rotatory cilia, capable of contracting and extending itself. 1. The *viridis*, is visible to the naked eye, appearing like a small green point: it appears to be destitute of limbs, notwithstanding which it keeps the water in continual motion; so that it probably has some invisible rotatory instrument. 2. The *spheroida*, appears also like a point: it occasions a vehement motion in the water, probably by means of some short hairs with which it is furnished. 3. The *cincla*, is of an irregular shape, sometimes assuming an oval figure, and appearing as if girt round with a transverse keel. 4. The *lunifera*, is found in salt water; has the fore part obtuse, the base broad, and hollowed away like a crescent, with a short protuberance in the middle of the concave part. 5. The *busfata*, is found in salt water, and is ventricose, crammed with molecules; the fore part truncated, and both sides of it pellucid. 6. The *varia* is cylindrical, truncated, opaque, and blackish coloured; the fore part ciliated. 7. The *sputarium*, is found in October, with the smaller lemna, and is one of the most singular of the animalcules. When viewed sideways, it is sometimes nearly cylindrical, only tapering a little towards the hinder part, and having a broad pellucid edge. Viewed from the top, it has a broad face or disk, furnished with radiated hairs, of a dark green colour. 8. The *polymorpha*, is visible to the naked eye, and appears like a green point moving with great agility; but, when viewed through a microscope, it assumes such a variety of forms, that it is impossible to describe them. 9. The *multiformis* is found in salt water, and very much resembles the former. 10. The *nigra*, is found in August in meadows covered with water: it may be seen with the naked eye, appearing like a black point swimming on the surface. Through the microscope it appears as a small conical body, obtuse and ventricose at one end and acute at the other. It moves continually in a vacillating manner on the top of the water. 11. The *cucullus*, is likewise visible to the naked eye: it is of a dirty red colour, of a shape somewhat conical, and resembling a grenadier's cap. 12. The *utriculata*, is green and ventricose; the belly capable of being lengthened or shortened; the fore part truncated, much in the shape of a common water-bottle. 13. The *ocrea*, is met

with in rivers, and in shape somewhat resembles the lower part of a boot. The apex of the upper part is truncated and ciliated, the heel pointed, and the foot round. 14. The *valga*, is as broad as long, and the apex truncated and ciliated: it is found in marshy waters. 15. The *pipillaris*, is likewise found in marshes where the *conserva nitida* grows: it is ventricose; the fore part truncated, with a beautiful papillary excrescence on the side. 16. The *facculus*, is thick, of an equal diameter every where, and full of molecules. The edge of the mouth is bent back, with cilia on both sides. 17. The *cirrata*, is found in ditch water: it is ventricose, the aperture sinuated, and two tufts of hair on each side of the belly. 18. The *nasuta*, is furnished with a rotatory organ encompassing the middle: it is pellucid, cylindrical, of an unequal size; the fore part truncated and ciliated, with a triangular prominence in the middle of the aperture; the hinder part is obtuse, with a point on each side the middle of the body. When the water is nearly exhaled, two rotatory organs are observable; and the quick and various motions of this apparatus are very surprising. 19. The *stellina*, is of an orbicular shape, with a molecular disk and ciliated margin. 20. The *discina*, is likewise orbicular, the edge ciliated, with a kind of handle on the under side. 21. The *scyphina*, is bowl-shaped, crystalline, with an opaque spherule in the middle. 22. The *albina*, is cylindrical in the fore part, the hinder part tapering, and almost ending in a point. 23. The *fritillina*, is empty and cylindrical, with a truncated apex. 24. The *truncatella*, is of a larger kind of animalcules, with a crystalline body, full of black molecules, the skin perfectly smooth and colourless, the hinder extremity rounded, and the anterior part truncated. 25. The *limacina*, is cylindrical, truncated, and has two pair of cilia. 26. The *fraxinina*, is cylindrical, the hinder part tapering, and full of opaque molecules; transparent towards the upper end. 27. The *cratægaria*, is found in April, both in the mud and on the tail of the monocular quadricornis: they are generally heaped together in a spherical form, and united to one common stalk: it has two small arms; and with a powerful magnifier a violent rotatory motion may be observed. 28. The *hamata*, with the body granulated, the fore part broad and truncated, the hinder part obtuse, and capable of being contracted or extended. 29. The *crateriformis*, is a lively animalcule, approaching somewhat to a square figure, with convex sides: the head is situated at the large end, the skin smooth, and some traces of intestines may be discovered with difficulty. 30. The *canaliculata*, appears to the naked eye as a number of white points adhering to the sides of the glass: it excites a continual whirling motion in the water, by means of a rotatory organ with which it is furnished. 31. The *versatilis*, is a pellucid gelatinous animalcule, of a greenish colour, and furnished with small radii about the circumference; so that it appears like a very small water hedge-hog. 32. The *ampulla*, is contained in a transparent bottle-shaped bag; the head divided into two lobes. 33. The *folliculata*, is gelatinous and cylindrical; and when most extended, the base appears attenuated, and the apex truncated. 34. The *larva*, is of a clay colour, the aperture ciliated, with a globular projection at times appearing to proceed from it. 35. The *faculata*, has the shape of an inverted cone, with an aperture in the figure of a crescent; the lower part of the trunk notched, forming as it were two teeth; the tail biphyllous. 36. The *aurita*, is cylindrical and ventricose, the aperture destitute of hairs; both sides of it are furnished with rotatory cilia, and the tail is biphyllous. 37. The *tremula*, has something of a conical shape; the mouth being divided into parts which are set with small spines; and a point projects from the tail. 38. The *serita*, is muscular, the fore part truncated: round the margin are rows of hairs; but it has also stiffer hairs or spines continually vibrating, with which it draws in all substances which it is able to manage. 39. The *lacinulata*, is shaped like an inverted cone, the aperture lobated, the tail small and furnished with two bristles. When swimming, the

rotatory organ may be discovered: it moves swiftly in an oblique direction. 40. The *conflicta*, is of two kinds; viz. of a pale yellow, and of a white colour: they move by fixing their tail to the place where they are, and then extending their body as much as possible: sometimes they turn round upon one of the points of their tail; at other times they spring forward with a jerk: when at rest they open their mouths very wide. 41. The *togata*, has a convex body, filled with molecules, and of a dark colour; the hinder part somewhat longer than the fore part; the latter ciliated. 42. The *rotatoria*, or *wheel animal*, is sometimes of a globular, and sometimes of a conic, shape: it puts out its wheels, swimming vigorously through the water in search of food; or else, fixing itself by the tail, works the wheels in such a manner as to bring its food to it. It is found in rain-water that has stood for some time. The most remarkable part of this animalcule is its wheel-work: this consists of a couple of semicircular instruments, round the edges of which many little fibrillæ move themselves very briskly, sometimes with a kind of rotation, and sometimes in a trembling or vibrating manner. When in this state, it swims along with a great deal of swiftness, seemingly in pursuit of its prey. Sometimes the wheels seem to be entire circles, armed with small teeth, like those of the balance-wheel of a watch, appearing projected forwards beyond the head, and extending sideways somewhat wider than its diameter. The teeth or cogs of these wheels seem to stand very regularly at equal distances; but the figure of them varies according to their position, the degree of their protrusion, and perhaps the will of the animal itself. The different appearances of its wheels are represented in the plate, at fig. 10, 11, 12, and 13; and fig. 14 and 15 shew this animalcule in its globular state. 43. The *furcata*, is commonly found in water, and has a cylindric body with a rotatory organ, consisting of a row of hairs at the apex: the tail is divided into two parts, turning a little inwards. 44. The *catulus*, is commonly found in marshy waters: the anterior part is connected to the body by a little neck; and it occasionally shews a small rotatory organ: its motion is rotatory, but in various directions. 45. The *canicula*, is cylindrical, the aperture plain, with a short articulated tail divided into two parts. 46. The *felis*, has a large body, the apex of an equal thickness, obtuse, with rotatory filaments. 47. The *stentorea*. See the article POLYPUS. 48. The *socialis*, when considerably magnified, appears like a circle surrounded with crowns or ciliated heads, tied by small thin tails to a common centre, from whence they advance towards the circumference, where they turn very briskly, occasioning a kind of whirlpool, which brings its food. When one of them has been in motion for a time, it stops and another begins; sometimes two or three may be perceived in motion at once: they are frequently to be met with separate, with the tail sticking in the mud. 49. The *sterculosa*, appears to the naked eye like a yellow globule adhering to the ceratophyllon like a little flower or a heap of yellow eggs. When magnified, they are seen to consist of a congeries of animalcula constituting a sphere from a mouldy centre. They contract and extend their bodies either alone or in society, and excite a vortex in the water by means of a disk. When they quit the society and act singly, they may be observed to consist of a head, abdomen, and tail. 50. The *citrina*, is found in stagnant water; the head full of molecules, round, every where of an equal size, and very transparent: both sides of the orifice are ciliated, and each has a rotatory motion. 51. The *piriformis*, is somewhat oval, with a very small retractile foot, which it can draw within itself. 52. The *tuberosa*, has a broad upper part, with two projections at the anterior end, furnished with a number of fibrillæ, which produce a current of water by their vibration, and thus collect food for the animal. 53. The *ringens*, is pear-shaped, pellucid, the middle of the aperture convex, both sides ciliated, the pedicle four times shorter than the body. 54. The *inclinans*, has a pendulous head; the anterior part truncated,

and occasionally contracting itself twice as short as the pedicle. It is shaped like a tobacco-pipe, and is represented in fig. 16 of the plate. 55. The *vaginata*, is erect, of the shape of a truncated egg; the pedicle is contained in a sheath. 56. The *globularia*, is frequent among the cyclopa quadricorni. It has a small spherical head, with the aperture of the mouth ciliated. 57. The *lunaris*, has a small goblet-shaped head, the margin of the orifice protuberant, ciliated on both sides, with undulating hairs, and the pedicle eight or ten times the length of the body. 58. The *convallaria*, or *bell-animal*, dwell in colonies together in a slimy kind of mucilaginous case; which, out of the water, has no determinate form, but, when expanded therein, has some resemblance to the figure of a bell with its mouth upwards. These bells, or colonies, are to be found adhering to the large leaves of duck-weed, and other aquatic plants. The whole colony together has a power of altering the position of the bell, or even of removing it from one place to another; and hence this bell is sometimes found standing perfectly upright, as represented at fig. 17 in the plate, with the little animals attached to it. Though no eyes can be discovered, yet these animalcules have a perception of the light: for, when kept in the dark, they always remain contracted; but on being exposed to the light of the sun, or of a candle, they constantly extend their arms, and shew evident signs of being pleased. 59. The *nutans*, has a simple pedicle; twists itself spirally; is extremely slender, with a kind of cap on its head. 60. The *nebulifera* is narrow at the base; open and truncated at top; the margin seemingly surrounded with a ring: but, when the aperture is shut, the animalcule is of the shape of an egg. 61. The *annularis*, is visible to the naked eye; the head an inverted cone, convex when the mouth is shut, but truncated when it is open; with a protuberant edge. 62. The *acinosa* inhabits that whitish substance which often entirely covers plants, wood, shells, &c. When this substance is examined by the microscope, it appears to be wholly composed of living animals of the polype kind. 63. The *fasciculata*, has a rotatory organ, which may sometimes be seen projecting beyond the aperture. A congealed green mass which is often found swimming about in ditches is composed of myriads of these animals, which are not visible to the naked eye, and when magnified appear like a bundle of green flowers. 64. The *hians*, resembles a citron; the apex is truncated, the base narrow, and a gaping cleft is observable, descending from the apex to one third of the body. 65. The *bellis*, is of a yellow colour, and much resembles the flower of a daisy; is ciliated round the margin of the head, and moves in a rotatory manner. 66. The *gamella*, has a long pedicle, constantly furnished with two small heads. 67. The *anastasia*. See the article POLYPUS. 68. The *polipina*, when viewed through a small magnifier, appear like so many little trees: the upper part, or heads, are egg-shaped, the top truncated, the lower part filled with intestines; the branches thick set with little knobs. 69. The *racemosa*, is only distinguished from the vorticella socialis by always adhering to the sides of the vessel in which it is placed. By the microscope, we discover a long pedicle sticking to the sides of the vessels, from which proceed an innumerable quantity of crystalline pellucid pearls; which, together with the stalk, are variously agitated in the water. Sometimes they move separately; sometimes they are drawn down to the root, and in a moment expanded again.

XVII. BRACHIONUS: a contractile worm, covered with a shell, and furnished with rotatory cilia. 1. The *striatus*, has an oblong pellucid shell, capable of altering its figure. The apex is truncated, with six small teeth on the edge of it, twelve longitudinal streaks down the back, the base obtuse and smooth. The animal itself is of a yellow colour, crystalline, and muscular; now and then putting out from the apex two or three little bundles of playing hairs, the two lateral ones shorter than that in the middle: it is found in sea-water. 2. The *squamula*, has an univalve

orbicular shell, a truncated apex, four teeth, smooth base, and no tail. 3. The *pala*, is of a yellow colour; univalved, with an oblong excavated shell; with four long teeth at the apex; with a smooth base. 4. The *pipalum*, is univalved, the shell oblong, and inflected, ten teeth at the apex, the base smooth, and a spurious tail. 5. The *patina*, is extremely bright and splendid, has a large body, a crystalline and nearly circular shell, without either ineision or teeth, only towards the apex it falls in so as to form a smooth notch. A double glittering organ, with ciliated edges, projects from the apex; both of them of a conical figure, and standing as it were upon a pellucid substance, which is divided into two lobes, between which and the rotatory organ there is a silver-coloured crenulated membrane. 6. The *chypeatus*, is univalved; the shell oblong, apex notched, the tail naked, and base smooth. 7. The *lamellaris*, is univalved; the shell extending considerably beyond the body; the base divided into three small horns, with two hairs at the end of the tail. 8. The *patella*, is found in marshy water in the winter time: it is univalve, the shell oval, plain, crystalline, with the anterior part terminating in two acute points on both sides: by these points it fastens itself, and whirls about the body erect: the rotatory cilia are perceived with great difficulty. 9. The *bradlea* is univalved, the shell somewhat orbicular, apex lunated, base smooth, and the tail furnished with two spines. 10. The *plicatilis*, is univalved, with an oblong shell, the apex hairy, and base notched. 11. The *ovalis* is bivalved; the shell flattened, apex notched, a hollow part at the base, the tail formed of two tufts of hair. 12. The *tripos* is bivalved, the apex of the shell beardless, three horns at the base, and double tail: it fixes itself to objects by the filaments of the tail. 13. The *dentatus*, is bivalved, with an arched shell; the apex and base are both toothed, and the tail formed of two spines. 14. The *mucronatus*, is bivalved, somewhat of a square form; the base and apex pointed; the tail consisting of two spines. 15. The *uncinatus*, is one of the smallest bivalved animalcules; the apex and anterior part round, the hinder part straight, terminating in a point, furnished with a hook on the fore part, a small rotatory organ, a long tail composed of joints, and divided at the end into two bristles. 16. The *cirratus*, is larger than the preceding; ventricose, somewhat transparent, the head conical, with a bundle of hairs on both sides; it has likewise a rotatory organ. 17. The *passus*, has a cylindric shell, with two long pendulous locks of hair proceeding from the front, the tail consisting of a single bristle. 18. The *quadratus*, has a quadrangular shell, with two small teeth at the apex, two horns proceeding from the base, and no tail. 19. The *impressus* has a quadrangular shell, a smooth undivided apex; obtuse base; notched margin; and flexuous tail. 20. The *brachionus Bakeri*, has a ventricose shell, four teeth at the apex, two horns at the base, and a long tail terminating in two short points. Mr. Muller has also discovered in this creature two small feelers, and a tongue. 21. The *patulus*, has a ventricose shell, with eight teeth at the apex; the base lunated, or hollowed into the form of a crescent, and furnished with four horns; the tail short, with two small points at the end.

These are the different kinds of animalcules which have yet been discovered, and to which we shall add the following observations by Mr. Adams.—“How many kinds of these invisibles there may be (says he) is yet unknown; as they are discerned of all sizes, from those which are barely invisible to the naked eye, to such as resist the force of the microscope as the fixed stars do that of the telescope, and with the greatest powers hitherto invented appear only as so many moving points. The smallest living creatures our instruments can shew, are those which inhabit the waters; for though animalcula equally minute may fly in the air, or creep upon the earth, it is scarcely possible to get a view of them; but, as water is transparent, by confining the creatures within it we can easily observe them by applying a drop of it to the glasses.

“Animalcules in general are observed to move in all directions with equal ease and rapidity, sometimes obliquely, some times straight forward; sometimes moving in a circular direction, or rolling upon one another, running backwards and forwards through the whole extent of the drop, as if diverting themselves; at other times greedily attacking the little parcels of matter they meet with. Notwithstanding their extreme minuteness, they know how to avoid obstacles, or to prevent any interference with one another in their motions: sometimes they will suddenly change the direction in which they move, and take an opposite one; and, by inclining the glass on which the drop of water is, as it can be made to move in any direction, so the animalcules appear to move as easily against the stream as with it. When the water begins to evaporate, they flock towards the place where the fluid is, and shew a great anxiety and uncommon agitation of the organs with which they draw in the water. These motions grow languid as the water fails, and at last cease altogether, without a possibility of renewal if they be left dry for a short time. They sustain a great degree of cold as well as insects, and will perish in much the same degree of heat that destroys insects. Some animalcules are produced in water at the freezing point, and some insects live in snow. By mixing the least drop of urine with the water in which they swim, they instantly fall into convulsions and die. The same rule seems to hold good in those minute creatures which is observable in the larger animals, viz. that the larger kinds are less numerous than such as are smaller, whilst the smallest of all are found in such multitudes, that there seems to be myriads for one of the others. They increase in size, like other animals, from their birth until they have attained their full growth; and, when deprived of proper nourishment, they in like manner grow thin and perish.”

The modes of propagation among these animalcules are various, and the observation of them is extremely curious. Some multiply by a transverse division; and it is remarkable, that, though in general they avoid one another, it is not uncommon, when one is nearly divided, to see another push itself upon the small neck which joins the two bodies in order to accelerate the separation.—Others, when about to multiply, fix themselves to the bottom of the water; then becoming first oblong, and afterwards round, turn rapidly as on a centre, but perpetually varying the direction of their rotatory motion. In a little time, two lines forming a cross are perceived; after which the spherule divides into four, which grow, and are again divided as before. A third kind multiply by a longitudinal division, which in some begins in the fore-part, in others in the hind-part; and from others a small fragment detaches itself, which in a short time assumes the shape of the parent animalcule. Lastly, others propagate in the same manner as the more perfect animals.

Many doubts have been suggested, whether all those minute bodies which go under the name of *animalcules*, really do enjoy animal life; or whether they are not in many cases to be accounted only inanimate and exceedingly minute points of matter actuated by the internal motion of the fluid. But to all hypotheses of this kind Mr. Adams makes the following reply: “From what has been said, it clearly appears, that their motions are not purely mechanical, but are produced by an internal spontaneous principle; and that they must therefore be placed among the class of living animals, for they possess the strongest marks and the most decided characters of animation; and, consequently, that there is no foundation for the supposition of a chaotic and neutral kingdom, which can only have derived its origin from a very transient and superficial view of these animalcules. It may also be further observed, that as we see that the motions of the limbs, &c. of the larger animals, are produced by the mechanical construction of the body, and the action of the soul thereon, and are forced by the ocular demonstration which arises from anatomical dissection to acknowledge this mechanism which is adapted to produce the various motions

motions necessary to the animal; and as, when we have recourse to the microscope, we find those pieces which had appeared to the naked eye as the primary mechanical causes of particular motions, to consist themselves of smaller parts, which are the causes of motion, extension, &c. in the larger; when the structure therefore can be traced no further by the eye, or by the glasses, we have no right to conclude that the parts which are invisible are not equally the subject of mechanism: for this would be only to assert, in other words, that a thing may exist because we see and feel it, and have no existence when it is not the object of our senses. The same train of reasoning may be applied to animalcules; we see them move; but, because the muscles and members which occasion these motions are invisible, shall we infer that they have no muscles, with organs appropriated to the motion of the whole and its parts? To say that they exist not because we cannot perceive them, would not be a rational conclusion. Our senses are indeed given us that we may comprehend some effects; but then we have also a mind, with reason, bestowed upon us, that, from the things which we do perceive with our senses, we may deduce the nature of those causes and effects which are imperceptible to the corporeal eye."

Besides the above systematic arrangement of animalcules, there has been another, and very singular species, suggested by Leeuwenhoek and Hartsoeker, as pervading the *semen masculinum* of every kind of animal; an opinion, which has also been warmly supported by Andry, Valisnieri, Bourguet, and other observers. The bodies of these animalcules, says Leeuwenhoek, are of an oblong oval form, with long tapering slender tails issuing from them; and, as by this shape they resemble tadpoles, they have been frequently called by that name; though the tails of them, in proportion to their bodies, are much longer than the tails of tadpoles are: and it is observable, that the animalcules in the semen of fishes have tails much longer and more slender than the tails of those in other animals; inasmuch, that the extremity of them is not to be discerned without the best glasses, and the utmost attention. The number of these animalcules, he says, is inconceivable. On viewing with a microscope the milt or semen of a living cod-fish, innumerable multitudes of animalcules were found therein, of such a diminutive size, that he supposed at least 10,000 of them capable of being contained in the bulk of a grain of sand; whence he concludes, that the milt of this single fish contained more living animalcules than there are to be found people living in the whole world. To find the comparative size of these animalcules, Leeuwenhoek placed an hair of his head near them; which hair, through his microscope, appeared an inch in breadth; and he was satisfied, that at least 60 such animalcules could easily lie within that diameter; whence, their bodies being spherical, it follows, that 216,000 of them are about equal to a globe whose diameter is the breadth of a hair. He observed, that when the water wherewith he had diluted the semen of a cod-fish was exhaled, the little bodies of the animalcules burst in pieces; which did not happen to those in the semen of a ram: and this he imputes to the greater firmness and consistency of the latter; as the flesh of a land-animal is more compact than fish. These animalcules appear to be very vigorous, and tenacious of life; for they may be observed to move long after the animal from which they are taken is dead. They have this peculiarity also, that they are continually in motion, without the least rest or intermission, provided there is fluid sufficient for them to swim about in. Leeuwenhoek farther says, that, having examined the semen of a cock, he perceived a number of animals similar to river eels; but they were so minute, that 50,000 of them were not equal in bulk to a grain of sand. Of those in the semen of a rat, it required many millions to make the thickness of a hair, &c. This curious observer was persuaded, that the whole substance of the semen was only a mass of animalcules. He saw these animalcules indiscriminately in the seed of men, of quadrupeds, of birds,

of fishes, and of insects. In the seed of a grass-hopper, the animalcules were long, and extremely thin. They appeared, he says, to be attached by their superior end; and the other end, which he calls their tail, had a brisk motion, like that of the tail of a serpent when its head is fixed. In the semen of young animals, when examined before they have any sexual appetite, he alleges that he saw the same minute animals, and that they had no motion: but, when the season of love arrived, the animalcules moved with great vivacity. In the semen of a male frog, he saw animalcules; but, at first, they were imperfect, and had no motion: some time after he found them alive. They were so minute, he observes, than 10,000 of them were only equal in bulk to a single egg of the female.

In the semen of a man and that of a dog, he pretended to see two species of animalcules, resembling males and females. Having shut up the semen of the dog in a small vial, he says, that a great number of animalcules died the first day; that, on the second and third day, still more of them died; and that few of them were alive on the fourth day. But, having repeated this experiment on the semen of the same dog, he found, at the end of seven days the animalcules as brisk and lively as if they had been newly extracted from the animal: and having opened a bitch, that, some time before the experiment, had been three times covered by the same dog, he could not perceive, with the naked eye, any male semen in the uterus or its appendages; but, by the assistance of the microscope, he found the spermatic animals of the dog in both horns of the uterus: in that part of the uterus which is nearest the vagina, he discovered great numbers, which evidently proves, says he, that the male semen enters the uterus, or, at least, that the spermatic animals of the dog had arrived there by their own motion, which enables them to pass over four or five inches in half an hour. In the uterus of a female rabbit, which had just received the male, he observed an infinite number of spermatic animals. He remarks, that the bodies of these animals are round; that they have long tails; and that they often change their figure, especially when the fluid in which they swim begins to dry up. In the preceding plate they are correctly delineated. Fig. 18 represents the animalcules in the seed of the rabbit; 19, shews the form of those in the seed of a dog; 20, shews the spermatic animals in the seed of a ram; and 21, are those found in the seed of a cock. The whole are exhibited of the largest size they could possibly be magnified.

These experiments of Leeuwenhoek were repeated by several people, who pretended to have found them exactly as above described. Mr. Andry says, that he could find no animals in the human semen previous to the age of puberty; that they exist not in the semen of very old men; that there are few of them in those who are affected with the venereal disease, and that these few are in a languishing state; that none of them appear alive in impotent persons; and that the animalcules in the semen of men have a larger head than those of other animals, which corresponds, he observes, with the figure of the foetus and infant; and he adds, that those who use women too frequently have generally few or no animalcules in their semen.

The discovery of these spermatic animalcules was thought to throw some light on the mysterious affair of generation, and these minute creatures were imagined to be each of them individuals of the same species with the parent. But here the infinite number of these animalcules was an objection, and the difficulty remained as great as before; for, as every one of these animalcules behaved to be produced from a male and female, to explain their origin by animalcular generation in the same manner was only explaining generation by itself.

The act of conception is thus described by the learned Boerhaave: The male seed, which abounds with living animalcules, animated with great strength, extreme heat, and perhaps with a great quantity of animal spirits, is ejected with a violent impetuosity through the uterine orifice,

ficc, which is then open, by its neck, the valvules of which are then more limber, into the matrix of the woman, which is then swelled by motion, by heat, and becomes turgid by a sort of slight inflammation which seems to take place; moistened also by its lymph and the spirits which are excited; the excitation produced in the nervous papillæ of the wrinkles of the vagina, causes the womb to close immediately and spasmodically. The male semen being then retained, heated, agitated, meeting with the ovum of the woman, its vivifying portion, which is of inconceivable smallness, insinuates itself through the pores, already dilated, of the little glandulous membrane of the egg, where it is retained, fixed, cherished by a gentle heat, nourished, takes root by the umbilical membrane, and soon suffocates or destroys all the other animalcules which have less strength. Thus is conception completed; but, as it sometimes happens that more than one of these animalcules is preserved, hence plural conceptions; hence two children, by this internal struggle, are sometimes born joined together. *Boerh. Inst. Med.* 673.

This hypothesis, however, not proving satisfactory, another hath been suggested by M. Buffon, by which, indeed, he at once annihilates the whole animalcular world; yet in this he hath been followed by several very ingenious philosophers. His system being founded upon a vast number of experiments, we shall give the particulars of them in his own words:

“Having procured the feminal vessels of a man who died a violent death, and whose body was still warm, I extracted all the liquor from them, and put it in a vial. I examined, by the microscope, a drop of this liquor, without any dilution. As soon as the vapours which arose from the liquor, and obscured the glass, were dissipated, I observed pretty large filaments, as represented in *fig. 22* of the preceding plate, which, in some places, spread out into branches, and, in others, intermingled with each other. These filaments clearly appeared to be agitated with an internal undulatory motion, like hollow tubes, which contained some moving substance. I saw distinctly two of these filaments, which were joined longitudinally, separate from each other in the middle, and alternately approach and recede, like two stretched cords, fixed by the ends, and drawn asunder at the middle. These filaments were composed of globules which touched one another, and resembled a chaplet of beads, as represented in *fig. 23* of the same plate. I then observed filaments which were blown up, and swelled in certain places, as shewn in *fig. 24*; and perceived small oval globules issue from these swelled parts, which had a vibratory motion, like that of a pendulum, as represented in *fig. 25*. These small bodies were attached to the filaments by little threads, which gradually lengthened as the bodies moved: and, lastly, I observed these small bodies detach themselves entirely from the large filament, and draw after them the little thread, which resembled a tail. As the liquor was too thick, and the filaments too near each other, I diluted another drop with pure rain water, after satisfying myself that it contained no animalcules. I then perceived that the filaments were more distant from each other, and saw distinctly the motion of the small bodies above taken notice of, which was more free, and they appeared to swim with greater agility, and trailed their threads after them with greater ease; and, if I had not seen them separate from the filaments, and draw the threads out of them, I should have believed, from this second observation, the moving bodies to be real animals, and their threads to be tails. This appearance is faithfully delineated in *fig. 26* of the same plate. After examining with great attention one of the filaments, which was three times thicker than the small bodies, I perceived two of these bodies detach themselves with much difficulty, and drag after them long slender threads, which impeded their motion. When the feminal liquor became more fluid, the filaments disappeared; but the small bodies were exceedingly numerous, as shewn in *fig. 27*. Their motion, for

the most part, resembled that of a pendulum; each of them had a long thread, from which they evidently endeavoured to disengage themselves; their progressive motion was extremely slow, during which they vibrated to the right and left. At each vibration, they had a rolling unsteady motion; so that, besides their horizontal vibrations, they roll or vibrate in a vertical direction; which proves these bodies to be of a globular figure, or at least that their inferior part is not a flat base sufficiently extensive to keep them in one position. At the end of two or three hours, when the liquor was more fluid, a still greater number of these moving bodies appeared, as represented in *fig. 28*. They were more free of incumbrances; their threads were shorter; their progressive motion was more direct; and their horizontal vibration was greatly diminished; for the longer the threads were, their vibratory motion was increased, and their progress forward was diminished. The vertical vibration was still apparent. In five or six hours, the liquor had almost all the fluidity it could acquire, without being decomposed. We then discovered that most of these small moving bodies were entirely disengaged from their threads, as shewn in *fig. 29*. Their figure was oval; they moved forward with considerable quickness; and, by their motion backward and forward, and to every side, they had now more than ever the appearance of real animals. Those which had tails or threads sticking to them, seemed to have less vivacity than the others. Of those which had no threads, some appeared to change both their figure and their size. Some were round; but the greatest part of them were oval, and a few were thicker at the extremities than in the middle. The rolling and vibratory motions were still perceptible. In twelve hours, the liquor had deposited, at the bottom of the vial, a kind of gelatinous, bluish, or rather ashy-coloured, substance; and the fluid that swam on the top was nearly as clear as water, only it had a tincture of blue, like water in which a small quantity of soap had been dissolved. It still, however, retained its viscosity. The little bodies, which were now entirely freed from their threads, moved with great activity on all sides, and some of them turned round their centres. Most of them were oval, though some of them were round. I have seen them change figures, and from oval become round: I have seen them divide, and, from a single oval or globule, separate into two. Their activity always increased as their size diminished. At the end of twenty-four hours, the liquor had deposited a greater quantity of gelatinous matter, which I diluted, with some difficulty, in water. It appeared to consist of a multitude of opaque tubes resembling lace, but without any regularity or the smallest motion. In the clear semen itself, there were a few small bodies still moving; next day their number was still farther diminished. After this nothing was to be seen but globules without the least appearance of motion. These experiments were often repeated with great exactness; and they convinced me that the threads which adhere to the moving bodies are not tails, nor any part proper to these bodies; for the tails or threads have no proportion to the rest of the body; they are of different dimensions, though the bodies are always nearly of the same size at the same time. The motion of the globule is embarrassed in proportion to the length of the tail. When the tail is too long, it sometimes prevents the progressive motion altogether, leaving nothing but the vibrations from right to left; and the globules make evident efforts to disentangle themselves from this incumbrance.

“Having procured the feminal fluid of another man recently dead, I put a pretty large drop of it on the glass of the microscope, and it soon liquefied without any mixture. It had the appearance of a close net-work, the filaments of which were of a considerable length and thickness, and they seemed to proceed from the thickest part of the liquor, as shewn in *fig. 30*. These filaments separated in proportion as the liquor became more fluid; and at last they divided into globules, which seemed at first to have

have too little force to put them in motion: but their power of moving increased as they receded from the filaments, and they appeared to make considerable efforts to disengage themselves. In this manner each of them gradually drew tails of different lengths out of the filaments. Some of these tails were so long and so thin, that they had no proportion to the bodies, which were always more or less embarrassed, according to the length of the threads or tails. When the tail was long, the angle of the vibratory motion was increased; and, when the tail was short, the progressive motion was more conspicuous. I continued my observations, almost without interruption, for fourteen hours; and I discovered, that the length of the tails or threads gradually diminished, and became so thin and delicate, that their extremities successively ceased to be visible; and at last the whole disappeared. The horizontal vibrations of the globules then ceased, and their progressive motion was then direct, though they still had vertical oscillations, or, rather, they rolled like a vessel at sea. The small bodies, when deprived of their tails, were oval and transparent, and resembled those pretended animals which are seen in oyster-water on the sixth or seventh day, or those found in the jelly of roasted veal at the end of the fourth day.

"Between the tenth and twelfth hour, the liquor was become very fluid, and all the globules appeared to proceed in troops from one side of the drop, as represented in *fig. 31*. They passed over the field of the microscope in less than four seconds; they marched in lines of seven or eight in front; and succeeded each other without interruption, like the defiling of soldiers. I observed this singular phenomenon for more than five minutes; and, as the current of animals did not then cease, I was desirous of discovering the cause. I therefore gently shifted the glass, and perceived that all these moving globules proceeded from a kind of mucilage or net-work of filaments, as shewn in *fig. 32*, which continually produced them, and with more rapidity and copiousness than the filaments had done ten hours before. There was still a difference more remarkable between the globules produced by the liquor, when thick, and those produced when it was more fluid; for, in the latter case, they drew no threads or tails after them, their motion was quicker, and they went in flocks like sheep. I examined the mucilage from which they proceeded for a long time, and perceived that it gradually diminished, and was converted into moving globules, till more than one half of it was destroyed. After which, the liquor being too dry, this mucilage became obscure in the middle, and it was surrounded with small threads, forming square intervals, as shewn in *fig. 33*. These small threads seemed to be composed of the bodies of the moving globules which had been killed by the drying of the liquor, and the whole resembled the web of a spider besprinkled with drops of dew. By the first experiments, I perceived that these small moving bodies changed their figures; and I imagined, that, in general, they diminished in bulk, though I was not then altogether certain of the fact. But my subsequent observations removed every doubt. At the twelfth and thirteenth hour, the bodies were visibly smaller; but, as they diminished in bulk, their specific gravity increased, especially when they ceased to move, which they generally did all at once, and fell down to the bottom in form of an ash-coloured sediment, which was perceptible by the naked eye; and, by the assistance of the microscope, it appeared to be composed of globules attached to one another, sometimes by threads, and at other times by groups, but always in a regular manner."

From these experiments, M. Buffon concludes, that what Leeuwenhoek, Hartsoecker, and others, have called spermatic animals, are not creatures really endowed with life, but something proper to compose a living creature; and he distinguishes them by the name of *organic particles*. The same individual kinds of animals he declares he has found in the fluids separated from the ovaria of females:

and for the truth of this appeals to the testimony of Mr. Needham, who was an eye-witness of his experiments. He also brings an additional proof of his doctrine from Mr. Needham's observations on the milt of the *calmar*, a species of cuttle-fish, which, he says, contains no animalcules; and therefore we may from analogy conclude, that the small moving bodies which are to be seen in the semen of other animals, are not really creatures endowed with life. M. Buffon extends the analogy still further; and concludes, that all the moving bodies which are to be found in the infusions either of animal or vegetable substances are of a similar nature. "To discover (says he) whether all the parts of animals, and all the seeds of plants, contained moving organic particles, I made infusions of the flesh of different animals, and of the seeds of more than twenty different species of vegetables; and after remaining some days in close glasses, I had the pleasure of seeing organic moving particles in all of them."

These systems, however, both of *spermatic animalcules*, and of *organic particles*, notwithstanding the specious mode in which they were introduced, and the credit given them by men of the first philosophical ability, are now fallen into disrepute, and totally rejected by later physiologists, for reasons which may be seen under the article *IMPREGNATION*, and by consulting other observations in *ANATOMY*, p. 642, 643, &c.

ANIMALITY, *f.* The state of animal existence.

To ANIMATE, *v. a.* [*animo*, Lat.] To quicken; to make alive; to give life to: as, The soul *animates* the body; Man must have been *animated* by a higher power. To give powers to; to heighten the powers or effect of any thing. To encourage; to incite:

But none, ah! none can *animate* the lyre,
And the mute strings with vocal souls inspire:
Whether the learn'd Minerva be her theme,
Or chaste Diana bathing in the stream;
None can record their heav'nly praise so well
As Helen, in whose eyes ten thousand Cupids dwell.

Dryden.

ANIMATE, *adj.* Alive; possessing animal life.—All bodies have spirits and pneumatical parts within them; but the main differences between *animate* and *inanimate*, are two: the first is, that the spirits of things *animate* are all contained within themselves, and are branched in veins and secret canals, as blood is; and, in living creatures, the spirits have not only branches, but certain cells or seats, where the principal spirits reside, and whereunto the rest do resort: but the spirits in things *inanimate* are shut in, and cut off by the tangible parts, and are not pervious one to another, as air is in snow. *Bacon.*

Nobler birth

Of creatures *animate* with gradual life,
Of growth, sense, reason, all summ'd up in man. *Milton.*
There are several topics used against atheism and idolatry; such as the visible marks of divine wisdom and goodness in the works of the creation, the vital union of souls with matter, and the admirable structure of *animate* bodies. *Bentley.*

ANIMATED, *part. adj.* Lively; vigorous:

Warriors the fires with *animated* sounds;
Pours balm into the bleeding lovers wounds. *Pope.*

ANIMATED-NEEDLE, a needle touched with a magnet or loadstone.

ANIMATENESS, *f.* The state of being animated.

ANIMATION, *f.* The act of animating or enlivening. The state of being enlivened.—Two general motions in all *animation* are its beginning and encrease; and two more to run through its state and declination. *Brown.*

Animation is therefore, in a physical sense, the particular effect produced by the *vis vitalis*, in all animated bodies, by which life is begun and supported. The different hypotheses of physicians and philosophers, concerning the time of animation, have had their influence on the

penal

penal laws made against artificial abortions: it having been made capital to procure miscarriage in the one state, while in the other it was only deemed a venial crime. The emperor Charles V. by a constitution published in 1532, put the matter on another footing; instead of the distinction of an animated and unanimated fœtus, he introduced that of a vital and non-vital fœtus, as a thing of more obvious and easy decision, and not depending on any system either of creation, transduction, or infusion. Accordingly a fœtus is said, in a legal sense, to be animated, when it is perceived to stir in the womb; which usually happens about the middle of the term of gestation.

ANIMATION, is an ænigmatical word used by alchemists in their employ of transmuting metals. Quicksilver is said to be animated, when, by conjunction with a perfect metal, it is reduced to a certain species.

ANIMATIVE, *adj.* That which has the power of giving life, or animating.

ANIMATOR, *f.* That which gives life; or any thing analogous to life, as motion.

ANIME, *f.* [the Portuguese corrupted the word *anima* into *anime*.] It is improperly called *gum anime*, being a resinous substance imported from New Spain and the Brazils. It is also called *courbaril rezina*, *aminaca*, *animum*. Piso calls the tree from whence it is obtained *jetaiba*, and the Indians call it *courbaril*. It is the *hymenæa courbaril* of Linnæus.

The *gum anime* is a transparent, yellowish-white, resinous, gum, obtained from a large tree in Brazil and New Spain, and also in the eastern parts of the world. That from the east, Dioscorides calls by the names *myrrha* and *minaca*; but, in our shops, we have no other than the American forts. The small tears are the purest. It hath but little taste, though to the smell it is very agreeable. It easily breaks between the teeth; but, if chewed for some time, it softens and becomes adhesive. If it is laid on a red-hot iron, it immediately melts, catches flame, and burns quickly away, leaving only very little white ashes. It dissolves in *sp. vini R.* but is very little affected by water, except in distillation, by which it gives a part of its flavour, and a small quantity of oil.

The Brazilians are said to use it in fumigations for pains and aches from a cold cause. With us it is esteemed diuretic. The dose is $\mathfrak{z}$ i. The *gum copal* is often sold for it.

ANIME, in heraldry, a term used when the eyes of a rapacious creature are borne of a different tincture from the creature itself.

ANIMET'TA, *f.* among ecclesiastical writers, denotes the cloth wherewith the cup of the eucharist is covered.

ANIMO'SE, *adj.* [*animosus*, Lat.] Full of spirit; hot; vehement.

ANIMO'SENESS, *f.* Spirit; heat; vehemence of temper.

ANIMO'SITY, *f.* [*animositas*, Lat.] Vehemence of hatred; passionate malignity. It implies rather a disposition to break out into outrages, than the outrage itself.—No religious sect ever carried their aversions for each other to greater heights than our state parties have done; who, the more to inflame their passions, have mixed religious and civil *animosities* together; borrowing one of their appellations from the church. *Swift*.

ANIN'GA, *f.* a root which grows in the Antilles islands, much resembling the China plant. It is used by sugar-bakers for refining sugar.

ANJOU', a ci-devant province of France, forms, with the late provinces of Maine and Touraine, the four departments of Maine and Loire, Indre and Loire, Maine and Sarte. The air is temperate, and the country agreeably diversified with hills and meadows. There are thirty-three forests of oak-trees mixed with beech. The country produces white-wine, wheat, barley, rye, oats, pease, beans, flax, hemp, walnuts, and chestnuts. In Lower Anjou they make cider. There are fruit-trees of all kinds, and good pasture. The greatest riches of the province consist in cows, oxen, and sheep. There are several coal and iron mines; and quarries of marble and of slate; as

well as quarries of white stone, proper for building, on the side of the river Loire. Here are also several salt-petre-works and some glass-houses. The remarkable towns, besides Angers the capital, are Saumur, Brissac, Pons de Cea, La Fleche, and Beaufort.

ANIO, or A'NIEN, now *il Teverone*; a river of Italy, which falls into the Tiber, three miles to the north of Rome. It rises in a mountain near Treba; and, running through the country of the *Æquiculi*, or *Æqui*, it afterwards separated the Latins from the Sabines; but, nearer its mouth, or confluence, it had the Sabines on each side. It forms three beautiful lakes in its course. In the territories of Tibur it falls from a great height, and there forms a very rapid cataract; hence the epithet *præceps*, and hence the steam caused by its fall. *Anienus* is the epithet formed from it. *Anienus* is also the god of the river.

ANISA'TUM, *f.* A wine in which aniseeds are infused thus: take of Ascalon wine, (this was a strong wine,) $\mathfrak{f}$ ss xxx. honey $\mathfrak{f}$ ss x. aniseeds $\mathfrak{z}$ v. mix them and let them stand together a few days, then strain off the clear liquor.

A'NISE, *f.* [*anisum*, Lat.] A species of apium or parsley with large sweet-scented seeds. See *ILLICUM*, *PIMPINELLA*, and *BUBON*.

ANISIFO'LIUM, *f.* in botany. See *LIMONIA*.

ANISOMARA'THRUM, *f.* in botany. See *SCANDIX*.

A'NIUS, in fabulous history, king of the island of Delos, and high-priest of Apollo. He had three daughters, Oeno, Spermo, and Elais, to whom Bacchus gave the power of changing whatever they pleased into wine, corn, and oil. When Agamemnon went to the Trojan war, he wished to carry them with him to supply his army with provisions; but they complained to Bacchus, who changed them into doves.

AN'KER, *f.* [*ancher*, Du.] A liquid measure chiefly used at Amsterdam. It is the fourth part of the awm, and contains two *stekans*: each *stekan* consists of sixteen mingles; the mingle being equal to two of our wine quarts.

AN'KLE, *f.* [*ahcleow*, Sax. *anchel*, Du.] The joint which joins the foot to the leg.

ANKLE-BONE, *f.* [from *ankle* and *bone*.] The bone of the ankle.

AN'NA, or ANNE, [אנה Heb. gracious.] A Christian name of women.

ANNA, one of the three principalities into which Arabia Deserta is divided.

ANNA, one of the chief cities of the above principality, and formerly a famed mart-town, is situated in lat. 33. 57. and lon. 42. 10. E. on the river Euphrates, in a fruitful and pleafant soil. It has two streets, which are divided by the river. That on the Mesopotamia side is about two miles long, but thinly peopled, and by none but tradesmen; that on the opposite side is about six miles in length, and it is there that the principal inhabitants of the city dwell. Every house has some ground belonging to it; and these grounds are loaded with noble fruit trees, as lemons, oranges, citrons, quinces, figs, dates, pomegranates, olives, all very large and in great plenty. Some of the flat grounds are sown with corn and other grain, which yield likewise a considerable crop. This city is the common rendezvous of all the robbers that infest the country, and from which they disperse themselves into all parts of the Desert. Here they meet to consult; here they hold their grand council, and deliberate where to rob next with success. It is with great difficulty that the Turkish aga, and the janissaries, who are kept here, can levy the tribute imposed by the Turks on all the commodities carried through this city, which is one of the great thoroughfares for the passing of the caravans that go to and from Aleppo, Tripoli, Damascus, Bagdad, and some other parts of the Turkish empire.

ANNA, in fabulous history, the sister of Pygmalion and Dido, who followed her sister into Africa. After the death of Dido, she retired to Malta, from whence Pygmalion would have carried her away; but she got safe into Italy, where *Æneas* gave her honourable reception, for the

the kindness she had shewn him when he was at Carthage. However, Lavinia, the wife of Æneas, contrived her death; and, being informed of this by her sister in a dream, she fled to the river Numicius, of which she became a nymph.

ANNA'LE, *f.* in the church of Rome, a term applied to the masses celebrated for the dead during a whole year.

ANNA' LIS CLAVUS, *f.* the nail which the prætor, consul, or dictator, drove into the wall of Jupiter's temple annually upon the ides of September, to shew the number of years. But this custom was superseded by reckoning years by consulships. The ceremony was sometimes performed to avert the plague, &c.

AN'NALIST, *f.* A writer of annals.

ANNALS, *f.* [*annales*, Lat.] Histories digested in the exact order of time; narratives in which every event is recorded under its proper year. It has no singular:

Could you with patience hear, or I relate,
O nymph! the tedious *annals* of our fate;
Through such a train of woes if I should run,
The day would sooner than the tale be done! *Dryden.*

—We are assured, by many glorious examples in the *annals* of our religion, that every one, in the like circumstances of distress, will not act and argue thus; but thus will every one be tempted to act. *Rogers.*

Annals differ from perfect history in this, that annals are but a bare relation of what passes every year, as a journal is of what passes every day; whereas history relates not only the transactions themselves, but also the causes, motives, and springs, of actions. Annals require nothing but brevity; history demands ornament. Cicero informs us of the origin of annals. To preserve the memory of events, the *pontifex maximus*, says he, wrote what passed each year, and exposed it on tables in his own house, where every one was at liberty to read: this they called *annales maximi*; and hence the writers who imitated this simple method of narrating facts were called *annalists*.

ANNAN, the capital of Annandale, a division of Dumfriesshire in Scotland; a small town, containing about 600 inhabitants, and situated on a river of the same name, in lon. 3. o. W. lat. 54. 40. N. This place, which is a royal borough, has some trade in wine, and exports annually between 20,000 and 30,000 Winchester bushels (10,000 and 15,000 bolls) of corn. Vessels of about 250 tons can come within half a mile of the town; and of sixty, as high as the bridge; which consists of five arches defended by a gateway. A fabric for carding and spinning of cotton has lately been erected, and the town begins to increase. Here was formerly a castle; which was built by the Bruces after they became lords of Annandale. Upon the death of David II. the son of king Robert, in 1371, this castle (Lochmaben), and the lordship of Annandale, came to Thomas Randolph earl of Murray, and went with his sister Agnes to the Dunbars earls of March: after their forfeiture it went to the Douglasses, who also lost it by the same fate; and then having come to Alexander duke of Albany, he, for rebelling against his brother king James III. and plundering the fair of Lochmaben in 1484, was also forfeit. Since which time it continued in the hands of the king, and became the great key of the west border.

The stewartry or district of Annandale, of which Lochmaben castle was the chief fortalice, is a fertile vale, twenty-four miles long, and about fourteen miles broad: from its vicinity to England, and the continual incursions and predatory wars of the borderers, the greatest part of it was uncultivated and common: but, within the last forty years, all these wastes and commons have been divided and brought into culture, and the country has assumed a new appearance; which may be ascribed not only to the division of the commons, but likewise to the improvement made in the roads, and particularly in the great western road from Edinburgh to London by Moffat, Grately, and Carlisle. Annandale formed a part of the Roman province of Valentia; and, Severus's wall ending here, it abounds with Roman stations and antiquities. The camps

at Birrens in Middlebie, and on the hill of Burnfwork, are still entire, and their form is preserved; and the traces and remains of a military road are now visible in different parts of the country. The ruins of the house or castle of Auchincass, in the neighbourhood of Moffat, once the seat of that potent baron, Thomas Randolph, earl of Murray, lord of Annandale, and regent of Scotland, in the minority of David II. covers above an acre of ground, and even now conveys an idea of the plan and strength of the building. The ancient castle of Comlongan, formerly belonging to the Murrays, earls of Annandale, is still in a tolerable state of preservation.

ANNA'NO, a strong fort of Italy, in the duchy of Milan. It has been twice taken by the French; but was restored to the duke of Savoy in 1706. It is seated on the river Tanaro, in lat. 44. 40. N. lon. 8. 30. E.

ANNA'POLIS, the capital of Maryland, and the wealthiest town of its size in North America. It is situated at the mouth of Severn river, and was originally known by that name, which was changed for its present one in 1694, when it was made a port-town, and the residence of a collector and naval officer. It stands on a healthy spot, thirty miles south of Baltimore, in lat. 29. 25. N. and is a place of but little note in the commercial world. The houses are generally large and elegant, indicative of great wealth; the number of inhabitants does not exceed 2000. The design of those who planned the city was to have the whole in the form of a circle, with the streets like radii, beginning at the centre, where the state-house stands, and thence diverging in every direction. The principal part of the buildings are arranged agreeably to this plan.

ANNAPOLIS ROYAL, a town of Nova Scotia, is seated in the bay of Fundy; and, though a mean place, was formerly the capital of the province. It has one of the finest harbours in America, capable of containing 1000 vessels at anchor in the utmost security. The place is also protected by a fort and garrison. At the bottom of the harbour is a point of land, which divides two rivers; and on each side there are pleasant meadows, which in spring and autumn are covered with all sorts of fresh water fowl. There is a trade carried on by the Indians with furs, which they exchange for European goods. Lat. 45. 10. N. lon. 64. 5. W.

ANNAS, [of אָנָּא Heb. gracious.] A high-priest of the Jews.

AN'NATS, *f.* [*annates*, Lat.] First fruits; because the rate of first fruits, paid to spiritual livings, is after one year's profit. Masses said in the Romish church for the space of a year, or for any other time, either for the soul of a person deceased, or for the benefit of a person living. It has no singular. See FIRST FRUITS.

ANNE, queen of Great Britain. This amiable and illustrious princess was descended from a race of kings, the most ancient of any in Europe. She was second daughter of James duke of York, afterwards king James II. by Mrs. Anne Hyde, eldest daughter of Edward earl of Clarendon. The duke was privately married to this lady during his first exile, in 1659. In 1660, she was, by an order of council, declared duchess of York, and to have the precedence of the princesses of Orange and the queen of Bohemia. The duchess died at the palace of St. James's, March 15, 1671; she had issue by the duke four sons and four daughters: Charles, born October 22, 1660; Mary, born April 30, 1662; James, born July 12, 1663; Anne, born February 6, 1664; Charles, born July 4, 1665; Edgar, born September 14, 1667; Henrietta, born January 13, 1669; and Catharine, born February 9, 1670; of whom Charles, James, Charles, and Henrietta, died in her life-time; and Edgar and Catharine did not survive her a year; but Mary and Anne lived to be queens of England. Princess Mary was about nine years old, and princess Anne about seven, at the death of their mother. On the death of king William III. who died on Sunday, March 8, 1702, about eight in the morning, princess Anne was, about three the same afternoon, proclaimed queen of Great Britain, France, and Ireland,

Ireland, in the cities of London and Westminster, and was crowned April 23 following. The most remarkable events in her reign were, War declared against France and Spain, May 4; prince George made lord high admiral; the earl, afterwards duke, of Marlborough, generalissimo; an unsuccessful attempt on Cadix; Vigo taken by the English and Dutch, October 12; 1702. Admiral Bembow betrayed; the great storm, November; 1703. Order of the thistle revived; victory at Schellenburgh; the great battle at Hochstet or Blenheim, where the French lost 30,000 men, had 10,000 men taken prisoners, and marshal Tallard their general, in August; the sea-fight off Malaga, August 13; 1704. The battle of Ramilies, May 12; the union between England and Scotland, signed July 22; and the battle of Turin; all in 1706. The battle of Almanza, April 14, 1707. Sir Cloudesley Shovel wrecked on the rocks of Scilly; the battle of Oudenarde, June 30; Minorca taken by general Stanhope, September 18; the action of Wymondale, September 28; the city of Lille taken, October 12; 1708. The battle of Malplaquet, September 11, 1709. The battle of Saragossa, August 9; general Stanhope taken prisoner at Brihuega, November 26; the battle of Villa Viciosa, November 29; 1710. The duke of Ormond separates the British forces from the allies, July 5; and the action of Denain, July 13; 1712. The peace of Utrecht signed March 30, 1713. Sunday, at a little after seven o'clock in the morning, August 1, 1714, the queen died, having lived forty-nine years, five months, and six days; and reigned twelve years and five months, wanting seven days. There had been a new vault made on the south side and towards the east end of Henry VII's chapel, to deposit the body of Charles II. in which that prince, queen Mary, king William III. and prince George of Denmark, were laid. Here the remains of queen Anne were likewise deposited; and, there being no more room left, the vault is closed with brick-work. She had been married to his royal highness prince George, brother to the then king of Denmark, July 28, 1683, by whom she had a daughter still-born, May 12, 1684; lady Mary, born June 2, 1685, died February, 1690; lady Anne Sophia, born May 12, 1686, died February following; William duke of Gloucester, born July 24, 1689, and lived till eleven-years of age; Mary, born October, 1690, and lived long enough to be baptized; and George, who died soon after he was born. Prince George, her husband, died October 28, 1710.

Thus died Anne Stuart, queen of Great Britain, and one of the best and greatest monarchs that ever filled that throne. In her person she was of the middle stature, and, before she bore children, well made. Her hair was dark, her complexion sanguine, her features strong, but not irregular; her whole countenance was dignified and agreeable. In the accomplishments of the mind, as a woman, she was not deficient; she understood music, loved painting, and had some taste for works of genius. What was most remarkable, was a clear harmonious voice, always admired in the graceful delivery of her speeches to parliament, inasmuch that it used to be a common saying in the mouth of every one, "that her very speech was music." Good-nature, the true characteristic of the Stuarts, predominated in her temper, which was a compound of benevolence, generosity, indolence, and timidity, but not without a due sensibility of any slight which she thought was offered to her person or her dignity; to these all her actions, both as a monarch and as a woman, may be ascribed; these were the sources both of her virtues and her failings; her greatest blessing upon earth was that entire union of affections and inclinations between her and her royal consort, which made them a perfect pattern of conjugal love. She was a fond and tender mother, an easy and indulgent mistress, and a most gracious sovereign; but she had more than once reason to repent her giving up her heart, and trusting her secrets without reserve to her favourites. She was never expensive, but saved money out of her 50,000*l.* a-year, which, after she came to the

crown, was paid to prince George of Denmark, and was his by right. She retained to the last the true principles of that religion which she had early imbibed; and was charitable without ostentation. She had a great reverence for clergymen eminent for learning and good lives, and was particularly beneficent to the poorer sort of them, of which she left an evidence which bears her name, and will perpetuate both that and her bounty to all succeeding generations.

We cannot here omit the character of queen Anne, as written by the duchess of Marlborough, a lady who had such an opportunity of thoroughly knowing the queen, and who bore so great a part in many of the transactions of that glorious reign:

"Queen Anne was very graceful and majestic in her person: religious without affectation; she always meant well; she had no false ambition, which appeared by her never complaining at king William's being preferred to the crown before her, when it was taken from the king, her father, for following such counsels, and pursuing such measures, as rendered the revolution necessary. It was her greatest affliction to act against him, even for security. Her journey to Nottingham was never concerted, but occasioned by the great consternation she was under at the king's sudden return from Salisbury. She always paid the greatest respect to king William and queen Mary; never insisted upon any one circumstance of grandeur more than what was established in her family by king Charles II. though, after the revolution, she was presumptive heir to the crown, and, after the death of her sister, was in the place of prince of Wales. Upon her accession to the throne, the civil list was not increased. The late earl of Godolphin, lord high-treasurer of England, has often said, that from accidents in the customs, and lenity in the collection, it did not arise, one year with another, to more than 500,000*l.* a-year. She had no vanity in her expences, nor bought any one jewel in the whole time of her reign. She paid out of her civil list many pensions granted in former reigns, which have since been thrown upon the public. When a war was necessary, to secure Europe against the power of France, she contributed in one year towards the war, out of her civil list, 100,000*l.* in ease of her subjects. She granted the revenues arising from the first-fruits, to augment the provisions of the poorer clergy. She never refused her private charity to proper objects. Till a few years before her death, she never had but 20,000*l.* a-year for her privy-purse; at the latter end of her reign it did not exceed twenty-six thousand pounds a-year; which was much to her honour, because it is subject to no account: and, as to her robes, it will appear by the records in the exchequer, that in nine years she spent only 32,050*l.* including the coronation expence. She was extremely well-bred: treated her chief ladies and servants as if they had been her equals: her behaviour to all that approached her was decent and full of dignity, and shewed condescension, without art or meanness. All this I know to be true, *Sarah Marlborough.*"

The above character is cut round the pedestal, on which stands a full-length figure of the queen, at Blenheim, the seat of the duke of Marlborough.

ANNE of AUSTRIA, widow of Lewis XIII. was invested with the regency of France, on the death of her husband. She soon resigned herself entirely to the influence of cardinal Mazarine; and it is now generally supposed that she married him, and had by him a son, afterwards so mysteriously confined in the Bastille, under the appellation of the man with the iron-mask. Lewis XIV. was about five years old at the death of his father. Madame de Bavie, in her Letters, says, "Abbé ——— was detected in an intrigue: Anne of Austria however did much worse; she was not contented with intriguing with cardinal Mazarine, she married him." This she could do, as the cardinal had not taken priest's orders. Mazarine, however, became very soon tired of the queen, and used her very ill, the usual consequence of such a marriage. Yet, when

Mazarine

QUEEN ANNE.

Published at the Art director, July 1796.

Mazarine founded this queen respecting the marriage of her son Lewis XIV. with one of his nieces, she nobly replied, "If the king was capable of degrading himself so far, I would put myself with my second son at the head of the whole French nation against the king and against you." At the dukes of Norfolk's seat at Holme, near Hereford, there is a whole-length portrait of the princess, with this inscription, "*Anne reine de France, grosse de six mois; fait par Beaubrun 1638.*" and indeed the queen's pregnancy is pretty visible in the picture.

St. ANNE'S DAY, a festival of the Christian church, celebrated by the Latins on the 26th of July, but by the Greeks on the 9th of December. It is kept in honour of Anne, or Anna, mother of the Virgin Mary.

To ANNE'AL, *v. a.* [*alan*, Sax. to heat.] To heat glass, that the colours laid on it may be fixed:

But when thou dost *anneal* in glass thy story,
 ——— then the light and glory
 More rev'rend grows, and more doth win,
 Which else shews wat'rish, bleak, and thin. *Herbert.*

To heat glass after it is blown, that it may not break. To heat any thing in such a manner as to give it the true temper.

ANNE'ALING, *f.* by the workmen called *nealing*, is particularly used in tempering glass. It consists in placing the bottles, &c. whilst hot, in a kind of oven or furnace, where they are suffered to cool gradually; they would otherwise be too brittle for use. Metals are rendered hard and brittle by hammering: they are therefore made red-hot, in order to recover their malleability; and this is called *nealing*. The difference between unannealed and annealed glass, with respect to brittleness, is very remarkable. When an unannealed glass-vessel is broken, it often flies into a small powder, with a violence seemingly very unproportioned to the stroke it has received. In general, it is in greater danger of breaking from a very slight stroke than from one of some considerable force. One of those vessels will often resist the effects of a pistol-bullet dropt into it from the height of two or three feet; yet a small angular pebble falling into it will make it burst into small fragments. This takes place sometimes immediately on dropping the pebble into it: but often the vessel will stand for several minutes after, seemingly secure; and then, without any new injury, it will fly to pieces. If the vessel be very thin, it does not break in this manner, but seems to possess all the properties of annealed glass. The same phenomena are still more strikingly seen in glass drops or tears. They are globular at one end, and taper to a small tail at the other. They are the drops which fall from the melted glass on the rods on which the bottles are made. They drop into the tubs of water which are used in the work; and the greater part of them burst immediately in the water. When those that remain entire are examined, they discover all the properties of unannealed glass in the highest degree. They will bear a smart stroke on the thick end without breaking; but, if the small tail be broken, they burst into small powder with a loud explosion. They appear to burst with more violence, and the powder is smaller, in an exhausted receiver than in the open air. When they are annealed, they lose these properties. Some attempt to account for this phenomenon, by supposing that the sudden cold applied to the surface forms a strong coat by which the particles within are prevented from expanding as glass naturally does in passing from a fluid to a solid state. On the breaking of any part of this hard case, the particles are supposed to be set at liberty, and thus produce an explosion. This theory however will not bear examination, though it must be confessed philosophy does not furnish us with any that is better. See GLASS.

A process similar to what is practised with glass is now used for rendering kettles and other vessels of cast-iron less brittle: of it the same explanation may be given.

VOL. I. No. 46.

The greater number of metals diminish in bulk when they pass from a fluid to a solid state; but iron, on the contrary, expands. Forged iron has long been procured, by placing a mass of cast-iron under large hammers, and making it undergo violent and repeated compression. A process is now used for converting cast-iron into forged, by heat alone. The cast-iron is placed in an air-furnace, and kept for several hours in a degree of heat, by which it is brought near to a fluid state. It is then allowed to cool gradually, and is found to be converted into a substance similar to forged iron. This process is conducted under a patent; although, if Reaumur's experiments upon cast-iron be consulted, it will appear not to be a new discovery. By these experiments it is ascertained, that, if cast-iron be exposed for any length of time to a heat considerably below its melting point, the texture and properties are not changed: but, if it be kept in a heat near the melting point, the surface soon becomes lamellated like forged-iron; and the lamellated structure extends farther into the mass in proportion to the length of time in which it is exposed to that degree of heat. When it is continued for a sufficient time, and then allowed to cool gradually, it is found to possess the lamellated structure throughout. See IRON.

AN'NECY, a city of Savoy, seated between Chambery and Geneva, on the banks of a lake of the same name, from whence run several brooks, which flow thro' the town, and form a river. There are piazzas in most of the streets, which serve to shelter the inhabitants from rain. It has several collegiate and parish churches, as well as convents for men and women. The lake is about nine miles long and four broad. Lat. 45. 53. N. lon. 6. 12. E.

AN'NESLEY (Arthur), earl of Anglesey, and lord privy seal in the reign of Charles II. was the son of Sir Francis Annesley, Bart. and was born at Dublin on the 10th of July, 1614. He was of the university of Oxford, and afterwards studied the law at Lincoln's Inn. He had a considerable share in the public transactions of the sixteenth century: for in the beginning of the civil war he sat in the parliament held at Oxford; but afterwards became reconciled to the opposite party, and was sent commissioner to Ulster, to oppose the designs of the rebel Owen Roe O'Neal. He engaged in several other affairs with great success. He was president of the council of state after the death of Cromwell, and was principally concerned in bringing about the restoration: soon after which, Cha. II. raised him to the dignity of a baron, by the title of lord Annesley, of Newport-Pagnel, Bucks; and a short time after, he was made earl of Anglesey. During that reign he was made treasurer of the navy, and lord privy seal. In October 1680, his lordship was charged by Dangerfield, in an information delivered upon oath, at the bar of the house of commons, with endeavouring to stifle evidence in relation to the popish plot. The uneasiness he received from this attack did not prevent his speaking his opinion freely in the house of lords, particularly in regard to the popish plot. About the same time he answered lord Castlereagh's Memoirs, in which that nobleman endeavoured to paint the Irish rebellion in the lightest colours; and a sharp dispute was raised, which ended in the seals being taken from him. He possessed great abilities, had uncommon learning, and was well acquainted with the constitution and laws of England. He wrote, besides his Animadversions on Castlereagh's Memoirs, 1. The Privileges of the House of Lords and Commons stated. 2. A Discourse on the House of Lords. 3. Memoirs. 4. The History of the Troubles in Ireland, from the rebellion in 1641 till the restoration. 5. Truth unveiled, in behalf of the Church of England; and some other works. He died in April 1686, in the 73d year of his age; and was succeeded by his son James.

To ANNE'X, *v. a.* [*annecto*, *annexum*, Lat. *annexer*, Fr.] To unite to at the end; as, He *annexed* a codicil to his will. To unite, as a smaller thing to a greater; as, He *annexed* a province.

a province to his kingdom. To unite *à posteriori*; annexion always pre-supposing something: thus we may say, Punishment is *annexed* to guilt, but not guilt to punishment:

Nations will decline so low
From virtue, which is reason, that no wrong,
But justice, and some fatal curse *annex'd*,
Deprives them of their outward liberty.

Milton.

He cannot but love virtue wherever it is, and *annex* happiness always to the exercise of it. *Atterbury*.—The temporal reward is *annexed* to the bare performance of the action, but the eternal to obedience. *Rogers*.

ANNEX, *f.* The thing annexed; additament.—Failing in his first attempt to be but like the highest in heaven, he hath obtained of men to be the same on earth, and hath accordingly assumed the *annexes* of divinity. *Brown*.

ANNEXATION, *f.* Conjunction; addition. Union; act or practice of adding or uniting.—If we can return to that charity and peaceable-mindedness, which Christ so vehemently recommends to us, we have his own promise, that the whole body will be full of light, (Matt. vi.) that all other Christian virtues will, by way of concomitance or *annexation*, attend them. *Hammond*.

ANNEXATION, in law, a term used to imply the uniting of lands or rents to the crown.

ANNEXION, *f.* The act of annexing; addition.—It is necessary to engage the fears of men, by the *annexion* of such penalties as will overbalance temporal pleasure. *Rogers*.

ANNEXMENT, *f.* The act of annexing. The thing annexed.

ANNIHILABLE, *adj.* [from *annihilate*.] That which may be reduced to nothing; that which may be put out of existence.

To ANNIHILATE, *v. a.* [ad and *nihilum*, Lat.] To reduce to nothing; to put out of existence.—It is impossible for any body to be utterly *annihilated*; but that, as it was the work of the omnipotency of God to make somewhat of nothing, so it requireth the like omnipotency to turn somewhat into nothing. *Bacon*. To destroy, so as to make the thing otherwise than it was. To annul; to destroy the agency of any thing.

ANNIHILATION, *f.* The act of reducing to nothing. The state of being reduced to nothing:

That knowledge, which as spirits we obtain,
Is to be valued in the midst of pain:

Annihilation were to lose heav'n more:

We are not quite exil'd where thought can soar. *Dryden*.

Christians, Heathens, Jews, divines, philosophers, &c. have their peculiar systems concerning annihilation; and we find great disputes among them about the reality, the possibility, the means, measures, prevention, ends, &c. of annihilation. The first notions of the production of a thing from, or reduction of it to, nothing, Dr. Burnet shews, arose from the Christian theology; the words *creation* and *annihilation*, in the sense now given to them, having been equally unknown to the Hebrews, the Greeks, and the Latins. The ancient philosophers in effect denied all annihilation as well as creation, resolving all the changes in the world into new modifications, without supposing the production of any thing new, or destruction of the old. By daily experience, they saw compounds dissolved; and that in their dissolution nothing perished but their union or connection of parts: when in death the body and soul were separated, the man they held was gone, but that the spirit remained in its original the great soul of the world, and the body in its earth from whence it came; these were again wrought by nature into new compositions, and entered new states of being which had no relation to the former.

The Socinians, and other Christian writers, shocked with the horrible prospect of eternal torments, have taken refuge in the system of annihilation. This system seems countenanced by Scripture; for that the words *death*, *destruction*, and *perishing*, whereby the punishment of the wicked is most frequently expressed in Scripture, do most

properly import annihilation and an utter end of being. To this Tillotson answers, that these words, as well as those corresponding to them in other languages, are often used, both in Scripture and other writings, to signify a state of great misery and suffering, without the utter extinction of the miserable. Thus God is often said in Scripture to bring *destruction* on a nation, when he sends judgments upon them, but without exterminating or making an end of them. So, in other languages, it is frequent, by *perishing*, to express a person's being made miserable; as in that known passage in Tiberius's letter to the Roman senate: *Ita me dii, deaque omnes, pejus perdant, quam hodie perire me sentio*. As to the word *death*, a state of misery which is as bad or worse than death may properly enough be called by that name; and thus the punishment of wicked men after the day of judgment is in the book of Revelations frequently called the *second death*.

It has been much disputed among divines, whether, at the consummation of all things, this earth is to be annihilated, or only purified, and fitted for the habitation of some new order of beings. Gerard in his Common Places, and Hakewil in his Apology, contend earnestly for a total abolition or annihilation. Ray, Calmet, and others, think the system of renovation or restitution more probable, and more consonant to Scripture, reason, and antiquity. The fathers who have treated on the question are divided; some holding that the universe shall not be annihilated, but only its external face changed; others asserting, that the substance of it shall be destroyed.

ANNI NUBILES, in law, denotes the marriageable age of a woman, viz. after she has arrived at twelve.

ANNIVERSARY, *f.* [*anniversarius*, Lat.] A day celebrated as it returns in the course of the year. The act of celebration, or performance, in honour of the anniversary day.—For encouragement to follow the example of martyrs, the primitive Christians met at the places of their martyrdom, to praise God for them, and to observe the *anniversary* of their sufferings. *Stillingfleet*.—Anniversary is an office in the Romish church, celebrated now only once a year, but which ought to be said daily through the year, for the soul of the deceased. *Ayliffe*.

ANNIVERSARY, *adj.* [*anniversarius*, Lat.] Returning with the revolution of the year; annual; yearly.—The heaven whirled about with admirable celerity, most constantly finishing its *anniversary* vicissitudes. *Ray*.

ANNOBON', a small island of Africa, on the coast of Loango, belonging to the Portuguese. It lies in lat. 1. 50. S. lon. 5. 10. E. and receives its name from being discovered on New-year's Day. According to Pyrad, it is about six French leagues in compass. Here are two high mountains, the tops of which being continually covered with clouds, occasion frequent rains. On the south-east of the island are two rocks; one of which is low, and upon a level with the surface of the sea; the other higher and larger, but both dangerous in the night to shipping; but between them the channel is deep and clear. These rocks are inhabited by vast numbers of birds, so tame, that the sailors frequently catch them with their hands. On the same side of the island is a convenient watering-place at the foot of a rivulet, which tumbles from the mountains down to a valley covered with orange and citron trees, &c. affording a pleasant and refreshing shade; but the road on the north-west side is difficult and dangerous, though most frequented by ships who have no intention of touching upon the continent. In either place it is difficult to take in a sufficient quantity of water, on account of the violent breakings of the sea, and a stone entrenchment erected by the negroes, from which they annoy all strangers that attempt to land. The true road for shipping lies on the north-east side, where they may anchor in seven, ten, thirteen, or sixteen, fathoms, on a fine sand close to the land, opposite to the village where the negroes have thrown up their entrenchments. The climate is wholesome, and the air clear and serene for the greatest part of the year. Every part of the island is watered by pleasant brooks, and fresh water

Bartow sculp.

water springs, which, however, at the new and full moons, or in all high tides, acquire a brackishness. The banks of every rivulet are covered with palms, whence the inhabitants extract their wine by incision. Here are a number of fertile valleys, which produce Turkey-corn, rice, millet, yams, potatoes, &c. and afford pasture for abundance of oxen, sheep, goats, &c. Poultry and fish also abound here; but the only mercantile production is cotton, which is esteemed equal in quality to any produced in India, though the quantity is small. All the inhabitants are meanly clothed; the women go bare-headed, and have also the upper part of the body naked, modesty being defended by a piece of linen wrapt under their stomach, and falling down in form of a petticoat, or wide apron, to the knees. The men wear only a linen girdle round the loins, with a small flap before. The women carry their children on their backs, and suckle them over the shoulder. All the inhabitants are subject to the Portuguese governor, who is the chief person in the island; at the same time that the negroes have their own chief subordinate to him.

AN'NO DO'MINI, the computation of time from the incarnation of our Saviour. The Romans began their æra of time from the building of Rome; the Grecians computed by Olympiads; and the Christians reckon from the birth of Jesus Christ.

ANNOI'SANCE, *f.* [from *annoy*, but not now in use.] In law, it hath a double signification. Any hurt done either to a public place, as highway, bridge, or common river; or to a private, by laying any thing that may breed infection, by encroaching, or such-like means. The writ that is brought upon this transgression. See NUISANCE, the word now used.

ANNOMÆ'ANS, the name of the thorough-placed Arians in the fourth century, because they held the essence of the Son of God to be unlike that of the Father.

ANNOMINATION, *f.* in rhetoric, the fame with what is otherwise called *paronomasia*. See PARONOMASIA.

ANNO'NA, *f.* In botany, a genus of the polyandria polygynia class, ranking in the natural order of eoadunatae. The generic characters are—Calyx: perianthium three-leaved, small; leaflets cordate, concave, acuminate. Corolla: petals six, cordate, sessile; the three alternate interior ones less. Stamina: filaments scarcely any; antheræ very numerous, placed on the receptacle. Pistillum: germ roundish, placed on a roundish receptacle; styles none; stigmas obtuse, numerous, covering the whole germ. Pericarpium: a berry, very large, roundish, clothed with a scaly bark, one-celled. Seeds: very many, hard, ovate-oblong, placed in a ring, nestling.—*Essential Character.* Calyx, three-leaved; petals, six; berry, many-seeded, roundish, with a scaly bark.

Species. 1. *Annona muricata*, or rough-fruited custard-apple, or sour sop: leaves oval-lanceolate, smooth, acute; fruits muricate; petals ovate, the interior ones obtuse, shorter. The first species is a middle-sized tree, rarely above twelve or fourteen, or at most twenty, feet high. Trunk upright, with stiff, round, smooth, branches, and a brownish ash-coloured bark. It is a native of the West Indies, and is common in every savannah of Jamaica, flowering in the spring. The large succulent fruit is agreeable to new-comers, and over-heated habits; but it is so common, and so much in use among the negroes, that it is hardly ever used among the better sort of people. The smell and taste of the fruit, flowers, and whole plant, resemble very much those of black currants. There is a variety of it in Jamaica with inodorous leaves, larger flowers of a fulvous colour, and spherical mucronate fruits.

2. *Annona tripetala*, or broad-leaved custard-apple: leaves ovate, acute, pubescent beneath; flowers three-petalled; petals lanceolate, coriaceous, tomentose. The second sort grows to a very large tree in South America, and is well furnished with branches. Leaves bright green, much larger than those of any other species. The fruit is oblong, scaly on the outside, and of a dark purple colour when ripe; the flesh is soft and sweet, and has many

brown seeds intermixed with it, which are very smooth and shining. This fruit is esteemed by the Peruvians as one of their most delicate sorts.

3. *Annona squamosa*, or undulated custard-apple or sweet sop: leaves oblong, acute, smooth; fruits obtusely sealed; outer petals lanceolate, inner ones minute. The third sort is a small tree, about eight feet in height, and is frequently rather a shrub. The trunk is smooth, and the branches spreading and round. Flowers usually in pairs, green without, whitish within. Seeds flattened a little, black with a white scar on the side, wrapped in a succulent cottony substance. It is a native both of the East and West Indies. The fruit is sweet, and is eaten in those countries.

4. *Annona reticulata*, or netted custard-apple: leaves oblong-lanceolate, acute, smooth; fruits ovate, reticulate-areolate; outer petals lanceolate, inner minute. The fourth sort is a tree which grows to the height of twenty-feet or more, with spreading branches; the bark is smooth and of an ash-colour. The leaves are of a light green colour, and have several deep transverse ribs, ending in acute points. They are alternate in two rows, elongate, broad, rounded at the base, acuminate with a blunted tip, entire about the edge, veined, smooth on both sides. Petioles gibbous, short, excavated, smooth. Flowers three or four close together, peduncled, nodding, whitish. It is a native both of the East and West Indies; and, according to Browne, the fruit is much esteemed by many people. Swartz says, that it is seldom eaten. It was cultivated in 1690, in the royal garden at Hampton-court.

5. *Annona hexapetala*, or long-leaved custard-apple: leaves elliptic-oblong, acute, smooth; petals spatulate, equal, acute. It is a native of China, and is cultivated in the East Indies.

6. *Annona palustris*, or shining-leaved custard-apple: leaves oblong, rather obtuse, smooth; fruits areolate. This is a small tree, only a fathom in height, or little more. It grows wild in soft marshy places in Jamaica; and bears a fine sweet-scented fruit, of no disagreeable flavour; but it is said to be a strong narcotic, and is not eaten on that account. It is called *alligator-apple*. The wood of this tree is so very soft, even after it is dried, that it is frequently used by the country-people instead of corks, to stop up their jugs and calabashes; whence it has now universally obtained the name of *cork-wood* in Jamaica.

7. *Annona triloba*, or trifid-fruited custard-apple: leaves elliptic, acute, smooth; flowers pendulous, campanulate; calyxes ovate; petals many, oval. The trunk of this tree is seldom bigger than the small of a man's leg, and rises ten or twelve feet high, having a smooth greenish-brown bark. In March, when the leaves begin to sprout, its blossoms begin to appear, consisting each of six greenish-white petals. The fruit grows in clusters of three, and sometimes four, together; they are at first green, and when ripe yellow, covered with a thin smooth skin, which contains a yellow pulp, of a sweet luscious taste; in the middle of which lie, in two rows, twelve seeds, divided by so many thin membranes. All parts of the tree have a rank, if not a fetid, smell; and the fruit is relished by few, except negroes. These trees grow usually in low shady swamps, and in a very fat soil. Mr. Miller observes, that this is rather a shrub than a tree, and that the flowers, at least in England, are of a rusty purple colour. He mentions, that the largest plant he had seen, was in the duke of Argyll's garden at Whitton, near Hounslow, which produced flowers the beginning of May. It is a native of the Bahama islands, Carolina, Maryland, and Virginia; and the seeds are frequently brought to England by the title of papaw-tree. Introduced here in 1736 by Collinson.

8. *Annona glabra*, or smooth custard-apple: leaves lanceolate-ovate, fruits conoid smooth. This shrub, or small tree, grows to the height of about sixteen feet, covered with a smooth greenish bark; the leaves are thick, stiff, and shaped like those of a lemon. The fruit is covered with a smooth yellowish-green skin; the pulp is of the consistence of a ripe pear, and contains many conical

brown.

brown seeds: this is an eatable fruit, of a sweet insipid taste; it is the food of guanas, and many other wild creatures. It is a native of North America.

9. *Annona Asiatica*, or Asiatic custard-apple: leaves lanceolate, smooth, shining, marked with lines. This is a middle-sized tree, with spreading branches. Native of the East Indies. Cultivated there and in China.

10. *Annona Africana*, or African custard-apple: leaves lanceolate pubescent. The branches are rugged with little dots. This, though it has the name of *Africana*, is said to be a native of America. These fruits are much esteemed by the natives of the countries where they grow naturally, are reckoned very cooling and wholesome, and are frequently given to sick persons.

Propagation and Culture. The seventh fort will thrive in the open air in England, if it is planted in a warm situation; but the plants should be trained up in pots, and sheltered in winter for two or three years, until they have acquired some strength; then they may be turned out of the pots in the spring, and planted in full ground, where they are to remain. This fort produced flowers in the curious garden of his grace the duke of Argyle, at Whitton, near Hounslow, where it grew in the open air for some years, as also in the nursery of the late Mr. Gray, near Fulham. The seeds are frequently brought to England from North America; they are much larger than those of the other species, and many plants have been raised in the gardens near London. The shape of the leaves is also different; this casts its leaves in autumn, whereas all the others retain their leaves, never casting them until the spring, when the new leaves come out. The fruit is very different from those of the other species, two or three growing together at their foot-stalks. When the seeds of this fort are sown, they frequently remain a whole year in the ground; therefore the earth in the pots should not be disturbed, where they are sown, if the plants do not come up the first year; and the pots should be sheltered in winter, and the following spring, if they are plunged into a new hot-bed, the plants will come up much sooner than those which are sown in the open air, and will have more time to get strength before the winter. All the other forts, which are natives of the hot parts of America, or the East Indies, are too tender to live in this country, if they are not preserved in warm stoves; they come up very easily from the seeds which are brought over, if they are fresh; but these seeds must be sown on a good hot-bed, or in pots of light earth, and plunged into a hot-bed of tanner's bark in February, which is by much the best time; because, when the plants come up early, they will have time to get strength before the cold weather comes on in the autumn. Some of these plants are twelve or fourteen feet high in our gardens, and there were plants of the seventh fort in the garden at Chelsea, which were more than twenty feet high, and they produced flowers two or three years.

ANNONA, *f.* in Roman antiquity, denotes provision for a year of all sorts, as of flesh, wine, &c. but especially of corn. *Annona* is likewise the allowance of oil, salt, bread, flesh, corn, wine, hay, and straw, which was annually provided by the contractors for the maintenance of an army.

ANNO'NÆ PREFEC'TUS, *f.* in antiquity, an extraordinary magistrate, whose business it was to prevent a scarcity of provision, and to regulate the weight and fineness of bread.

ANNONA'Y, a town of France in the department of Ardeche and late province of Dauphiny, seated on the confluence of the Cances and Deumes, twelve miles south-west of Vienne. Lat. 45. 15. N. lon. 4. 52. E.

ANN'OT, a small city in the mountains of Provence in France. Lat. 44. 4. N. lon. 7. 0. E.

ANNOTA'TIO, *f.* The very beginning of a febrile paroxysm, called also the attack of the paroxysm. There is another *annotatio* or *epifemafia*, which is proper to hectic fevers, happening an hour or two after eating: in this there is no shivering with cold, as in the other fort.

ANNO'TATION, *f.* [*annotatio*, Lat.] Explications or remarks written upon books; notes.—It might appear very improper to publish *annotations*, without the text itself whereunto they relate. *Boyle*.

ANNO'TATOR, *f.* [Lat.] A writer of notes, or annotations; a scholiast; a commentator.—I have not that respect for the *annotators*, which they generally meet with in the world. *Felton*.

To ANNO'UNCE, *v. a.* [*annoncer*, Fr. *annuncio*, Lat.] To publish; to proclaim. To pronounce; to declare by a judicial sentence:

Of the Messiah I have heard foretold
By all the prophets; of thy birth at length
Announc'd by Gabriel with the first I knew. *Milton*.

To ANNO'Y, *v. a.* [*annoyer*, Fr.] To incommode; to vex; to teaze; to molest:

As one who long in populous city pent,
Where houses thick, and sewers, annoy the air,
Forth issuing on a summer's morn to breathe
Among the pleasant villages, and farms
Adjoin'd, from each thing nict conceives delight. *Milton*.

—Insects seldom use their offensive weapons, unless provoked: let them but alone, and annoy them not. *Ray*.

ANNOY, *f.* Injury; molestation; trouble:
Sleep, Richmond, sleep in peace, and wake in joy;
Good angels guard thee from the boar's annoy.

Shakespeare.

"After annoy comes joy:" H. Ger. *Auf schmerzen, schertzen*. After rain, sun-shine, *Post nubila phœbus*. A saying people are apt to comfort themselves with in trouble, upon a supposition, that, as sun-shine follows rain, so good fortune must necessarily succeed evil fortune.

ANNOY'ANCE, *f.* That which annoys; that which hurts.—Crows, ravens, rooks, and magpies, are great annoyances to corn. *Mortimer*.—The state of being annoyed; or act of annoying.—The greatest annoyance and disturbance of mankind has been from one of those two things, force or fraud. *South*.

ANNOY'ER, *f.* The person that annoys.

AN'NUAL, *adj.* [*annuel*, Fr. from *annus*, Lat.] That which comes yearly:

Annual for me the grape, the rose, renew
The juice nectareous, and the balmy dew. *Pope*.

That which is reckoned by the year. That which lasts only a year.—The dying in the winter of the roots of plants that are *annual*, seemeth to be caused by the over-expend of the sap; which being prevented, they will superannuate, if they stand warm. *Bacon*.—Every tree may, in some sense, be said to be an *annual* plant, both leaf, flower, and fruit, proceeding from the coat that was superinduced over the wood the last year. *Ray*.

ANNUAL MOTION of the EARTH. See *ASTRONOMY*.

ANNUAL LEAVES, are such leaves as come up afresh in the spring, and perish in winter. These stand opposed to *EVER-GREENS*.

ANNUAL PLANTS, called also simply *annuals*, are such as only live their year, i. e. come up in the spring and die again in the autumn; and accordingly are to be recruited every year.

ANNUALLY, *adv.* Yearly; every year.—The whole strength of a nation is the utmost that a prince can raise *annually* from his subjects. *Swift*.

AN'NUEL of NORWAY, of which mention is made in the acts of parliament of king James III. was an annual payment of an hundred marks sterling, which the kings of Scotland were obliged to pay to the kings of Norway, in satisfaction for some pretensions which the latter had to the Scottish kingdom, by virtue of a conveyance made thereof by Malcolm Kenmore, who usurped the crown after his brother's decease. This *annuel* was first established in 1266; in consideration whereof the Norwegians

regions renounced all title to the succession to the isles of Scotland. It was paid till the year 1468, when the annu- el, with all its arrears, was renounced in the contract of marriage between king James III. and Margaret daughter of Christian I. king of Norway, Denmark, and Sweden.

ANNUITANT, f. He that possesses or receives an annuity.

ANNUITY, f. [*annuité*, Fr.] A yearly allowance. A yearly rent to be paid for term of life or years. The differences between a *rent* and an *annuity* are, that every rent is going out of land; but an annuity changes only the granter, or his heirs, that have assets by descent. The second difference is, that, for the recovery of an annuity, no action lies, but only the writ of annuity against the granter, his heirs, or successors; but, of a rent, the same actions lie as do of land. The third difference is, that an annuity is never taken for assets, because it is no freehold in law, nor shall be put in execution upon a *statute-merchant*, *statute-staple*, or *elegit*, as a rent may. *Cowell*.

If a man by deed grant to another the sum of 20l. a-year, without expressing out of what lands it shall issue; no land at all shall be charged with it, but it is a mere personal annuity. 2 *Blackst.* 40.

ANNUITIES, a term for any periodical income, arising from money lent, or from houses, lands, salaries, pensions, &c. payable from time to time; either annually, or at other intervals of time. Annuities may be divided into such as are *certain*, and such as depend on some *contingency*, as the continuance of a life, &c. Annuities are also divided into annuities in *possession*, and annuities in *reversion*; the former meaning such as have commenced; and and the latter such as will not commence till some particular event has happened, or till some given period of time has elapsed. Annuities may be farther considered as payable either *yearly*, or *half-yearly*, or *quarterly*, &c. The *present value* of an annuity, is that sum, which, being improved at interest, will be sufficient to pay the annuity.

The *present value* of an *annuity certain*, payable yearly, is calculated in the following manner: Let the annuity be 1, and let r denote the amount of 1l. for a year, or 1l. increased by its interest for one year. Then, 1 being the present value of the sum r , and having to find the present value of the sum 1, it will be, by proportion thus, $1 : r$

$:: 1 : \frac{1}{r}$ the present value of 1l. due a year hence. In like manner $\frac{1}{r^2}$ will be the present value of 1l. due 2

years hence; for $r : 1 :: \frac{1}{r} : \frac{1}{r^2}$. In like manner $\frac{1}{r^3}$, $\frac{1}{r^4}$, &c. will be the present value of 1l. due at the end of

3, 4, 5, &c. years respectively; and, in general, $\frac{1}{r^n}$ will be the value of 1l. to be received after the expiration of n years. Consequently the sum of all these, or $\frac{1}{r} + \frac{1}{r^2} +$

$\frac{1}{r^3} + \frac{1}{r^4} +$ &c. continued to n terms, will be the present value of all the n years annuities. And the value of the perpetuity, is the sum of the series continued, *ad infinitum*. But this series, it is evident, is a geometrical progression, whose first term and common ratio are each $\frac{1}{r}$, and the number of its terms n ; and therefore the sum s of all the terms, or the present value of all the annual payments, will be $s = \frac{1}{r-1} - \frac{1}{r-1} \times \frac{1}{r^n}$.

When the annuity is a perpetuity, it is plain that the last term $\frac{1}{r^n}$ vanishes, and therefore $\frac{1}{r-1} \times \frac{1}{r^n}$ also vanishes; and consequently the expression becomes barely

$s = \frac{1}{r-1}$; that is, any annuity divided by its interest for one year, is the value of the perpetuity. So, if the rate of interest be 5 per cent. then $\frac{100}{5} = 20$ is the value of the perpetuity at 5 per cent. Also $\frac{100}{4} = 25$ is the value of

the perpetuity at 4 per cent. And $\frac{100}{3} = 33\frac{1}{3}$ is the value of the perpetuity at 3 per cent. interest: and so on. If the annuity is not to be entered on immediately, but after a certain number of years, as m years; then the present value of the reversion is equal to the difference between two present values, the one for the first term of m years, and the other for the end of the last term n ; that is, equal to the difference between $\frac{1}{r-1} - \frac{1}{r-1} \times \frac{1}{r^m}$, and $\frac{1}{r-1} -$

$$\frac{1}{r-1} \times \frac{1}{r^n}, \text{ or } = \frac{1}{r-1} \times \frac{1}{r^m} - \frac{1}{r^n}.$$

Annuities certain differ in value, as they are made payable yearly, half-yearly, or quarterly. And, by proceeding as above, using the interest or amount of a half-year, or a quarter, as those for the whole year were used, the following set of theorems will arise; where r denotes as before, the amount of 1l. and its interest for a year, and n the number of years during which any annuity is to be paid; also P denotes the perpetuity $\frac{1}{r-1}$, Y denotes $\frac{1}{r-1}$

$- \frac{1}{r-1} \times \frac{1}{r^n}$ the value of the annuity supposed payable yearly, H the value of the same when it is payable half-yearly, and Q the value when payable quarterly; or univ-ersally, M the value when it is payable every m part of a year.

$$\text{THEOR. 1. } Y = P - P \times \left(\frac{1}{r}\right)^n.$$

$$\text{THEOR. 2. } H = P - P \times \left(\frac{2}{r+1}\right)^{2n}.$$

$$\text{THEOR. 3. } Q = P - P \times \left(\frac{4}{r+3}\right)^{4n}.$$

$$\text{THEOR. 4. } M = P - P \times \left(\frac{m}{r+m-1}\right)^{mn}.$$

Example 1.

Let the rate of interest be 4 per cent. and the term 5 years; and consequently $r = 1.04$, $n = 5$, $P = 25$; also let $m = 12$, or the interest payable monthly in theorem 4: then the present value of such annuity of 1l. a-year, for 5 years, according as it is supposed payable 1l. yearly, or $\frac{1}{2}$ l. every half year, or $\frac{1}{4}$ l. every quarter, or $\frac{1}{12}$ l. every month or $\frac{1}{12}$ th part of a year, will be as follows:

$$Y = 25 - 25 \times .821928 = 4.4518$$

$$H = 25 - 25 \times .820348 = 4.4913$$

$$Q = 25 - 25 \times .819543 = 4.5114$$

$$M = 25 - 25 \times .818996 = 4.5251$$

Example 2. Supposing the annuity to continue 25 years, the rate of interest and every thing else being as before; then the values of the annuities for 25 years will be

$$Y = 25 - 25 \times .375118 = 15.6221$$

$$H = 25 - 25 \times .371527 = 15.7118$$

$$Q = 25 - 25 \times .369709 = 15.7573$$

$$M = 25 - 25 \times .368477 = 15.7881$$

Example 3. And, if the term be 50 years, the values will be

$$Y = 25 - 25 \times .140713 = 21.4822$$

$$H = 25 - 25 \times .138032 = 21.5492$$

$$Q = 25 - 25 \times .136685 = 21.5829$$

$$M = 25 - 25 \times .135775 = 21.6056$$

Example 4. Also, if the term be 100 years, the values will be

$$\begin{aligned} Y &= 25 - 25 \times .019800 = 24.5050 \\ H &= 25 - 25 \times .019053 = 24.5237 \\ Q &= 25 - 25 \times .018683 = 24.5329 \\ M &= 25 - 25 \times .018435 = 24.5391 \end{aligned}$$

Hence the difference in the value by making periods of payments smaller, for any given term of years, is the more as the intervals are smaller, or the periods more frequent. The same difference is also variable, both as the rate of interest varies, and also as the whole term of years n varies; and, for any given rate of interest, it is evident that the difference, for any periods m of payments, first increases from nothing as the term n increases, when n is 0, to some certain finite term or value of n , when the difference D is the greatest or a maximum; and that afterwards, as n increases more, that difference will continually decrease to nothing again, and vanish when n is infinite: also the term or value of n , for the maximum of the difference, will be different according to the periods of payment, or value of m . And the general value of n , when the difference is a maximum between the yearly payments and the payments of m times in a year, is expressed by this formula, viz.

$$n = \frac{\frac{ml \cdot \frac{m+r-1}{m}}{l \cdot r}}{\frac{ml \cdot \frac{m+r-1}{m}}{m} - l \cdot r}, \text{ where } l \text{ denotes the logarithm of the quantity following it.}$$

Hence, taking the different values of m , viz. 2 for half-years, 4 for quarters, 12 for monthly payments, &c. and substituting, in the general formula, the term or value of n for each case, when the difference in the present worths of the annuities, will be as follows, reckon-interest at 4 per cent. viz.

$$\begin{aligned} n &= \frac{\frac{2l \cdot \frac{r+1}{2}}{l \cdot r}}{\frac{2l \cdot \frac{r+1}{2}}{2} - l \cdot r} = 25.3777 \text{ for half-yearly payments,} \\ n &= \frac{\frac{4l \cdot \frac{r+3}{4}}{l \cdot r}}{\frac{4l \cdot \frac{r+3}{4}}{4} - l \cdot r} = 25.3200 \text{ for quarterly payments,} \\ n &= \frac{\frac{12l \cdot \frac{r+11}{12}}{l \cdot r}}{\frac{12l \cdot \frac{r+11}{12}}{12} - l \cdot r} = 25.2643 \text{ for monthly payments.} \end{aligned}$$

Annuities may also be considered as in arrears, or as forborn, for any number of years; in which case each payment is to be considered as a sum put out to interest for the remainder of the term after the time it becomes due. And as $1l.$ due at the end of 1 year amounts to r at the end of another year, and to r^2 at the end of the third year, and to r^3 at the end of the 4th year, and so on; therefore by adding always the last year's annuity, or 1, to the amounts of all the former years, the sum of all the annuities and their interests will be the sum of the following geometrical series, $1+r+r^2+r^3+r^4 \dots$ to r^n , continued till the last term be r^{n-1} , or till the number of terms be n , the number of years the annuity is forborn. But the sum of this geometrical

progression is $\frac{r^n-1}{r-1}$, which therefore is the amount of $1l.$ annuity forborn for n years. And this quantity being multiplied by any other annuity a , instead of 1, will produce the amount for that other annuity.

But the amounts of annuities, or their present values, are easiest found by the two following Tables of numbers for the annuity of $1l.$ which are ready computed from the foregoing principles.

TABLE I.
The Amount of an Annuity of $1l.$ at Compound Interest.

n	at 3 per cent.	$3\frac{1}{2}$ per cent.	4 per cent.	$4\frac{1}{2}$ per cent.	5 per cent.	6 per cent.

The Use of TABLE I.

To find the Amount of an Annuity forborn any number of Years. Take out the amount from the first table, for the proposed years and rate of interest; then multiply it by the annuity in question; and the product will be its amount for the same number of years, and the rate of interest. And the converse to find the rate or time.

EXAM. 1. To find how much an annuity of 50l. will amount to in 20 years at 3½ per cent. compound interest. On the line of 20 years, and in the column of 3½ per cent. stands 28.27968, which is the amount of an annuity of 1l.

for the 20 years; and therefore 28.27968, multiplied by 50, gives 1413.984l. or 1413l. 19s. 8d. for the answer.

EXAM. 2. In what time will an annuity of 20l. amount to 1000l. at 4 per cent. compound interest? Here the amount of 1000l. divided by 20l. the annuity, gives 50, the amount of 1l. annuity for the same time and rate. Then, the nearest tabular number in the column of 4 per cent. is 49.96758, which, standing on the line of 28, shews that 28 years is the answer.

EXAM. 3. If it be required to find at what rate of interest an annuity of 20l. will amount to 1000l. forborn for 28 years. Here 1000 divided by 20 gives 50 as before; then looking along the line of 28 years, for the nearest to this number 50, I find 49.96758 in the column of 4 per cent. which is therefore the rate of interest required.

The Use of TABLE II.

EXAM. 1. To find the present value of an annuity of 50l. which is to continue 20 years, at 3½ per cent. By the table, the present value of 1l. for the same rate and time, is 14.21240; therefore 14.21240 × 50 = 710.62l. or 710l. 12s. 4d. is the present value sought.

EXAM. 2. To find the present value of an annuity of 20l. to commence 10 years hence, and then to continue for 40 years, or to terminate 50 years hence, at 4 per cent. interest. In such cases as this, it is plain we have to find the difference between the present values of two equal annuities for the two given times; which therefore will be effected by subtracting the tabular value of the one term from that of the other, and multiplying by the annuity. Thus,

Tabular value for 50 years 21.48218

Tabular value for 10 years 8.11090

The difference 13.37128

Multiply by 20

Gives 267.4256, or 267l. 8s. 6d. [the answer.]

The foregoing observations, rules, and tables, contain all that is important in the doctrine of *annuities certain*. And, for farther information, reference may be had to arithmetical writings, particularly Malcolm's Arithmetic, page 595; Simpson's Algebra, sect. 16; Dodson's Mathematical Repository, page 298, &c. Jones's Synopsis, ch. 10; Philos. Trans. vol. lxxvi. page 109.

For what relates to the doctrine of *annuities on lives*, see ASSURANCE, COMPLEMENT, EXPECTATION, LIFE ANNUITIES, &c.

To ANNU'L, *v. a.* [from *nullus*, Lat.] To make void; to nullify; to abrogate; to abolish.—That which gives force to the law, is the authority that enacts it; and whoever destroys this authority, does, in effect, *annul* the law. Rogers. To reduce to nothing; to obliterate:

Light, the pure work of God, to me's extinct;

And all her various objects of delight

Annul'd, which might in part my grief have eas'd. Milton.

AN'NULAR, *adj.* [annulus, Lat.] Something in the form of, or resembling, a ring. It is also a peculiar denomination of the fourth finger, commonly called the *ring-finger*.

AN'NULARY, *adj.* [annulus, Lat.] In the form of rings.—Because continual respiration is necessary, the wind-pipe is made with *annular* cartilages, that the sides of it may not flag and fall together. Ray.

AN'NULET, *f.* [annulus, Lat.] a little ring.—In heraldry, a difference or mark of distinction, which the fifth brother of any family ought to bear in his coat of arms. *Annulets* are also a part of the coat-armour of several families; they were anciently reputed a mark of nobility and jurisdiction, it being the custom of prelates to receive their investiture *per baculum & annulum*.—In architecture, the small square members in the Doric capital, under the quarter round, are called *annulets*. *Annulet* is also used for a narrow

a narrow flat moulding common to other parts of the column; so called, because it encompasses the column round.

To ANNUMERATE, *v. a.* [*annumero*, Lat.] To add to a former number; to unite to something before mentioned.

ANNUMERATION, *f.* [*annumeratio*, Lat.] Addition to a former number.

ANNUNCIADA, or ANNUNTIATA, *f.* An order of knighthood in Savoy, first instituted by Amadeus I. in the year 1409. Their collar was of fifteen links, interwoven one with another, in form of a true-lover's knot; and the motto, F. B. R. T. signifying, *Fortitudo ejus Rhodum tenuit*. Amadeus VIII. gave the name *Annunciada* to this order, which was formerly known by that of *The knot of love*; changing at the same time the image of St. Maurice, patron of Savoy, which hung at the collar, for that of the Virgin Mary; and, instead of the motto above-mentioned, substituting the words of the angel's salutation.

ANNUNCIADA is also a title of several religious orders, instituted at different times and at different places, in honour of the annunciation.

To ANNUNCIATE, *v. a.* [*annuncio*, Lat.] To bring tidings; to relate something that has happened: a word not in popular use.

ANNUNCIATION, *f.* The tidings brought by the angel Gabriel to the virgin Mary of the incarnation of Christ.

ANNUNCIATION is also a festival, kept by the church on the 25th of March, in commemoration of these tidings. This festival appears to be of very great antiquity, having been observed before the time of the council of Trullo, in which there is a canon forbidding the celebration of all festivals in Lent, excepting the Lord's day, and the feast of the annunciation: so that we may date its original from the seventh century. In the Romish church, on this feast, the pope performs the ceremony of marrying or cloystering a certain number of maidens, who are presented to him in the church, clothed in white serge, and muffled up from head to head to foot. An officer stands by; with purses containing notes of fifty crowns for those who make choice of marriage, and notes of a hundred for those who choose to veil.

ANNUNCIATION is likewise a title given by the Jews to part of the ceremony of the passover.

ANNUNCIATOR, *f.* The name of an officer in the church of Constantinople. It was his business to inform the people of the festivals that were to be celebrated.

ANUS CLIMACTERICUS, the years 63 and 81, of which, in astrology, there is an opinion, that those years have an influence on man's life. They consist of a number of nines; as 7 times 9 is 63, and 9 times 9 is 81.

AN'ODA, *f.* in botany. See SIDA.

ANO'DUS, a word used by chemists for what is separated from the nourishment by the kidneys. The Greek word *anodes*, *anodus*, from *a* neg. and *odus*, a tooth, signifies toothless.

ANODYNE, *f.* [from *a* neg. and *odyn*, pain.] Anodynes are medicines which ease pain, and procure sleep. They are divided into three sorts, viz. 1. *Paregorica*. *Παρεγογεω*, *mitigo*, called also *anetica*. Paregorics are such as assuage pain. 2. *Hypnotica*, *hypnopaos*. Hypnotics, or such as relieve by procuring sleep, *πνους*, *somnus*. 3. *Narcotica*. Narcotics, or such as ease the patient by stupifying him; *ναρκωω*, *stupefacio*. Opiates and narcotics destroy sensation. Some hypnotics and paregorics procure ease and sleep by removing the offending cause, as nitre, camphor, &c. But the term anodyne is now generally employed for those means only which relieve pain by diminishing or destroying sensibility. The doses of these medicines are generally regulated by the pulse; yet this rule is not without exceptions. If the pulse is strong, a larger dose is safe; if weak, a less dose must be given. Camphor is the best anodyne in nervous cases, and at the decline of fevers. Hemlock procures ease and sleep without causing that

head-ach, next morning, usually complained of after taking opium. Anodynes should not be given without great caution, on a full stomach, nor in dropfies.

ANODYNE-BALSAM. See PHARMACY.

To ANOIN'T, *v. a.* [*oindre*, *enoindre*, part. *oint*, *enoint*, Fr.] To rub over withunctuous matter, as oil, or unguents. To consecrate by unction. To smear; to be rubbed upon:

Warm waters then, in brazen caldrons borne,
Are pour'd to wash his body, joint by joint,
And fragrant oils the stiffen'd limbs anoint. *Dryden.*

ANOIN'TER, *f.* The person that anoints.

ANOIN'TERS, *f.* A religious sect in some parts of England, so called from the ceremony they used of anointing all persons before they admitted them into their church. They founded their opinion of anointing upon the fifth chapter of James, verses 14 and 15.

ANOLYMPIADES, *f.* in antiquity, a name given by the Elians to those Olympic games which had been celebrated under the direction of the Pisceans and Arcadians. The Elians claimed the sole right of managing the Olympic games, in which they sometimes met with competitors. The hundred and fourth Olympiad was celebrated by order of the Arcadians, by whom the Elians were at that time reduced very low; this, as well as those managed by the inhabitants of Pisa, they called *Ανολυμπιαδες*, that is, "unlawful Olympiads;" and left them out of their annals, wherein the names of their victors and other occurrences were registered.

ANO'MALISM, *f.* Anomaly; irregularity; deviation from the common rule.

ANOMALISTICAL YEAR, in astronomy, called also *periodical year*, is the space of time in which the earth, or a planet, passes through its orbit. The anomalistical, or common, year, is somewhat longer than the tropical year; by reason of the precession of the equinox. And the apses of all the planets have a like progressive motion; by which it happens that a longer time is necessary to arrive at the aphelion, which has advanced a little, than to arrive at the same fixed star. For example, the tropical revolution of the sun, with respect to the equinox, is - - - - - 365d 5h 48' 45"; but the sidereal, or return to the same star, 365 6 9 11; and the anomalistic revolution is - 365 6 15 20, because the sun's apogee advances each year 65" $\frac{1}{2}$ with respect to the equinoxes, and the sun cannot arrive at the apogee till he has passed over the 65" $\frac{1}{2}$ more than the revolution of the year answering to the equinoxes. To find the anomalistic revolution, say, As the whole secular motion of a planet minus the motion of its aphelion, is to 100 years or 3155760000 seconds, so is 360 degrees, to the duration of the anomalistic revolution.

ANO'MALOUS, *adj.* [*anomale*, Fr. *anomalus*, Lat. of *ανωμαλ*, of *a* priv. and *ομαλ*, equal, Gr.] Irregular; out of rule; deviating from the general method or analogy of things. It is applied, in grammar, to words deviating from the common rules of inflexion: and, in astronomy, to the seemingly irregular motions of the planets.—Metals are gold, silver, copper, tin, lead, and iron: to which we may join that *anomalous* body, quicksilver or mercury. *Locke.*

ANO'MALOUSLY, *adv.* Irregularly; in a manner contrary to rule.—Eve was not solemnly begotten, but suddenly framed, and *anomalously* proceeded from Adam. *Brown.*

ANO'MALY, *f.* in astronomy, is an irregularity in the motion of a planet, by which it deviates from the aphelion or apogee; or it is the angular distance of the planet from the aphelion or apogee; that is, the angle formed by the line of the apses, and another line drawn through the planet. Kepler distinguishes three kinds of anomaly; *mean*, *eccentric*, and *true*.

Mean or *Simple Anomaly*, in the ancient astronomy, is the distance of a planet's mean place from the apogee; which Ptolemy calls the angle of the mean motion. But, in the modern

perpendicular to the transverse axis AB, and meet the circle in D described on the same axis; then the mean anomaly may also be represented by the circular trilineal ASD, which is always proportional to the elliptic one ASP. Or, drawing SG perpendicular to the radius DC produced; then the mean anomaly is also proportional to SG + the circular arc AD, as is demonstrated by Keil, in his *Leß. Astron.* Hence, taking $DH = SG$, the arc AH, or angle ACH, will be the mean anomaly in practice, as expressed in degrees of a circle, the number of those degrees being to 360° , as the elliptic trilineal area ASP, is to the whole area of the ellipse; the degrees of mean anomaly, being those in the arc AH, or angle ACH.

Eccentric Anomaly, or of the centre, in the modern astronomy, is the arc AD of the circle ADB intercepted between the apsis A and the point D determined by the perpendicular DPE to the line of the apses, drawn through the place P of the planet. Or it is the angle ACD at the centre of the circle. Hence the eccentric anomaly is to the mean anomaly, as AD to AD + SG, or as AD to AH, or as the angle ACD to the angle ACH.

True or Equated Anomaly, is the angle ASP at the sun, which the planet's distance AP from the aphelion appears under; or the angle formed by the radius vector or line SP drawn from the sun to the planet, with the line of the apses. The true anomaly being given, it is easy from thence to find the mean anomaly. For the angle ASP, which is the true anomaly, being given, the point P in the ellipse is given, and thence the proportion of the area ASP to the whole ellipse, or of the mean anomaly to 360° degrees. And for this purpose, the following easy rules for practice are deduced from the properties of the ellipse, by M. de la Caille, in his *Elements of Astronomy*, and M. de la Lande, art. 1240, &c. of his *Astronomy*. 1st, As the square root of SB the perihelion distance, is to the square root of SA the aphelion distance, so is the tangent of half the true anomaly ASP, to the tangent of half the eccentric anomaly ACD. 2d, The difference DH or SG between the eccentric or mean anomaly, is equal to the product of the eccentricity CS, by the sine of SCG the eccentric anomaly just found. And in this case, it is proper to express the eccentricity in seconds of a degree, which will be found by this proportion, as the mean distance 1 : the eccentricity :: 206264.8 seconds, or $57^\circ 17' 44'' .8$, in the arc whose length is equal to the radius, to the seconds in the arc which is equal to the eccentricity CS; which being multiplied by the sine of the eccentric anomaly, to radius 1, as above, gives the seconds in SG, or in the arc DH, being the difference between the mean and eccentric anomalies. 3d, To find the radius vector SP, or distance of the planet from the sun, say either, As the sine of the true anomaly is to the sine of the eccentric anomaly, so is half the less axis of the orbit, to the radius vector SP; or, as the sine of half the true anomaly is to the sine of half the eccentric anomaly, so is the square root of the perihelion distance SB, to the square root of the radius vector or planet's distance SP.

But, the mean anomaly being given, it is not so easy to find the true anomaly, at least by a direct process. Kepler, who first proposed this problem, could not find a direct way of resolving it, and therefore made use of an indirect

one, by the rule of false position, as may be seen page 695 of Kepler's *Epitome Astron.* Copernic. See also §. 623 of Wolfius *Elem. Astron.* Now the easiest method of performing this operation, would be to work first for the eccentric anomaly, viz. assume it nearly, and from it to assume compute what would be its mean anomaly by the rule above given, and find the difference between this result and the mean anomaly given; then assume another eccentric anomaly, and proceed in the same way with it, finding another computed mean anomaly, and its difference from the given one; and treating these differences as in the rule of position for a nearer value of the eccentric anomaly: repeating the operation till the result comes out exact. Then, from the eccentric anomaly, thus found, compute the true anomaly by the first rule above laid down.

Of this problem, Dr. Wallis first gave the geometrical solution by means of the protracted cycloid; and Sir Isaac Newton did the same at prop. 31. lib. 1. Princip. But, these methods being unfit for the purpose of the practical astronomer, various series for approximation have been given, viz. several by Sir Isaac Newton, in his "*Fragmenta Epistolæ*," page 26, as also in the Schol. to the prop. above-mentioned, which is his best, being not only fit for the planets, but also for the comets, whose orbits are very eccentric. Dr. Gregory, in his *Astron.* lib. 3. has also given the solution by a series, as well as M. Reyneau, in his "*Analyse Démontrée*," page 713, &c. And a better still for converging is given by Keil, in his "*Prælect. Astron.*" page 375; he says, if the arc AH be the mean anomaly, calling its sine e , cosine f , the eccentricity g , also putting $z = ge$, and $a = 1 + fg$; then the eccentric anomaly

AD will be $= \frac{\tau z}{a} \times (1 - \frac{z^2}{a^2} \&c.)$ supposing $\tau = 57^\circ 29' 57'' .8$

degrees; of which the first term $\frac{\tau z}{a}$ is sufficient for all the planets, even for Mars itself, where the error will not exceed the 200th part of a degree; and in the orbit of the earth, the error is less than the 10000th part of a degree.

Dr. Seth Ward, in his "*Astronomia Geometrica*," takes the angle AFP at the other focus, where the sun is not, for the mean anomaly, and thence gives an elegant solution. But this method is not sufficiently accurate when the orbit is very eccentric, as in that of the planet Mars, as is shewn by Bullialdus, in his defence of the Philolaic. Astron. against Dr. Ward. However, when Newton's correction is made, as in the Schol. above-mentioned, and the problem resolved according to Ward's hypothesis, Sir Isaac affirms that, even in the orbit of Mars, there will scarcely ever be an error of more than one second.

ANO'MIA, *f.* in zoology, a genus of insects belonging to the order of vermes testacea. The shell is bivalve, and the valves are unequal. One valve is perforated near the hinge; affixed by that perforation to some other body. There are twenty-five species of the anomia; of which only two are natives of the British seas, viz. 1. The ephippium, with the habit of an oyster; the one side convex, the other flat; perforated; adherent to both bodies, often to oyster-shells, by a strong tendinous ligature; colour of the inside perlaceous. Size, near two inches diameter. 2. The squammula, with shells resembling the scales of fish; very delicate and silvery; much flattened; perforated; very small. Adheres to oysters, crabs, lobsters, and shells. The species of this genus are commonly called *beaked cochles*. No name has been given to the fish that inhabit it; for the recent shells of this kind are so very rare, that there is scarcely one to be found perfect. They are perhaps, as well as that which has given its form to the *corru ammonis*, inhabitants of the deepest part of the ocean; consequently it must be some extraordinary agitation of that great body of water that can bring them at all to our knowledge in their recent state. The fossil species of the anomia genus are uncommonly numerous in this island, in our chalk-

pits and limestone-quarries; and, in Gloucestershire, they are as common on the ploughed lands as pebbles in other places.

ANOMOE'ANS, *f.* in ecclesiastical history, the name by which the pure Arians were called in the fourth century, in contradiction to the Semi-Arians. The word is formed from the Greek, *ἀνομοι*, different, dissimilar: for the pure Arians asserted, that the Son was in nature different from, and in nothing like, the Father; whereas the Semi-Arians acknowledged a likeness of nature in the Son; at the same time that they denied, with the pure Arians, the consubstantiality of the world. The Semi-Arians condemned the Anomoeans in the council of Se-lencia; and the Anomoeans, in their turn, condemned the Semi-Arians in the councils of Constantinople and Antioch, erasing the word *ἀνομοι*, like, out of the Formula of Rimini and that of Constantinople.

ANOMORHOMBOIDIA, *f.* in natural history, the name of a genus of spars; the word is derived from the Greek *ἀνωμαλῆς*, irregular, and *ρομβοειδής*, a rhomboidal figure. The bodies of this genus are pellucid crystalline spars of no determinate or regular external form, but always breaking into regularly rhomboidal masses; easily fissile, and composed of plates running both horizontally and perpendicularly through the masses, but cleaving more readily and evenly in an horizontal than in a perpendicular direction; the plates being ever composed of irregular arrangements of rhomboidal concretions. Of this genus there are five known species. 1. A white, bright, and shattery, one; found in great quantities in the lead-mines of Derbyshire, Yorkshire, and Wales. 2. A milk-white, opaque, and shattery, one, found in some parts of France, and very plentifully in Germany, and sometimes in Wales and Scotland, and in the hills of Yorkshire. 3. A hard, dull, and snow-white, one, found in some of the mines in Derbyshire, and in many of our northern counties. 4. A hard, grey, and pellucid, one, found in the lead-mines of Yorkshire, and very common in Germany. And, 5. A pellucid and colourless one, found in the lead-mines of Derbyshire and Yorkshire. All these, in some degree, have their double refraction of the island crystal. See **ISLAND-CRYSTAL**.

ANOM'PHALOUS, *adj.* [of *α* and *ὀμφαλ*, a navel, Gr.] Without a navel, as it is supposed our first parents were created, not wanting nourishment in the womb that way.

A'NOMY, *f.* [of *α* priv. and *νομ*, Gr.] Breach of law.—If sin be good, and just, and lawful, it is no more evil, it is no sin, no *anomy*. *Bramhall*.

ANON', *adv.* [Junius imagines it to be an elliptical form of speaking for *in one*, that is, *in one minute*; Skinner from *a* and *anon*, or *near*; Minshew from *on on*.] Quickly; soon; in a short time.—He was not without design at that present, as shall be made out *anon*; meaning by that device to withdraw himself. *Clarendon*. Sometimes; now and then; at other times. In this sense is used *ever and anon*, for now and then:

Full forty days he pass'd, whether on hill
Sometimes, *anon* in shady vale, each night,
Or harbour'd in one cave, is not reveal'd. *Milton*.

ANO'NA, *f.* in botany. See **ACHRAS**, **ANNONA**, **CHRISOPHYLLUM**, **CRATÆVA**, **SLOANEA**.

ANO'NIS, *f.* in botany. See **GLYCINE**, **HEDISARUM**, **ONONIS**, **SOPHORA**.

ANO'NYMOUS, *adv.* [of *α* priv. and *ὄνομα*, nameless, Gr.] Something that is nameless, or of which the name is concealed. It is a term usually applied to books which do not express the author's name, or to authors whose names are unknown.

ANONYMOUS, in law. The sending anonymous letters demanding money, &c: is felony by the black act, 9 Geo. I. cap. 22. See **LETTER**.

ANO'NYMOUSLY, *adv.* Without a name.—I would know whether the edition is to come out *anonymously*, among complaints of spurious editions.

ANOREX'IA, or **AN'OREXY**, *f.* [from *α* neg. and *ὄρεξις*, appetite, Gr. also *ἀποψitia*, *ψitia*.] A want of appetite, without loathing of food. See **MEDICINE**.

ANOS'MIA, *f.* [from *α*, non, and *ὀσμη*, odour, Gr.] A diminution or loss of smelling. See **MEDICINE**.

ANOS'SI, a province of the island of Madagascar, lying between lat. 23. 18. and 26. 0. S. It is watered by many rivers, most of which run into the *Franchere*, *Ramcavate*, or *Immour*, the spring of which is in a mountain called *Mang-hage*, and discharges itself into the sea in lat. 25. 18. S. The mouth of this river is often stopped, and the course to the sea interrupted, unless kept open by the overflowings of great rains and high tides. Next in size to the *Franchere* is the *Manghofia*, which springs from a mountain called *Siliva*, and empties itself into the sea, where large ships may ride at anchor. Crocodiles breed in these and all the other rivers of the island. Between the two rivers lies Cape St. Romain, half a mile distant from the mouth of the *Franchere*. When the Cape is passed, the coast forms a great bay, which extends to the mouth of the river called *Dian Panouge* or *Pitorah*. In the middle of this bay the land runs out, and almost forms a peninsula called *Tholangare*. Fort Dauphin lies to the north of this peninsula, and Port Dauphin over-against it. The country is beautiful; abounds in fruit-trees; is fertile in pasture for cattle; and, if carefully cultivated, would produce all the necessaries of life. It is surrounded by high mountains, which are covered with woods and shrubs; but, about four miles distant from Fort Dauphin, the adjacent hills are quite destitute of verdure. The French often dug in this neighbourhood for mines of gold and silver, particularly in one mountain, where several springs flow near each other and empty themselves into a neighbouring river. In this river they found several stones and heaps intermixed with yellow clay, with a great quantity of black and white spangles shining like silver, which they carefully pounded and washed, but without effect. About sixty yards above these springs the grass, and every sort of vegetable, appears half dried and yellow, from a metalline sulphur, which gives that aspect; but the top of the mountain is covered with a fresh and beautiful verdure. It is said that the Portuguese found gold at the foot of this mountain on the north side, but that the place they had dug was filled up by the chiefs of the country after the Portuguese had been driven out.

The province of Anossi is inhabited by three different sorts of whites, and four sorts of negroes. The whites are distinguished by the names of *Rohandrians*, *Anacandrians*, and *Ondzatsi*. The whites are distinguished from the negroes by the general name of *Zaferamina*, or *Rahimini*; and the Rohandrians are distinguished above the other whites. When they proceed to an election of a sovereign, whom they call *Ompiandrian*, or *Dian Bahouache*, he is chosen from the Rohandrian race. Next to him the others hold the rank of princes, and are honoured as such by all the rest of the subjects. The Anacandrians are descendants of the chiefs, but who have degenerated, and are accounted the bastards of princes, or those who are descended from a Rohandrian and any inferior white or black woman. These are likewise called by the name of *Ontempassemaca*, or people from the sandy parts of Mecca, from whence, they say, came the Rohandrians. Both the Rohandrians and Anacandrians wear long hair, which hangs down in curls; and enjoy the privilege of killing beasts. The Ondzatsi, or lowest class of whites, are descended from the bastards of the Anacandrians. These are all fishermen, and are allowed to kill no land animal except a chicken.

The four classes of negroes are named *Voadziri*, *Lohavohits*, *Ontsoa*, and *Ondeves*. The Voadziri, the most powerful and the richest, are masters of several villages, and descended from the aborigines of the country. They enjoy the privilege of killing beasts, when at a distance from the whites, and no Rohandrian or Anacandrian in the village. The Lohavohits are descendants from the Voadziri, and also lords; but with this difference, that the one commands

mands a whole district, and the jurisdiction of the others extends only to their own village and family. They are also permitted to kill those beasts they intend to eat, when at a distance from the whites. The Ontsoa are next to the Lohavohits, and are their near relations. The Ondeves are the lowest of all, being originally slaves by father and mother. The inhabitants of this province have no temples, and very little appearance of religion; only they keep up a custom of immolating beasts upon particular occasions, as in sickness, planting yams or rice, on assemblies, &c. They offer the first-born beast to the devil and to God, naming the devil first, in this manner, *Dianbilis Aminhanhabare*, or "Lord Devil and God." There are several towns on the river Franchere; and near this river the Portuguese had a fort built upon a steep rock, and several buildings below, with inclosures, which furnished all forts of necessities for their subsistence; but they were all massacred by the natives.

This province seems originally to have been inhabited by negroes. The whites or Zaferamini settled in it about 250 years ago, and conquered the negroes. But they themselves were conquered by the French, though under the government of a king whom they honoured as a god. In 1642, Captain Rivault obtained a permission to establish a colony in this part of the island; and accordingly he took possession of it in the name of the king of France, in September, that same year. The French landed 200 men, well armed, and provided with store of ammunition and necessities for building a fort, which they immediately set about; but no sooner did the natives observe their intention, than they used their utmost art to prevent their design from taking effect. This created a war, in which the French were victors; and, the natives becoming in time much better reconciled to them, they intermarried, and lived up and down in several towns at some distance from one another, not above five or six in a place. This tranquillity lasted for some years; but at last the natives, growing jealous, resolved to free themselves from a foreign yoke; and accordingly formed a conspiracy to cut off all the French in one day; which they soon after effected, not leaving a single person alive. In 1644, the above-mentioned Fort Dauphin was erected in lat. 25. 6. S. Many buildings were erected behind the fort, adjoining to the governor's house, with great inclosures, that produced every sort of fruit and kitchen herb. In 1656, this fort was accidentally destroyed by fire; but was soon after repaired, and still continues, notwithstanding the catastrophe above-mentioned, and its garrison carries on frequent wars with the natives.

ANOTHER, *adj.* [from *an* and *other*.] Not the same. One more; a new addition to the former number. Any other; any one else.—If one man sin against *another*, the judge shall judge him. 1 *Samuel*, ii. 25.

Why not of her? prefer'd above the rest
By him with knightly deeds, and open love profess'd;
So had *another* been, where he his vows address'd. *Dryden*.

Not one's self. Widely different; much altered.—When the soul is beaten from its station, and the mounds of virtue are broken down, it becomes quite *another* thing from what it was before. *South*.

ANOTHERGAINES, *adj.* Of another kind. This word is found only in Sidney.—If my father had not plaid the haily fool, I might have had *anothergainies* husband than Dametas. *Sidney*.

ANOTHERGUESS, *adj.* [This word, though rarely used in writing, is somewhat frequent in colloquial language: it appears to be corrupted from *another guise*; that is, of a different *guise*, or manner, or form.] Of a different kind.—Oh Hocus! where art thou? It used to go in *anotherguess* manner in thy time. *Arbutnot*.

ANOTTA, or **ARNOTTA**, *f.* in dying, an elegant red colour, formed from the pellicles or pulp of the seeds of the *bixa*, a tree common in South America. It is also called *Terra Orleana*, and *Roucou*.—See **BIXA**. The red

seeds, cleared from the pods, are steeped in water for seven or eight days, or longer, till the liquor begins to ferment; then strongly stirred, stamped with wooden paddles and beaters, to promote the separation of the red skins: this process is repeated several times, till the seeds are left white. The liquor, passed through close canesieves, is pretty thick, of a deep red colour, and a very ill smell; in boiling, it throws up its colouring matter to the surface in form of scum, which is afterwards boiled down by itself to a due consistence, and made up while soft into balls. The anotta commonly met with among us, is moderately hard and dry, of a brown colour on the outside, and a dull red within. It is difficultly acted upon by water, and tinges the liquor only of a pale brownish-yellow colour. In rectified spirit of wine, it very readily dissolves, and communicates a high orange or yellowish-red. Hence it is used as an ingredient in varnishes, for giving more or less of an orange-cast to the simple yellows. Alkaline salts render it perfectly soluble in boiling water, without altering its colour. Wool or silk boiled in the solution acquire a deep, but not a very durable, orange-dye. Its colour is not changed by alum or by acids, any more than by alkalis: but, when imbibed in cloth, it is discharged by soap, and destroyed by exposure to the air. It is said to be an antidote to the poisonous juice of manioc or cassava. Labat informs us, that the Indians prepare an anotta greatly superior to that which is brought to us, of a bright shining red colour, almost equal to carmine: that, for this purpose, instead of steeping and fermenting the seeds in water, they rub them with the hands, previously dipt in oil, till the pellicles come off, and are reduced into a clear paste; which is scraped from off the hands with a knife, and laid on a clean leaf in the shade to dry. De Laet, in his notes on Margrave's Natural History of Brazil, mentions also two kinds of anotta; one of a permanent crimson colour, used as a fucus or paint for the face; and another which gives a colour inclining more to that of saffron. This last, which is our anotta, he supposes to be a mixture of the first sort with certain resinous matters, and with the juice of the root of the tree. The wax or pulp in which the seeds are inclosed, is a cool agreeable rich cordial, and has been long in use among the Indians and Spaniards in America, who still mix it with their chocolate, both to heighten the flavour and raise the colour. It is said to be a successful remedy in bloody fluxes. The roots have much the same properties with the wax; but these are observed to work more powerfully by the urinary passages: they are used by some people in their broths, and seem to answer all the purposes of the pulp, but in a more faint degree.

ANOUT, a small island in the Schagerrack, or that part of the sea of Denmark which has Norway on the north, Jutland on the west, and the isle of Zealand on the south; it lies in lat. 56. 36. N. lon. 13. 0. E.

AN'SÆ, or **AN'SES**, in astronomy, those seemingly prominent parts of the ring of the planet Saturn, discovered in its opening, and appearing like handles to the body of the planet; from which appearance the name *ansæ* is taken.

ANSA'RIANS, a people of Syria, so called in the country, but styled in Delile's maps *Enfarians*, and in those of Danvill, *Nassaris*. The territory occupied by these Ansaria is that chain of mountains which extends from Antakia to the rivulet called *Nahr-el-Kahir*, or the Great River. The history of their origin, though little known, is yet instructive. The following account is from the *Bibliothèque Orientale* of Affemani, a writer who has drawn his materials from the best authorities. "In the year of the Greeks 1202, (A. D. 891,) there lived at the village of Nasar, in the environs of Koufa, an old man, who, from his fastings, his prayers, and his poverty, passed for a saint: several of the common people declaring themselves his partisans, he selected from among them twelve disciples to propagate his doctrine. But the commandant of the place, alarmed at his proceedings, seized the old

man,

man, and confined him in prison. In this reverse of fortune, his situation excited the pity of a girl who was slave to the gaoler, and she determined to give him his liberty: an opportunity soon offered to effect her design. One day when the gaoler was gone to bed intoxicated, and in a profound sleep, the gently took the keys from under his pillow, and, after opening the door to the old man, returned them to their place unperceived by her master. The next day, when the gaoler went to visit his prisoner, he was extremely astonished at finding he had made his escape, and the more so since the prison-door was locked, and he could perceive no marks of violence. He therefore judiciously concluded he had been delivered by an angel, and eagerly spread the report, to avoid the reprehension he merited: the old man, on the other hand, asserted the same thing to his disciples, and preached his doctrines with more earnestness than ever. He even wrote a book, in which, among other things, he says, 'I have seen Christ, who is the word of God, who is Ahmad, son of Mohammad, son of Hanafa, of the race of Ali; who also is Gabriel: and he said to me, Thou art he who readeth with understanding; thou art the man who speaketh truth; thou art the camel which preserveth the faithful from wrath; thou art the beast which carrieth their burden; thou art the Spirit, and John, the son of Zachary.' Go, and preach to men, that they make four genuflections in praying; two before the rising of the sun, and two before his setting, turning their faces towards Jerusalem.' This old man, passing into Syria, propagated his opinions among the lower orders of the country people, numbers of whom believed in him: and after a few years he went away, and no one ever knew what became of him." Such was the origin of the Ansfarians, who are, for the most part, inhabitants of the mountains before-mentioned.

The Ansfaria are divided into several tribes or sects; among which are distinguished the Shamsia, or adorers of the sun; the Kelbia, or worshippers of the dog; and the Kadimousia, who are said to pay a particular homage to that part in women which corresponds to the priapus. Many of the Ansfaria believe in the metempsychosis; others reject the immortality of the soul; and in general, in that civil and religious anarchy, that ignorance and rudeness, which prevail among them, these peasants adopt what opinions they think proper, following the sect they like best, and frequently attaching themselves to none. Their country is divided into three principal districts, farmed by the chiefs called *Mohaddamim*. Their tribute is paid to the pacha of Tripoli, from whom they annually receive their title. Their mountains are in general not so steep as those of Lebanon, and consequently are better adapted to cultivation; but they are also more exposed to the Turks; and hence, doubtless, it happens, that with greater plenty of corn, tobacco, wines, and olives, they are more thinly inhabited than those of their neighbours, the Maronites and the Druzes.

ANSATED, *adj.* [*ansatus*, Lat.] Having handles; or something in the form of handles.

ANSE, an ancient town of France, in the late Lyonnais, ten miles north of Lyons. Lat. 45. 55. N. lon. 6. 55.

ANSELM, [*Anselm*, Teut. a defender of his companions.] A proper name of men.

ANSELM, archbishop of Canterbury, in the reigns of William Rufus and Henry I. He was born in the year 1033, at Aost, a town in Savoy, at the foot of the Alps. He became a monk in the abbey of Bec, in Normandy; of which he was afterwards chosen prior, and then abbot. In the year 1092, he was invited to England by Hugh earl of Chester; and in the year following was made archbishop of Canterbury. He enjoined celibacy on the clergy; for which he was banished by king Rufus, but recalled by Henry at his coming to the crown. He refused to consecrate such bishops as were invested by the king, according to pope Urban's decree; flatly denying it to be the king's prerogative: for this he was ousted again; till, the pope and king agreeing, he was recalled in 1107. At the coun-

cil of Bari, in the kingdom of Naples, the pope being puzzled by the arguments of the Greeks against the Holy Ghost's proceeding from the Father, he called upon Anselm, who was present, and he discussed their objections with great applause. He wrought many miracles, if we believe the author of his life, both before and after his death, which happened at Canterbury, in the 76th year of his age, anno 1109. He was canonised in the reign of Henry VII. Anselm, though we may disregard him as a saint, deserves to be remembered as one of the principal revivers of literature, after three centuries of profound ignorance. His works have been printed at Nuremb. 1491. Paris, 1544 and 1549. Venice, 1549. Cologne, 1573 and 1612. Lyons, 1630. The best edition is that of father Gerberon, printed at Paris in 1675. It is divided into three parts; the first contains dogmatical tracts, and is intitled *Monologia*; the second contains practical and devotional tracts; the third part consists of letters, in four books.

ANSER, *f.* in ornithology, the trivial name of a species of Anas. See ANAS.

ANSER, in astronomy, a small star, of the fifth or sixth magnitude, in the milky way, between the swan and eagle, first brought into order by Hevelius.

ANSERES, *f.* the name which Linnæus gives to his third order of birds. See ZOOLOGY.

ANSE/RINA, *f.* in botany. See POTENTILLA.

ANSIBA'RII, or ANSIVA'RII, an ancient people of Germany, situated in the neighbourhood of the Chauci. All we know of their history is, that, in the reign of the emperor Nero, they were driven from their own possessions by the Chauci. Being then in a forlorn condition, they took possession of some uninhabited lands, which had been used as pasture for the horses of the Roman soldiers. They were led by one Boiocalus, a man of great valour, and of known fidelity to the Romans. He remonstrated to the Romans, who objected to their taking possession of these lands, That the territory in dispute was large; and requested, that it might be allowed to an unhappy people, driven from their own habitations; that, at the same time, wide tracts might be retained for the horses and cattle of the soldiers to graze in; that it was inconsistent with humanity to famish men in order to feed beasts, &c. and at last, lifting up his eyes to heaven, he asked the celestial luminaries how they could behold a desolate soil, and if they would not more justly let loose the sea to swallow up usurpers, who had engrossed the whole earth? To this the Roman commander, Avitus, replied, That the weakest must submit to the strongest; and, that since the gods, to whom they had appealed, had left the sovereign judgment to the Romans, they were resolved to suffer no other judges than themselves. To Boiocalus himself, however, he privately offered lands, as a reward for his long attachment to the Romans: but this offer the brave German rejected, as a price for betraying his people; adding, "A place to live in we may want, but a place to die in we cannot." The Ansibarii now invited the neighbouring nations to join them against the Romans; but they, dreading the power of that nation, refused to give them any assistance: upon which they applied to the neighbouring nations, begging leave to settle in their territories; but, being every where driven out as enemies and intruders, these unhappy people were reduced to wander up and down, till every one of them perished.

ANSIKO, a kingdom of Africa, bounded on the west by the river Umbre, which runs into the Zaire, the kingdom of Wangua, and the Amboes who border on Loango; on the north, by some deserts of Nubia; and on the south, by Songo and Sonda, provinces of Congo. Here are great numbers of wild beasts, as lions, rhinoceroses, &c. and many copper-mines. The king of Anisiko, or the great Macoco, commands thirteen kingdoms, and is esteemed the most powerful monarch in Africa. The inhabitants of Angola have a tradition, that this is the proper country of the Giagas, who came originally from Sierra Leona, and

over-ran like a torrent the whole coast as far as Benguela; that, being weakened by numerous battles, and unable to force the defiles in order to return to Sierra Leona, they arrived on the borders of Monomotapa, where being defeated, they were forced to remain in the provinces of Anfiko. Be this as it will, the Anfikans yield not in the least to the Giagas in fierceness and barbarity. They are cannibals, who try the courage of their prisoners of war by shooting at them as at marks, directing their arrows above or around their heads; and whoever discovers the least signs of fear, is immediately devoured. Those who appear intrepid and resolute, have their noses and ears bored, and two fore-teeth of the upper jaw drawn. They are then improved in brutality, by accustoming them to the most horrid cruelties.

The Anfikans are well-proportioned and strong; wandering about from place to place, without either sowing or reaping. They are dreaded for their extreme brutality, and never traded with by the Europeans. Their language is barbarous, and difficult to be learned, even by the inhabitants of Congo. The most distinguished among them wear red and black caps of Portuguese velvet: the lower ranks go naked from the waist upwards; and anoint their bodies with a composition of pounded white sandal-wood and palm-oil. Their arms are battle-axes, and small but very strong bows, adorned with serpents skins. Their strings are made of supple and tender shoots of trees, that will not break, and their arrows of hard and light wood. These people, who kill birds flying, shoot with such surprising swiftness, that they are said to discharge twenty-eight arrows from the bow before the first falls to the ground. With equal dexterity they manage their battle-axes. The current money in this country is the zimbo or shell, which is fished for, and passes among several African nations. They worship the sun as their chief deity; whom they represent by the figure of a man, and the moon by that of a woman. They have also an infinite number of inferior deities, each individual having a particular idol whom he addresses on certain occasions.

AN'SLO, a sea-port town of Norway, in the province of Aggerhuys, with a bishop's see. The supreme court of justice is held here for Norway. It is seated on a bay of the same name. Lat. 50. 24. N. lon. 16. 14. E.

AN'SON (George), a gentleman whose merit and good fortune, as a naval commander, exalted him to the rank of nobility. He was the son of William Anson, Esq. of Huckborough, in Staffordshire; and, shewing an early inclination for the sea, received a suitable education. The first command he enjoyed was that of the Weazle sloop in 1722; but the most memorable action of his life, and the foundation of his future good fortune, took place on his receiving the command of five ships, a sloop, and two victuallers, equipped to annoy the Spaniards in the South Seas, and to co-operate with admiral Vernon across the isthmus of Darien; an expedition the principal object of which failed by the unaccountable delay in fitting out. He sailed, however, in Sept. 1740; doubled Cape Horn in a dangerous season; lost most of his men by the scurvy; and with only one remaining ship, the Centurion, crossed the great Pacific Ocean. If no considerable national advantage resulted from this voyage, commodore Anson made his own fortune, and enriched his surviving companions, by the capture of a rich galleon on her passage from Acapulco to Manilla; with which he returned home round the Cape of Good Hope. If he was lucky in meeting this galleon, he was no less fortunate in escaping a French fleet then cruising in the channel, by sailing through it during a fog. He arrived at Spithead in June 1744. In a short time after his return, he was appointed rear-admiral of the blue, and one of the lords of the admiralty. In April 1745, he was made rear-admiral of the white, and the following year vice-admiral of the blue; at which time he was chosen to represent the borough of Heydon in parliament. In 1747, being on-board the Prince George of 90 guns, in company with admiral Warren, and twelve other ships, he

intercepted, off Cape Finisterre, a powerful fleet bound from France to the East and West Indies; when, by his valour and conduct, he again enriched himself and his officers, and at the same time strengthened the British navy, by taking six men of war and four East Indiamen, not one of them escaping. The French admiral, M. Jonquiere, on presenting his sword to the conqueror, said, *Monsieur, vous avez vaincu l'Invincible, et la Gloire vous suit*: "Sir, you have conquered the Invincible, and Glory follows you;" pointing to the ships, named the *Invincible* and *Glory*, he had taken. For his signal services, he was created baron of Soberton in Hants. The same year he was appointed vice-admiral of the red; and, on the death of Sir John Norris, was made vice-admiral of England. In 1748 he was made admiral of the blue: he was afterwards appointed first lord of the admiralty, and was at length made admiral and commander in chief of his majesty's fleet; in which rank he continued, with a very short interval, until his death; and the last service he performed was to convoy queen Charlotte to England. He died in June 1762. No performance ever met with a more favourable reception, than the account of Anson's voyage round the world. Though it is printed under the name of his chaplain, it was composed under his lordship's own inspection, and from the materials he himself furnished, by the ingenious Mr. Benjamin Robins.

AN'SPACH (the marquisate of), a small territory of Franconia, in Germany, bounded on the north by the bishoprics of Wartburg and Bamberg, which last likewise lies to the west; by the earldoms of Holach and Oeting, with the bishoprick of Aichstet, on the south; and the palatinate of Bavaria and the territory of Nuremberg on the east. The country is fruitful, and interspersed with woods, which render it agreeable for hunting. Besides the city Anspach, which is the capital, the chief towns are Kreglin, Swabach, Kreilsheim, Rot, and Wasser-Trudung.

ANSPACH is a small but pretty town, very well built, and has several churches. It is walled round, but has no other fortifications. In the palace there is a remarkable cabinet of curiosities. It is seated on a river of the same name, and belongs to the house of Brandenburg. Lat. 49. 14. N. long. 10. 42. E.

ANSPESSA'DES, in the French armies, a kind of inferior officers in the foot, below the corporals, but above the common centinels. There are usually four or five of them in a company.

ANSTRUTHER *East* and *West*, two royal boroughs of Scotland, situated on the south-east coast of the county of Fife, in lat. 56. 20. N. long. 2. 25. W.

To AN'SWER, *v. n.* [The etymology is uncertain: the Saxons had *andswarian*, but in another sense; the Dutch have *antwoorden*.] To speak in return to a question:

Are we succour'd? are the Moors remov'd?

Answer these questions first, and then a thousand more.

Answer them all together.

Dryden.

To speak in opposition.—No man was able to *answer* him a word. *Matthew*, xxii. 46.—To be accountable for: with *for*.—Some men have sinned in the principles of humanity, and must *answer for* not being men. *Brown*.—To vindicate; to give a justificatory account of; with *for*.—The night, so imprudently fixed for my last, made little impression on myself; but I cannot *answer for* my family. *Swift*.—To give an account.—How they have been since received, and so well improved, let those *answer* either to God or man, who have been the authors and promoters of such wise council. *Temple*.—To correspond to; to suit with.—As in water face *answereth* to face, so the heart of man to man. *Prov.* xxvii. 19.—To be equivalent to; to stand for something else.—A feast is made for laughter, and wine maketh merry: but money *answereth* all things. *Ecc.* x. 19.—To satisfy any claim or petition of right or justice.—Zelmane with rageful eyes bade him defend himself; for no less than his life would *answer* for it. *Sidney*.—To act reciprocally:

Say, dost thou yet the Roman harp command?
Do the strings *answer* to thy noble hand?

Dryden.

To stand as opposite or correlative to something else.—There can but two things create love, perfection and usefulness; to which *answer*, on our part, 1. Admiration; and, 2. Desire: and both these are centered in love. *Taylor.*—To bear proportion to.—Weapons must needs be dangerous things, if they *answered* the bulk of so prodigious a person. *Swift*—To perform what is endeavoured or intended by the agent.—Our part is, to choose out the most deserving objects, and the most likely to *answer* the ends of our charity; and, when this is done, all is done that lies in our power: the rest must be left to Providence. *Atterbury.*—To comply with:

He dies that touches of this fruit,
Till I and my affairs are *answered*.

Shakespeare.

To succeed; to produce the wished event.—In operations upon bodies for their version or alteration, the trial in great quantities doth not *answer* the trial in small: and so deceiveth many. *Bacon.*—To appear to any call or authoritative summons; in which sense, though figuratively, the following passage may be, perhaps, taken.—Thou wert better in thy grave, than to *answer* with thy uncovered body this extremity of the skies. *Shakespeare.*—To be over-against any thing:

Fire *answers* fire, and, by their paly beams,
Each battle sees the other's umber'd face.

Shakespeare.

AN'SWER, *f.* That which is said, whether in speech or writing, in return to a question, or position.—How can we think of appearing at that tribunal, without being able to give a ready *answer* to the questions which he shall then put to us, about the poor and the afflicted, the hungry and the naked, the sick and imprisoned? *Atterbury.* An account to be given to the demand of justice. In law, a confutation of a charge exhibited against a person.—A personal *answer* ought to have three qualities; it ought to be pertinent to the matter in hand; it ought to be absolute and unconditional; it ought to be clear and certain. *Ayliffe.*

AN'SWER-JOBBER, *f.* [from *answer* and *jobber*.] He that makes a trade of writing answers.—What disgusts me from having any thing to do with *answer-jobbers*, is, that they have no conscience. *Swift.*

ANSWERABLE, *adj.* [from *answer*.] That to which a reply may be made; that which may be answered; as, the argument, though subtle, is yet *answerable*. Obligated to give an account; obliged to answer any demand of justice; or stand the trial of an accusation.—Will any man argue, that if a physician should manifestly prescribe poison to all his patients, he cannot be justly punished, but is *answerable* only to God? *Swift.*—Correspondent.—The daughters of Atlas were ladies who, accompanying such as came to be registered among the worthies, brought forth children *answerable* in quality to those that begot them. *Raleigh.*—Proportionate; suitable:

Only add

Deeds to thy knowledge *answerable*; add faith,
Add virtue, patience, temperance; add love,
By name to come call'd charity, the soul
Of all the rest.

Milton.

Suitable; suited. Equal; equivalent.—There be no kings whose means are *answerable* unto other men's desires. *Raleigh.*—Relative; correlative.—That, to every petition for things thankful, there should be some *answerable* sentence of thanks provided particularly to follow, is not requisite. *Hooker.*

ANSWERABLY, *adv.* In due proportion; with proper correspondence; suitably.—The broader seas are, if they be entire, and free from islands, they are *answerably* deeper. *Brewster.*

ANSWERABLENESS, *f.* The quality of being answerable.

ANSWERER, *f.* He that answers; he that speaks in return to what another has spoken.—I know your mind, and will satisfy it; neither will I do it like a niggardly *answerer*, going no farther than the bounds of the question. *Sidney.*—He that manages the controversy against one that has written first.—It is very unfair in any writer to employ ignorance and malice together; because it gives his *answerer* double work. *Swift.*

ANT, in zoology. See FORMICA, and TERMES.

ANT-BEAR, or Ant-eater, in zoology. See MYRMECOPHAGA.

ANT-EGGS, a name popularly given to a kind of little white balls found in the banks or nests of ants, supposed to be the ova of this insect. Later naturalists, however, have observed, that these are not properly the ants eggs, but the young brood themselves in their first state; they are so many little vermiculi wrapped up in a film, or skin, composed of a sort of silk, which they spin out of themselves as silk-worms and caterpillars do. At first they are hardly observed to stir: but, after a few days continuance, they exhibit a feeble motion of flexion and extension; and begin to look yellowish and hairy, shaped like small maggots, in which shape they grow up till they are almost as big as ants. When they pass their metamorphosis, and appear in their proper shape, they have a small black speck on them close to the anus of the inclosed ant, which M. Leeuwenhoek probably enough imagines to be the feces voided by it. These supposed ants eggs are brought up every morning in summer, near the top of the bank, where they are lodged, all the warm part of the day, within reach of the sun's influence. At night, or if it be cool, or likely to rain, they carry them down to a greater depth; so that you may dig a foot deep before you come at them. The true ants eggs are the white substance which, upon opening their banks, appears to the eye like the scatterings of fine white sugar, or salt, but very soft and tender. Examined by a microscope, it is found to consist of several pure white appearances, in distinct membranes, all figured like the smaller sort of birds eggs, and as clear as a fish's bladder.

ANT-HILLS, are little hillocks of earth, which the ants throw up for their habitation and the breeding of their young. They injure dry pastures, not only by wasting so much land as they cover, but by hindering the scythe in mowing the grass, and yielding a poor hungry food pernicious to cattle. The usual manner of destroying these hills is to cut them into four parts from the top, and then dig into them so deep as to take out the core below, so that, when the turf is laid down again, it may lie somewhat lower than the level of the ground; by this means it will be wetter than the rest of the land; and this will prevent the ants from returning to the same place, which otherwise they would certainly do. The earth that is taken out must be scattered to a great distance, otherwise they will collect it together and make another hill just by. The proper time for doing this is in winter. Human dung is a better remedy than all these, as is proved by experiment; for it will kill great numbers of them, and drive all the rest away, if only a small quantity of it be put into their hills. A considerable reward was lately given to M. Tatin, at Paris, for the invention of the following composition to destroy ants, caterpillars, &c. Take of black soap, of the best quality, 1½ lb. flowers of sulphur, 1½ lb. mushrooms, of any kind, 2 lb. river or rain water, 15 gallons. Divide the water into two equal parts; pour one part into a barrel, of any convenient size, which should be used only for this purpose; let the black soap be stirred in till it is dissolved, and then add to it the mushrooms, after they have been slightly bruised. Let the remaining half of the water be made to boil in a kettle; put the whole quantity of sulphur into a coarse open cloth, tied up, with a stone or other weight, to make it sink to the bottom. During twenty minutes (being the time the boiling should continue) stir it well with a stick, and let the packet of sulphur be squeezed, so as to make it yield

to the water all its power and colour. The water, when taken off the fire, is to be poured into the barrel, containing the other half; where it is to be stirred for a short time with a stick; this stirring must be repeated every day, until the mixture becomes fetid in the highest degree. When we wish to make use of this water, we need only sprinkle it, or pour it, upon the plants, or plunge their branches into it. Ants, caterpillars, beetles, bed-bugs, *aphides*, and many other insects, are killed by a single injection of this water. Insects which live under ground, those which have a hard shell, hornets, wasps, &c. require to be gently and continually injected, till the water has penetrated to the bottom of their abode. Ant-hills, particularly, require two, four, six, or eight, quarts of water, according to the size and extent of the ant-hill, which should not be disturbed till twenty-four hours after the operation. If the ants which happen to be absent should assemble, and form another hill, it must be treated in the way before mentioned. We may advantageously add to the mixture two ounces of *nux vomica*, which should be boiled with the sulphur; the water, by this means, will acquire more power, particularly if used for destroying ants. When all the water has been made use of, the sediment should be thrown into a hole dug in the ground, lest the poultry, or other domestic animals, should eat it.

AN'T, a contraction for *and it*, or rather, *and if it*; as, *a'nt please you*; that is, *and if it please you*.

AN'TA, in the ancient architecture, a square pilaster, placed at the corners of buildings.

ANTA, of *Ante*, a small kingdom on the gold-coast of Africa, extending about ten leagues in length. The soil is exceedingly rich, and the face of the country beautiful. The air is also much more salubrious than in most other places of the gold-coast; it being observed by all writers, that the number of deaths here bears no proportion to that on any other part of the coasts of Guinea. This country contains the following villages, which deserve a particular description on account of the commerce they carry on; viz. *Bourtrey*, *Tokorari*, *Sukooda*, and *Sama*. Formerly Anta was potent and populous, inhabited by a bold and rapacious people, who greatly annoyed the Europeans by their frequent incursions; but, by continual wars with their neighbours, they are now greatly enfeebled, and the country is in a manner depopulated.

ANTÆUS, in fabulous history, a giant of Libya, son of Neptune and Terra. Designing to build a temple to his father, of men's skulls, he slew all he met; but Hercules fighting him, and perceiving the assistance he received from his mother (for by a touch of the earth he refreshed himself when weary), he lifted him up from the ground, and squeezed him to death.

ANTÆUS, was king of Mauritania; and from several circumstances, with which we are supplied by various authors, it appears extremely probable that he was the same person with Atlas: they were both of them the sons of Neptune, who reigned over Mauritania, Numidia, and a great part of Libya. They both ruled with absolute power over a great part of Africa, particularly Tingitania. Hercules defeated and slew Antæus in the fame war wherein he took the Libyan world from Atlas: both Atlas and Antæus invaded Egypt, and contended with Hercules in the wars with the gods, and were both vanquished by him. Antæus, as well as Atlas, was famed for his knowledge in the celestial sciences: from whence we may fairly conclude them to have been the same king of Mauritania. Antæus, in his wars with Hercules, who commanded an army of Egyptians and Ethiopians, behaved with great bravery and resolution. Receiving large reinforcements of Libyan troops, he cut off vast numbers of Hercules's men: but that celebrated commander, having at last intercepted a strong body of Mauritanian or Libyan forces sent to the relief of Antæus, gave him a total overthrow, wherein both he and the best part of his forces were put to the sword. This decisive action put Hercules in possession of

Libya and Mauritania, and consequently of all the riches in those kingdoms; hence arose the fable, that Hercules finding Antæus, a giant of an enormous size, with whom he was engaged in single combat, to receive fresh strength as often as he touched his mother earth when thrown upon her, at last lifted him up in the air and squeezed him to death. Hence likewise may be deduced the fable, intimating, that Hercules took Atlas's globe upon his own shoulders, overcame the dragon that guarded the orchards of the Hesperides, and made himself master of all the golden fruit. The golden apples, so frequently mentioned by the old mythologists, were the treasures that fell into Hercules's hands upon Antæus's defeat, the Greeks giving the Oriental word *ἄντα* riches, the signification affixed to their own term, *ἄντα*, apples. After the most diligent and impartial examination of all the different hypotheses of historians and chronologers, relating to Atlas and Antæus, we find none so little clogged with difficulties as that of Sir Isaac Newton. According to that illustrious author, Ammon, the father of Sefac, was the first king of Libya, or that vast tract extending from the borders of Egypt to the Atlantic Ocean; the conquest of which country was effected by Sefac in his father's life-time. Neptune afterwards excited the Libyans to a rebellion against Sefac; slew him; and then invaded Egypt under the command of Atlas or Antæus, the son of Neptune, Sefac's brother and admiral. Not long after, Hercules, the general of Thebais and Ethiopia for the gods or great men of Egypt, reduced a second time the whole continent of Libya, having overthrown and slain Antæus near a town in Thebais, from that event called Antæa or Antæopolis: this is the notion advanced by Sir Isaac Newton, who endeavours to prove, that the first reduction of Libya by Sefac happened a little above a thousand years before the birth of Christ, as the last by Hercules did some few years after.

ANTAGOGÉ, in rhetoric, a figure by which, when the accusation of the adversary is unanswerable, we load him with the same or other crimes.

ANTAGONIST, *f.* [*antagoniste*, Fr. *antagonista*, Lat. of *ανταγωνιστης*, of *αντι*, against, and *αγωνισμα*, to strive, Gr.] One who contends with another; an opponent. It implies generally a personal and particular opposition.—It is not fit that the history of a person should appear till the prejudice both of his *antagonists* and adherents be softened and subdued. *Addison*.—Contrary.—The short club consists of those who are under five feet; ours is to be composed of such as are above six. These we look upon as the two extremes and *antagonists* of the species; considering all these as neutrals, who fill up the middle space. *Addison*.

ANTAGONIST MUSCLES, in anatomy, those which have opposite functions; as flexors and extensors, abductors and adductors, &c.

To ANTAGONIZE, *v. n.* [from *αντι* and *αγωνιζω*.] To contend against another.

ANTALGIC, *adj.* [from *αντι*, against, and *αλγη*, pain.] That which alluages pain; anodyne.

ANTANACLASIS, *f.* [Lat. from *αναντακλασις*, from *αναντακλω*, Gr. to drive back.] A figure in rhetoric, when the same word is repeated in a different, if not in a contrary, signification; as, *In thy youth learn some craft, that in old age thou mayest get thy living without craft.* *Craft*, in the first place, signifies science or occupation; in the second, deceit or subtilty. It is also a returning to the matter at the end of a long parenthesis; as, *Shall that heart (which does not only feel them, but hath all motion of his life placed in them), shall that heart, I say, &c.*

ANTANISOPHYLLUM, *f.* in botany. See BOERHAAVIA.

ANTANDROS, a city and port of Troas, where Æneas built his fleet after the destruction of Troy. There is a hill in its neighbourhood called Alexandria, where Paris sat, as some suppose, when the three rival goddesses appeared before him contending for the prize of beauty. It takes its name from Antandros, a general of the Eolians. It is now called *S. Dimitri*.

ANTAPHRODITIC,

ANTAPHRODITIC, *adj.* [from *αντι*, against, and *Αφροδιτη*, Venus.] That which is efficacious against the venereal disease. That which is proper to diminish the semen, and consequently extinguish or lessen all desires of venery.

ANTAPODOSIS, *f.* [*ανταποδοσις*, of *αντι*, *απο*, and *διδωμι*, Gr.] The counterpart or latter clause of a similitude, answering to the former.

ANTAPOPLECTIC, *adj.* [*αντι*, against, and *αποπληξις*, Gr. an apoplexy.] Good against apoplexy.

ANTARCTIC POLE, [*antarcticque*, F. *antarcticus*, L. of *ανταρκτικος*, of *αντι*, against, or opposition to, and *αρκτικος*, northern, Gr.] denotes the southern pole, or southern end of the earth's axis.—The stars near the antarctic pole never appear above our horizon in these latitudes:

They that had sail'd from near the antarctic pole,
Their treasure safe, and all their vessels whole,
In sight of their dear country ruin'd be,
Without the guilt of either rock or sea.

Waller.

ANTARCTIC CIRCLE, is a small circle parallel to the equator, at the distance of $23^{\circ} 28'$ from the antarctic or south pole.—At one time of the year the sun never rises above the horizon of any part within this circle; and at other times he never sets.

ANTARES, in astronomy, the scorpion's heart; a fixed star of the first magnitude, in the constellation *Scorpio*.

ANTARTHRETIC, *adj.* [*αντι*, against, and *αρθριτις*, Gr. the gout.] Good against the gout.

ANTASTHMATIC, *adj.* [from *αντι* and *ασθμα*, Gr.] Good against the asthma.

ANTAVARE, a province of the island of Madagascar, lying about $21^{\circ} 30'$ S. lat. and bounded by the province and cape of Manoufi. The greatest part of it is watered by the river Mananzari, whose source is in the red mountains of Ambohitimene.

AN'TE, in heraldry, denotes that the pieces are let into one another in such a form as there is expressed; for instance, by dove-tails, rounds, swallow-tails, or the like.

AN'TE, a Latin particle signifying *before*, which is frequently used in compositions; as, *antediluvian*, before the flood; *antechamber*, a chamber leading into another apartment.

AN'TEACT, *f.* [from *ante* and *act*, Lat.] A former act.

ANTEAMBULATION, *f.* [from *ante* and *ambulatio*, Lat.] A walking before.

ANTECANIS, is used by some astronomers, to denote the constellation otherwise called *canis minor*, or the star *procyon*. It is so called, as preceding or being the forerunner of the *canis major*, and rising a little before it.

To **ANTECE'DE**, *v. n.* [from *ante*, before, and *cedo*, Lat. to go] To precede; to go before.—It seems consonant to reason, that the fabric of the world did not long *anteced* its motion. *Hale*.

ANTECE'DENCE, *f.* The act or state of going before; precedence.—It is impossible that mixed bodies can be eternal, because there is necessarily a pre-existence of the simple bodies, and an *antecedence* of their constitution preceding the existence of mixed bodies. *Hale*.

ANTECE'DENCE, in astronomy, is when a planet appears to move contrary to the usual course or order of the signs in the zodiac, as from east to west.

ANTECE'DENT, *adj.* [*antecedens*, Lat.] Going before; preceding. *Antecedent* seems used only with regard to time; *precedent*, with regard both to time and place. It has to before the thing which is supposed to follow.—No one is so hardy as to say, God is in his debt; that he owed him a nobler being: for existence must be *antecedent* to merit. *Collier*.

ANTECE'DENT, *f.* in mathematics, denotes the first of the two terms of a ratio, or that term which is compared with the other. Thus, if the ratio be 2 to 3, or *a* to *b*; then 2 or *a* is the antecedent.

ANTECE'DENT, *f.* That which goes before.—A duty of

fo mighty an influence, that it is indeed the necessary *antecedent*, if not also the direct cause, of a sinner's return to God. *South*.—In grammar, the noun to which the relative is subjoined; as, the *man* who comes hither.—Let him learn the right joining of substantives with adjectives, the noun with the verb, and the relative with the *antecedent*. *Ascham*.—In logic, the first proposition of an enthymeme, or argument consisting only of two propositions.—Conditional or hypothetical propositions are those whose parts are united by the conditional particle *if*; as, *if* the sun be fixed, the earth must move; *if* there be no fire, there will be no smoke. The first part of these propositions, or that wherein the condition is contained, is called the *antecedent*, the other is called the *consequent*. *Watts*.

ANTECE'DENTLY, *adv.* In the state of antecedence, or going before; previously.—We consider him *antecedently* to his creation, while he yet lay in the barren womb of nothing, and only in the number of possibilities. *South*.

ANTECES'SOR, *f.* [Latin.] One that goes before, or leads another; the principal. It was an appellation given to those who excelled in any science. Justinian applied it particularly to professors of civil law; and, in the universities of France, the teachers of law take the title *anteceffores* in all their theses.

ANTECEDENTAL METHOD, is a branch of general geometrical proportion, or universal comparison, and is derived from an examination of the antecedents of ratios, having given consequents, and a given standard of comparison, in the various degrees of augmentation and diminution, which they undergo by composition and decomposition. This is a method invented by Mr. James Glenie, and published by him in 1793; a method which he says he always used instead of the fluxional and differential methods, and which is totally unconnected with the ideas of motion and time. See the author's treatise above-mentioned, and also his *Doctrine of Universal Comparison, or General Proportion*, 1789, upon which it is founded.

ANTECHAMBER, *f.* The chamber that leads to the chief apartment:

The empress has the antechambers past,

And this way moves with a disorder'd haste. *Dryden*.

To **AN'TEDATE**, *v. a.* [from *ante*, and *do*, *datum*, Lat.] To date earlier than the real time, so as to confer a fictitious antiquity.—By reading, a man does, as it were, *antedate* his life, and makes himself contemporary with the ages past. *Collier*. To take something before the proper time:

Our joys below it can improve,

And antedate the bliss above.

Pope.

ANTEDILUVIAN, *adj.* [from *ante*, before, and *deluvium*, Lat. a deluge.] Existing before the deluge.—During the time of the deluge, all the stone and marble of the *antediluvian* earth were totally dissolved. *Woodward*.—Relating to things existing before the deluge.—The text intends only the line of Seth, conduceable unto the genealogy of our Saviour, and the *antediluvian* chronology. *Brown*.

ANTECIANS, or **ANTOECI**, *f.* in geography, the inhabitants of the earth which occupy the same semicircle of the same meridian, but equally distant from the equator, the one north, and the other south; as Peloponnesus and the Cape of Good Hope. These have their noon, or midnight, or any other hour, at the same time; but their seasons are contrary, being spring to the one, when it is autumn with the other; and summer with the one, when it is winter with the other; also the length of the day to the one, is equal to the length of the night to the other.

ANTEDILUVIANS, *f.* a general name for all mankind who lived before the flood, in which are included the whole of the human race from Adam to Noah, and his family. Moses not having set down the particular time of any transaction before the flood, except only the years of the fathers' age wherein the several descendants of Adam

in

in the line of Seth were begotten, and the length of their several lives; it has been the business of chronologers to endeavour to fix the years of the lives and deaths of those patriarchs, and the distance of time from the creation to the deluge. In this there would be little difficulty were there no varieties in the several copies we now have of Moses's writings; which are, the Hebrew, the Samaritan, and the Greek versions of the Septuagint; but, as these differ very considerably from one another, learned men are much divided in their opinions concerning the chronology of the first ages of the world; some preferring one copy, and some another. That the reader may the better judge of the variations with respect to the ages of the patriarchs, in the three copies in this period, they are exhibited in the following table, with the addition of those of Josephus.

AGES OF THE ANTEDILUVIAN PATRIARCHS.

Their ages at their sons' birth.					Years they lived after their sons' birth.		
	Heb.	Sam.	Sept.	Jof.	Heb.	Sam.	Sept.
Adam, -	130	130	230	130	800	800	700
Seth, -	105	105	205	105	807	807	707
Enos, -	90	90	190	90	815	815	715
Cainan, -	70	70	170	70	840	840	740
Mahalaaleel, -	65	65	165	65	830	830	730
Jared, -	162	62	162	62	800	785	800
Enoch, -	65	65	165	65	300	300	200
Methufelah, -	187	67	167	187	782	653	802
Lamech, -	182	53	188	182	595	600	565
Noah, as aged at the flood, }	600	600	600	600			
To the flood,	1656	1307	2262	1556			

How long each of these lived is at once known by respectively adding the age at his sons' birth to the number of years he existed afterwards. Some writers, in order to explain the variations in the lives or ages of the same patriarchs, have added separate chronological tables, shewing in what year of his contemporaries the birth and death of each patriarch happened, according to the computation of each of the three copies alluded to. St. Jerom tells us, that, in his time, there were some copies of the Samaritan Pentateuch which make Methufelah 187 years old at the birth of Lamech, and Lamech 182 at the birth of Noah, just as the Hebrew does. Now, if these numbers be approved as the true original numbers, the interval from the creation to the flood will be 1556 years; differing from the Hebrew computation but 100 years in the age of Jared at the birth of Enoch; and if this last be allowed to be a mistake of the transcriber, by his dropping a number, and writing 62 instead of 162, as has been suspected, the Samaritan will be perfectly reconciled with the Hebrew, and all differences between them will vanish. As to the Septuagint, in the common editions of that version, the age of Methufelah at the birth of Lamech is 167; and consequently the sum of this period, according to them, is no more than 2242. But in this case Methufelah will outlive the flood 14 years; and we may well wonder, with Eusebius, where he was preserved. To obviate this objection, we are told, that, in some copies, Methufelah is said to have lived but 782 (not 802) years after the birth of Lamech, and no more than 949 in all. But the Alexandrian manuscript entirely takes away the difficulty, by giving the same number in this place with the Hebrew. Pezron is of opinion, that the age of Lamech at the birth of Noah should be but 182, as it is both in the Hebrew and in Josephus, supposing, with St. Austin, that the present number is the error of the scribe who first copied the original Septuagint manuscript in Ptolemy's library. So that he computes 2256 years to the flood. And, if this correction be admitted, and one more mentioned also by St. Austin, viz. that Lamech lived 595 years after the birth of Noah, and not 565, as in the present copies, there

there will then remain no other difference between the Septuagint and the Hebrew than 600 years added to the ages of the six patriarchs when they begat their sons, and Methufelah will, conformably to the Hebrew and Samaritan, die in the year of the flood. Having premised this chronological view, we shall proceed to the history of that remote period. The antediluvian world was, in all probability, stocked with a much greater number of inhabitants than the present earth either actually does, or perhaps is capable of containing or supplying. This seems naturally to follow from the great length of their lives, which exceeding the present standard of life in the proportion, at least, of ten to one, the antediluvians must accordingly in any long space of time double themselves, at least in about the tenth part of the time in which mankind do now double themselves. It has been supposed that they began to get children as early, and left off as late, in proportion, as men do now; and that the several children of the same father succeeded as quickly one after another as they usually do at this day; and as many generations, which are but successive with us, were contemporary before the flood, the number of people living on the earth at once would be by that means sufficiently increased to answer any defect which might arise from other circumstances not considered. So that, if we make a computation on these principles, we shall find, that the number of mankind before the deluge would easily amount to above one hundred thousand millions (even according to the Samaritan chronology), that is, to twenty times as many as our present earth has, in all probability, now upon it, or can well be supposed capable of maintaining in its present constitution. With respect to the patriarchal history, and the Mosaic account of the antediluvian world, they are already, it is presumed, so much impressed on the reader's mind, by his acquaintance with the Scriptures, that it would be a needless and unnecessary task to repeat them here. The Jews and eastern nations, however, having recorded many important traditions concerning the antediluvians, which ancient and profane history contributes to support, it may not be uninteresting, nor unacceptable to the reader, to be informed how exactly these accounts agree with those of the sacred historian. They are as follow:

After the death of Adam, Seth, with his family, separated themselves from the profligate race of Cain, and chose for their habitation the mountain where Adam was buried, the Cainites remaining below, in the plain where Abel was killed; and, according to the tradition, this mountain was so high, that the inhabitants could hear the angels singing the praises of God, and even join them in that service. Here they lived in great purity and sanctity of manners. Their constant employment was praising God, from which they had few or no avocations; for their only food was the fruits of the trees which grew on the mountain, so that they had no occasion to undergo any servile labours, nor the trouble of sowing and gathering in their harvest. They were utter strangers to envy, injustice, or deceit. Their only oath was "By the blood of Abel;" and they every day went up to the top of the mountain to worship God, and to visit the body of Adam, as a mean of procuring the divine blessing. Here, by contemplation of the heavenly bodies, they laid the foundations of the science of astronomy; and, lest their inventions should be forgotten, or lost before they were publicly known, understanding, from a prediction of Adam's, that there would be a general destruction of all things, once by fire, and once by water, they built two pillars, one of brick, and the other of stone, that, if the brick one happened to be overthrown by the flood or otherwise destroyed, that of stone might remain. This last, Josephus says, was to be seen in his time in the land of Syriac, (thought to be Upper Egypt.) The descendants of Seth continued in the practice of virtue till the 40th year of Jared, when an hundred of them hearing the noise of the music and the riotous mirth of the Cainites below, agreed to go down to them from the holy mountain. On their arrival in the

plain, they were immediately captivated by the beauty of the women, who were naked, and with whom they defiled themselves; and this is what is meant by the intermarriage of the sons of God with the daughters of men, mentioned by Moses. The example of these apostate sons of Seth was soon followed by others; and from time to time great numbers continued to descend from the mountain, who in like manner took wives from the abandoned race of Cain. From these marriages sprung the giants (who, however, according to Moses, existed before); and these, being as remarkable for their impiety as for their strength of body, tyrannized in a cruel manner, and polluted the earth with wickedness of every kind. This defection became at last so universal, that none were left in the holy mountain, except Noah, his wife, his three sons and their wives.

Berosus, a Chaldean historian, who flourished in the time of Alexander the Great, enumerates ten kings who reigned in Chaldea before the flood; of whom the first, called *Alores*, is supposed to be Adam, and Xifuthrus, the last, to be Noah. This Alorus declared that he held his kingdom by divine right, and that God himself had appointed him to be the pastor of the people. According to this historian, in the first year of the world, there appeared out of the Red Sea, at a place near the confines of Babylon, a certain irrational animal called *Oannes*. He had his whole body like that of a fish: but beneath his fish's head grew another of a different sort (probably a human one). He had also feet like a man, which proceeded from his fish's tail, and a human voice, the picture of him being preserved ever after. This animal conversed with mankind in the day-time, without eating any thing: he delivered to them the knowledge of letters, sciences, and various arts: he taught them to dwell together in cities, to erect temples, to introduce laws, and instructed them in geometry: he likewise shewed them how to gather seeds and fruits, and imparted to them whatever was necessary and convenient for a civilized life; but after this time there was nothing excellent invented. When the sun set, *Oannes* retired into the sea, and continued there all night. He not only delivered his instructions by word of mouth, but, as our author assures us, wrote of the origin of things, and of political economy. This, or a similar animal, is also mentioned by other authors. Of Alasporus, the second king, nothing remarkable is related. His successor, Amelon, or Amillarus, was of a city called *Pantabibla*. In his time another animal resembling the former appeared, 260 years after the beginning of this monarchy. Amelon was succeeded by Metalarus; and he by Daonus, all of whom were of the same city. In the time of the latter, four animals of a double form, half man and half fish, made their appearance. Their names were, *Euedocus*, *Eneugamus*, *Encubulus*, and *Anementus*. Under the next prince, who was likewise of *Pantabibla*, appeared another animal of the same kind, whose name was *Odacon*. All these explained more particularly what had been concisely delivered by *Oannes*.

In the reign of the tenth king, Xifuthrus, happened the great deluge, of which Berosus gives the following account: Cronus, or Saturn, appeared to Xifuthrus in a dream, and warned him, that on the 15th day of the month *Dæsius* mankind would be destroyed by a flood; and therefore commanded him to write down the original, intermediate state, and end, of all things, and bury the writings under ground in Sippara, the city of the sun; that he should also build a ship, and go into it with his relations and dearest friends, having first furnished it with provisions, and taken into it fowls and four-footed beasts; and that when he had provided every thing, and was asked whither he was sailing, he should answer, *To the gods, to pray for happiness to mankind*. Xifuthrus did not disobey; but built a vessel, whose length was five furlongs, and breadth two furlongs. He put on-board all he was directed; and went into it with his wife, children, and friends. The flood being come, and soon ceasing, Xifuthrus let out certain birds, which finding no food, nor place to rest upon, returned again to the ship. Xifuthrus, after some

days, let out the birds again; but they returned to the ship, having their feet daubed with mud: but, when they were let go the third time, they came no more to the ship, whereby Xifuthrus understood that the earth appeared again; and thereupon he made an opening between the planks of the ship, and, seeing that it rested on a certain mountain, he came out with his wife, and his daughter and his pilot: and having worshipped the earth, and raised an altar, and sacrificed to the gods, he and those who went out with him disappeared. They who were left behind in the ship, finding that Xifuthrus and the persons that accompanied him did not return, went out themselves to seek for him, calling him aloud by his name; but Xifuthrus was no more to be seen by them: only a voice came out of the air, which enjoined them, as their duty was, to be religious; and informed them, that on account of his own piety he was gone to dwell with the gods, and that his wife and daughter and pilot were partakers of the same honour. It also directed them to return to Babylon, and that, as the fates had ordained, they should take the writings from Sippara, and communicate them to mankind; and told them that the place where they were was the country of Armenia. When they had heard this, they offered sacrifice to the gods, and unanimously went to Babylon; and, when they came thither, they dug up the writings at Sippara, built many cities, raised temples, and rebuilt Babylon.

The Egyptians, who would give place to no nation in point of antiquity, have also a series of kings, who, as is pretended, reigned in Egypt before the flood; and, to be even with the Chaldeans, began their account the very same year that theirs does according to Berosus. There was an ancient chronicle extant among the Egyptians, not many centuries ago, which contained 30 dynasties of princes who ruled in that country, by a series of 113 generations, through an immense space of 36,525 years, during which Egypt was successively governed by three different races; of whom the first were the *Auritæ*, the second the *Mestrai*, and the third the Egyptians. But this extravagant number of years Manetho, to whose remains we must chiefly have recourse for the ancient Egyptian history, has not adopted, however in other respects he is supposed to have been led into errors in chronology by this old chronicle, which yet seems to have been a composition since Manetho's time.

The account given by Berosus is manifestly taken from the writings of Moses; but we have another account of the first ages of mankind, in which no mention is made of the flood at all. This is contained in some fragments of a Phœnician author called *Sanchoniatho*, who is by some said to have been contemporary with Gideon, by others to have lived in the days of king David; while some boldly assert there never was such a person, and that the whole is a fiction of Philo-Biblius, in opposition to the books of Josephus, written against Apion. To gratify the reader's curiosity, however, we have subjoined an account of the first ten generations mentioned by him, which are supposed by the compilers of the Universal History to correspond to the generations mentioned by Moses before the flood. *Sanchoniatho* having delivered his cosmogony, or generation of the other parts of the world, begins his history of mankind with the production of the first pair of mortals, whom Philo, his translator, calls *Protogonus* and *Æon*; the latter of whom found out the food which was gathered from trees. Their issue were called *Genus* and *Genea*, and dwelt in Phœnicia: but, when the great droughts came, they stretched forth their hands to heaven towards the sun; for him they thought the only God and Lord of heaven, calling him *Beelsamen*, which in Phœnician is *Lord of heaven*, and in Greek *Zeus*.

Afterwards from *Genus*, the son of *Protogonus* and *Æon*, other mortal issue was begotten, whose names were *Phos*, *Pur*, and *Phlox*; that is, *Light*, *Fire*, and *Flame*. These found out the way of generating fire, by the rubbing of pieces of wood against each other, and taught men

the use thereof. They begat sons of vast bulk and height, whose names were given to the mountains on which they seized: so from them were named mount *Cassius*, *Libanus*, *Antilibanus*, and *Brathys*. Of these last were begotten *Memurum*, and *Hypsuranius*; but they were so named by their mothers, the women of those times, who without shame lay with any man they could light upon. *Hypsuranius* inhabited Tyre, and he invented the making of huts of reeds and rushes and the papyrus. He also fell into enmity with his brother *Ufous*, who first invented a covering for his body out of the skins of the wild beasts which he could catch. And, when violent tempests of winds and rains came, the boughs in Tyre, being rubbed against each other, took fire, and burnt the wood there. And *Ufous*, having taken a tree, and broke off its boughs, was so bold as to venture upon it into the sea. He also consecrated two rude stones, or pillars, to fire and wind; and he worshipped them, and poured out to them the blood of such wild beasts as had been caught in hunting. But, when these were dead, those that remained consecrated to them stumps of wood and pillars, worshipping them, and kept anniversary feasts unto them.

Many years after this generation came *Agreus* and *Halicus*, the inventors of the arts of hunting and fishing, from whom huntsmen and fishermen are named. Of these were begotten two brothers, the inventors of iron and of the forging thereof: one of these, called *Chroyfor*, the same with *Hephestus*, or *Vulcan*, exercised himself in words and charms and divinations; found out the hook, bait, and fishing-line, and boats slightly built; and was the first of all men that sailed. Wherefore he also was worshipped after his death for a god: and they called him *Zeus Michius*, or *Jupiter the engineer*; and some say his brothers invented the way of making walls of brick. Afterwards from this generation came two brothers; one of whom was called *Technites*, or the artist; the other, *Gienus Autochthon*, i.e. the home-born man of the earth. These found out to mingle stubble, or small twigs, with the brick-earth, and to dry them in the sun, and so made tiling. By these were begotten others; of which one was called *Agrus*, field; the other *Agroerus*, or *Agrotes*, husbandmen, who had a statue much worshipped, and a temple carried about by one or more yoke of oxen, in Phœnicia, and among those of Byblus he is eminently called the *greatest of the gods*. These found out how to make courts about mens houses, and fences, and caves or cellars. Husbandmen, and such as use dogs in hunting, derive from these; and they are also called *Aletæ* and *Titans*. Of these were begotten *Amynus* and *Magus*, who shewed men to constitute villages and flocks. In these men's age there was one *Eliun*, which imports in Greek *Hypsilus*, i.e. the most high, and his wife was named *Beruth*, who dwelt about Byblus: and by him was begot *Epigerus*, or *Autochthon*, whom they afterwards called *Uranus*, i.e. heaven; so that from him that element which is over us, by reason of its excellent beauty, is called *heaven*: and he had a sister of the same parents called *Ge*, the earth; and by reason of her beauty the earth had her name given to it. *Hypsilus*, the father of these, dying in fight with wild beasts, was consecrated, and his children offered sacrifices and libations to him. But *Uranus*, taking the kingdom of his father, married his sister *Ge*, and had by her four sons; *Ilus*, who is called *Cronus*, or *Saturn*; *Betylus*; *Dagon*, who is *Siton*, or the god of corn; and *Atlas*: but by other wives *Uranus* had much issue.

As to the customs, policy, and other general circumstances, of the antediluvians, we can only form conjectures. The only thing we know as to their religious rites, is, that they offered sacrifices, and that very early, both of the fruits of the earth, and of animals; but whether the blood and flesh of the animals, or only their milk and wool, were offered, is a disputed point.—Of their arts and sciences, we have not much more knowledge. The antediluvians seem to have spent their time rather in luxury and wantonness, to which the abundant fertility of the first

earth invited them, than in discoveries and improvements, which probably they stood much less in need of than their successors. The art of working metals was found out by the last generation of Cain's line; and music, which they might be supposed to practise for their pleasure, was not brought to any perfection, if invented, before the same generation. Some authors have supposed astronomy to have been cultivated by the antediluvians, though this is probably owing to a mistake of *Josephus*. As to their politics and civil constitutions, we have not so much as any circumstances whereon to build conjecture. It is probable, the patriarchal form of government, which certainly was the first, was set aside when tyranny and oppression began to take place, and much sooner among the race of Cain than that of Seth. It seems also, that their communities were but few, and consisted of vastly larger numbers of people than any formed since the flood; or rather, it is a question, whether, after the union of the two great families of Seth and Cain, there were any distinction of civil societies, or diversity of regular governments, at all. It is more likely, that all mankind then made but one great nation, though living in a kind of anarchy, divided into several disorderly associations; which, as it was almost the natural consequence of their having, in all probability, but one common language, so it was a circumstance which greatly contributed to that general corruption which otherwise perhaps could not have so universally overspread the antediluvian world. And for this reason chiefly, as it seems, so soon as the posterity of Noah were sufficiently increased, a plurality of tongues was miraculously introduced at Babel, in order to divide them into distinct societies, and thereby prevent any such total depravation for the future.

Of the condition of the antediluvians, Mr. Whitehurst, in his *Inquiry into the original state and formation of the earth*, has given us the following picture: "Under a mild and serene sky, and when the spontaneous productions of the earth were more than sufficient for the calls of nature, without art or labour, mankind had no need of any other protection from the inclemency of the seasons, nor of barns for winter's store, than the benevolent Author of nature had plentifully provided for them. Consequently, in a state of nature like this, there was no temptation to acts of violence, injustice, fraud, &c. every one having plenty and enough, each equally partook of the numerous blessings thus amply provided for him. Power and property being equally diffused, men lived together in perfect peace and harmony, without law, and without fear; therefore it may be truly said of the antediluvians, that they slept away their time in sweet repose on the ever-verdant turf. Such apparently was the state of nature in the first ages of the world, or from the creation to the first convulsion in nature, whereby the world was not only universally deluged, but reduced to a heap of ruins." But this ingenious author, whose *Inquiry* is not professedly repugnant to revelation, seems here to have lost himself in a pleasing reverie. At least he has forgot to inform us, For what purpose, under such circumstances, he supposes the deluge to have been sent upon the earth; and, How we are to understand the account given by Moses, who represents the antediluvians, not as an innocent race, quietly reposing on the ever-verdant turf, but as a corrupt generation, by whom "the earth was filled with violence."

One of the most extraordinary circumstances which occurs in the antediluvian history, is the vast length of human lives in those first ages, in comparison with our own. Few persons now arrive to eighty or an hundred years; whereas, before the flood, they frequently lived to near a thousand: a disproportion almost incredible, though supported by the joint testimonies of sacred and profane writers. Some, to reconcile the matter with probability, have imagined that the ages of those first men might possibly be computed, not by solar years, but months; an expedient which reduces the length of their lives rather to a shorter period than our own. But for this there is not

the least foundation; besides the many absurdities that would thence follow, such as their begetting children at about six years of age, as some of them in that case must have done, and the contraction of the whole interval between the creation and the deluge to considerably less than two hundred years, even according to the larger computation of the Septuagint. Again: Josephus, the Jewish historian, and some Christian divines, are of opinion, that before the flood, and some time after, mankind in general did not live to such a remarkable age, but only a few beloved of God, such as the patriarchs mentioned by Moses. They reason in this manner: Though the historian records the names of some men whose longevity was singular, yet that is no proof that the rest of mankind attained to the same period of life, more than that every man was then of gigantic stature, because he says, *in those days there were giants upon the earth*. Besides, had the whole of the antediluvians lived so very long, and increased in numbers in proportion to their age, before the flood of Noah, the earth could not have contained its inhabitants, even supposing no part of it had been sea. And had animals lived so long, and multiplied in the same manner as they have done afterwards, they would have consumed the whole produce of the globe, and the stronger would have extinguished many species of the weaker. Hence they conclude, that, for wise and good ends, God extended only the lives of the patriarchs, and a few beside, to such an extraordinary length.

But most writers maintain the longevity of mankind in general in the early world, not only upon the authority of sacred, but likewise of profane, history. And for such a constitution, the moral reasons are abundantly obvious. When the earth was wholly unpeopled, except by one pair, it was necessary to endow men with a stronger frame, and to allow them a longer continuance upon earth for peopling it with inhabitants. In the infant state of every mechanical art, relating to tillage, building, clothing, &c. it would require many years' experience to invent proper tools and instruments to ease men of their labour, and by multiplied essays and experiments to bring their inventions to any degree of maturity and perfection. Every part of their work must have been exceedingly arduous from such a penury and coarseness of tools, and must have required longer time and more strength of body than afterwards, when mechanical knowledge was introduced into the world. If parents at this period had not continued long with their children, to have taught them the arts of providing for themselves, and have defended them from the attacks of wild beasts, and from other injuries to which they were exposed, many families would have been totally extinguished. But one of the best and most valuable ends which longevity would answer was, the transmitting of knowledge, particularly of religious knowledge, to mankind. And thus, before writing was invented, or any such easy and durable mode of conveyance was found out, a very few men served for many generations to instruct their posterity, who would not be at a loss to consult living and authentic records.

The natural causes of this longevity are variously assigned. Some have imputed it to the sobriety of the antediluvians, and the simplicity of their diet; alleging that they had none of those provocations to gluttony, which wit and vice have since invented. Temperance might undoubtedly have some effect, but not possibly to such a degree. There have been many temperate and abstemious persons in later ages, who yet seldom have exceeded the usual period. Others have thought that the long lives of those inhabitants of the old world proceeded from the strength of their stamina, or first principles of their bodily constitutions: which might, indeed, be a concurrent, but not the sole and adequate, cause of their longevity; for Shem, who was born before the deluge, and had all the virtue of the antediluvian constitution, fell three hundred years short of the age of his forefathers, because the greater part of his life was passed after the flood. Others have imputed the longe-

vity of the antediluvians to the excellency of their fruits, and some peculiar virtue in the herbs and plants of those days. But to this supposition it has been objected, that, as the earth was cursed immediately after the fall, its productions we may suppose gradually decreased in their virtue and goodness till the flood; and yet we do not see the length of men's lives decreased considerably, if at all, during that interval. Waving this objection, as the import of the curse is variously interpreted, it appears certain that the productions of the earth were at first, and probably continued till after the deluge, of a different nature from what they were in future times. Buffon supposes this difference may have continued gradually to diminish for many ages subsequent to that catastrophe. The surface of the globe (according to his theory) was in the first ages of the world less solid and compact; because, gravity having only acted for a short time, terrestrial bodies had not acquired their present density and consistence. The surface being more loose and moist, its productions would of course be more ductile and capable of extension: their growth, therefore, and even that of the human body, would require a longer time of being completed. The softness and ductility of the bones, muscles, &c. would probably remain for a longer period, because every species of food was more soft and succulent. Hence the full expansion of the human body, or when it was capable of generating, must have required 120 or 150 years; and the duration of life would be in proportion to the time of growth, as is uniformly the case at present: for if we suppose the age of puberty, among the first races of men, to have been 130 years, as they now arrive at that age in 14 years, the age of the antediluvians will be in exact proportion to that of the present race; since by multiplying these two numbers by seven, for example, the age of the present race will be 90, and that of the antediluvians will be 910. The period of man's existence, therefore, may have gradually diminished in proportion as the surface of the earth acquired more solidity by the constant action of gravity: and it is probable, that the period from the creation, to the days of David, was sufficient to give the earth all the density it was capable of receiving from the influence of gravitation; and consequently that the surface of the earth has ever since remained in the same state, and that the terms of growth in the productions of the earth, as well as the duration of life, have been invariably fixed from that period.

It has been further supposed, that a principal cause of the longevity under consideration was the wholesome constitution of the antediluvian air, which, after the deluge, became corrupted and unwholesome, breaking, by degrees, the pristine crasis of the body, and shortening men's lives, in a very few ages, to near the present standard. The temperature of the air and seasons before that catastrophe are upon very probable grounds supposed to have been constantly uniform and mild: the burning heats of summer and the severities of winter's cold were not then come forth, but spring and autumn reigned perpetually together: and indeed, the circumstance above all others most conducive to the prolongation of human life in the post-diluvian world appears to be an equal and benign temperature of climate; whence it seems reasonable to infer, that the same cause might have produced the same effect in the antediluvian world.

ANTE'GO. See ANTI'GUA.

ANTEJURAMEN'TUM, *f.* by our ancestors called *juramentum calumnie*, an oath which anciently both accuser and accused were to take before any trial or purgation. The accuser was to swear, that he would prosecute the criminal; and the accused so make oath, on the day he was to undergo the ordeal, that he was innocent of the crime charged against him.

ANTELA'BIA, *f.* [*προχειλα*, from *προ* and *χειλος*, Gr. a lip.] The extremities of the lips.

ANTELOPE, *f.* in zoology. See CAPRA.

ANTELU'CAN,

ANTELUCAN, *adj.* in ecclesiastical writers, is applied to things done in the night or before day. We find frequent mention of the antelucan assemblies of the ancient Christians, in times of persecution for religious worship.

ANTEMERIDIAN, *adj.* [from *ante*, before, and *meridian*, Lat. noon.] Before noon.

ANTEMETIC, *adj.* [ἅντι, against, and ἔμεω, Gr. to vomit.] That which has the power of calming the stomach; of preventing or stopping vomit.

ANTEMUNDANE, *adj.* [from *ante*, before, and *mundus*, Lat. the world.] That which was before the creation of the world.

ANTEMURA'LE, *f.* in the ancient military art, denotes much the same with what the moderns call an *out-work*.

ANTENA'TI, *f.* in English history, is chiefly understood of the subjects of Scotland, born before king James the First's accession to the English crown, and alive after it. Those who were born after the accession were denominated *postnati*. The antenati were considered as aliens in England, whereas the postnati claimed the privilege of natural subjects.

ANTENCLE'MA, *f.* in oratory, is where the whole defence of the person accused turns on criminating the accuser. Such is the defence of Orestes, or the oration of Milo: *Occisus est, sed latro. Exfectus, sed raptor*.

ANTENEAS'MUS, *f.* The same with enthusiasm. A particular kind of madness; in it the patient is furiously irritated, and endeavours to lay violent hands on himself. These people are apt to be seized with sudden convulsive startings of the hands and feet; and therefore is thought to coincide with the *chorea sancti viti* in some degree.

ANTENICE'NE, *f.* in ecclesiastical writers, denotes a thing or person prior to the first council of Nice. We say, the Antenicene faith, Antenicene creeds, Antenicene fathers.

ANTEN'NÆ, *f.* in the history of insects, slender bodies with which nature has furnished the heads of these creatures, being the same with what in English are called *horns* or *feelers*. See **ENTOMOLOGY**.

ANTENUM'BER, *f.* [from *ante*, Lat. and *number*.] The number that precedes another.—Whatsoever virtue there is in numbers, for conducing to consent of notes, is rather to be ascribed to the *antenumber*, than to the entire number, as that the sound returneth after six, or after twelve; so that the seventh or thirteenth is not the matter, but the sixth or the twelfth. *Bacon*.

ANTENNA'RIA, *f.* in botany. See **GNAPHALIUM**.

ANTEN'OR, *f.* a Trojan prince, who was said to have betrayed his country, because he concealed Ulysses in his house. He had three sons, all killed at the siege of Troy; and, after the destruction of his country, he migrated to Italy, where he built a city, now called Padua.

ANTEPAGMEN'TA, *f.* in the ancient architecture, the jambs of a door. They are also ornaments, or garnishings, in carved work, of men, animals, &c. made either of wood or stone, and set on the architrave.

ANTEPAST, *f.* [from *ante*, before, and *pastum*, Lat. to feed.] A foretaste; something taken before the proper time.—Were we to expect our bliss only in the satiating our appetites, it might be reasonable, by frequent *antepasts*, to excite our gust for that profuse perpetual meal. *Decay of Piety*.

ANTEPENU'LT, *f.* [*antepenultima*, Lat.] The last syllable but two, as the syllable *te* in *antepenuli*: a term of grammar.

ANTEPILA'NI, *f.* in the Roman armies, a name given to the hastati and principes, because they marched next before the triarii, who were called *pilani*.

To ANTEPONE, *v. a.* [*antepono*, Lat.] To set one thing before another, to prefer one thing to another.

ANTEPOSITION, *f.* a grammatical figure, whereby a word, which by the ordinary rules of syntax ought to follow another, comes before it. As when, in the Latin, the adjective is put before the substantive, the verb before the nominative case, &c.

ANTEPREDICAMENT, *f.* [*antepredicamentem*, Lat.] Something to be known in the study of logic, previously to the doctrine of the predicament.

ANTEQUIE'RA, a handsome town of Spain, in the kingdom of Granada, divided into two parts, the upper and lower. The upper is seated on a hill, and has a castle: the lower stands in a fertile plain, and is watered with a great number of brooks. There is a large quantity of salt in the mountain; and five miles from the town, a spring famous for the cure of the gravel. Lat. 36. 51. N. long. 4. 40. W.

ANTE'RIOR, *adj.* [*anterior*, Lat.] Going before, either with regard to time or place.—If that be the *anterior* or upper part wherein the senses are placed, and that the posterior and lower part, which is opposite thereunto, there is no inferior or former part in this animal; for the senses being placed in both extremes, make both ends *anterior*, which is impossible. *Brown*.

ANTERIOR'ITY, *f.* Priority; the state of being before, either in time or situation.

ANTEROS, a son of Mars and Venus, and a deity that punished slighted love. Mars perceiving that Cupid did not grow, he demanded the reason of Themis, who told him it was because he had not a companion; upon which she gave him Anteros, with whom Cupid began to grow. They are often represented like two children, with wings on their shoulders, and striving for the branch of a palm-tree, to teach us that true love always endeavours to overcome by kindness and gratitude.

AN'TES, *f.* [Lat.] Pillars of large dimensions that support the front of a building.

ANTESIGNA'NI, *f.* in the Roman armies, soldiers placed before the standards to defend them, according to Lippius; but Cæsar and Livy mention the *antesigniani* as the first line, or first body, of heavy armed troops. The velites, who used to skirmish before the army, were likewise called *antesignani*.

ANTESTA'RI, *f.* in Roman antiquity, signifies to bear witness against any one who refused to make his appearance in the Roman courts of judicature, on the day appointed, and according to the tenor of his bail. The plaintiff, finding the defendant after such a breach of his engagement, was allowed to carry him into court by force, having first asked any of the persons present to bear witness. The person asked to bear witness in this case, expressed his consent by turning his right ear, which was instantly taken hold of by the plaintiff, and this was to answer the end of a subpoena.

ANTES'TATURE, *f.* in fortification, a small retrenchment made of palisadoes, of sacks of earth, with a view to dispute with an enemy the remainder of piece of ground.

ANTESTO'MACH, *f.* [from *ante*, Lat. before, and *stomach*.] A cavity which leads into the stomach.—In birds there is no mastication or comminution of the meat in the mouth; but it is immediately swallowed into a kind of *antestomach*, which I have observed in piscivorous birds. *Ray*.

ANTEUPHOR'BIUM, *f.* in botany. See **CACALIA**.

ANTHE'LION. See **CORONA** and **PARHELION**.

ANTHE'LIX, in anatomy, the inward protuberance of the external ear, most parallel to the helix.

ANTHELMIN'THIC, *f.* [ἅντι, against, and ἔλμινθος, Gr. a worm.] That which kills worms.—*Anthelminthics*, or contrary to worms, are things which are known by experience to kill them, as oils, or honey taken upon an empty stomach. *Arbutnot*.

AN'THEM, *f.* [ᾠδὴ μυσική, Gr. a hymn sung in alternate parts, and should therefore be written *anthymn*.] A holy song; a song performed as part of divine service.—There is no passion that is not finely expressed in those parts of the inspired writings, which are proper for divine songs and *anthems*. *Addison*. Anthems were first introduced into the reformed service of the English church, in the beginning of the reign of queen Elizabeth.

ANTHE'MIS, *f.* [ἄνθις, Gr. *flores*, from its abundance of]

of flowers, or from its luxuriance.] In botany, a genus of the Syngenesia polygamia superflua class, in the natural order of compositæ discoides. The generic characters are—Calyx: common hemispherical; scales linear, subequal. Corolla: compound radiate; corollules hermaphrodite, tubular, numerous in a convex disk; females more than five in the ray; proper of the hermaphrodite funnel-shaped, five-toothed, erect; of the female ligulate, lanceolate, sometimes three-toothed. Stamina: in the hermaphrodites; filaments five, capillary, very short; anthers cylindrical, tubular. Pistillum: in the hermaphrodites; germ oblong; style filiform, the length of the stamens; stigmas two reflex; in the females, germ oblong; style filiform, the length of the hermaphrodites; stigmas two, revolute. Pericarpium: none; calyx unchanged. Seeds: solitary, oblong; down margined or none. Receptaculum: chaffy, convex, or conical.—*Essential Character.* Receptaculum, chaffy; down, none; calyx, hemispherical, nearly equal; floscules of the ray more than five.

Species. 1. With a discolour or white ray. 1. *Anthemis cota*: chaffs of the flowers rigid, pungent. A native of Italy and Spain; growing in ploughed fields. Annual.

2. *Anthemis altissima*, or tall chamomile: erect, with leaves pinnate; the bases of the pinnae rough with a reflex toothlet. Annual; and grows wild in the south of France, Italy, and Spain.

3. *Anthemis maritima*, or sea chamomile: leaves pinnate, toothletted, fleshy, naked, dotted; stem prostrate; calyxes rather tomentose. The flowers have the smell of feverfew. It grows wild about Montpellier, and in Italy; and flowers in July and August.

4. *Anthemis tomentosa*, or downy chamomile: leaves pinnatifid, obtuse, flat, peduncles shaggy, leafy; calyxes tomentose. A native of Greece, Italy, and France.

5. *Anthemis mixta*, or simple-leaved chamomile: leaves simple, jagged, toothed. Annual. Grows wild in Italy and France. It was cultivated in 1731, by Mr. Miller.

6. *Anthemis alpina*, or alpine chamomile: leaves tooth-pinnate, quite entire, linear; stem villose, one-flowered; petals ovate, chaffs spiculate. Grows wild in the Tyrolese Alps, Monte Baldo, Tubingen, Piedmont, &c. Perennial.

7. *Anthemis chia*, or cut-leaved chamomile: leaves pinnatifid, jagged; peduncles naked, subvillose. It was observed by Tournefort in the isle of Chios.

8. *Anthemis nobilis*, or common or sweet chamomile: leaves pinnate-compound, linear, acute, subvillose. Root perennial. Abundant in Cornwall, and in most of the dry commons in Surrey; flowering in July and August. The leaves and flowers of common chamomile have a strong not ungrateful smell, and a very bitter nauseous taste. The latter are more bitter, and considerably more aromatic, than the leaves. The smell as well as the taste is rather improved by careful drying, and does not soon suffer any considerable diminution in keeping. An infusion of the flowers is often used as a stomachic, and as an antispasmodic. In large quantities it excites vomiting. The powdered flowers, in large doses, have cured agues, even when the bark had failed. Both the leaves and flowers possess very considerable antiseptic properties, and are therefore used in antiseptic fomentations and poultices. From their antispasmodic powers they are frequently found to relieve pain, either applied externally, or taken internally. In the London Pharmacopœia, an extract of the flowers is directed. The single flowers are ordered to be kept, and with good reason; the white florets of the ray, which are multiplied in the double flowers, being almost tasteless; notwithstanding this, double flowers only are to be found in the shops.

9. *Anthemis arvensis*, or corn chamomile: receptacles conic, chaffs bristle-shaped; seeds crown-margined; leaves thinly downed. Root biennial. It is a common weed in corn in most parts of Europe; and flowers in June and July. Linnæus thus distinguishes this from the eleventh species, or stinking mayweed. The appearance and stature

is the same in both, but the stalks are more diffused in this; the peduncles longer, with only four or five streaks or fine grooves, whereas that has about eight; the leaves are more hoary and inodorous. In plants that have so much resemblance as we find in several of this class, we can scarcely be too minute in discriminating them.

10. *Anthemis austriaca*, or Austrian chamomile: receptacles conic, chaffs oblong, mucronate, seeds naked, leaves bipinnate woolly-villose. Root annual. The leaves, but especially the flowers, have a powerful smell of *matricaria officinalis*, with something of the chamomile: the taste is bitter. Native of Austria, by way-sides and in corn-fields, sometimes covering the fallows. Flowers all the summer.

11. *Anthemis cotula*, or stinking chamomile or mayweed: receptacles conic, chaffs bristly, seeds naked, leaves smooth. Stinking chamomile or mayweed is an annual plant, the whole of which is extremely fetid and acrid, so as to blister the skin of those who handle it; the acrid matter probably resides in small glands, which are visible only with a microscope. The petals vary much in length and breadth, and it is found with double flowers. Linnæus observes, that the flowers are also sometimes profliferous; the disk being filled with smaller flowers, which are compound themselves, and have abundance of aphides among them. He adds, that it is a very grateful plant to toads; and, from Loeffelius, that it drives away fleas; is very disagreeable to bees, and is given as a medicine to sheep infested with the asthma. It has never been much in use as a medicine, nor are its effects well known. Decoctions of it are said to have been used as a bath or fomentation against hysterical suffocations, and hæmorrhoidal pains and swellings. Mr. Ray says, that it has been given internally, with success, in scrophulous cases. It is a common weed by way-sides, on dung-hills, and in corn-fields, where it sometimes abounds so much as greatly to diminish the crop. Mr. Curtis very justly observes, that farmers are not aware of the amazing increase from a single plant of this and some other weeds, which they suffer to exhaust their dunghills, in order to be dispersed afterwards over their fields. It flowers from May to August. Mr. Curtis has admirably well distinguished this plant from *matricaria chamomilla*, which it greatly resembles, by the following circumstances. The whole plant in that puts on a deep green colour, and somewhat thin appearance; this on the contrary assumes a much paler hue, and the stalk is often covered with a kind of woolly substance: the leaves in *matricaria* are nearly as fine as those of fennel, which they distantly resemble; in the *anthemis* they are almost twice as broad, and their points, which in that are simple, in this are often bifid. The radial florets of the *anthemis* are in general much broader, and somewhat shorter: the disk in this is not so prominent, but of a lighter yellow than in *matricaria*. If the heads of that are bruised, they emit a strong smell, somewhat resembling that of true chamomile, but not so pleasant; but those of *anthemis* are intolerably disagreeable; these, when handled, blister the skin, which those of *matricaria* do not. The seeds of *anthemis* are broad, truncate, wrinkled, and deep brown; those of *matricaria* are much smaller, paler, and different in shape.

12. *Anthemis pyrethrum*, or Spanish chamomile, or pellitory of Spain: stems simple, one-flowered, decumbent, leaves pinnate multifid. Root perennial, thick, running down a foot or more into the ground, about as big as a man's finger, the colour of horse-radish, white within, of an acrid biting taste. Flower large, the florets of the ray purple on the outside. Mr. Miller says, the first time he raised this plant was in 1732, from seeds picked out of raisins, and the year after the plants produced seeds, which ripened well, and the plants raised from these seeds continued several years, but did not perfect their seeds; so that, in the winter of 1753, the old roots being destroyed, he lost the species. It is a native of the Levant, and the southern parts of Europe, and was cultivated in 1570. The root, on being chewed, excites a glowing heat, and produces

produces a discharge of saliva, which relieves tooth-achs, and rheumatic affections of the face; it is recommended in lethargic complaints and paralyzes of the tongue.

11. With a concolour or yellow ray. 13. *Anthemis valentina*, or purple-stalked chamomile: stem branching, leaves pubescent, tripinnate, bristle-shaped, calyxes villose, peduncled. It grows to the height of two feet, and, when allowed room, throws out many side branches, especially in good land. This plant has been continued in most of the dispensaries for many ages, and is supposed to be the same which Dioscorides recommends as good for the jaundice, and to restore the skin to a good colour; but, of late years, it has been entirely disused in the shops: and, whenever ox-eye has been ordered, the greater ox-eye daisy (*chrysanthemum leucanthemum*) has been used. This grows naturally in Spain, Portugal, and Provence. The flowers are yellow, but there is a variety with white flowers: both are mentioned by Breynius. There is a third with naked flowers having no rays, which Linnaeus places in his genus of *anacyclus*; but all these will rise from the seeds of the same plant, and frequently both radiate and naked flowers appear on the same branch. These plants not only vary in their flowers; but the leaves are different; some being finely divided, and others having broader segments; and this from the same seeds. Mr. Miller has figured that with yellow flowers, whose leaves are not so finely divided as those of the white; and which is supposed to be the true medical ox-eye.

14. *Anthemis repanda*, or repand-leaved chamomile: leaves simple, ovate-lanceolate, repand-crenate. Native of Spain and Portugal.

15. *Anthemis trinerva*, or three-nerve-leaved chamomile: leaves ovate, serrate, three-nerved, opposite, petiolate, receptacle conic. Found in South America, by Mutis.

16. *Anthemis Americana*, or American chamomile: leaves triternate, peduncles terminal, longer than the branch. A native of America.

17. *Anthemis tinctoria*, or yellow chamomile, or ox-eye: leaves bipinnate, serrate, tomentose underneath, stem corymbd. A native of Sweden, Germany, &c. in dry open pastures. Mr. Ray found it near the river Tees, not far from Sogburn, in the bishopric of Durham. Linnaeus says, the flowers are used in Gothland in dying yellow.

18. *Anthemis Arabica*, or Arabian chamomile: stem decomposed, calyxes branch-bearing. The seeds were brought from Arabia by the late Dr. Shaw, and were distributed to many curious botanists in Italy, France, and England, where some of the plants were raised. It must have been lost afterwards, for Dr. Smith observes, (in 1792,) that it is scarcely to be met with in any garden, or even herbarium; and that his figure was drawn from a plant at the marchioness of Rockingham's, in 1790, the seed of which was received from the gardens at Carlsmith the preceding year, by Mr. Lee, of Hammer-smith. It is an ornamental plant, and merits a place among hardy annuals. Its flavour is bitter and aromatic, but far weaker than official chamomile. Annual.

19. *Anthemis odorata*, or shrubby chamomile: leaves pinnatifid at the tip, peduncles elongate, calyxes membranaceous, ray barren. Native of the Cape of Good Hope, where it was found by Mr. Francis Masson. It flowers from April to June.

Propagation and Culture. Some of these plants are annuals, and others perennials, both hardy enough, except the fifteenth and nineteenth, to bear the open air. They may be propagated by seeds sown in the spring, on poor land; and require no other culture but to thin the plants where they are too close, and to keep them clean from weeds. They flower in July; and, being generally bushy, require room. The common or sweet chamomile may be increased by slips planted in the spring a foot asunder, that they may have room to spread, and they will soon cover the ground. It was formerly planted for edges, to cover banks, and for walks. The variety with double flowers is equally hardy, and may be propagated in the

same manner. The seeds of Arabian chamomile should be sown in autumn, otherwise they are seldom perfected in England.

ANTHERA, *f.* [from *ανθος*, a flower: also *antera*.] A compound medicine used by the ancients, so called from its florid red colour. There are various compositions which had this name. They were prepared for any particular part of the body, in the form of powders, electaries, &c. and were used as collyriums, dentifrices, &c.

ANTHERÆ, or **AN'THERS**, *f.* in botany. A part of the flowers, big with pollen, or farina, a fine dust, which it emits, or explodes, when ripe; or big with granulated pollen, and that with fovilla: or it may be defined a vessel destined to produce and emit a substance for the impregnation of the germ. It forms a part of the stamen, and is placed on the top of the filament. It is the *apex* of Ray; *capsula flaminis* of Malpighi; *summit*, *semet*, *pendent*, or *tip*, of Grew, and other English writers.

ANTHERICUM, *f.* [*ανθος* *πρυον*, Gr. flower of the hedges.] In botany, a genus of the hexandria monogynia class, ranking in the natural order of coronariæ. The generic characters are—Calyx: none. Corolla: petals six, oblong, obtuse, spreading very much. Stamina: filaments subulate, erect; antheræ small, incumbent, four-furrowed. Pistillum: germ obscurely three-cornered; style simple, the length of the stamens; stigma obtuse, three-cornered. Pericarpium: capsule ovate, smooth, three-furrowed, three-celled, three-valved. Seeds: numerous, angular. Various species have woolly filaments; in others the petals are not deciduous. The character of the genus is very difficult to ascertain.—*Essential Character.* Corolla, six-petalled, expanding; capsule ovate.

Species. I. *Phalangium*; leaves channelled, filaments generally smooth. 1. *Anthericum floribundum*, or thick-spiked anthericum: leaves flat, smooth, linear-lanceolate, acute; scape simple; raceme many-flowered, cylindric, compact; petals spreading; stamens smooth. Native of the Cape of Good Hope, where it was found by Mr. Francis Masson. It flowers in March and April.

2. *Anthericum scrotinum*: leaves flattish, scape one-flowered. This is a vernal plant, appearing after the melting of the snows; and growing only on high mountains, in Switzerland, Dauphine, Piedmont, Austria, &c. and on Snowdon, &c. in Wales. Perennial, flowering in April and May.

3. *Anthericum græcum*: leaves flat, scape simple, flowers corymbd, filaments woolly. From the Levant.

4. *Anthericum planifolium*: leaves flat, scape and filaments woolly. Root thick, oblong, yellowish. A native of Portugal; flowering in April.

5. *Anthericum revolutum*, or curled-flowered anthericum: leaves flat, scape branched; corollas revolute. Roots fleshy, and composed of tubers joined at the crown. A native of the Cape of Good Hope.

6. *Anthericum ramosum*, or branching anthericum: leaves linear-subulate, flat; scape branched; peduncles solitary; corollas flat; pistils straight. Root round. A native of Sweden, the south of France, Switzerland, Austria, Carniola, &c. The flowers watch from seven in the morning to three or four in the afternoon. It was cultivated in 1597, by Gerard.

7. *Anthericum elatum*, or tall anthericum: leaves flat, scape branched, peduncles aggregate, corollas flat. Roots composed of many tubers, each about the size of a little finger at top, and diminishing gradually to the size of a straw. The flowers form a loose spike, and are white. This plant has probably been formerly in the Dutch gardens, for there are paintings of it in several flower-pieces, which are supposed to have been done above sixty years. However, it has been lost for some years in Europe, and has been lately recovered from seeds which were sent from the Cape of Good Hope to England and Holland. The first seeds received by Mr. Miller were in 1750; and the plants raised from them flowered in 1752, and perfected their seeds. When they are fully blown, which is usually

in August and September, they make a pretty variety among other exotic plants.

8. *Anthericum triflorum*, or three-flowered anthericum: leaves channelled-sword-shaped, scape simple, bractes remote, three-flowered. Native of the Cape of Good Hope. It flowers in November.

9. *Anthericum canaliculatum*, or channelled anthericum: leaves rather fleshy, hairy, sword-shaped-triangular, channelled on the narrow side; scape simple. Native of the Cape of Good Hope. It flowers in April.

10. *Anthericum albucoides*, or stripe-flowered anthericum: leaves linear, channelled, smooth, with a cartilaginous edge; scape simple. This and the foregoing were found at the Cape by Mr. Maillon. It flowers in August.

11. *Anthericum liliago*, or grass-leaved anthericum: leaves flat, scape perfectly simple, corollas flat, pistil bending down. It is a native of Italy, Switzerland, Germany, France, and Denmark.

12. *Anthericum liliastrum*, or Savoy anthericum, or spider-wort: leaves flat, scape perfectly simple, corollas bell-shaped, stamens bending down. There are two varieties of this; the *liliastrum alpinum majus*, and *liliastrum alpinum minus*, of Tournefort. The first rises with a flower-stalk more than a foot and half high; the flowers are much larger, and there is a greater number upon each stalk than in the second sort. There is no essential difference between them, but the first is by much the finest plant, though the second is what we have always observed in the gardens here; the leaves of this are somewhat like those of the spider-wort, are pretty firm, and grow upright; the flower-stalks grow about a foot and half high, and have several white flowers at top, shaped like those of the lily, which hang on each side, and have an agreeable scent; these are but of short duration, seldom continuing in beauty above three or four days; but, when the plants are strong, they will produce eight or ten flowers upon each stalk. The French call it St. Bruno's lily. It grows wild on the mountains of Switzerland and Savoy; and was cultivated in 1629.

13. *Anthericum spirale*: scape spiral. A plant without leaves. Native of the Cape of Good Hope.

II. Bulbine; leaves fleshy, filaments bearded. 14. *Anthericum frutescens*, or shrubby anthericum: leaves fleshy, columnar, stem shrubby. It differs from the fifteenth by rising into a stem and branches, by having the leaves greener, longer, and narrower, with a firmer pulp, and a viscid juice flowing copiously from them when cut, of a greenish yellow colour. In the fifteenth the leaves are paler, grow close, many together, are broader, and more translucent, soft, and pulpy; they pour out a limpid juice like the white of an egg, only when pressed, and then they are hollow, like those of an onion. The root of the fifteenth is tuberous, whereas in this it is fibrous, and not only the stem but even the branches pour out fibres, which hang down, and when they reach the ground strike root. It is a native of the Cape of Good Hope; was cultivated in the Chelsea garden in 1702; and was formerly known among the gardeners by the name of onion-leaved aloe.

15. *Anthericum alooides*, or aloe-leaved anthericum: leaves fleshy, subulate, flattish. It has broad, flat, pulpy, leaves, resembling those of some sorts of aloe, and was therefore formerly by gardeners called aloe with flowers of spiderwort. The leaves spread open; the flowers are produced on loose spikes, like the former, but are shorter; they are yellow, and appear at different seasons. This, and the next species, grow close to the ground, never rising with any stalk. A native of the Cape of Good Hope.

16. *Anthericum asphodeloides*, or glaucous-leaved anthericum: leaves fleshy, subulate, semicolumnar, upright, and stiff. The flowers are yellow, and grow on long loose spikes, as the former; these appear at different seasons: those of the spring and summer are succeeded by seeds in great plenty, which ripen very well. A native of the Cape of Good Hope.

17. *Anthericum agnatum*, or annual anthericum: leaves

fleshy, subulate, columnar, scape subracemed. This is a low annual plant, growing close to the ground, having pretty long succulent leaves which are taper, but flattened on their upper side; the flowers grow in loose spikes, which are shorter than either of the other sorts. They are yellow, and succeeded by round seed-vessels, like those of the former sorts; the plants perish soon after their seeds ripen. A native of the Cape of Good Hope.

18. *Anthericum hispidum*, or hairy-leaved anthericum: leaves fleshy, compressed, hispid. A native of the Cape of Good Hope.

III. *Narthecium*; leaves sword-shaped. 19. *Anthericum ossifragum*, or Lancashire anthericum, or asphodel: leaves sword-shaped, filaments woolly. It grows wild in the northern countries of Europe on bogs; in Lancashire, and other northern counties; in Cambridgeshire, Norfolk, on Putney-heath, &c. flowering in July and August.

20. *Anthericum calyculatum*: leaves sword-shaped, perianthium three-lobed, filaments smooth, flowers three-pistilled. An extraordinary liliaceous plant with a perianthium; the agreement in appearance with the last species forbids us to make a different genus of it, though it differs totally in the fructification; having naked filaments, three stigmas without styles, a subglobose pericarpium, and a three-valved perianthium. It grows wild on the mountains of Lapland, Sweden, Denmark, Siberia, Switzerland, &c. and in several places in Scotland.

21. *Anthericum japonicum*: leaves sword-shaped, convolute, smooth; scape branching, angled, flowers racemed, nodding. A native of Japan, China, and Java.

22. *Anthericum filiforme*, or thread-leaved anthericum: leaves filiform, rather cylindric, rough; filaments smooth, petals lanceolate. It is perennial. A native of the Cape of Good Hope; was discovered there by Mr. F. Maillon, and introduced in 1774. It flowers in April.

23. *Anthericum flexifolium*: leaves subulate, smooth, flexuose; stem branching. 24. *Anthericum muricatum*: leaves fleshy, compressed, muricated, streaked. 25. *Anthericum latifolium*: leaves fleshy, wide-sword-shaped, smooth; raceme very long; stem simple. 26. *Anthericum cauda-felis*: leaves channel-sword-shaped, scape simple, raceme oblong. 27. *Anthericum triquetrum*: leaves filiform, triquetrous, shorter than the simple scape; raceme ovate. 28. *Anthericum ciliatum*: leaves sword-shaped, fleshy-subtriquetrous, ciliate; scape simple; raceme very long. 29. *Anthericum falcatum*: leaves fleshy, sword-shaped-sickled, smooth; stem branching, racemed. 30. *Anthericum contortum*: leaves flat, sword-shaped; stem branching, flowers very remote. 31. *Anthericum scabrum*: leaves triquetrous, serrulate, stem branching, rugged; fruit-bearing peduncles recurved. 32. *Anthericum squameum*: scape imbricate, with membranous tunid scales. Natives of the Cape of Good Hope; where all but the last were found by Thunberg.

33. *Anthericum cirratum*: leaves lanceolate, flattish; scape paniced, leaves bearded, bicirrate. A native of New Zealand.

34. *Anthericum adenantha*: leaves linear-ensiform, connate at the base; a gland between the filament and antheræ. A native of New Caledonia.

Propagation and Culture. All these, except the seventeenth, are perennial plants, and may in general be increased by offsets or suckers, taken off during the summer or autumn; and the species which do not throw out these freely, may be propagated by seeds, sown in the spring or autumn, on a bed of light sandy earth, in a warm situation. In autumn, when the leaves decay, they should be carefully taken up, and transplanted into a bed of light earth, at the distance of a foot from each other. If the winter should prove severe, the bed must be covered with straw, pease-haulm, or such light covering, to keep out the frost; or some old tan from a hot-bed may be spread over the ground. In this bed they may remain one year; by which time they will be strong enough to flower; therefore the following autumn they should be carefully taken

up, so as not to break their roots, and planted in the borders of the flower-garden, where they will last several years, if they are not killed by frost; to prevent which, some rotten tan may be laid over the roots in winter. The species which come from the Cape of Good Hope require of course some shelter in winter; although some of them will live through a mild season in a warm situation.

ANTHERMUS, a Chian sculptor, son of Micciades, and grandson to Malas. He and his brother Bupalus made a statue of the poet Hipponax, which caused universal laughter, on account of the deformity of its countenance. The poet was so incensed upon this, and inveighed with so much bitterness against the statuary, that they hung themselves. *Pliny*.

ANTHERYLUM, *f.* in botany, a genus of the class icofandria, order monogynia. Generic essential characters—Calyx inferior, four-parted; petals four; capsule one-celled, three-valved, many-seeded.

Antherylum Rohrii, a single species. It is a tree with ovate entire slightly emarginate leaves; a short prickles on each side the petiole; peduncles axillary, one-flowered; stamina 12—16. Inhabits St. Thomas's.

ANTHESPHORIA, *f.* in antiquity, a Sicilian festival instituted in honour of Proserpine. The word is derived from the Greek *ανθος*, a flower, and *φερω*, I carry; because that goddess was forced away by Pluto when she was gathering flowers in the fields. It seems to be the same thing with the *florifertum* of the Latins; and answers to the harvest-home among us.

ANTHESTERIA, *f.* in antiquity, a feast celebrated by the Athenians in honour of Bacchus. The word is from the Greek *ανθος*, a flower; it being the custom at this feast to offer garlands of flowers to Bacchus.

ANTHESTERIA, *f.* [from the Athenian festival, observed in honour of Bacchus, on the 11th, 12th, and 13th, days of the month Anthesterion, as mentioned in the preceding article.] In botany, a genus of the class polygamia, order monoecia, natural order of gramina or grasses. The generic characters are—Calyx: glume four-valved, three or four flowered; valves equal, oblong, flat, blunt, leathery, erect-expanding; hermaphrodite floscule sessile; males pedicelled, very like the hermaphrodite. Corolla: glume two-valved: valves lanceolate, acute, awnless; the outer larger. Stamina: filaments three, short, filiform; antheræ oblong, erect. Pistillum, in the hermaphrodite: germ oblong; from the base a twisted awn; styles two; stigmas club-shaped, hairy. Pericarpium: none except the closed calyx. Seed: oblong, smooth, marked with a furrow. It is distinguished from all the known genera of grasses by its four-valved calyx.—*Essential Character*. Calyx, cleft at the base into four equal divisions.

There is only one species, called *Antheateria ciliata*. The root is annual; culms many, a foot high, branched, jointed, smooth, nodding a little: leaves several, alternate, smooth, except that they are scabrous about the edge, and ciliate towards the sheath; which is compressed, striated, keeled, and ciliate, on the upper edge. Raceme terminating, leafy, decomposed, nodding. Partial racemes also leafy, ciliate. Peduncles lateral, in pairs, straight, filiform.

ANTHESTERION, *f.* in ancient chronology, the sixth month of the Athenian year. It contained twenty-nine days; and answered to the latter part of our November and beginning of December. The Macedonians called it *desion* or *desion*. It had its name from the festival *antheateria* kept in it.

ANTHIAS, *f.* [Greek; from *αγος*, and *θεος*, divine.] The SACRED FISH, or GRUNTLING; in ichthyology, a genus of fishes formed by Bloch, being a division from the genera of *labrus*, *lutjanus*, *perca*, and *sciaenæ*; but, as Dr. Gmelin, in his new edition of Linnæus's *Système Naturel*, does not adopt this genus, we must refer for the species to the genera above-mentioned.

ANTHISTERIA, *f.* in botany. See **ANTHESTERIA**.

ANTHINE, *adj.* Medicated with the flowers of plants.

ANTHOCEROS, *f.* in botany, a genus among the algæ, in the class cryptogamia. In the male flower the ca-

lyx is sessile, cylindrical, entire; anther very long, subulate, two-valved; in the female, the calyx is cut into six divisions, and contains three seeds.

Species. 1. *A. punctatus*, with the fronds undivided, indented, dotted; a native of Britain, growing on heaths and moist shady places. 2. *A. laevis*, with smooth, undivided, indented, fronds. 3. *A. multifidus*, with bipinnated linear fronds. See Hedwig's *Figures*, and *Flor. Dan.* 396.

ANTHOLOGION, *f.* The title of the service-book used in the Greek church. It is divided into twelve months, containing the offices sung throughout the year, on the festivals of our Saviour, the Virgin, and other remarkable saints.

ANTHOLOGY, *f.* [*ανθολογια*, from *ανθος*, a flower, and *λεγω*, to gather.] A collection of flowers. A collection of devotions in the Greek church. A collection of poems.

ANTHOLOMA, *f.* in botany, a genus of the class polyandria, order monogynia. Generic essential characters—Calyx two to four leaved; corolla cup-shaped; capsule four-celled, many-seeded.

Antholoma montana, a single species. It is a branched shrub: leaves ovate, obtuse, very entire, erect, at the ends of the branches; flowers terminal, corymbed. Native of New Caledonia.

ANTHOLYZA, *f.* [*ανθος*, a flower, and *λυσσα*, madness.] In botany, a genus of the class triandria, order monogynia, natural order of *ensæte*. The generic characters are—Calyx: spathes two-valved, alternate, imbricated, permanent. Corolla: petal one, gradually dilated from the tube into a compressed ringent throat; upper lip straight, slender, very long, furnished with two short divisions at the base; under lip shorter, trifid. Stamina: filaments long, slender, under the upper lip; antheræ acute. Pistillum: germ inferior; style filiform; stigma trifid, capillary, reflex. Pericarpium: capsule roundish, three-cornered, three-celled, three-valved. Seeds: many, triangular.—*Essential Character*. Corolla, tubular irregular, recurved. Capsule, inferior.

Species. 1. *Antholyza ringens*, or narrow-leaved *antholyza*: lids of the corolla divaricated, throat compressed. This rises two feet high, is hairy, and has several flowers coming out on each side. These are of one leaf, cut into six unequal parts at the top; one of these segments is stretched out much beyond the others, standing erect; the margins are waved, and closed together. The flowers are red, and appear in June; and the seeds ripen in September.

2. *Antholyza plicata*, or plaited-leaved *antholyza*: leaves plaited, stem branching hirsute; corolla, ringent, shorter than the stamina. It was found at the Cape of Good Hope, by Thunberg and Mañon.

3. *Antholyza cunonia*, or scarlet-flowered *antholyza*: corollas straight, the two outer lobes of the five-parted lip broader and ascending. This flower is of a beautiful scarlet colour, and makes a fine appearance about the latter end of April, or beginning of May, which is the season of its flowering. After the flowers decay, the germ becomes an oval smooth capsule, opening in three cells, which are filled with flat bordered seeds. At the Cape of Good Hope it grows naturally.

4. *Antholyza Ethiopica*, or broad-leaved *antholyza*: corollas incurvate, the two alternate lobes of the five-parted lip spreading, larger, and lanceolate. Flowers in May and June.

5. *Antholyza Meriana*, or red-flowered *antholyza*: corollas funnel-shaped, leaves linear. Root bulbous, compressed, shaped like a kidney, covered with a fibrous brown skin. Leaves sword-shaped, about a foot long, and an inch broad, ending in points; the two sides have sharp edges, but the middle is thicker, and has a prominent midrib; they are of a dark green colour, and rise immediately from the root. The stalk comes out from the root between the leaves, and rises a foot and a half high towards the upper part. Dr. Trew named this plant *Meriana*, in

honour of Sybilla Merian, the celebrated female Dutch botanist.

6. *Antholyza Merianella*, or dwarf antholyza: corollas funnel-shaped, leaves linear. It is of humbler growth than the fifth; the leaves are rarely more than six inches long, but full as broad as those of the fifth, and of a lighter green.

7. *Antholyza lucidor*: radical leaves with filiform base, broad-awled, furrowed at top; stem simple, leafy, spiked. All the species of *antholyza* are natives of the Cape of Good Hope.

Propagation and Culture. The antholyzas are propagated by offsets, which the bulbous roots send forth in great plenty; or by seeds, which are sometimes perfected in Europe. These seeds should be sown soon after they are ripe; for, if they are kept out of the ground till the following spring, they often miscarry, or at least remain a year in the ground before they grow. If the seeds are sown in pots of light earth, and plunged into an old bed of tan, which has lost its heat, and shaded in the middle of the day in hot weather, the seeds will come up the following winter; therefore they must be kept covered with glasses to screen them from cold, otherwise the young plants will be destroyed. These may remain in the pots two years, if the plants are not too close, by which time they will have strength enough to be planted each into a separate small pot filled with light earth. The time for transplanting is in July or August, when their leaves are decayed. In summer, the pots may be placed in the open air, but in winter they must be removed, and placed under a hot-bed frame, for they are not very tender; but, where any damp arises, it is very apt to occasion a mouldiness upon their leaves. The roots shoot up in autumn, and the flowers begin to appear in May; the seeds ripen in August, and soon after their leaves and stalks decay: the roots may then be taken up, and kept six weeks or two months out of the ground, so that they may be easily transported from one country to another at that time. These flowers are ornamental when they appear, and, being plants which require little culture, deserve a place in every good garden.

ANTHOMANIA, *f.* [from the Greek *ανθος*, a flower, and *μανια*, madness.] An extravagant fondness for curious flowers.

ANTHONY, [*ανθος*, Gr. a flower.] A proper name of men.

ANTHONY (St.) was born in Egypt in 251, and inherited a large fortune, which he distributed among his neighbours and the poor, retired into solitude, founded a religious order, built many monasteries, and died anno 356. Many legendary tales are told of his conflicts with evil spirits, and of his miracles. There are seven epistles extant attributed to him. St. Anthony is sometimes represented with a fire by his side, signifying that he relieves persons from the inflammation called after his name; but always accompanied by a hog, on account of his having been a swine-herd, and curing all disorders in that animal.

ANTHONY (Knights of St.), a military order, instituted by Albert, duke of Bavaria, Holland, and Zealand, when he designed to make war against the Turks in 1382. The knights wore a collar of gold made in form of a hermit's girdle, from which hung a stick cut like a crutch, with a little bell, as they are represented in St. Anthony's pictures. St. Anthony also was the denomination of an order of religious founded in France about the year 1095, to take care of those afflicted with St. Anthony's fire.

ANTHONY'S FALLS, a beautiful cataract in the river Mississippi, ten miles north-west of the mouth of St. Pierre river, which joins the Mississippi from the west, and are situated in about lat. 44. 50. N. and were so named by father Louis Hennipin, who travelled into these parts about the year 1680, and was the first European ever seen by the natives there. These falls are peculiarly situated, as they are approachable without the least obstruction from any intervening hill or precipice; which cannot be said, perhaps, of any other considerable fall in the world. The scene

around is exceedingly beautiful. It is not an uninterrupted plain where the eye finds no relief, but composed of many gentle ascents, which, in the spring and summer, are covered with verdure, and interspersed with little groves, that give a pleasing variety to the prospect. At a little distance below the falls is a small island, about an acre and a half, on which grow a great number of oak-trees, all the branches of which, able to bear the weight, are, in the season of incubation, loaded with eagles' nests. Their instinctive wisdom has taught them to choose this place, as it is secure, on account of the rapids above, from the attacks either of man or beast.

ANTHONY'S FIRE, a name popularly given to the erysipelas. Apparently it took this denomination from those afflicted with it having made their peculiar application to St. Anthony for a cure. It is well known, that anciently particular diseases had their peculiar saints; thus, in the ophthalmia, persons had recourse to St. Lucia; in the tooth-ach, to St. Appollonia; in the hydrophobia, to St. Hubert, &c.

ANTHONY'S NOSE, a point of land in the Highlands of North America, on Hudson River, in the state of New York, from which, to Fort Montgomery on the opposite side, a large boom and chain was extended in the American war, which cost not less than 70,000l. sterling. It was partly destroyed, and partly carried away, by general sir Henry Clinton, in October 1777.—Also the name given to the point of a mountain on the north bank of Mohawk River, about thirty miles above Schenectady.

ANTHONY, Mark. See *ANTONIUS*.

ANTHORA, *f.* in botany, the trivial name of a species of aconitum. See *ACONITUM*.

ANTHORIS'MUS, *f.* in rhetoric, denotes a contrary description or definition of a thing from that given by the adverse party. Thus, if the plaintiff urge, that to take any thing away from another without his knowledge or consent, is a theft; this is called *opos*, or definition. If the defendant reply, that to take a thing away from another without his knowledge or consent, provided it be done with design to return it to him again, is not theft; this is an *ανθορισμος*.

ANTHOS, *f.* [Greek, a flower.] Hippocrates used this word to signify flowers in general; and, if Galen is right in his comment, Hippocrates includes the seeds with the flowers. It is also used for *æris flos*. And when used alone signifies the flowers of rosemary; and is sometimes taken for the plant, but improperly.

ANTHOSPERMUM, *f.* [*ανθος*, and *σπερμα*, Gr. flower-feed.] In botany, a genus of the polygamia dioecia, or rather dioecia tetrandria, class, ranking in the natural order of stellatæ. The generic characters are—I. Male. Calyx: perianthium one-leaved, conical, quadrifid beyond the middle; divisions ovate-oblong, revolute, obtuse, a little coloured. Corolla: none, unless you so name the calyx. Stamina: filaments four, capillary, erect, the length of the calyx, inserted into the receptacle; antheræ twin, oblong, four-cornered, obtuse, erect. II. Female. Calyx and corolla: as in the male. Pistillum: germ inferior, ovate, four-cornered; styles two, recurved; stigma simple.—*Essential Character.* Calyx, four-parted; corolla, none; stamina, four; pistillum, two; germ inferior. Male and female in the same or a distinct plant.

Species. 1. *Anthospermum Æthiopicum*, or amber-tree: leaves polished. The male flowers are on one plant, and the hermaphrodite flowers on another. The beauty of this shrub is in its small evergreen leaves, which grow as close as heath; and, being bruised between the fingers, emit a very fragrant odour.

2. *Anthospermum ciliare*: leaves ciliated along the keel and edge. Root perennial, woody. Many branches scarcely dividing. Leaves narrow, lanceolate. Flowers axillary, sessile. Calyxes four-parted. Stamens four.

3. *Anthospermum herbaceum*: leaves six, polished; stem herbaceous. Flowers axillary. All these plants are natives of the Cape of Good Hope. Thunberg observes, that

that all the anthospermums are dioecous without any hermaphrodite; which is expressly contrary to Linnæus's and Miller's observations on the first species.

Propagation and Culture. These plants may easily be propagated by cuttings during any of the summer months, in a border of light earth; they will take root in six weeks time, provided they are watered and shaded as the season may require: or, if these cuttings are planted in pots, and plunged into a very moderate hot-bed, they will take root sooner, and there will be a greater certainty of their growing. Afterwards they should be taken up, with a ball of earth to their roots, and planted into pots filled with light sandy earth, and may be exposed to the open air until October; at which time they should be removed into the conservatory.

ANTHOXAN'THON, *f.* in botany. See RUMEX MARITIMUS.

ANTHOXAN'THUM, *f.* [*ανθος* and *ξανθος*, Gr. yellow flower.] In botany, VERNAL GRASS; a genus of the class diandria, order digynia, natural order of gramina or grasses. The generic characters are—Calyx: glume one-flowered, two-valved; valves ovate, acuminate, concave, the inner one larger. Corolla: glume one-flowered, two-valved, the length of the greater valve in the calyx, each valve emitting an awn from the lower part of the back, one of them jointed; nectary two-leaved, very slender, cylindric; leaflets fubovate, embracing. Stamina: filaments two, capillary, very long; antheræ oblong, forked at both ends. Pistillum: germ oblong; styles two, filiform; stigmas simple. Pericarpium: glume of the corolla grows to the seed. Seed: one, acuminate at both ends, roundish.—*Essential Character.* Calyx, glume two-valved, one-flowered; corolla, glume two-valved, acuminate; seed one.

Species. 1. *Anthoxanthum odoratum*, or sweet vernal grass: spike oblong ovate; flowers longer than the awn, on short peduncles. This is easily distinguished from all our wild grasses; for, besides its having only two stamina, in common with others of the genus, and each spicule containing only one flower; one valve of the calyx is small and membranous, the other large, inclosing the fructification, both pointed, and smooth, or sometimes having soft white hairs scattered over them; they are also sprinkled over with minute yellow dots, similar to those of black currants, whence possibly its peculiar scent. Haller makes the *anthoxanthum* one of his two-flowered *avenas*; but Dr. Stokes observes, that it is a genus truly distinct; that it has the awn of *avena*, the corolla of *poa*, and the double one of *phalaris*; and that in a natural arrangement it should stand between *poa* and *avena*. The usual colour of the spike is a pale yellow, whence its generic name *anthoxanthum*. From the sweetness both of the flowers and leaves, which it imparts to new-mown hay, it has derived its specific or trivial name *odoratum*, or sweet-scented. From the earliness of its flowering, it has acquired its other English name of *vernal* or *spring grass*. It grows on almost any kind of soil, but it seems to prefer that which is moderately dry. It is common in pastures; and also in woods, where the spikes are usually slender and loose. Towards the middle of May it is in full bloom; and about the middle of June the seed is ripe, and may easily be separated by rubbing. Mr. Stillingfleet remarks, that from its being found on such pastures as sheep are fond of, and whence excellent mutton comes, it is most likely to be a good grass for sheep-pastures; that he has found it on all grounds, from the most sandy and dry to the most stiff and moist, and even in bogs; that it is very plentiful in the best meadows about London, as about Hampstead and Hendon.

2. *Anthoxanthum indicum*: spike linear, flowers sessile shorter than the awn. Native of the East Indies.

3. *Anthoxanthum crinitum*: panicle spike-form cylindrical awned, the awns long, spreading loose. Native of New Zealand. For the propagation and culture, see GRASS.

ANTHOXAN'THUM ACULEA'TUM, in botany. See CRYPsis.

ANTHOXAN'THUM PANICULA'TUM, in botany. See FESTUCA SPADICEA.

ANTHERACOSIS, [from *ανθραξ*, a hot coal.] A scaly corrosive tumour of the eye, attended with a defluxion.

AN'THRAX, *f.* [*ανθραξ*, Gr. a burning coal.] A scab or blotch that is made by a corrosive humour, which burns the skin, and occasions sharp pricking pains; a carbuncle.

ANTHRE'NUS, *f.* in entomology, a genus of insects belonging to the order of coleoptera; the characters of which are—Antennæ clavate, the club solid: feelers unequal filiform: jaws membranaceous, linear, bifid: lip entire: head retractile under the thorax. Thirteen species of this little insect are now ascertained; three of which, the *scrophularia*, *muscorum*, and *verbasci*, are natives of England.

1. *Anthrenus pimpinellæ*: black; shells with a white band, the tip ferruginous with a white blotch. Thorax black spotted with white and ferruginous. Inhabits Europe.

2. *Anthrenus histrio*: black; shells with two marginal white spots and a white blotch behind. The shells have two transverse white spots on the outer edge, and a dot or two in the middle; body whitish; abdomen with marginal black dots. Inhabits Germany; size of the last.

3. *Anthrenus scrophularius*: so named from its scurfy appearance. It is of an oval shape, and black with white spots formed by scales; the future of the elytra red. This insect is met with frequently and in great numbers upon flowers of most kinds, and especially upon those of the elder and of fruit-trees; but they frequent houses also, and other places where they find nourishment suited to their larvæ; seeking a convenient situation for their eggs. It is very small, not more than a line and three quarters long, and one line wide, so that the body is oval or nearly round. It is flattened above, convex beneath, contrary to most insects which have elytra. The head, corselet, and elytra, are shining black above, marked with small white spots and dots, especially at the angles of the corselet; the whole under part of the body is a brown grey, which colour is also produced by scales on a black ground. This little insect, when touched, will counterfeits death; bringing the head under the corselet in which it is partly inserted, and clinging the feet close to the body, where there are cavities to receive the thighs: what is still more remarkable, there is on each side of the corselet underneath a deep cavity to receive the antennæ completely; so that the insect, when it thus shrinks from the touch, appears to have neither legs nor horns. The larva has six scaly legs; it is of a blackish brown, and very hairy. It is met with among furs and skins, which it feeds upon, as also upon dead insects, dried birds, &c. like the *Dermestes lardarius*. This insect is represented of its natural size on the annexed Plate, at fig. 1, beneath which is a magnified under-view of the head and part of the corselet, taken at the moment the insect was contracting its legs, as mentioned above: *t*, the head; *c, c*, the corselet; *p, p*, the two front legs; *a, a*, the antennæ lodged in the cavities left in the corselet to receive them. On the right-hand side of fig. 4 is shown one of the antennæ of the same insect magnified; *a*, the first articulation, larger than the following which join the antennæ to the head; *b, c*, the stem, made up of rounded articulations; *d, e, f*, the round knob at the end, really divided in three parts, though closely pressed together.

4. *Anthrenus muscorum*: clouded; shells faintly clouded. Found principally in books and museums.

5. *Anthrenus verbasci*: black; shells with three-waved white bands. Inhabits Europe, on the *verbasum*.

6. *Anthrenus varius*: thorax and shells variegated with brown and cinereous: body cinereous. Inhabits Paris; size of the former ones.

7. *Anthrenus*

7. *Anthrenus pubescens*: thorax and shells grey, pubescent. Inhabits Germany.

8. *Anthrenus hirtus*: black; thorax and shells pubescent. Inhabits Germany.

9. *Anthrenus glaber*: smooth, black; shells, legs, and antennæ, brown. Inhabits Berlin.

10. *Anthrenus vagus*: cinereous; shells with three black obsolete bands. Inhabits Sweden; is perhaps not of this genus.

11. *Anthrenus fuscus*: brown, clothed with fine yellow down pale at the tip. Inhabits Europe.

12. *Anthrenus ferraticornis*: black, spotted with white; antennæ yellow, the club elongated ferrate. Head cinereous; shells black varied with white, and rufous at the base, three white spots in the middle, and two-waved white streaks on the tip. Inhabits the island of Santa Cruz.

13. *Anthrenus denticornis*: black; thorax yellowish at the edge; shells spotted with white; antennæ yellow, the club elongated, ferrate. Head black; shells black speckled with white; body black; legs yellowish. Inhabits the island of Santa Cruz.

ANTHRIS'CUS, *f.* in botany. See *CHÆROPHYLLUM* and *SCANDIX*.

ANTHROPOGLOT'TUS, *f.* among zoologists, an appellation given to such animals as have tongues resembling that of mankind, particularly to the parrot kind.

ANTHROPOG'RAPHY, *f.* [from the Greek *ανθρωπος*, a man, and *γραφη*, description.] The anatomical description of the human body.

ANTHROPOLA'TRÆ, in church-history, an appellation given to the Nestorians, on account of their worshipping Christ, notwithstanding that they believed him to be a mere man.

ANTHROPOLA'TRIA, *f.* The act of paying divine honours to man; supposed to be the most ancient kind of idolatry.

ANTHROPOLI'THUS, *f.* in mineralogy, petrifications of the human body. See *MINERALOGY*.

ANTHROPOL'OGY, *f.* [from *ανθρωπος*, man, and *λογω*, Gr. to discourse.] The doctrine of anatomy; the doctrine of the form and structure of the body of man. Among divines, it denotes that manner of expression by which the inspired writers attribute human parts and passions to God.

ANTHROPOM'ANCY, *f.* A species of divination performed by inspecting the entrails of a human creature.

ANTHROPOMOR'PHA, *f.* A term formerly given to the *primates*, or that class of animals which have the greatest resemblance to the human kind.

ANTHROPOMOR'PHISM, *f.* among ecclesiastical writers, denotes the heresy or error of the *Anthropomorphites*.

ANTHROPOMOR'PHITES, *f.* [*anthropomorphita*, Lat. *ανθρωπομορφισται*, Gr. of *ανθρωπος*, a man, and *μορφη*, form.] A sect of ancient heretics, who, taking every thing spoken of God in Scripture in a literal sense, particularly that passage of Genesis, in which it is said, *God made man after his own image*, maintained that God had a human shape. They are likewise called *Audeans*, from Audeus their leader. —Christians as well as Turks have had whole sects contending that the Deity was corporeal and of human shape; though few profess themselves *anthropomorphites*, yet we may find many amongst the ignorant of that opinion. *Locke*.

ANTHROPOMOR'PHOUS, *adj.* Something that bears the figure or resemblance of a man. Naturalists give instances of anthropomorphous plants, anthropomorphous minerals, &c. These come under the class of *lusus naturæ*.

ANTHROP'ATHY, *f.* [*ανθρωπος*, man, and *παθος*, Gr. passion.] The sensibility of man; the passions of man.

ANTHROP'AGI, *f.* [*ανθρωπος*, man, and *φαγω*, Gr. to eat.] Man-eaters; cannibals; those who eat human flesh. It is never used in the singular:

The cannibals that each other eat,
The *anthropophagi*, and men whose heads
Do grow beneath their shoulders. *Shakespeare*.

The Cyclops, the Lestrygons, and Scylla, are all repre-

sented in Homer as anthropophagi, or man-eaters; and, the female phantoms, Circe and the Syrens, first bewitched with a show of pleasure, and then destroyed. This, like the other parts of Homer's poetry, had a foundation in the manner of the times preceding his own. It was still, in many places, the age spoken of by Orpheus:

When men devour'd each other like the beasts,
Gorging on human flesh.

Some remains of the usage subsisted much longer, even among the most civilized nations, in the practice of offering human sacrifices.

History gives us divers instances of persons driven by excess of hunger to eat their own relations. Others commence anthropophagi out of revenge and hatred; there are many instances of soldiers, who in the heat of battle have been carried to such excess of rage, as to tear their enemies with their teeth. The violence of love has sometimes produced the same effect as the excess of hatred. The Tapuii eat the bodies of their friends and nearest relations to preserve them from worms and putrefaction, thinking they do not only hereby afford them an honourable grave, but even a new life, a kind of revivification in themselves. Artemisia did something like this, when she swallowed the ashes of her dead husband Mausolus.

According to Herodotus, among the Etesdonians, when a man's father died, the neighbours brought several beasts, which they killed, mixed up their flesh with that of the deceased, and made a feast. Among the Massagete, when any person grew old, they killed him, and ate his flesh; but, if he died of sickness, they buried him, esteeming him unhappy. The same author also assures us, that several nations in the Indies killed all their old people and their sick, to feed on their flesh: he adds, that persons in health were sometimes accused of being sick, to afford a pretence for devouring them. According to Sextus Empiricus, the first laws that were made, were for the prevention of this barbarous practice, which the Greek writers represent as universal before the time of Orpheus. Of the practice of anthropophagy in later times, we have the testimonies of all the Romish missionaries who have visited the internal parts of Africa, and even some parts of Asia. Herrera speaks of great markets in China, furnished wholly with human flesh. Marcus Paulus speaks of the like in his time, in the kingdom of Concha towards Quinsay, and the island of Zapengit; others of the great Java: Barbosa, of the kingdom of Siam and the island of Sumatra; others, of the islands in the gulf of Bengal, of the country of the Samogitians, &c.

When America was first discovered, this practice was represented, by the Portuguese and Spanish authors, to be almost universal; it also appears from Dr. Hawkesworth's Account of the Voyages to the South Seas, that the inhabitants of the island of New Zealand sacrifice and eat the bodies of their enemies. Mr. Marsden also informs us, that this horrid custom is practised by the Battas, a people in the island of Sumatra: "They do not eat human flesh (says he) as a means of satisfying the cravings of nature, owing to a deficiency of other food; nor is it sought after as a gluttonous delicacy; they eat it as a species of ceremony; as a mode of showing their detestation of crimes, by an ignominious punishment; and as an indication of revenge and insult to their unfortunate enemies. The objects of this barbarous repast are the prisoners taken in war, and offenders convicted and condemned for capital crimes. Persons of the former description may be ransomed or exchanged, for which they often wait a considerable time; and the latter suffer only when their friends cannot redeem them, by the customary fine of twenty benchangs, or eighty dollars. These are tried by the people of the tribe where the fact was committed, but cannot be executed till their own particular raja or chief has been acquainted with the sentence; who, when he acknowledges the justice of the intended punishment, sends a cloth to cover the delinquent's head, together with a large

1. *Anthrenus scrophularius*, with the Parts magnified. 2. *Antipathes spiralis*.
3. *Antipathes cupressus*. 4. *Antipathes oricalcea*.

large dish of salt and lemons. The unhappy object is then tied to a stake: the people assembled throw their lances at him from a certain distance; and, when mortally wounded, they run up to him, as if in a transport of passion; cut pieces from the body with their knives; dip them in the dish of salt and lemon-juice; slightly broil them over a fire prepared for the purpose; and swallow the morsels with a degree of enthusiasm. Sometimes, (perhaps according to the degree of their animosity and resentment,) the whole is devoured; and instances have been known, where, with barbarity still aggravated, they tear the flesh from the carcase with their mouths. To such a depth of depravity may man be plunged, when neither religion nor philosophy enlighten his steps! All that can be said in extenuation of the horror of this diabolical ceremony is, that no view appears to be entertained of torturing the sufferers; of increasing or lengthening out the pangs of death; the whole fury is directed against the corse; warm indeed with the remains of life, but past the sensation of pain. A difference of opinion however prevails, in regard to their eating the bodies of their enemies slain in battle. Some persons long resident there, and acquainted with their proceedings, assert that it is not customary; but, as one or two particular instances have been given by other people, it is just to conclude, that it is a ceremony that sometimes takes place, though not generally. It was supposed to be with this intent that raja Neabin maintained a long conflict for the body of Mr. Nairne, a most respectable gentleman and valuable servant of the India company, who fell in an attack upon the campong of that chief in the year 1775."

It was said by the conquerors of Mexico, that Montezuma sacrificed every year 20,000 infants; that human victims were offered in all the temples of the city, of which there were, according to Antonio Solis, 2000 in that capital. The truth is, that there was but one chapel, built in the form of an amphitheatre, in the whole place. It is evident, that Solis meant not so much to inform posterity, as to palliate the atrocious cruelty of the Spanish conquerors. It was on the same principle, that Livy, with a view to prejudice his readers against the enemies of Rome, asserts seriously, that Hannibal distributed human flesh for food to his soldiers, in order to render them more fierce in battle. Much of misrepresentation, and much of the marvellous, has indeed been and said written on this subject; and yet it appears, that the Scythians, Egyptians, Chinese, Indians, Phœnicians, Persians, Greeks, Romans, Arabians, Gauls, Germans, Britons, Spaniards, Negroes, and Jews, were in early times in the habit of sacrificing enemies. If it is not possible to prove that they were all anthropophagi in this state of barbarism, it is probably because that state hath preceded the records of history.

In the account of China, published by the abbé Renaudot, it is said, that there were anthropophagi in this empire so late as the ninth century, which is hardly to be believed; yet Marc Paolo, who had never read this account written by the Arabians, relates, that the inhabitants of the provinces of Xandu and Concha eat their prisoners. "The barbarity of the Chinese (says M. Pauw) with respect to the infants whom they will not rear, and of whom they destroy every year throughout the empire not fewer than 30,000, by smothering them in tubs of hot water, or exposing them in the streets and highways, is likewise hardly to be believed, and yet it is true." The Peruvians, who had gone before the other nations of America in civilization, did not, when first discovered, sacrifice human victims; they were content to draw from the frontal vein or from the nose of a child a certain portion of blood, which, being mixed with flour, was made into cakes, and distributed to all the subjects of the empire on a certain annual solemnity. This clearly proves that the Peruvians had been originally eaters of human flesh; it is, at the same time, a manifest mitigation of a barbarous species of worship; their manners and habits had been in some degree softened, and religion followed the revolution in their moral character. Happy had it

been for more civilized nations, that this correspondence had been carefully preserved; and that good sense in religious matters had kept pace with their advances in science, and a polish in their manners!

ANTHROPOPHAGY, *f.* [*ανθρωπος*, a man, and *φαγω*, Gr. to eat.] The quality of eating human flesh, or man-eating.—Upon slender foundations was raised the *anthropophagy* of Diomedes his horses. *Brown*.

The annals of Milan furnish an extraordinary instance of anthropophagy. A Milanese woman, named Elizabeth, from a depraved appetite, like that which some women with child, and those whose menses are obstructed, frequently experience, had an invincible inclination to human flesh, of which she made provision by enticing children into her house, where she killed and salted them; a discovery of which having been made, she was broken on the wheel and burnt in 1519.

ANTHROPOSCOPIA, *f.* [*ανθρωπος*, and *σκοπεω*, Gr. I consider.] The art of judging or discovering a man's character, disposition, passions, and inclinations, from the lineaments of his body. In which sense, anthroposcopia seems of somewhat greater extent than physiognomy or metoposcopy. Otto has published an *Anthroposcopia, sive judicium hominis de homine ex lineamentis externis*.

ANTROPO'SOPHY, *f.* [*ανθρωπος*, man, and *σοφια*, Gr. wisdom.] The knowledge of the nature of man.

ANTHROPTHY'SIA, *f.* the inhuman practice of offering human sacrifices. See **SACRIFICE**.

AN'THUS, *f.* in ornithology, a synonyme of a species of loxia. See **LOXIA**.

ANTHYLLIS, *f.* [*ανθυλλια*, Gr. a downy flower.] In botany, a genus of the diadelphia decandria class, ranking in the natural order of papilionaceæ or leguminosæ. The generic characters are—Calyx: perianthium one-leaved, ovate-oblong, swelling, villose; the mouth five-toothed, unequal, permanent. Corolla: papilionaceous; banner longer, the sides reflex, claw the length of the calyx; wings oblong, shorter than the banner; keel compressed, the length of the wings, and similar to them. Stamina: filaments connate, rising; antheræ simple. Pistillum: germ oblong; style simple, ascending; stigma obtuse. Pericarpium: legume roundish, concealed within the calyx, very small, bivalve. Seeds: one or two.—*Essential Character*. Calyx swelling; legume roundish, concealed.

Species. I. Herbaceous. 1. *Anthyllis tetraphylla*, or four-leaved anthyllis or kidney-vetch: leaves pinnate with four lobes, flowers lateral. This is an annual plant with trailing branches, which spread flat on the ground. The leaves grow by fours at each joint; or rather, as Linnæus expresses it, they are pinnate with four leaflets instead of five, the lowest leaflet wanting its opposite. The flowers come out in clusters on the sides of the stalks, having large swelling calyxes, out of which the extreme parts of the petals do but just appear; these are of a yellow colour, and are succeeded by short pods inclosed within the calyx. This species has the stamens really diadelphous, and not all connate, as in most of the others. It is a native of the south of France, Spain, Portugal, Italy, and Sicily, where it is a weed in their arable land. It flowers with us in July, and ripens its seeds in September. It was cultivated in 1640, by Parkinson; but, the flowers having little beauty, this plant is seldom permitted to have a place, except in botanic gardens.

2. *Anthyllis vulneraria*, or common ladies' finger or kidney-vetch: leaves pinnate, unequal; head double. Linnæus observes, that in Oeland, where the soil is a red calcareous clay, the flowers of *anthyllis vulneraria* are red; but that, in Gothland, where the soil is white, the flowers also are white: ours are yellow. Mr. Miller affirms, that, having cultivated them many years, he found that they never altered from seeds: that the leaves of the yellow-flowering kidney-vetch are much narrower than those of the red, and have generally one or two pairs of leaflets more in each; that the heads of flowers are single in this, whereas the red has double heads; and that the root

is perennial in our wild fort, whereas the other seldom lasts longer in gardens than two years, although on poor land it will sometimes continue three years. It is a native of most parts of Europe, and flowers from May to July. The scarlet-flowering kidney-vetch, which is a variety of this species, is also found wild in several parts of Europe. Mr. Miller received the seeds from Spain and Portugal; Mr. Ray says it is common in Italy; and we have it in Wales, both in Pembrokeshire, where it was first found by Edward Llwyd, and the isle of Anglesea, where Dillenius observed it; also in the isle of Man. The anthyllis vulneraria is recommended as an excellent pasturage for sheep; and Mr. Young informs us, that it abounds greatly in the best meadows of the Pyrenees: at the same time he says, that the produce is not large. With us the whole plant is dry, and looked upon as astringent. This, however, is owing to its affecting dry calcareous soils: cultivated in a rich soil, it would be doubtless become more succulent, though it would probably never rival several other leguminous plants.

3. *Anthyllis montana*, or mountain anthyllis or kidney-vetch: leaves pinnate, equal; head terminal, one-ranked, flowers oblique. Legume smooth, the length of the calyx, containing few seeds, of which only one ripens, in July. Native of the south of France, Switzerland, Austria, Carniola, Italy, and Spain.

4. *Anthyllis cornicina*: leaves pinnate, unequal; heads solitary. According to Miller, when it flowers early in the summer, it commonly decays soon after the seeds are ripe, whereas those plants which flower later in the season, and do not perfect their seeds, will abide another year. It is a native of Spain.

5. *Anthyllis lotoides*: leaves three-parted; calyxes prismatic, fascicled, the length of the legumes. Native of Spain. Annual.

6. *Anthyllis Gerardi*: leaves pinnate, unequal, peduncles lateral, longer than the leaf, heads leafless. Annual. Grows wild on the sea-shores of Provence.

7. *Anthyllis quinqueflora*, or five-flowered anthyllis: leaves ternate, linear; head five-flowered. A native of the Cape of Good Hope.

8. *Anthyllis involucreta*: sub-herbaceous; leaves ternate, petiolate, stipuled, sword-shaped; flowers in a head. Native of the Cape of Good Hope.

II. Shrubby. 9. *Anthyllis linifolia*: leaves ternate, sessile, sword-shaped; flowers in a head. Stem eight feet high, shrubby, round, equal; branchlets hoary; the flowers are yellow.

10. *Anthyllis barba Jovis*, or silvery anthyllis or Jupiter's beard: leaves pinnate, equal, tomentose; flowers in a head. This species is a shrub which often grows ten or twelve feet high, and divides into many lateral branches, with winged leaves, composed of an equal number of narrow leaflets, which are very white and hairy; the flowers are produced at the extremities of the branches, collected into small heads: these are of a bright yellow colour, and appear in June; sometimes they are succeeded by short woolly pods, containing two or three kidney-shaped seeds; which, except the season proves warm, do not ripen in this country. A native of the south of France, Spain, Portugal, Italy, and the East.

11. *Anthyllis heterophylla*: leaves pinnate, the floral leaves ternate. Grows naturally in Portugal and Spain.

12. *Anthyllis visciflora*: leaves digitate-pinnate, calyxes flaggy. Observed at the Cape by Sparrman.

13. *Anthyllis cytisoides*, or downy-leaved anthyllis: leaves ternate, unequal; calyxes woolly, lateral. This is a low shrub, seldom rising above two feet high, but sends out many slender branches, with hoary leaves, which are sometimes single, but generally have three oval leaflets, the middle one being longer than the other two; the flowers are yellow, and come out from the side of the branches, three or four joined together, having woolly calyxes; but these are rarely succeeded by seeds in England. Native of Spain and about Montpellier.

14. *Anthyllis hermannike*, or lavender-leaved anthyllis: leaves ternate, sub-peduncled; calyxes naked. This species is a shrub which grows five or six feet high; the branches are garnished with oblong ternate leaves; the flowers, which are yellow, are produced in small clusters on the side of the branches; these appear in July and August, but are not succeeded by seeds in this country. Grows naturally in Greece, Crete, and also in Palestine: this was formerly in some of the English gardens, but the severe winter of 1739-40 destroyed most if not all the plants in this country.

15. *Anthyllis erinacea*, or prickly anthyllis: spinose, leaves simple. The height of this shrub is nine or ten feet. It grows naturally in Spain and Portugal.

16. *Anthyllis tragacanthoides*: shrubby; leaves pinnate tomentose, petioles spinose, flowers in racemes. Native of Mount Lebanon.

17. *Anthyllis Indica*: shrubby; leaves pinnate equal smooth; racemes oblong subterminating. A large shrub, with an upright stem, and scanty unarmed branches. Native of the mountains of Cochinchina.

Propagation and Culture. The seeds should be sown on a bed of light earth in April, where the plants are to remain, and will require no other care, but to thin them to the distance of two feet, and to keep them clean from weeds. Or, if they are permitted to scatter on the ground, they will come up with the first warmth of spring. The tenth, and several other of the shrubby sorts may be propagated either by seeds or cuttings; if by seeds, they should be sown in the autumn, in pots filled with light earth, and placed under a frame in winter, to protect them from frost. The following spring the plants will rise, and, when they are strong enough to remove, they should be each planted in a small pot, filled with light earth, and placed in the shade, till they have taken new root; after which, they may be put along with other hardy exotic plants, in a sheltered situation, till October, when they must be removed into shelter. These plants are always housed in winter, yet some of them will live abroad three or four years, when they are planted against a wall, with a south-west aspect. They may also be propagated by cuttings, which may be planted during any of the summer months, observing to water and shade them till they have taken root; when they should be planted in pots, and treated in the same manner as those which are raised from seed. See *ARENARIA*, *ASPALATHUS*, *CAMPHOROSMA*, *CRESSA*, *EBENUS*, *POLYCARPON*, *POLYCNEMUM*, *SALSOLA*, and *TEUCRIUM*. *ANTHYLLIS VALENTINA*, *f.* in botany. See *FRANKENIA*.

ANTHYLLOIDES, *f.* in botany. See *SALSOLA*.

ANTHYPNOTIC, *adj.* [from *αντι*, against, and *υπνος*, Gr. sleep.] That which has the power of preventing sleep; that which is efficacious against a lethargy.

ANTHYPOCONDRIACS, *f.* [from *αντι*, against, and *υποχονδρια*, Gr. the hypochondria.] Medicines against the disorders of the hypochondria.

ANTHYPOPHORA, *f.* [*αντι* *υποφορα*, Gr.] A figure in rhetoric, which signifies a contrary illation, or inference, and is when an objection is refuted or disproved by the opposition of a contrary sentence.

ANTHYSTERICA, *f.* [from *αντι*, against, and *υστερα*, the uterus.] Medicines against the hystERIC passion. These medicines might be called *uterines*, for many of them remove the disorders of the uterus, that produce hystERIC fits.

ANTI, [*αντι*, Gr.] A particle much used in composition with words derived from the Greek, and signifies *contrary to*; as, *Anti-monarchical*, opposite to monarchy.

ANTI, in matters of literature, is a title given to divers pieces written by way of answer to others, whose names are usually annexed to the anti. See the *Anti* of M. Baillet; and the *Anti-Baillet* of M. Menage: there are also *Anti-Menagiani*, &c. Cæsar the dictator wrote two books by way of answer to what had been objected to him by Cato, which he called *Anti-Catones*; these are mentioned by

by Juvenal, Cicero, &c. Vives assures us, he had seen Cæsar's Anti-Catones in an ancient library.

ANTIA'CID, *adj.* [from *ἄντι*, Gr. and *aciaus*, Lat. four.] Contrary to fourness; alkalis.—Oils are *antiacids*, so far as they blunt acrimony; but, as they are hard of digestion, they produce acrimony of another sort. *Arbutus*.

ANTI'ADES, *f.* [*αντιαδες*, Gr.] The glandules and kernels, commonly called the almonds, of the ears; also an inflammation in those parts.

ANTI'AGRI, *f.* [from *αντιαδες*, the tonsils, and *αγρα*, Gr. a prey.] Tumours of the tonsils.

ANTIBAC'CHIUS, *f.* in ancient poetry, a foot consisting of three syllables, the two first long, and the last one short; such is the word "ἀμβίρε."

ANTI'BES, a sea-port town in the department of Var, and late province of Provence in France. It is opposite to Nice, in the Mediterranean. Lat. 43. 35. N. lon. 7. 13. E.

AN'TIC, *adj.* [probably from *antiquus*, Lat. ancient, as things out of use appear old.] Odd; ridiculously wild; buffoon in gesticulation:

Of all our *antic* fights, and pageantry,
Which English idiots run in crowds to see. *Dryden.*

—The prize was to be conferred upon the whistler, that could go through his tune without laughing, though provoked by the *antic* postures of a merry Andrew, who was to play tricks. *Addison.*

ANTIC, *f.* He that plays antics; he that uses odd gesticulation; a buffoon:

Within the hollow crown,
That rounds the mortal temples of a king,
Keeps death his court; and there the *antic* fits,
Scoffing his state. *Shakespeare.*

To **ANTIC**, *v. a.* To make antic:

Mine own tongue
Splits what it speaks; the wild disguise hath almost
Antic'd us all. *Shakespeare.*

ANTICAR'DIUM, *f.* [of *αντικαρδιον*, Gr. of *αντι*, against, and *καρδια*, the heart.] The pit of the stomach, or heart-pit.

ANTICAUSO'TICS, *f.* [from *αντι*, against, and *καυσος*, Gr. a burning fever.] Remedies against burning fevers.

ANTICHACHE'C'TIC, *adj.* [from *αντι*, against, and *καχεξια*, Gr. a bad habit.] Things adapted to the cure of a bad constitution.

ANTICHAM'BER, *f.* This word is corruptly written for **ANTECHAMBER**, which see.

ANTICHOLE'RICA, *f.* in botany. See **SOPHORA**.

ANTICHO'LICS, *f.* [of *αντι*, and *χολικον*, Gr. cholic.] Remedies against the cholic.

ANTICHO'RUS, *f.* [In the accented catalogus of names given by the Lichfield Society, the accent is placed on the antepenultima, as if it were derived from *χουρος*; but, if it be derived from *χουρος*, then it should be placed on the penultima.] In botany, a genus of the octandria monogynia class, ranking in the natural order of columniferæ. The generic characters are—Calyx: perianthium four-leaved, very much expanded; leaflets lanceolate, acuminate, deciduous. Corolla: petals four, obovate, obtuse, the length of the calyx. Stamina: filaments setaceous, erect, shorter than the corolla; antheræ roundish. Pistillum: germ superior, ovate; style cylindric, the length of the filaments; stigma obtuse. Pericarpium: capsule subulate, four-celled, four-valved. Seeds: very many, truncate, placed over each other in four rows.—*Essential Character.* Calyx, four-leaved; petals, four; capsule, superior, subulate, four-celled, four-valved. Seeds, very many.

There is only one species, called *antichorus depressus*. It resembles the *corydalis*, and is a small procumbent annual plant. Stem round, three or four inches long, alternately branching, growing close to the ground. Leaves alternate, petioled, oval, grossly serrate, smooth, somewhat

plaited. Stipules subulate. Flowers axillary, two together, opposite, on very short thickish peduncles, yellow. Bractæ two, on the upper side of the peduncle. Fruits nodding, closely reflected under the stem. A native of Arabia.

ANTICHRIST, *f.* [*antichristus*, Lat. of *αντιχριστος*, Gr. of *αντι*, against, and *χριστος*, Christ.] Among ecclesiastical writers, denotes a great adversary of Christianity, who is to appear upon the earth towards the end of the world. We have demonstrations, disputations, and proofs, in great and order number, both that the pope is, and that he is not, Antichrist. F. Calmet is very large in describing the father and mother of Antichrist, his tribe and pedigree, his wars and conquests, his achievements against Gog, Magog, &c. Some place his capital at Constantinople, others at Jerusalem, others at Moscow, and some few at London; but the generality at Rome, though these last are divided. Grotius and some others suppose Rome Pagan to have been the seat of Antichrist: most of the Lutheran and reformed doctors contend earnestly for Rome Christian under the papal hierarchy. In fact, the point having been maturely debated at the council of Gap, held in 1603, a resolution was taken thereupon, to insert an article in the confession of faith, whereby the pope is formally declared to be Antichrist. Pope Clement VIII. was stung to the quick with this decision; and even king Henry IV. of France was not a little mortified, to be thus declared, as he said, "an imp of Antichrist."

M. le Clerc holds, that the rebel Jews and their leader Simon, whose history is given by Josephus, are to be reputed as the true Antichrist. Lightfoot and Vanderhart rather apply this character to the Jewish sanhedrim. Hippolitus and others held that the devil himself was the true Antichrist; that he was to be incarnate, and make his appearance in human shape before the consummation of all things.

Father Malvenda, a Jesuit, hath published a large work intitled *Antichristo*, in which this subject is amply discussed. It consists of thirteen books. In the first he relates all the opinions of the fathers with regard to Antichrist. In the second, he speaks of the times when he shall appear; and shews, that all the fathers who supposed Antichrist to be near at hand, judged the world was near its period. In the third he discourses of his origin and nation; and shews that he is to be a Jew, of the tribe of Dan: this he founds on the authority of the fathers; on the passage in Genesis xlix. 17. *Dan shall be a serpent by the way*, &c. on that of Jeremy viii. 16. where it is said, *The armies of Dan shall devour the earth*; and on Rev. vii. where St. John, enumerating all the tribes of Israel, makes no mention of that of Dan. In the fourth and fifth books he treats of the signs of Antichrist. In the sixth, of his reign and wars. In the seventh, of his vices. In the eighth, of his doctrine and miracles. In the ninth, of his persecutions: and, in the rest, of the coming of Enoch and Elias, the conversion of the Jews, the reign of Jesus Christ, and the death of Antichrist, after he has reigned three years and an half. See also *Lowman on the Revelation*.

Upon the whole, the Antichrist mentioned by the apostle John, 1 Eph. ii. 18. and more particularly described in the book of Revelation, seems evidently to be the same with the *Man of Sin*, &c. characterised by St. Paul in his second Epistle to the Thessalonians, ch. ii. Had the right of private judgment, says an excellent writer, been always adopted and maintained, Antichrist could never have been; and, when the sacred right comes to be universally asserted, and men follow the voice of their own reason and consciences, Antichrist can be no more.

ANTICHRISTIAN, *adj.* [from *αντι*, against, and *χριστιανος*, Gr.] Opposite to Christianity.—That despised, abject, oppressed, sort of men, the ministers, whom the world would make *antichristian*, and so deprive them of heaven. *South.*

ANTICHRISTIANISM, *f.* Opposition or contrariety to Christianity.—Have we not seen many, whose opinions have

have fastened upon one another the brand of *antichristianism*? *Decay of Piety.*

ANTICHRISTIANITY, *f.* Contrary to Christianity.

ANTICHRISTIANS, *f.* are more particularly those who set up or believe a false Christ, or Messiah.

ANTI'CHRONISM, *f.* [*αντι*, against, and *χρονος*, Gr. time.] Deviation from the right order or account of time.

ANTICHTHONES, *f.* in ancient geography, an appellation given to the inhabitants of opposite hemispheres.

To **ANTICIPATE**, *v. a.* [*anticipo*, Lat.] To take something sooner than another, so as to prevent him that comes after; to take first possession.—God hath taken care to *anticipate* and prevent every man, to draw him early into his church; to give piety the prepossession, and so to engage him in holiness. *Hammond.*—To take up before the time at which any thing might be regularly had.—I find I have *anticipated* already, and taken up from Boccace, before I come to him; but I am of the temper of kings, who are for present money, no matter how they pay it. *Dryden.*—To foretaste, or take an impression of something, which is not yet, as if it really was.—The life of the desperate equals the anxiety of death, who but act the life of the damned, and *anticipate* the desolations of hell. *Brown.*

Why should we

Anticipate our sorrows; 'tis like those
That die for fear of death.

Denham.

To prevent any thing by crowding in before it; to preclude.—I am far from pretending to instruct the profession, or *anticipating* their directions to such as are under their government. *Arbutnot.*

ANTICIPATION, *f.* The act of taking up something before its time.—It is not enough to be miserable when the time comes, unless we make ourselves so beforehand, and by *anticipation*. *L'Estrange.*—Foretaste.—If we really live under the hope of future happiness, we shall taste it by way of *anticipation* and forethought; an image of it will meet our minds often, and stay there, as all pleasing expectations do. *Atterbury.*—Opinion implanted before the reasons of that opinion can be known.—The east and west, the north and south, have the same *anticipation* concerning one supreme disposer of things. *Stillington.*—What nation is there, that, without any teaching, have not a kind of *anticipation*, or pre-conceived notion, of a Deity? *Derham.*

ANTICIPANS, *f.* The Greeks express this by *πινυμενοι*; it is applied to diseases whose succeeding paroxysms anticipate the time of the preceding fit, that is, each of whose fits begins somewhat sooner than the preceding. If the catamenia arrive before their ordinary period, they are said to anticipate.

ARTICLE'A, the mother of Ulysses. It is said that she was ravished by Sisyphus, and was pregnant of Ulysses when the married Laertes; and that she killed herself when she heard a false report of her son's death.

ANTICLIMAX, *f.* [*from αντι and κλιμαξ*, Gr.] A sentence in which the last part expresses something lower than the first.—A certain figure, which was unknown to the ancients, is called by some an *anticlimax*. *Addison.*—This distich is frequently mentioned as an example:

Next comes Dalhoussey, the great god of war,
Lieutenant colonel to the earl of Mar.

ANTICLY, *adv.* In an antic manner; with odd postures; wild gesticulations, or fanciful appearance:

Scrambling, out-facing, fashion-mongring, boys,
That lye, and cog, and flout, deprave, and slander,
Go *anticly*, and shew an outward hideousness,
And speak of half a dozen dangerous words. *Shakespeare.*

ANTICONVULSIVE, *adj.* [*from αντι*, Gr. against, and *convulsive*.] Good against convulsions.—Whatever produces an inflammatory disposition in the blood, produces the asthma, as *anticonvulsive* medicines. *Floyer.*

ANTICOR, *f.* [*from αντι*, Gr. against, and *cor*, Lat. the

heart.] A preternatural swelling of a round figure, occasioned by a sanguine and bilious humour, and appearing in a horse's breast, opposite to his heart. An anticor may kill a horse, unless it be brought to a suppuration by good remedies.

ANTICOS'TE, a barren island lying in the mouth of the river St. Laurence, in North America. Lat. from 49° to 53° N. lon. 64. 16. W.

ANTICOURTIER, *f.* [*from αντι*, Gr. against, and *courtier*.] One that opposes the court.

ANTICYRA, anciently a town of Phocis, on the Corinthian bay, opposite to Cirrha. The Phocceans seizing the temple of Apollo at Delphi, a war, called the *sacred*, commenced, and lasted ten years; when Philip, father of Alexander the Great, avenged the god by destroying many of the cities of the pillagers. Anticyra was one of the number. It was again taken and subverted by Antilius a Roman general in the war with the Macedonians. It afterwards became famous for its hellebore. That drug was the chief produce of the rocky mountains above the city, and of two kinds; the black, which had a purgative quality; and the white, which was an emetic. Sick persons resorted to Anticyra to take the medicine, which was prepared there by a peculiar and very excellent recipe: hence the adage, *Naviget Anticyram*. By the port was a temple of Neptune, built with selected stones, and the inside white-washed; the statue of brass. The walls and other edifices at Anticyra were probably erected, like the temple of Neptune, with stones or pebbles. The site is now called *Asprospitia*, or the "white houses;" and some traces of the buildings from which it was so named remain. The port is land-locked, and frequented by vessels for corn.

ANTIDES'MA, *f.* [*αντι*, *pro*, and *δεσμευ*, *vinculum*; excellent for making ropes.] In botany, a genus of the dioecia pentandria class. The generic characters are—1. Male. Calyx: perianthium five-leaved; leaflets oblongish, concave. Stamina: filaments five, capillary, longer than the calyx, equal; antheræ roundish, semibifid. 11. Female. Calyx: as in the male, permanent. Pistillum: germ superior, ovate; style none; stigmas five, obtuse. Pericarpium: drupe roundish, one-celled, crowned with the stigmas, and having a furrowed shell. Seed: none.—*Essential Character.* Male. Calyx, five-leaved; corolla, none; antheræ, semibifid. Female. Calyx, five-leaved; corolla, none; stigmas, five; berry cylindric, one-seeded.

Species. 1. *Antidesma alexiteria*. It is a middle-sized tree, with leaves resembling those of the lemon. Flowers in racemes. Fruit red, and acid like the barberry. Common in Malabar, is an evergreen, and continues to bear fruit to the age of seventy years; the fruit is esteemed for its pleasant cooling qualities. A decoction of the leaves is reputed to be an antidote against the bite of serpents. The bark is used for making ropes.

2. *Antidesma acida*: leaves obovate, spikes solitary. A native of the East Indies.

3. *Antidesma scandens*: leaves palmate serrate, stem climbing. Native of China near Canton.

ANTIDICOMARIANITES, ancient heretics, who pretended that the holy virgin did not preserve a perpetual virginity, but that she had several children by Joseph after our Saviour's birth. Their opinion was grounded on some expressions of our Saviour, wherein he mentions his brothers and his sisters; and of St. Matthew, where he says, that Joseph knew not Mary till she had brought forth her first-born son. The Antidicomarianites were disciples of Helvidius and Jovinian, who appeared in Rome toward the close of the fourth century.

ANTIDIPNICA, *f.* [*from αντι*, against, and *διψω*, circumgyration.] Medicines against a vertigo.

ANTIDORON, *f.* a name given by the Greeks to the consecrated bread, out of which the middle part, marked with the cross, wherein the consecration resides, being taken away by the priest, the remainder is distributed after
mass

mass to the poor. The antidoron is also called *panis præ-sanctificatus*.

ANTIDO'SIS, *f.* in antiquity, denotes an exchange of estates, practised by the Greeks on certain occasions with peculiar ceremonies, and first instituted by Solon. When a person was nominated to an office, the expence of which he was not able to support, he had recourse to the antidosis; that is, he was to seek some other citizen of better substance than himself, who was free from this and other offices; in which case the former was excused. In case the person thus substituted denied himself to be the richest, they were to exchange estates, after this manner: the doors of their houses were close shut up and sealed, that nothing might be conveyed away; then both took an oath to make a faithful discovery of all their effects, and within three days an exchange of estates was made.

ANTIDO'TAL, *adj.* That which has the quality of an antidote, or the power of counteracting poison.—Animals that can innocuously digest these poisons, become *antidotals* to the poison digested. *Brown*.

ANTIDOTE, *f.* [ἀντίδοτον, Gr. *antidotus*, Lat. a thing given in opposition to something else.] A medicine given to expel the mischiefs of another, as of poison:

Trust not the physician;
His *antidotes* are poison, and he slays
More than you rob.

Shakespeare.

ANTIDYSENTE'RIC, *adj.* [from ἀντί, Gr. against, and *dyenteria*, Lat. a bloody flux.] Good against the bloody flux.

AN'TIENT. See **ANCIENT**.

ANTI-EPILEPTICS, *f.* [from ἀντί, against, ἐπιληψία, Gr. *the epilepsy*.] Remedies against an epilepsy and other convulsive disorders.—That bezoar is antidotal, lapis judaicus diuretical, coral *antepileptical*, we will not deny. *Brown*.

ANTIFE'BRILE, *adj.* [from ἀντί, Gr. against, and *febris*, Lat. a fever.] Good against fevers.—*Antifebrile* medicines check the ebullition. *Floyer*.

ANTI'GONE, in fabulous history, a daughter of Oedipus king of Thebes, by his mother Jocasta. She buried by night her brother Polyneices, contrary to the orders of Creon, who, when he heard it, ordered her to be buried alive: she however strangled herself; and Æmon, who was to have married her, killed himself on her grave. Also a daughter of Laomedon, and sister of Priam; who was changed into a stork for comparing herself to Juno.

ANTIGONE'A, or **ANTIGO'NIA**, anciently a town of Bithynia, so called from Antigonus, the son of Philip, and afterwards called *Nicaa*. Another of Epirus, to the north of the Montes Ceraunii, opposite to the city of Oricum. A third of Arcadia, namely *Mantineia*, so called in honour of king Antigonus. A fourth in Macedonia, in the territory of Mygdonia. A fifth in the territory of Chalcidice, in Macedonia, on the east side of the Sinus Thermaicus. A sixth of Syria, built by Antigonus, not far from Antioch, on the Orontes; but soon after destroyed by Seleucus, who removed the inhabitants to Seleucia. A seventh of Troas, called Alexandria in Pliny's time.

ANTI'GONUS, one of Alexander's commanders, to whom Asia fell. He conquered Eumenes, and expelled Seleucus out of Syria; who flying to Ptolemy Lagus in Egypt, a bloody war commenced betwixt him, Cassander, and Antigonus, wherein, by the help of his son Demetrius, Antigonus prevailed, and built the city Antigonía. Afterward Cassander, Seleucus, and Lyfimachus, uniting, overthrew him, in league with king Pyrrhus, and slew him near Epirus, 301 years before Christ.

ANTIGONUS, king of the Jews, was the son of Aristobulus. He entered into an alliance with the king of the Parthians, and besieged Jerusalem. He cut off his uncle Hircanus's ears, to incapacitate him for the high-priesthood; and put Josephus, Herod's brother, to death. At length, Herod took him and sent him to Marc Antony; who, to gratify Herod, cut off his head, and thereby ex-

tinguished the Asmonians, who had reigned 126 years. This happened 36 years before Christ.

ANTIGRA'PHUS, in antiquity, an officer of Athens, who kept a counterpart of the apodecti, or chief treasurer's accounts, to prevent mistakes, and keep them from being falsified.

ANTI'GRAPHUS, in middle-age writers, was a secretary or chancellor. He is thus called, according to the old glossarists, on account of his writing answers to the letters sent to his master. The antigraphus is sometimes also called *archigraphus*; and his dignity *antigraphia*, or *archigraphia*.

ANTI'GRAPHUS is also used in Isidorus for one of the notes of sentences which is placed with a dot to denote a diversity of sense in translations.

ANTI'GRAPHUS, in ecclesiastical writers, is an abbreviator of the papal letters. In which sense the word is used by pope Gregory the Great in his register. Of late days the office of antigraphus consists in making minutes of bulls from the petitions agreed to by his holiness, and renewing the bulls after engrossing.

ANTI'GUA, one of the Antilles, or Caribbees, is situated about twenty leagues east of St. Christopher's, in lon. 62. 5. W. and lat. 17. 30. N. It is about fifty miles in circumference, and is reckoned the largest of all the British Leeward islands. It is remarkable that it has neither stream nor spring of fresh water; this inconvenience, which rendered it uninhabitable to the Caribbees, deterred for some time Europeans from attempting a permanent establishment upon it; but few, if any, are the obstacles of nature, which civilised man will not overcome, more especially when interest spurs him on. The soil of Antigua was found to be fertile, and it soon presented itself to the view of enterprising genius, that by means of cisterns the necessity of springs and streams might be superseded. Hence, as early as 1632, a son of Sir Thomas Warner, and a number of other Englishmen, settled there, and began the cultivation of tobacco. In 1674, colonel Codrington, of Barbadoes, removed to this island, and succeeded so well in the culture of sugar, that, animated by his example, and aided by his experience, many others engaged in the same line of business. Mr. Codrington dying in 1691, was succeeded by his son Christopher, who, pursuing his father's steps, held the government till 1704, when he was superseded by Sir William Matthews, who died soon after his arrival. Queen Anne then bestowed the government on Daniel Park, Esq. a man who for debauchery, villany, despotism, though he may have been equalled, was certainly never excelled. His government lasted till December 1710, when his oppressions roused the inhabitants to resistance: he was seized by the enraged multitude and torn to pieces, and his reeking limbs scattered about the streets. An inquiry was instituted with respect to the perpetration of this act; the people of England were divided, some looking upon his death as an act of rebellion, others viewing it as a just sacrifice to liberty. The government, however, after a full enquiry, were so fully satisfied of Park's guilty and illegal conduct, that, much to their honour, they issued a general pardon for all persons concerned in his death.

The principal article produced in this island is sugar; besides which, cotton-wool and tobacco is raised in considerable quantities, and likewise provisions to a considerable amount in favourable years. The crops, in general, are very unequal; in 1779, there was shipped 3382 hogheads, and 579 tierces, of sugar; in 1782, the crop was 15102 hogheads, and 1603 tierces; in 1770, 1773, and 1778, there were no crops of any kind, owing to the long-continued drought.

The island is divided into six parishes and eleven districts, and contains six towns and villages. St. John's, (the capital,) Parham, Falmouth, Willoughby-bay, Old-road, and James's Fort; the two first are the legal ports of entry. The island has many excellent harbours, particularly English-harbour and St. John's, at the former of

which there is a dock-yard and arsenal established by the English government. The military establishment here is two regiments of infantry and two of militia, besides which there is a squadron of dragoons and a battalion of artillery raised in the island. The governor, or captain-general, of the Leeward islands, though directed by his instructions to visit each island within his government, is generally stationary at Antigua: in hearing the causes from the other islands he sits alone, but in causes arising within the island he is assisted by a council; and by an act of assembly sanctioned by the crown, the president, and a majority of the council, may hear and determine chancery causes during the absence of the governor-general; besides this court, there is a court of king's bench, a court of common pleas, and a court of exchequer. The legislature of Antigua consists of the commander in chief, a council of twelve members, and an assembly of twenty-five. This island set the first example of a melioration of the criminal law respecting negro-slaves, by allowing them a trial by jury, &c. And the inhabitants, still more to their honour, have encouraged the propagation of the gospel among their slaves.

ANTI'GUG'LER, *f.* is a crooked tube of metal, so bent as easily to be introduced into the necks of bottles, and used in decanting liquors, without disturbing them. For this purpose the bottle should be a little inclined, and about half a spoonful of the liquor poured out, so as to admit an equal quantity of air; let one end of the bent tube be stopped with the finger, whilst the other is thrust into the body of the liquor near to the bubble of air already admitted. When the finger is taken off, the bottle will have vent, and the liquor will run out steadily and undisturbed.

ANTIHEC'TICS, *f.* in pharmacy, medicines good in hectic fevers. The *antiheticum poterii* was a medicine formerly much celebrated.

ANTILIBANUS, a mountain of Cœlosyria, which bounds it on the south, running parallel with Libanus: they both begin a little above the sea, Libanus near Tripolis, Antilibanus at Sidon: and both terminate near the mountains of Arabia, which run to the north of Damascus. The Scripture, making no distinction between Libanus and Antilibanus, calls them by the common name of *Lebanon*.

ANTI'LES, the French name for the **CARIBBEE ISLANDS**.

ANTI'LOCHUS, a son of Nestor and Eurydice, who accompanied his father to the siege of Troy, and was killed by Menon, in parrying the blow that was aimed at his father.

ANTILOGARITHM, *f.* [from *anti* and *logarithm*.] The complement of the logarithm of a sine, tangent, or secant; or the difference of that logarithm from the logarithm of ninety degrees.

ANTI'LOGY, *f.* [*αντιλογία*, Gr.] A contradiction between any words and passages in an author.

ANTI'LOQUIST, *f.* [from *anti*, and *loquor*, Lat. to speak.] A contradicter.

ANTILYS'SUS, *f.* [from *αντι*, against, and *λυσσα*, Gr. the madness caused by the bite of a mad dog.] It is the name of any medicine for the cure of the hydrophobia.

ANTIMACHUS, a Greek poet of Ionia, reckoned the next to Homer in excellence. He wrote a poem upon the Theban war; and, before he had brought his heroes to the city of Thebes, he had filled twenty-four volumes. Also a son of Hercules by one of the Thetiades.

ANTIMEN'SIUM, *f.* a kind of consecrated table-cloth, occasionally used in the Greek church, in places where there is no proper altar. It answers to the *altare portabile*, or portable altar, in the Latin church. They are both of late invention, though Habertus would have them as old as St. Basil.

ANTIMENSIA is also applied to other tables, used in offices of religion, besides those whereon the eucharist is administered: such, for example, are those whereon the host is exposed, &c. The origin of the antimensia is described by Meursius: when the bishop had consecrated a church,

the cloth, which had been spread on the ground and over the communion-table, was torn in pieces, and distributed among the priests, who carried each a fragment away, to serve to cover the tables in their churches and chapels. Not that it was necessary that such cloths should be laid on all tables; but only on those which either were not consecrated, or at least whose consecration was doubted of.

ANTIME'RIA, *f.* in grammar, a figure whereby one part of speech is used for another: e. g. *velle suam cuique est*, for *voluntas sua cuique est*; also, *populus late rex*, for *populus late regnans*. In a more restrained sense, antimeria is a figure where the noun is repeated instead of the pronoun. The antimeria is frequent in the Hebrew, and is sometimes retained in our version of the Old Testament: *Hear my voice, ye wives of Lamech, for my wives*, Gen. iv. 23.

ANTIMETABOLE, *f.* [of *αντι*, against, and *μεταβολη*, from *μεταβαλλω*, Gr. I shift or transfer; a shifting or setting two things over-against each other.] In rhetoric, a figure which sets two things in opposition to each other. This figure is twice exemplified in an apophthegm of Mufonius; which, on account of its excellence, is called *aureum monitum*, the "golden maxim or precept:"

Αν τι πράξης καλον μετα πονε, ο μεν πονος οίχεται, το δε καλον μενει.

Αν τι ποιήσης αισχρον μετα ηδους, το μεν ηδυ οίχεται, το δε αισχρον μενει.

Thus translated: "Allowing the performance of an honourable action to be attended with labour; the labour is soon over, but the honour immortal: whereas, should even pleasure wait on the commission of what is dishonourable, the pleasure is soon gone, but the dishonour eternal."

ANTIMETATHE'SIS, *f.* in rhetoric, is the inversion of the parts or members of an *antithesis*. Such is that of Cicero, in Verrem, lib. iv. cap. 52. "Compare this peace with that war; the arrival of this governor with the victory of that general; his profligate troops with the invincible army of the other; the luxury of the former with the temperance of the latter: you will say that Syracuse was founded by him who took it; and taken by him, who held it when founded."

ANTIMONAR'CHICAL, *adj.* [from *αντι*, against, and *μοναρχια*, Gr. government by a single person.] Against government by a single person.—When he spied the statue of king Charles in the middle of the crowd, and most of the kings ranged over their heads, he concluded that an *antimonarchical* assembly could never choose such a place. *Addison*.

ANTIMONAR'CHICALNESS, *f.* The quality of being an enemy to regal power.

ANTIMO'NIAL, *adj.* Made of antimony; having the qualities of antimony; relating to antimony:

Though *antimonial* cups, prepar'd with art,
Their force to wine through ages should impart,
This dissipation, this profuse expence,
Nor shrinks their size, nor wastes their stores immense.

Blackmore.

ANTIMONY, *f.* [The stibium of the ancients, by the Greeks called *σμμι*. The reason of its modern denomination is referred to Basil Valentine, a German monk; who, as the tradition relates, having thrown some of it to the hogs, observed that, after it had purged them heartily, they immediately fattened; and therefore he imagined his fellow monks would be the better for a like dose. The experiment, however, succeeded so ill, that they all died of it; and the medicine was thenceforward called *antimoine*, *antimohk*.] Antimony is a mineral substance, of a metalline nature, having all the seeming characters of a real metal, except malleability; and may be called a femetall, being a fossil glebe of some undetermined metal, combined with a sulphureous and stony substance. Mines of all metals afford it; that in gold mines is reckoned best. It has also its own mines in Hungary, Germany, and France. Its texture is full of little shining veins or threads, like needles; brittle as glass. Sometimes veins of a red or golden

golden colour are intermixed, which is called *male antimony*; that without them being denominated *female antimony*. It fuses in the fire, though with some difficulty; and dissolves more easily in water. It destroys and dissipates all metals fused with it, except gold; and is therefore useful in refining. It is a common ingredient in speculums, or burning concaves; serving to give them a finer polish. It makes a part in bell-metal; and renders the sound more clear. It is mingled with tin, to make it more hard, white, and sound; and with lead, in the casting of printers' types, to render them more smooth and firm. It is a general help in the melting of metals, and especially in casting of cannon ball. Antimony found its way into medical practice with great difficulty; the ancients considered it as a poison, and only fit for external uses. Basil Valentine, in the fifteenth century, first brought it into vogue as an internal medicine, published a work called *Currus triumphalis Antimonii*; but it soon lost its reputation, until Paracelsus raised its credit again, after which it was received and rejected several times, until, by the success of empyrics, it acquired an established place in regular practice; and is now justly ranked with the most valuable part of the *materia medica*. In its crude state, notwithstanding what has been said by many authors of its efficacy in rheumatic, cancerous, and other cases, it appears from repeated trials to be an inert substance with regard to the human body; yet it is ordered by some physicians to be taken from one scruple to a dram, two or three times a day, in cutaneous and leprous disorders, in its levigated state. Its preparations are, in general, used both as alteratives and evacuants, and hardly any article in the *materia medica* will admit of so extensive a use in acute diseases, as well as chronic; some of them are equally a principal in the cure, the varieties of these complaints requiring some difference in their adjuncts. In fevers of the inflammatory and putrid kinds, antimonials are alike the proper remedy; and in chronic diseases, whether from the rigid or lax habit, they may be depended on. They promote all the secretions and excretions, particularly those of the skin, intestines, urinary passages, and salivary ducts, by gently irritating the whole nervous and vascular compages. If given in small doses, gradually increasing them, yet keeping to that proportion which excites no sensible discharge, they are efficacious in regenerating a healthy state of the blood; for this purpose their effects are not so speedy as those of iron, but they are more lasting. Thus it is easy to perceive how justly it is asserted that antimonials are curative in so many disorders, and those too of opposite natures. As auxiliary to other medicines, on which the cure more directly depends, their efficacy is no less to be admired; they quicken their action and increase their powers, particularly those by which any evacuation is to be promoted; mixed in under-doses with such medicines, their operation is generally more easy too; as an expectorate, some of its preparations excel; and provoke the salivary discharge in the same manner as when mercury hath been freely taken; but that made by antimony is ropy, whereas that with mercury is very thin. If any preparation of antimony is too free in its operation upwards, it may be carried through the intestines by taking a little common salt in any small drink made warm, or it is restrained by a draught of water acidulated with the acidum vitrioli dilutum. The preparations of this drug are very numerous, for which see *CHEMISTRY, PHARMACY, &c.*

The virtues of antimony in the diseases of the horse and other animals are also justly extolled. The virtues of this drug in fattening cattle have been thought imaginary, but experiment proves it to be a real truth. A horse that is lean and scabby, and not to be fatted by any other means, will become fat by taking a dose of antimony every morning for about two months. If to a boar fed for brawn an ounce of antimony be given every morning, he will become fat a fortnight sooner than others fed in the same manner, but without the antimony.

ANTINEPHRETIC, *f.* [from *anti*, and *νεφρις*, a pain

in the kidneys.] Remedies against disorders of the reins and the kidneys.

ANTIN'OE, a city of Egypt. See *ENFINE*.

ANTINOETIA, *f.* in antiquity, annual sacrifices, and quinquennial games, in memory of Antinous the Bithynian. They were instituted at the command of Adrian the Roman emperor, at Mantinea in Arcadia, where Antinous was honoured with a temple and divine worship.

ANTINO'MIANS, *f.* [*αντινομια*, of *anti*, against, and *νομος*, the law, Gr.] In ecclesiastical history, certain heretics who maintain the law of no use or obligation under the gospel-dispensation, or who hold doctrines that clearly supersede the necessity of good works and a virtuous life. The antinomians took their origin from John Agricola about the year 1538; who taught, that the law is no ways necessary under the gospel; that good works do not promote our salvation, nor ill ones hinder it; that repentance is not to be preached from the decalogue, but only from the gospel. Luther, Rutherford, Schlusfeldburg, Sedgwick, Gataker, Witius, Bull, Williams, &c. have written refutations; Crisp, Richardson, Saltmarsh, &c. defences, of the antinomians; Wigandus, a comparison between ancient and modern antinomians. The moderns held, that the keeping of Moses's law was unprofitable under the gospel, and that children are born without sin; and that good works do not further, nor evil hinder, but that faith alone is sufficient for salvation.

AN'TINOMY, *f.* [from *anti* and *νομος*.] A contradiction between two laws, or two articles of the same law.—*Antinomies* are almost unavoidable in such variety of opinions and answers. *Baker*.

ANTINOUS, the favourite of Adrian, was born at Bithynus in Bithynia. His beauty engaged the heart of Adrian in such a manner, that there never was a more boundless and extravagant passion than that of this emperor towards this youth. After his death the emperor ordered divine honours to be paid to him; and he also erected a city to his honour, calling it Antinopolis, and in it a magnificent temple.—The name of one of Penelope's suitors, who advised his companions to destroy Telemachus; and even struck Ulysses, when he came to the palace in a beggar's dress, imploring for bread.

ANTI'NOUS, in astronomy, a part of the constellation *aquilo*, or the eagle.

AN'TIOCH, a city of Syria in Asia, situated on the river Orontes, in lat. 36. 20. N. lon. 37. 5. E. It was built by Seleucus Nicator, founder of the Syro-Macedonian empire, who made it his capital. It stood on the above-mentioned river, about twenty miles from the place where it empties itself into the Mediterranean; being equally distant from Constantinople and Alexandria in Egypt, that is, about 700 miles from each. Seleucus called it *Antioch*, from his father's name, according to some; or from that of his son, according to others. He built sixteen other cities bearing the same name; of which one, situated in Pisidia, is probably that where the name of *Christians* was first given to the followers of Jesus Christ. But that situated on the Orontes, by far eclipsed, not only all others of this name, but all the cities built by Seleucus. Antigonus, not long before, had founded a city in that neighbourhood, which from his own name he called *Antigonia*, and designed it for the capital of his empire; but it was raised to the ground by Seleucus, who employed the materials in building his metropolis, and also transplanted the inhabitants thither.

The city of Antioch was afterwards known by the name of *Tetrapolis*, being divided as it were into four cities, each of them being surrounded with its proper wall, besides a common one which enclosed them all. The first was built by Seleucus Nicator, already mentioned; the second by those who flocked thither on its being made the capital of the Cyro-Macedonian empire; the third by Seleucus Callinicus; and the fourth by Antiochus Epiphanes.—About four or five miles distant, stood a place called *Daphne*, which was reckoned a suburb of Antioch. Here Seleucus

cus planted a grove, and in the middle of it built a temple which he consecrated to Apollo and Diana, making the whole an asylum. To this place the inhabitants of Antioch resorted for their pleasures and diversions; whereby it became at last so infamous, that "to live after the manner of Daphne" was used as a proverb to express the most voluptuous and dissolute life. Here Lucius Verus, the colleague of M. Aurelius, chose to take up his residence, instead of marching against the Parthians; while his general Cassius forbade by proclamation any of his soldiers to enter or even go near the place. In short, so remarkable was Daphne of old, that the metropolis itself was distinguished by it, and called *Antioch near Daphne*.

Though Antioch continued to be, as Pliny calls it, the queen of the East, for near 1600 years; yet scarce any city hath undergone such calamities, both from the attacks of its enemies, and its visitation by earthquakes.—The first disaster that befel the Antiochians happened about 145 years before Christ. Being very much disaffected to the person and government of Demetrius their king, they were continually raising tumults and seditions; inso-much that he found himself at last obliged to solicit assistance from the Jews; and was furnished by Jonathan, one of the Maccabees, with 3000 men; by which reinforcement, believing himself sufficiently strong to reduce the mutineers by force, he ordered them immediately to deliver up their arms. This unexpected order caused a great uproar in the city. The inhabitants ran to arms, and invested the king's palace, to the number of 120,000, with a design to put him to death. All the Jews hastened to his relief, fell upon the rebels, killed 100,000 of them, and set fire to the city. On the destruction of the Syrian empire by the Romans, Antioch submitted to them as well as the other cities of that kingdom, and continued for a long time under their dominion. About the year 115, in the reign of the emperor Trajan, it was almost entirely ruined by one of the most dreadful earthquakes mentioned in history. Trajan himself happened to be there, just returned from an expedition against the Parthians; so that the city was full of troops, and strangers had come from all quarters, either out of curiosity, or upon business and embassies: the calamity was therefore felt almost in every province of the Roman empire. The earthquake was preceded by violent thunder, unusual winds, and a dreadful noise under ground. The shock was so terrible, that numbers of houses were overturned, and others tossed to and fro like a ship at sea. Those who happened to be in their houses were for the most part buried under their ruins: those who were walking in the streets or in the squares, were, by the violence of the shock, dashed against each other, and most of them either killed or maimed. This earthquake continued, with some small intermission, for many days and nights; so that vast numbers perished. The most violent shock, according to St. Ignatius, was on a Sunday, December 23. By this Trajan was much hurt, but escaped through a window. Dio Cassius says, that mount Lison, which stood at a small distance from the city, bowed its head and threatened to fall down upon it; that other mountains fell; that new rivers appeared, and others that had flowed before forsook their course and vanished. When the earthquake ceased, a woman was heard crying under the ruins; which being immediately removed, she was found with a living child in her arms. Search was made for others; but none was found alive except one child, which continued sucking its dead mother.

No doubt, Trajan, who was an eye witness of this calamity, contributed largely towards the re-establishment of Antioch in its ancient splendour. Its good fortune, however, did not continue long; for in 135, it was almost entirely destroyed by fire; it was again restored by Antoninus Pius. In 176 or 177, the inhabitants having sided with Cassius, the Roman general who had revolted from M. Aurelius, that emperor published a severe edict against them, deprived them of all their privileges, suppressed their public assemblies, and took from them

the shows and spectacles to which they were so much addicted: but, his anger being appeased, he restored them to their former splendour, and even condescended to visit their city. In 194, having sided with Niger against Severus, the latter again deprived them of their privileges, and subjected Antioch as a mere village to Laodicea; he however pardoned them the next year, at the intreaties of his eldest son, then a child.

When the Roman empire began to decline, Antioch became a bone of contention between them and the eastern nations; and accordingly, on the breaking out of a Persian war, it was continually liable to suffer. In 242, it was taken and plundered by Sapor; and, though he was defeated by Gordian, it underwent the same misfortune in the time of Valerian, about 18 years after; and, on the defeat and captivity of Valerian, being taken by the Persian monarch a third time, he not only plundered it, but levelled the public buildings with the ground. The Persians, however, being soon driven out, the city continued free from any remarkable calamity, till the division of the Roman empire by Constantine in 331. It was then afflicted with so grievous a famine, that a bushel of wheat was sold for 400 pieces of silver. During this distress, Constantine sent to the bishop 30,000 bushels of corn; besides an incredible quantity of all kinds of provisions, to be distributed among the ecclesiastics, widows, orphans, &c. In the year 347, Constantine II. caused an harbour to be made at Seleucia, for the convenience of Antioch. This was effected at an immense expence, the mouth of the Orontes being full of sands and rocks. When the emperor Julian set out on his expedition against the Persians, he made a long stay at Antioch; the Roman provinces being then afflicted with a famine, which raged more violently at Antioch than in other places. Under a mistaken view of remedying this evil, Julian fixed the prices of corn to a certain standard, by which means the famine was still increased, the merchants conveying their corn privately to other places, so that this metropolis was reduced to a most deplorable situation. In 381, in the reign of Theodosius the Great, Antioch was again visited by famine, accompanied with a grievous plague. The latter soon ceased: but, the famine still continuing, the bishop, Libanius, applied to Icarus, count of the East, requesting him to relieve the poor, who flocked from all parts to the metropolis, and were daily perishing in the streets; but to this Icarus gave no other answer, than that they were abhorred and justly punished by the gods. This inhuman treatment raised great disturbances; which, however, were terminated without bloodshed. In 387, Theodosius finding his exchequer quite drained, and being obliged to be at an extraordinary expence in celebrating the fifth year of the reign of his son Arcadius, and the tenth of his own, an extraordinary tax was laid upon the whole empire. Most of the cities submitted willingly, but the people of Antioch, complaining of it as an unreasonable oppression, crowded to the forum; and would have torn the governor in pieces, had not the guard kept back the enraged multitude till he made his escape. Upon this, they broke some of the emperor's statues, and dragged others through the city, uttering the most abusive expressions against him. They were, however, dispersed by a body of archers, who, by wounding only two of the rabble, struck terror into the rest. The governor proceeded against the offenders with the utmost cruelty; exposing some to wild beasts in the theatre, and burning others alive. Theodosius, on hearing of this tumult, was so much enraged, that he commanded the city to be destroyed, and the inhabitants to be put to the sword without distinction. On this occasion, St. Chyrosostom and the hermits, who were very numerous in the neighbourhood, exerted all their eloquence in behalf of the unhappy people, and, being joined by Flavianus, they obtained a general pardon, and the city was restored to its former privileges.

In the year 458, Antioch was again almost destroyed by an earthquake, which happened on the 14th of September; scarcely

scarcely a single house being left standing in the most beautiful and opulent part of the city. The like misfortune again happened in 525, during the reign of the emperor Justin; and fifteen years after, being taken by Cosroes king of Persia, that haughty monarch gave it up for plunder to his soldiers, who put all they met to the sword. The king himself seized on the gold and silver vessels belonging to the churches; and caused all the valuable statues, pictures, &c. to be conveyed into Persia, while his soldiers carried off every thing else, and then set fire to the city. Such of the inhabitants as escaped the sword were carried into Persia, and sold as slaves. Notwithstanding these calamities, the city of Antioch soon recovered its wonted splendour; and as suddenly underwent its usual fate, being almost entirely destroyed by an earthquake in 587, by which 30,000 persons lost their lives. In 634 it fell into the hands of the Saracens, who kept possession of it till the year 858, when it was surprised by Burtas, and again annexed to the Roman empire. The Romans now continued masters of it until the civil dissensions in that empire gave the Turks an opportunity of seizing upon it, as well as of the whole kingdom of Syria. From them it was again taken by the crusaders in 1098. In 1262 it was taken by Bybaris sultan of Egypt, who put a final period to its glory.

Antioch is now no more than a ruinous town, whose houses, built with mud and straw, and narrow and miry streets, exhibit every appearance of misery and wretchedness. These houses are situated on the southern bank of the Orontes, at the extremity of an old decayed bridge: they are covered to the south by a mountain, upon the slope of which is a wall, built by the crusaders. Notwithstanding the unpolished manners of its inhabitants, Antioch was better calculated than Aleppo to be the emporium of the Europeans. By clearing the mouth of the Orontes, which is six leagues lower down, boats might have been towed up that river, though they could not have sailed up, as Pococke has asserted, its current being too rapid. The natives, who never knew the name Orontes, call it, on account of the swiftness of its stream, *El-aasi*, the rebel. It is to be remembered, we now no longer hear at Antioch, either the Grove, or of Daphne, or of the voluptuous scenes of which it was the theatre.

ANTIO'CHE (Pertuis d'), a channel in the Atlantic, on the French coast, near the northern part of the island of Oleron, and on the southern of the isle of Rhé.

ANTIOCHET'TA, a town of Asiatic Turkey, on the sea-coast of Caramania: eighty-eight miles south of Cogni.

ANTIO'CHIA, in the ancient geography, a town of Assyria, situated between the rivers Tigris and Tormadotus.—Another of Caria, on the Meander; called also *Pythopolis*, *Athymbra*, and *Nysa*.—A third of Cilicia Trachea, on Mount Cragus.—A fourth, called *Epidaphnes*, capital of Syria, distinguished from cities of the same name, either by its situation on the Orontes, by which it was divided, or by its proximity to Daphne (See ANTIOCH).—A fifth Antiochia, a town of Comagene, on the Euphrates.—A sixth, of Lydia, *Tralles*, so called.—A seventh, of Margiana, on the river Margus, taking its name from Antiochus, son of Seleucus, who rebuilt it, and walled it round, being before called *Alexandria*, from Alexander the founder, and surnamed *Syria*; in compass seventy stadia; whither Orodes carried the Romans after the defeat of Crassus.—An eighth in Mesopotamia, on the lake Calirrhoe, the old name of Edeffa.—A ninth on the river Mygdonius, in Mesopotamia, situate at the foot of Mount Masius, and is the same with Nisibis. It was the bulwark and frontier-town of the Romans against the Parthian and Persians, till given up to the Persians, by Jovian, by an ignominious peace.—A tenth in the north of Pisidia; it was a Roman colony, with the appellation of *Cæsarea*.—There is also an Antiochia at Mount Taurus, mentioned by Ptolemy, but by no other author.

ANTIO'CHIA, a town of South America, in the kingdom of Popayan.

ANTIO'CHIAN, *adj.* Belonging to Antioch.
VOL. I. No. 49. (695.)

ANTIO'CHIAN, *f.* An inhabitant or native of Antioch.

ANTIO'CHIAN SECT, or ACADEMY, a name given to the fifth academy, or branch of academics. It took its name from being founded by Antiochus, a philosopher contemporary with Cicero; and it succeeded the Philonian academy. Though Antiochus was really a stoic, and only nominally an academic.

ANTIO'CHIAN EPOCHA, a method of computing time from the proclamation of liberty granted to the city of Antioch, about the time of the battle of Pharsalia.

ANTI'OCHIS, the name of a woman. 2 *Mac.* iv. 30.

ANTI'OCHUS, the name of several kings of Syria.—Also the name of a celebrated philosopher, the disciple of Philo of Larissa, the master of Cicero, and the friend of Lucullus and Brutus. He was founder of a fifth academy; but, instead of attacking other sects, he set himself down to reconcile them together, particularly the sect of the stoics with that of the ancient academy.—The name of a man. 1 *Mac.* i. 10.

ANTI'OPE, the daughter of Nycteus king of Thebes, who was carried away by Epopeus king of Sicyon. After the death of her father, she was recovered by her uncle Lycus, who married her, but soon divorced her to marry Dirce. Soon after her repudiation she became pregnant by Jupiter, who enjoyed her in the likeness of a satyr; and Dirce, suspecting that her husband still kept the company of Antiope, confined her in a prison, from whence she escaped to Mount Cytheron, and was there delivered of Zethus and Amphion, who afterwards avenged her wrongs upon Lycus and Dirce.—A daughter of Mars, queen of the Amazons, who married Theseus, and had a son by him called Hippolytus. She is also called Hippolyte.

ANTIPÆDOBAPTISTS, *f.* [from *anti*, against, *παῖς*, child; and *βαπτίζω*, to baptize.] A denomination given to those who object to the baptism of infants; because they say infants are incapable of being intrusted, and of making that profession of faith which entitles them to this ordinance and an admission into church-communion.

ANTIPAGMENTS, *f.* in architecture, the garnishing of posts and pillars.

ANTIPAPIS'TICAL, *adj.* [from *anti*, Gr. and *papa*, Lat.] Averse to popery.—It is pleasant to see, how the most *antipapistical* poets are inclined to canonize their friends. *Jortin on Milton's Lycidas.*

ANTIPARALYTIC, or ANTIPARALYTICAL, *adj.* Good against the palsy.

ANTIPARASIASIS, *f.* in rhetoric, a figure which admits the position of the adversary, but turns it directly against him.

ANTIPARASTASIS, *f.* in rhetoric, a figure that admits the position of the adversary, but denies the inference.

ANTIPA'ROS, one of the Greek islands in the Archipelago, opposite to Paros, from which it is separated by a strait about seven miles over. It is the *Oleas* mentioned by Strabo, Pliny, Virgil, &c. and was, according to Heracles Ponticus, first peopled by a Phœnician colony from Sidon. According to Mr. Tournefort, it is about sixteen miles in circumference, producing a little wine and cotton, with as much corn as is necessary for the maintenance of sixty or seventy families, who live together in a village at one end of the island, and are mostly Maltese and French corsairs.

This island is remarkable for a subterraneous cavern or grotto, accounted one of the greatest natural curiosities in the world. It was discovered in the last century by one Magni, an Italian traveller; but the best account of it we have met with is in a periodical publication called the Zoological Magazine; which, as it seems to bear sufficient marks of authenticity, we shall here insert. "Its entrance lies in the side of a rock, about two miles from the sea-shore; and is a spacious and very large arch, formed of rough craggy rocks, overhung with brambles and a great many climbing plants, that give it a gloominess

which is very awful and agreeable. Our surgeon, myself, and four passengers, attended by six guides with lighted torches, entered this cavern about eight o'clock in the morning, in the middle of August. We had not gone twenty yards in this cavity when we lost all light of daylight: but, our guides going before us with lights, we entered into a low narrow kind of alley, surrounded every way with stones, all glittering like diamonds by the light of our torches; the whole being covered and lined throughout with small crystals, which gave a thousand various colours by their different reflections. This alley grows lower and narrower, till at length one can scarcely get along it. At the end of this passage we were each of us presented with a rope to tie about our middles; which, when we had done, our guides led us to the brink of a most horrible precipice. The descent was quite steep, and the place dark and gloomy. We could see nothing, in short, but some of our guides with torches in a miserable dark place, at a vast distance below us. The dreadful depth of this place, and the horror of the descent through a miserable darkness into it, made me look back to the lane of diamonds, if I may so call it, through which we had just passed; and I could not but think I was leaving heaven, to descend into the infernal regions. The hope of something fine at my journey's end, tempted me, however, to trust myself to the rope, and to let myself down. After about two minutes dangling in this posture, not without much pain as well as terror, I found myself safe at the bottom; and our friends all followed the example. When we had congratulated each other on our safe descent, I was inquiring where the grotto, as they called it, was. Our guides, shaking their heads, told us, we had a great way to that yet; and led us forward about thirty yards under a roof of ragged rocks, in a scene of terrible darkness, and at a vast depth from the surface of the earth, to the brink of another precipice, much deeper and more terrible than the former. Two of the guides went down here with their torches first; and by their light we could see, that this passage was not so perpendicular indeed as the other, but lay in a very steep slant, with a slippery rock for the bottom; vast pieces of rough rugged rocks jutting out in many places on the right hand, in the descent, and forcing the guides sometimes to climb over, sometimes to creep under, and sometimes to go round them; and on the left, a thousand dark caverns, like so many monstrous wells, ready, if a foot should slip, to swallow them up for ever. We stood on the edge to see these people descend before us; and were amazed and terrified to see them continue descending till they appeared at a monstrous and frightful depth. When they were at the bottom, they called out to us; and we, trembling and quaking, began to descend after them. We had not gone thirty feet down, when we came to a place where the rock was perfectly perpendicular; and a vast cavern seemed to open its mouth to swallow us up on one side, while a wall of rugged rock threatened to tear us to pieces on the other. I was quite disheartened at this terrible prospect, and declared I would go back; but our guides assured us there was no danger; and, the rest of the company resolving to see the bottom now they were come so far, I would not leave them: so on we went to a corner where was placed an old slippery and rotten ladder, which hung down close to the rock; and down this, one after another, we at length all descended. When we reached the bottom, we found ourselves at the entrance of another passage, which was terrible enough indeed; but in this there was not wanting something of beauty. This was a wide and gradual descent; at the entrance of which one of our guides seated himself on his breech, and began to slide down, telling us we must do the same. We could discover, by the light of his torch, that this passage was one of the noblest vaults in the world. It is about nine feet high, seven wide; and has for its bottom a fine green glossy marble. The walls and arch of the roof being as smooth in most places as if wrought by art, and made of

a fine glittering red-and-white granite, supported here and there with columns of a deep blood-red shining porphyry, made, with the reflection of the lights, an appearance not to be conceived. This passage is at least forty yards long, and of a steep descent. Our guides could here keep on each side of us; and, what with the prodigious grandeur and beauty of the place, our easy travelling through it, and the diversion of now and then running over one another whether we would or not, made this the pleasantest part of our journey. When we had entered this passage, I imagined we should at the bottom join the two guides we had first sent down: but, alas! when we were got there we found ourselves only at the mouth of another precipice, down which we descended a second ladder not much better than the former. I could have admired this place also, would my terror have suffered me; but the dread of falling kept all my thoughts employed during my descent. I could not but observe, however, as my companions were coming down after me, that the wall, if I may so call it, which the ladder hung by, was one mass of blood-red marble, covered with white sprigs of rock-crystal as long as my finger, and making, with the glow of the purple from behind, one continued immense sheet of amethysts. From the foot of this ladder we slid on our bellies through another shallow vault of polished green-and-white marble, about twenty feet; and, at the bottom of this, joined our guides. Here we all got together once again, and drank some rum, to give us courage before we proceeded any further. After this short refreshment, we proceeded by a straight but slanting passage, of a rough, hard, and somewhat coarse, stone, full of a thousand strange figures of snakes rolled round, and looking as if alive; but in reality as cold and hard as the rest of the stone, and nothing but some of the stone itself in that shape. We walked easily along this descent for near 200 yards, when we saw two pillars seemingly made to support the roof from falling in: but in reality it was no such thing; for they were very brittle, and made of a fine glittering yellow marble. When we had passed these about 200 yards, we found ourselves at the brink of another very terrible precipice: but this our guides assured us was the last; and, there being a very good ladder to go down by, we readily ventured. At the bottom of this steep wall, as I may call it, we found ourselves for some way upon plain even ground; but, after about forty yards walking, were presented by our guides with ropes again, which we fastened about our middles, though not to be swung down by, but only for fear of danger, as there are lakes and deep waters all the way from hence on the left hand. With this precaution we entered the last alley; and horrible work it was indeed to get through it. All was perfectly horrid and dismal here: the sides and roof of the passage were of black stone; and the rocks in our way were in some places so steep, that we were forced to lie all along on our backs, and slide down; and so rough, that they cut our clothes and bruised us in passing. Over our heads, there was nothing but ragged black rocks, some of them looking as if they were every moment ready to fall in upon us; and on our left hand the light of our torches showed us continually the surfaces of dirty and miserably-looking lakes of water. If I had heartily repented of my expedition before, here I was all in a cold sweat, and fairly gave myself over for lost; heartily cursing all the travellers that had written of this place; that they had described it so as to tempt people to see it, and never told us of the horrors that lay in the way. In the midst of these reflections, and in the very dullest part of the cavern, on a sudden we had lost four of our six guides. What was my terror on this occasion! The place was a thousand times darker and more terrible for want of their torches; and I expected no other but every moment to follow them into some of these lakes, into which I doubted not but they were fallen. The remaining two guides said all they could, indeed, to cheer us up; and told us we should see the other four again soon, and that we were near the end of

of our journey. I do not know what effect this might have upon the rest of my companions; but I believed no part of the speech but the last, which I expected every moment to find fulfilled in some pond or precipice. Our passage was by this time become very narrow, and we were obliged to crawl on all-fours over rugged rocks; when in an instant, and in the midst of these melancholy apprehensions, I heard a little hissing noise, and found myself in utter and undescribable darkness. Our guides called indeed cheerfully to us, and told us that they had accidentally dropped their torches into a puddle of water, but we should soon come to the rest of them, and they would light them again; and told us there was no danger, and we had nothing to do but to crawl forward. I cannot say but I was amazed at the courage of these people; who were in a place where, I thought, four of them had already perished, and from whence we could none of us ever escape; and determined to lie down and die where I was. Words cannot describe the horror or extreme gloominess of the place. One of our guides, perceiving that I did not advance, came up to me; and, clapping his hand firmly over my eyes, dragged me a few paces forward. While I was in this strange condition, expecting every moment death in a thousand shapes, and trembling to think what the guide meant by this rough proceeding, he lifted me at once over a great stone, set me down on my feet, and took his hand from before my eyes. What words can describe at that instant my astonishment and transport! Instead of darkness and despair, all was splendour and magnificence before me: our guides all appeared about us; the place was illuminated by fifty torches, and the guides all welcomed me into the grotto of Antiparos. The four that were first missing, I now found had only given us the slip, to get the torches lighted up before we came; and the other two had put out their lights on purpose to make us enter out of utter darkness into this pavilion of splendour and glory.

"The people told us, the depth of this place was 485 yards; the grotto, in which we now were, is a cavern of 120 yards wide and 113 long, and seems about 60 yards high in most places. Imagine, then, an immense arch like this, almost entirely lined with fine bright crystallized white marble; and the mind will then acquire some faint idea of the place I had the pleasure to spend three hours in. This, however, is but a faint description of its beauties. The roof, which is a fine vaulted arch, is hung all over with icicles of white shining marble, some of them ten feet long, and as thick as one's middle at the root; and among these there hang at least a thousand festoons of leaves and flowers, of the same substance; but so very glittering, that there is no bearing to look up at them. The sides of the arch are planted with seeming trees of the same white crystal, rising in rows one above another, and often inclosing the points of the icicles. From these trees are also hung festoons, tied as it were from one to another in vast quantities: and in some places among them there seem rivers of marble winding through them in a thousand meanders. All these things are only made, in a long course of years, from the dropping of water, but really look like trees and brooks turned into marble. The floor we trod upon was rough and uneven, with crystals of all colours growing irregularly out of it, red, blue, green, and some of a pale yellow. These were all shaped like pieces of saltpetre; but so hard that they cut our shoes; among these, here and there, are placed icicles of the same white shining marble with those above, seeming to have fallen down from the roof and fixed there. Our guides had tied torches two or three to a pillar, and kept continually beating them to make them burn bright; imagine, then, what a glare of splendour and beauty must be the effect of this illumination, among such rocks and columns of marble! All round the lower part of the sides of the arch are a thousand white masses of crystal, in the shape of oak-trees, which are large enough to inclose, in many places, a piece of ground big enough for a bed-chamber. One of these chambers has a fair white curtain, whiter than

satin, of the same marble, stretched all over the front of it. In this we cut our names, and the date of the year; and then returned highly gratified with our arduous perambulation."

ANTIPAS (Herod), the son of Herod the Great by Cleopatra. Herod, in his first will, appointed Antipas his successor in the kingdom; but afterwards, altering that will, he named his son Archelaus his successor, giving to Antipas the title only of tetrarch of Galilee and Peræa. Antipas married the daughter of Aretas king of Arabia, whom he divorced about the year of Christ 33, to marry his sister-in-law Herodias, wife to his brother Philip, who was still living. St. John the Baptist, exclaiming against this incest, was taken into custody by order of Antipas, imprisoned in the castle of Machærus, and afterwards beheaded, as related in Matth. xiv. 3-12. Aretas, king of Arabia, to revenge the affront which Herod had offered to his daughter, declared war against him, and overcame him in a very obstinate engagement. Herod, being afterwards detected as a party in Sejanus's conspiracy, was banished by the emperor Caius into Lyons in Gaul; whether Herodias accompanied him. This Antipas is the Herod who, being at Jerusalem at the time of our Saviour's passion, (Luke xxiii. 11.) ridiculed him, by dressing him in a white robe, and directing him to be conducted back to Pilate, as a mock king, whose ambition gave him no umbrage.

ANTIPATER, [ἀντί, against, and πατήρ, father, Gr. i. e. instead of, or against, a father.] A proper name of men.

ANTIPATER, the disciple of Aristotle, and one of Alexander the Great's generals, was a man of great abilities, and a lover of the sciences; but was accused of poisoning Alexander. He subdued the revolted Thracians, relieved Megalopolis, and overthrew the Spartans there. He died 321 years before the Christian æra.

ANTIPATER, an Idumean of illustrious birth, and possessed of great riches and abilities, taking advantage of the confusion into which the two brothers Hyrcanus and Aristobulus plunged Judea by their contest for the office of high-priest, took such measures as to gain Hyrcanus that office, and under his government to obtain the absolute direction of all affairs; while his great abilities and application to business made him so considerable, that he was honoured as much as if he had been invested with the royal authority in form: but he was at last poisoned by a Jew, named Malachus, forty-three years before the Christian æra. He left, among his other children, the famous Herod, king of the Jews.

ANTIPATER (Cælius), a Roman historian, who wrote a history of the Punic war, much valued by Cicero. The emperor Adrian preferred him to Sallust.

ANTIPATER, of Sidon, a stoic philosopher, and likewise a poet, commended by Cicero and Seneca. He flourished about the 171st Olympiad. We have several of his epigrams in the *Anthologia*.

ANTIPATER, or CAPHAR SABA, a seaport town of Syria, at the mouth of a river which runs into the Mediterranean: six leagues south-south-west of Jaffa.

ANTIPATHES, *f.* [from a superstitious notion among the ancients that this coral, as well as many stones and gems, had a power to drive away enchantments.] The DARK CORAL; in helminthology, it is a genus of worms of the order of zoophyta. The generic characters are—Animal growing in the form of a plant; stem expanded at the base, internally horny beset with small spines, externally covered with a gelatinous flesh beset with numerous polype-bearing tubercles.

Species. 1. *Antipathes spiralis*, or spiral antipathes: with a very simple spiral rough stem. Inhabits the Indian, Mediterranean, and North Seas: of a hard horny black substance exceedingly brittle, very long and variously twisted, and about the size of a writing-pen. See Plate of ANTHREUS, fig. 2. The fleshy part that covers the spiny surface of the bone is full of little gelatinous wart-like figures. When we have soaked these warts for some time in warm water, they appear like polypes with fixed claws.

claws surrounding a cup in the centre, which probably is their mouth. This species spreads itself with a broad base on a coral rock. The bone, or hard part, when broke obliquely, horizontally shows that the internal as well as external layers are full of little spines. It is of a hard horny black shining substance, brittle almost as glass.

2. *Antipathes ulex*, or furze-like antipathes: very much branched, with scattered spreading very rough subulate branches. Inhabits the Indian Ocean; deep black, with irregularly disposed and variously directed ovate cavities dispersed about the branches of a brownish-yellow colour, and supposed to be the ovaries. See *Helminthology* Plate V. fig. 5.

3. *Antipathes alopecurioides*, or fox-tail antipathes: with spinous fetaceous closely-panicled branches. Inhabits South Carolina, about two feet high, and rises from a broad spread base, dividing into several large branches flat on one side with a groove along the middle; it then subdivides into smaller branches, forming close panicles not unlike the fox-tail grass; the outside greyish, the inside black and very brittle.

4. *Antipathes cupressus*, or cypress antipathes: growing in the form of a simple rough panicle, with recurved branches; about two feet long, and covered with a brownish down, under which it is deep black. Linnæus classed this elegant sea-production under his genus *Gorgonia*, to which it is very nearly allied; but the flesh of this tribe is so remarkably gelatinous, and the whole bone, or hard part, is so covered with spines, which even are to be distinguished in the interior laminæ, that there is sufficient reason for making it of another genus, which has been done by Gmelin. There is a most elegant specimen in the British Museum, and very good figures of it in Rumphius and Seba, from the latter of which our design, fig. 3, is taken. It grows in the East-Indian Ocean, among the Spice Islands.

5. *Antipathes orichalcea*, or brassy antipathes: of a horny substance, and in colour a bright brown, like brass. Stems a foot long, straight, with small alternate knots or knobs, and each terminating in a brush-like appearance, as in the preceding. Inhabits the Indian Ocean; also England and Scotland. See fig. 4.

6. *Antipathes subpinnata*: branched, pinnate, rough, with fetaceous alternate subdivisions, and a few others proceeding transversely from them. Inhabits the Mediterranean; cinereous, with amber spines.

7. *Antipathes myriophylla*: with numerous incurved pinnate branches, the subdivisions with other smaller pinules on the upper side. Inhabits the Indian Ocean, and has the appearance of a fine shady shrub; very rough, and yellowish-brown.

8. *Antipathes dichotoma*: very long, dichotomous, and upright. Inhabits the Mediterranean; two feet high, round, dusky.

9. *Antipathes clathrata*: very much branched, intricate, with confused subdivisions every-where coalescing, the younger ones fetaceous. Inhabits the Indian Ocean; a foot long, and black within.

10. *Antipathes flabellum*: dilated, very much branched and subdivided, the subdivisions branching both ways, and cohering together in a reticulate manner. Inhabits the Indian Ocean; half a foot wide, black, rough.

11. *Antipathes pennacea*: branched, somewhat incurved, the branches with fetaceous very-crowded rough subdivisions. Inhabits the Indian Ocean; about a foot high, and nearly as thick at the stem; grey, within black.

12. *Antipathes ericoides*: very much branched, very rough, black, with scattered branches covered every-where with subulate divisions. Inhabits the Indian Ocean; a foot high, black.

ANTIPATHETICAL, *adj.* Having a natural contrariety to any thing.—The soil is fat and luxurious, and antipathetical to all venomous creatures. *Howell*.

ANTIPATHETICALNESS, *f.* The quality or state of having a natural contrariety to any thing.

ANTIP'ATHY, [from *anti*, against, and *πάθος*, feeling, Gr. *antipathie*, Fr.] A natural contrariety to any thing, so as to shun it voluntarily; aversion; dislike. It is opposed to *sympathy*. It has sometimes the particle *against* before the object of antipathy.—I had a mortal antipathy against standing armies in times of peace; because I took armies to be hired by the master of the family to keep his children in slavery. *Swift*.—Sometimes to:

Ask you, what provocation I have had?

The strong antipathy of good to bad.

When truth, or virtue, an affront endures,

Th' affront is mine, my friend, and should be your's. *Pope*.

Formerly *with*; but improperly.—Tangible bodies have an antipathy with air: and any liquid body, that is more dense, they will draw, condense, and, in effect, incorporate. *Bacon*.

With respect to the doctrine of antipathies, physically considered, it is defined to be, "a natural horror and detestation, an insuperable hatred, an involuntary aversion, which a sensitive being feels for some other object, whatever it is, though the person who feels this abhorrence is entirely ignorant of its cause, and can by no means account for it." Such is, they say, the natural and reciprocal hostility between the salamander and the tortoise; between the toad and the weasel; or between sheep and wolves. Such is the invincible aversion of particular persons against cats, mice, spiders, &c. a prepossession which is sometimes so violent, as to make them faint at the sight of these animals. Of these, and a thousand other antipathies, the ancient naturalists, the schoolmen, and the vulgar, form so many legends; and relate them as certain facts, that they may demand an explication of them from the philosophers. But these sages begin with investigating whether such antipathies actually exist or not.

To explore the matter without prejudice, we shall find it necessary to abstract from the subjects of this disquisition, 1. All such antipathies as are not ascertained; as that which is supposed to be felt by hens at the sound of an harp whose strings are made of a fox's bowels, between the salamander and the tortoise, and between the weasel and the toad. Nothing is less confirmed, or rather nothing is more false, than these facts, with which vulgar credulity and astonishment are amused and actuated: and, though some of these antipathies should be ascertained, this would be no proof that the animals which feel them are not acquainted with their causes, according to their mode and proportion of knowledge; in which case it will be no longer the antipathy which we have defined.

2. We must abstract those antipathies which can be extinguished or resumed at pleasure; those fictitious aversions, which certain persons feel, or pretend to feel, with affected airs, that they may appear more precise and finical, or singularly and prodigiously elegant; that they may seem to have qualities so exquisitely fine, as require to be treated with peculiar delicacy. One who bestows any attention on the subject, would be astonished to find how many of these chimerical aversions there are, which are pretended, and passed upon the world by those who affect them as natural and unconquerable.

3. When we abstract those aversions the causes of which are known and evident, we shall be surprised to find how small, how inconsiderable, is the quantity of those which are conformable to our definition. Will any one pretend to call by the name of antipathy, those real, innate, and incontestible, aversions which prevail between sheep and wolves? Their cause is obvious; the wolf devours the sheep, and subsists upon its victims; and every animal naturally flies with terror from pain or destruction: sheep ought therefore to regard wolves with horror, which for their nutrition tear and mangle the unresisting prey. From principles similar to this, arises that aversion which numbers of people feel against serpents; against small animals, such as reptiles in general, and the greatest number of insects.

sects. During the credulous and susceptible period of infancy, pains have been taken to impress on our minds the frightful idea that they are venomous; that their bite is mortal; that their sting is dangerous, productive of tormenting inflammations or tumours, and sometimes fatal. These horrible prepossessions are industriously inculcated from our infancy; and often supported by dismal tales, which are greedily imbibed, and indelibly engraven on our memories. Is it then wonderful, if these false impressions have neither been corrected by future reflections nor experiments, that we should entertain, during our whole lives, an aversion for such objects, even when we have forgot the admonitions, the conversations, and examples, which have taught us to believe and to regard them as noxious beings? The frightful stories of dogs and cats, which have gone mad, and killed their masters, or which have given them mortal wounds, are more than sufficient to inspire a timorous person with an aversion for these animals; and, if the olfactory nerves of such a person be delicate, he will immediately discover the smell of them in his chamber: disturbed by the apprehension which these effluvia excite in his mind, he gives himself up to the most violent uneasiness, which is tranquillized when he is assured that the animal is no longer in the room. All this is nothing but the effect of a childish fear, founded on certain confused and exaggerated ideas of the hazard which one may run with these animals. The antipathy which some people entertain against eels, though they are eaten by others with avidity, arises from nothing but the fear of serpents, to which these fishes are in some degree similar. There are likewise other antipathies which do not originate in the imagination, but arise from some natural incongruity; such as we often remark in children, for particular kinds of viands, with which their taste is not offended, but which their stomachs cannot digest, and are therefore thrown up as soon as swallowed.

To what then are those antipathies, of which we have heard so much, reducible? Either to legendary tales, or to aversions against objects which we believe dangerous; or to a childish terror of imaginary perils; or to a dislike, of which the cause is disguised; or to a ridiculous affectation of delicacy; or to an infirmity of the stomach; in a word, to a real or pretended reluctance for things which are either invested, or supposed to be invested, with qualities hurtful to us. Too much care cannot be taken in preventing, or regulating, the antipathies of children; in familiarising them with objects of every kind; in discovering to them, without emotion, such as are dangerous; in teaching them the means of defence and security, or the methods of escaping their noxious influence: and, when the rational powers are matured by age, in reflecting on the nature of those objects which we fear, in ascertaining what has been told concerning their qualities, or in vigorously operating upon our own dispositions to overcome those vain repugnancies which we may feel.

ANTIPATHY, in ethics, hatred, aversion, repugnancy. *Hatred* is entertained against persons; *aversion*, and *antipathy*, indiscriminately against persons or things; and *repugnancy*, against actions alone. Hatred is more voluntary than aversion, antipathy, or repugnancy. These last have greater affinity with the animal constitution. The causes of antipathy are less known than those of aversion. Repugnancy is less permanent than either the one or the other. We hate a vicious character, we feel aversion to its exertions: we are affected with antipathy for certain persons at first sight; there are some affairs which we transact with repugnancy; hatred calumniates; aversion keeps us at a distance from certain persons: antipathy makes us detest them; repugnancy hinders us from imitating them.

ANTI'PATRIS, a town of Palestine, anciently called *Caphar-Saba*, according to Josephus, but named *Antipatris* by Herod the Great, in honour of his father Antipater. It was situated in a pleasant valley, in the way from Jerusalem to Cæsarea.

ANTIPELAG'IA, *f.* among the ancients, a law, Vol. I. No. 49.

whereby children are obliged to furnish necessaries to their aged parents. The ciconia, or stork, is a bird famous for the care it takes of its parents when grown old. Hence, in some Latin writers, this is rendered *lex ciconiaria*, or the stork's law.

ANTIPERISTA'SIS, *f.* [from *αντιπεριστασις*, formed of *αντι*, and *περιστασις*, Gr. to stand round.] The opposition of a contrary quality, by which the quality it opposes becomes heightened or intended; or the action by which a body, attacked by another, collects itself, and becomes stronger by such opposition; or an intention of the activity of one quality caused by the opposition of another. Thus quicklime is set on fire by the affusion of cold water; so water becomes warmer in winter than in summer; and thunder and lightning are excited in the middle region of the air, which is continually cold, and all by *antiperistasis*. This is an exploded principle in the Peripatetic philosophy.—The riotous prodigal detests covetousness; yet let him find the springs grow dry which feed his luxury, covetousness shall be called in: and so, by a strange *antiperistasis*, prodigality shall beget rapine. *Decay of Piety*.

ANTIPESTILENTIAL, *adj.* [from *anti*, and *pestilential*.] Efficacious against the infection of the plague.—Perfumes correct the air before it is attracted by the lungs; or, rather, *antipestilential* unguents, to anoint the nostrils with. *Harvey*.

ANTI'PHATES, king of the Læstrigones, who were said to be cannibals. Ulysses, returning from Troy, came upon his coasts, and sent three men to examine the country. Antiphates devoured one of them, and pursued the others, and sunk the fleet of Ulysses with stones, except the ship in which Ulysses was.

ANTI'PHLOGIS'TICS, *f.* [*αντι*, against, and *φλογισις*, inflammation.] Medicines or remedies suited to resist, diminish, or cure, inflammation, or an inflammatory diathesis of the constitution. Under which head may be classed all watery diluents, cooling saline aperients, diaphoretics, and diuretics; antimonials in small doses; but particularly *bleeding*, general and topical. Besides living on watery cooling vegetables, drinking copiously of simple watery liquids, and abstaining totally from all animal food and stimulating diet, may be classed not amongst the weakest of the materials proper for promoting the desired intent, under circumstances where antiphlogistics are required.

ANTI'PHONARY, or ANTI'PHONA'RIVM, *f.* a service-book, which contained all the inventories, responses, collects, and whatever else was sung or said in the choir, except the lessons. This is otherwise called *responsorium*, from the responses therein contained. The author of the Roman *Antiphonary* was pope Gregory the Great. By the provincial constitutions of archbishop Winchelsey, made at Merton, A.D. 1305, it is required, that one of these should be found in every church within the province of Canterbury. The use of them was forbidden by the 3d and 4th of Edward VI. c. 10.

ANTI'PHONY, *f.* the answer made by one choir to another, when the psalm or anthem is sung between two. It also sometimes denotes a species of psalmody, wherein the congregation, being divided into two parts, repeat the psalms, verse for verse, alternately. In this sense antiphony stands contradistinguished from symphony, where the whole congregation sing together. Antiphony differs from responsorium, because in this latter, the verse is only spoken by one person; whereas in the former, the verses are sung by the two choirs alternately.

ANTI'PHONY, is also used to denote the words given out at the beginning of the psalm, to which both the choirs are to accommodate their singing.

ANTI'PHONY, in a more modern sense, denotes a kind of composition made of several verses extracted out of different psalms, adapted to express the mystery solemnized on the occasion.

ANTI'PHRA'SIS, *f.* [from *αντι*, against, and *φρασις*, 9 L

a form of speech.] The use of words in a sense opposite to their proper meaning.—You now find no cause to repent, that you never dipt your hands in the bloody high courts of justice, so called only by *antiphrasis*. *South*.

ANTIPHTHISICS, *f.* [from *αντι*, against, and *φθισις*, a kind of consumption.] Remedies against a consumption.

ANTIPHTHO'RA, *f.* [from *αντι*, against, and *φθορα*, corruption.] A species of wolf's-bane, which resists corruption.

ANTIPHY'SICS, *f.* [from *αντι*, against, and *φυσας*, to blow.] Remedies against wind.

ANTIPLEURITICS, *f.* [from *αντι*, against, and *πλευριτις*, a pleurisy.] A remedy against a pleurisy.

ANTIPODAL, *adj.* Relating to the countries inhabited by the antipodes.—The Americans are *antipodal* unto the Indians. *Brown*.

ANTIPODES, *f.* [from *αντι*, against, and *ποδες*, feet.] Those people who, living on the other side of the globe, have their feet directly opposite to ours. It has no singular:

So shines the sun, though hence remov'd, as clear,
When his beams warm th' *antipodes*, as here. *Waller*.

ANTIPODES, in geography, are the inhabitants of two places on the earth which lie diametrically opposite to each other, or that walk feet to feet; that is, if a line be continued down from our feet, quite through the centre of the earth, till it arrive at the surface on the other side, it will fall on the feet of our antipodes, and *vice versa*. Antipodes are 180 degrees distant from each other every way on the surface of the globe; they have equal latitudes, the one north and the other south, but they differ by 180 degrees of longitude: they have therefore the same climates or degrees of heat and cold, with the same seasons and length of days and nights; but all of these at contrary times, it being day to the one when it is night to the other; summer to the one, when it is winter to the other, &c. they have also the same horizon, the one being as far distant on the one side as the other on the other side; and therefore, when the sun, &c. rises to the one, it sets to the other. The antipodes to London are a part a little S. of New Zealand. It has been said that Plato first started the notion of antipodes, and gave them the name; which is likely enough, as he conceived that the earth was of a globular figure: but there have been great disputes upon this point, and the fathers of the church have greatly opposed it, especially Lactantius and Augustine, who laughed at it, and were greatly perplexed to think how men and trees should hang pendulous in the air with their feet uppermost, as he thought they must do in the other hemisphere.

ANTI'POLIS, now ANTIBES, on the coast of Provence, a colony of the Massilians, near the river Verus, in Gallia Narbonensis, three leagues to the west of Nice. Lat. 43. 40. lon. 7. 0. E.

ANTIPOPE, *f.* [from *anti*, against, and *pope*.] He that usurps the popedom, in opposition to the right pope.—This house is famous in history, for the retreat of an antipope, who calls himself Felix V. *Addison*.

ANTIP'TOSIS, *f.* [from *αντιπρωσις*, of *αντι*, against, or for, and *πρωσις*, a case, Gr.] Medicines which temper and allay too much heat in fevers, as acids do; also a figure in grammar, when one case is put for another.

ANTIQUA'RE, *f.* among Roman lawyers, properly denotes the rejecting of a new law, or refusing to pass it. In which sense, *antiquating* differs from *abrogating*; as the latter imports the annulling an old law, the former the rejecting a new one. Antiquare is also used for a law's growing obsolete, or into disuse, either by age or non-ob servance.

ANTIQUA'RIL, *f.* a name given to copiers of old books. After the decline of learning amongst the Romans, and when many religious houses were erected, learning was chiefly in the hands of the clergy; the greatest number of whom were regulars, and lived in monasteries. In these houses were many industrious men, who were continually

employed in making new copies of old books, either for the use of the monastery, or for their own emolument. These writing monks were distinguished by the name of *antiquarii*. They deprived the poor librarii, or common scribes, of great part of their business, so that these found it difficult to gain a subsistence for themselves and families. This put them upon finding out more expeditious methods of transcribing books. They formed the letters smaller, and made use of more jugations and abbreviations than had been usual. They proceeded in this manner till the letters became exceedingly small; the abbreviations were very numerous, and extremely difficult to be read. This in some measure accounts for the great variety of hands in the species of writing called *Modern Gothic*. When a number of copies were to be made of the same work, it was usual to employ several persons at the same time in writing it; each person, except him who wrote the first skin, began where his assistant was to leave off.

ANTIQUARY, *f.* [*antiquarius*, Lat.] A man studious of antiquity; a collector of ancient things.—All arts, rarities, and inventions, are but the reliques of an intellect defaced with sin. We admire it now, only as *antiquaries* do a piece of old coin, for the stamp it once bore. *South*. In the chief cities of Greece and Italy, there were persons of distinction called *antiquaries*, whose business it was to shew strangers the antiquities of the place, to explain the ancient inscriptions, and to give them all the assistance they could in this way of learning. Pausanias calls these antiquaries *Εξρηγται*. The Sicilians call them *myslogogi*. There was an ancient college of antiquaries erected in Ireland by Ollamh Fodhla, 700 years before Christ, for composing a history of that country: and to this, say the Irish historians, it is owing, that the histories and antiquities of that kingdom may be traced back beyond those of most other nations. There is a society of antiquaries in London, and another in Edinburgh, incorporated by the king's charter. Henry VIII. gave John Leland the title of his antiquary; a title which, says the author of his life, no body ever enjoyed besides himself. The kings of Sweden have been at great expence to illustrate the antiquity of their country, having established an academy of antiquaries with this single view. The office of the ancient Irish antiquaries was to preserve the genealogies of the kings of Ireland, to correct the regal tables of succession, and deliver down the pedigree of every collateral branch of the royal family.

To ANTIQUATE, *v. a.* [*antiquo*, Lat.] To put out of use; to make obsolete.—Milton's *Paradise Lost* is admirable. But cannot I admire the height of his invention, and the strength of his expression, without defending his *antiquated* words, and the perpetual harshness of their sound? *Dryden*.

ANTIQUATEDNESS, *f.* The state of being antiquated, worn out of use, or obsolete.

ANTI'QUE, *adj.* [*antique*, Fr. *antiquus*, Lat. It was formerly pronounced according to the English analogy, with the accent on the first syllable; but now after the French, with the accent on the last, at least in prose; the poets use it variously.] Ancient; old; not modern:

Such truth in love as th' *antique* world did know,
In such a style as courts may boast of now. *Waller*.

Of genuine antiquity.—The seals which we have remaining of Julius Cæsar, which we know to be *antique*, have the star of Venus over them. *Dryden*. Of old fashion. Odd; wild; antic:

And sooner may a gulling weather-spy,
By drawing forth heav'n's scheme, tell certainly
What fashion'd hats, or ruffs, or suits, next year
Our giddy-headed *antique* youth will wear. *Donne*.

ANTI'QUE, *f.* An antiquity; a remain of ancient times; an ancient rarity.—I leave to Edward, now earl of Oxford, my seal of Julius Cæsar; as also another seal, supposed to be a young Hercules; both very choice *antiques*, and set in gold. *Swift*.

1. The dark flowered Toadflax. 2 and 3. Plant-lice. 4. The Chinese Bee. 5. The Virginian Bee. 6. The Surinam Bee. 7. The New York Bee. 8. *Apalus bimaculatus*. 9. the Head & Corselet of the same magnified.

ANTIQUE is sometimes contradistinguished from *ancient*, which signifies a less degree of antiquity. Thus antique architecture is frequently distinguished from ancient architecture.

ANTIQUENESS, *f.* The quality of being antique; an appearance of antiquity.—We may discover something venerable in the *antiqueness* of the work; but we would see the design enlarged. *Addison*.

ANTIQUITY, *f.* [*antiquitas*, Lat.] Old times; time past long ago.—I mention Aristotle, Polybius, and Cicero, the greatest philosopher, the most impartial historian, and the most consummate statesman, of all *antiquity*. *Addison*.—The people of old times; the ancients.—That such pillars were raised by Seth, all *antiquity* has avowed. *Raleigh*.—The works or remains of old times.—As for the observation of Machiavel, traducing Gregory the Great, that he did what in him lay to extinguish all heathen *antiquities*: I do not find that those zeals last long; as it appeared in the succession of Sabinian, who did revive the former *antiquities*. *Bacon*.—Old age; a ludicrous sense.—Is not your voice broken? your wind short? your chin double? your wit single? and every part about you blasted with *antiquity*? and will you yet call yourself young? *Shakespeare*.—Ancientness; as, This ring is valuable for its *antiquity*.

Antiquities form a very extensive science, which is indispensable to the theologian; who ought to be thoroughly acquainted with the antiquities of the Jews, to enable him properly to explain numberless passages in the Old and New Testaments: to the lawyer; who, without the knowledge of the antiquities of Greece and Rome, can never well understand and properly apply the greatest part of the Roman laws: to the physician and the philosopher, that they may have a complete knowledge of the history and principles of the physic and philosophy of the ancients: to the critic, that he may be able to understand and interpret ancient authors: to the orator and poet, who will be thereby enabled to ornament their writings with the most elevated images, allusions, comparisons, &c.

Antiquities are divided into sacred and profane, into public and private, universal and particular, &c. hence it is easy to conceive that they form a species of study equally extensive and complicated, and with which only a very small acquaintance could have been attainable by any one man, if our predecessors had not prepared the way, by leaving us such inestimable works as those of Gronovius, Grævius, Montfaucon, Count Caylus, Winckelman, the Hebraic antiquities of D. Iken of Bremen, the Grecian antiquities of Brunings, the Roman antiquities of Nieupoort, Bibliographia Antiquaria Joh. Alberti Fabricii professor at Hamburg, &c. &c. Nor must we omit to mention that valuable work of Mr. Robert Wood, entitled, The Ruins of Palmyra, and those of Balbec. Also Stuart and Revett's Antiquities of Athens; the last remains of which, in that land of elegance, must be deemed of importance in the present day, when we consider, that, in addition to the mouldering decay of all-devouring time, the present possessors of that country are converting those beautiful remains into lime, and to other uses of no higher estimation!

ANTIRRHEA, *f.* in botany. See CUNNINGHAMIA.

ANTIRRHINUM, *f.* [*antirrhinos*, *aqualis*, and *en*, *nasus*.] In botany, snap-dragon, calves-snout, or toad-flax. This is a genus of the didynamia angiospermia class, ranking in the natural order of personate. The generic characters are—Calyx: perianthium five-parted, permanent; divisions oblong, the two lower more gaping. Corolla: monapetalous, ringent; tube oblong, gibbous; limb bilabiate; upper lip bifid, reflex on the sides; lower trifid, obtuse; palate convex, usually closed by a prominence between the lips, produced from the under lip; the throat being concave beneath; nectary at the base of the corolla produced downwards, prominent. Stamina: filaments four inclosed under the upper lip, nearly of the same length with the corolla, yet two are shorter; anthers converging.

Pistillum: germ roundish; style simple, of the length and in the situation of the stamens; stigma obtuse. **Pericarpium**: capsule roundish, obtuse, two-celled, of different form and aperture in the different species. Seeds: very many; receptacles reniform, solitary, affixed to the partition.—*Essential Character*. Calyx, five-leaved; corolla, with the base produced downwards and nectariferous; capsule, two-celled.

Species. I. Leaves angular. 1. *Antirrhimum cymbalaria*, or ivy-leaved toad-flax: leaves heart-shaped, five-lobed, alternate; stalks procumbent. Root perennial, fibrose, inserting itself so into the crevices of walls and rocks as scarcely to be eradicated. Stalks numerous, growing in a tuft, creeping at bottom, branched, round, purplish, and stringy. Leaves roundish, thinning; somewhat fleshy, some opposite, others alternate, frequently purplish: lobes of the lower ones blunt, upper acute, the smallest only three-lobed. Seeds black, roundish, wrinkled like the nut of the walnut. The whole plant is smooth, and has a disagreeable smell. It varies with a white flower. Linnæus has a fancy that this plant might be produced from the impregnation of antirrhimum elatine by the pollen of campanula hederasfolia. It grows wild on old walls at Basil, Baden, and many other towns of Switzerland, where, however, Haller says, it was unknown in the time of Cherler. In Germany, as at Heidelberg; Haerlem in Holland; also about Paris, and most of the towns in the south of France. It is a native of Italy; from whence it came to us, according to Miller, and is now common on the walls in and near London, that are within reach of the Thames; as on the Temple walls, &c. and on those of the physic-garden at Chelsea; whence it probably originated about London. Dr. Richardson remarked it in the quarries about Darford in Yorkshire: and it has long grown upon the walls about the old manor-house, at Dry Drayton, in Cambridgeshire; also at Burleigh, by Stamford, &c. Johnson (in Gerard) calls it *Italian bastard navel-wort*, and does not hint at its being wild in his time. Parkinson, a few years after says, that it groweth naturally in divers places of our land. It is one of the plants adapted to the ornament of rock-work, which it will cover, if moist, with a thick tapestry; and flowers from June to October.

2. *Antirrhimum pilosum*, or hairy-leaved toad-flax: leaves kidney-shaped, very hairy, alternate; stalks procumbent. This species is found on the Alps, and is of the same size with the foregoing.

3. *Antirrhimum elatine*, or sharp-pointed toad-flax or fluellin: leaves hastate, alternate; stalks procumbent. It is more bitter than the other sorts, and the expressed juice of the plant, or the distilled water, is affirmed to check foul-ulcers. It varies with blue flowers. This grows wild in corn-fields, in Italy, Carniola, Switzerland, France, Germany, and England; flowering with us from July to October.

4. *Antirrhimum spurium*, or round-leaved toad-flax or fluellin: leaves ovate, alternate; stalks procumbent. This differs from the last, in having all the leaves ovate, or roundish, sometimes slightly toothed; and the spur shorter than the body of the corolla. It is rather a larger plant; the stems are more branched, and the leaves are more hairy. It is found among corn, and flowers at the same season with the foregoing. It grows wild in the fields of Germany, England, France, and Italy.

5. *Antirrhimum cirrhosum*, or tendrilled toad-flax: leaves hastate, alternate; stems spreading; petioles every where tendrilled. Native of Egypt. Annual.

6. *Antirrhimum Ægyptiacum*, or Egyptian toad-flax: leaves hastate, alternate; stem erect, very branching; peduncles stiffish. This resembles the third species; and is an Egyptian plant, as its name implies.

II. Leaves opposite. 7. *Antirrhimum triphyllum*, or three-leaved toad-flax: leaves ternate, ovate. This is an annual plant, which rises with an upright branching stalk near a foot and a half high, with oval smooth grey leaves, placed often by threes, and sometimes by pairs opposite.

at the joints; the flowers grow in short spikes at the top of the stalks; they are shaped like those of the common fort, but have not such long tubes: they are yellow, with saffron-coloured chaps. This fort flowers in July and August, the seeds ripen in the autumn, and the plants soon after decay. It grows naturally about Valetia and in Sicily. There is a variety of this, whose flowers have a purple standard and spur, which make a pretty appearance in a garden. The leaves of this are longer than those of the yellow. Mr. Miller also mentions a third variety, which he makes a distinct species, under the name of *linaria lusitanica*. It has spear-shaped smooth leaves, placed sometimes by fours round the stalk, and at others by opposite pairs; the stalks are terminated by large purple flowers with long spurs, standing upon foot-stalks. This grows naturally in Spain and Portugal. It flowers in July, but seldom ripens seeds in England. This species was cultivated in 1640.

8. *Antirrhinum triornithophorum*: leaves in fours, lanceolate; stem erect, branching; flowers peduncled. Flowers purple, and very large. A native of Portugal and America.

9. *Antirrhinum purpureum*, or purple toad-flax: leaves quaternate, linear; flower-bearing stem erect, spiked. Root perennial. Stem two feet high, round, smooth. Native of Italy. Ray remarked it about Naples, and particularly at the foot of Vesuvius. It was cultivated in 1648, in the Oxford garden, and flowers from July to September.

10. *Antirrhinum versicolor*, or spiked-flowered toad-flax: leaves linear-lanceolate; the lower ones ternate; stem erect, spiked. It resembles common toad-flax (No. 33), but the stems are narrower. A native of the southern countries of Europe.

11. *Antirrhinum repens*, or creeping toad-flax: leaves linear, crowded, below quaternate; calyxes equalling the capsule. This has a perennial root, from which arise several stalks near two feet high, which branch out on every side, with narrow leaves growing in clusters towards the bottom, but upwards they are sometimes by pairs, and at others single. The flowers are produced in loose spikes at the end of the stalks; they are of a pale blue colour, appear in June and July, and the seeds ripen in autumn. The flowers have no scent. According to Allioni, this differs but little from the next. The flower of that is rather less, and besides two bearded yellow lines, which run along the throat on the lower lip, it has two distinct yellow spots at the origin of the beard. In this, the flower is every where striated with purple lines: the branches are also more wand-like and crowded. The leaves are rather less in the following species. A native of Italy, France, and England: as in Hertfordshire, and about Henley in Oxfordshire.

12. *Antirrhinum Monpeffulanum*, or Montpellier toad-flax: leaves linear-filiform succulent, scattered, crowded; stem erect; spur shorter than the calyx. This has a perennial root, from which arise many branching stalks near two feet high, with very narrow leaves growing in clusters, and of a greyish colour. The flowers are produced in loose spikes at the end of the branches; they are of a pale blue, and have a sweet smell. These appear in June; and there is often a succession of flowers on the plants till winter. Hudson thinks this does not differ specifically from the foregoing. It grows wild about Montpellier, and other places in the south of France; and near Penryn in Cornwall.

13. *Antirrhinum sparteum*, or branching toad-flax: leaves awl-shaped, channelled, fleshy; the lower ones ternate; stem panicled, and corollas very smooth. It differs from the next species in having pedunculate flowers, three times greater; and in the whole plant being much larger. According to Mr. Curtis, it is a hardy annual of small stature, flowering most part of the summer: and deserves to be more generally cultivated. Some regard it as a biennial; but, as the seeds of it sown in the spring flower in the ensuing summer, and as the plant dies when it has

ripened its seeds, there appears more propriety in considering it as an annual. It will flower earlier if the seeds are sown in autumn. The upper part of the stalk, as well as the leaves of the calyx, are beset with viscous hairs, in which respect it does not perfectly accord with Linnaeus's description. Cavanilles however affirms, that the stems and the whole plant are smooth. Found in Spain, by Loeßling; very common about Madrid, in a dry sandy soil, flowering in May and June. Introduced in 1772, by M. Richard.

14. *Antirrhinum bipunctatum*, or dotted-flowered toad-flax: leaves linear, smooth; the lower ones quaternate; stem erect, panicled; flowers spike-headed. It grows wild in the corn-fields of France, Spain, and Italy; flowering in May and June. Annual.

15. *Antirrhinum triste*, or dark-flowered toad-flax: leaves linear, scattered, the inferior ones opposite; nectaries awl-shaped; flowers subsessile. A native of Spain. Introduced in 1727, by Sir Charles Wager, from Gibraltar seeds. It flowers during most of the summer months.

16. *Antirrhinum supinum*, or procumbent toad-flax: leaves subquaternate, linear; stalk diffused; flowers racemed, spur straight. A native of France and Spain, growing in sandy grounds.

17. *Antirrhinum arvense*, or yellow corn toad-flax: leaves sublinear, the lower ones quaternate; calyxes hairy, viscid; flowers spiked, stem erect. Grows wild in the sandy corn-fields of Italy, France, Germany, and England: annual; flowering with us in July and August. It varies in the colour of its flowers, blue and yellow.

18. *Antirrhinum pelisserianum*, or violet-coloured toad-flax: stem-leaves linear, alternate; root-leaves lanceolate, ternate; flowers corymbed. A native of France and Italy. Cultivated in 1640.

19. *Antirrhinum saxatile*, or rock toad-flax: leaves lanceolate-linear, scattered, villose, the inferior quaternate; stem decumbent; flowers spiked. Native of Spain.

20. *Antirrhinum viscosum*, or clammy snap-dragon: root-leaves quaternate, lanceolate; stem-leaves linear, alternate; calyxes villose, approximating the stem. An erect plant the stature of No. 18, but the flowers the size of No. 33. A native of Spain. Annual.

21. *Antirrhinum multicaule*, or many-stalked toad-flax: leaves quinate, linear, fleshy; flowers headed. This is an annual plant, from whose root arise many stalks which are lax, rushy, very slender, and about a foot high: on their lower part, they have five very narrow, linear, obtuse, leaves at each joint; but upwards they are sometimes by pairs, and sometimes single: the stalks are divided into many small branches, with little yellow flowers coming out singly, at a distance from each other; these appear in July, and the seeds ripen in August. There are two varieties, one with a deep yellow, and the other with a sulphur-coloured, flower. A native of Sicily, and the Levant.

22. *Antirrhinum glaucum*: leaves quaternate, awl-shaped, fleshy; stems erect; flowers spiked. An annual plant. Native of the south of Europe and the Levant.

23. *Antirrhinum Alpinum*, or Alpine toad-flax: leaves quaternate, linear-lanceolate, sea-green; stem diffuse; flowers racemed, with a straight spur. Root perennial. Stems slender, branching at bottom, growing thicker towards the top, from two to seven inches long, ascending, round, and smooth. Leaves quite entire, without veins, and thick; the lowest smaller, and in fours; the upper ones solitary, or two opposite, or sometimes three. Flowers very elegant, of a fine violet purple colour, with a rich gold-colour in the middle; and are in blow most part of the summer. Native of the Alps in moist rocky places. It has a bitter disagreeable taste.

24. *Antirrhinum bicorn*, or horned toad-flax: leaves opposite, ovate-oblong, serrate; stem erect, flowers racemed, capsules two-horned. Annual. A native of the Cape of Good Hope.

25. *Antirrhinum villosium*: all the leaves opposite, ovate, villose; stems simple; flowers opposite, lateral. Observed in Spain by Alstroemer. Perennial.

26. *Antirrhinum*

26. *Antirrhinum origanifolium*: leaves mostly opposite, oblong; flowers alternate. Annual; growing wild on the Pyrenees, and near Marfeilles.

27. *Antirrhinum pinnatum*: leaves opposite, pinnatifid; stem erect, flowers racemed. Found at the Cape by Thunberg.

III. Leaves alternate. 28. *Antirrhinum minus*, or smaller toad-flax: leaves mostly alternate, lanceolate, obtuse; stem very much branched, diffuse. Annual; growing wild in corn-fields, dry-pastures, on walls, &c. in most parts of Europe, and flowering from June to September.

29. *Antirrhinum dalmaticum*: leaves alternate, heart-shaped, stem-clasping. This rises with a strong woody stalk, three feet high, having smooth spear-shaped leaves, placed alternately, and sitting close to the stalk. The flowers are produced at the end of the branches in short loose spikes; these are of a deep yellow colour, much larger than those of the common sort, and stand upon short foot-stalks. It flowers in July, but the seeds very rarely ripen in England, so that the plants are seldom seen in any gardens here. According to Linnaeus, the flowers proceed from the axils of the leaves, are solitary and peduncled. A native of Crete, also of Armenia, whence it was known to Caspar Bauhin, in 1594.

30. *Antirrhinum hirtum*, or hairy toad-flax: leaves lanceolate, shaggy; flowers spiked, the upper leaf of the calyx largest. This is an annual plant, which rises with a single stalk, about a foot and a half high, with hairy spear-shaped leaves, sitting close to the stalk, and placed alternately. The flowers grow on the top of the stalks in loose spikes; they are of a pale yellow colour, with a few dark stripes, and the chaps are of a gold colour; the upper segment of the calyx is much larger than the lower. The flowers are as large as those of the common sort; they appear in July, and the seeds will in warm seasons ripen in autumn in England. Native of Spain.

31. *Antirrhinum genitifolium*, or broom-leaved toad-flax: leaves lanceolate, acuminate; panicle wand-like, flexuose. It is a native of Siberia, Lower Austria, Switzerland, Dauphiné, and Piedmont.

32. *Antirrhinum junceum*, or rush-stalked toad-flax: leaves linear, alternate; stem paniced, wand-like; flowers racemed. Height half a yard. Found in Spain by Loe-fling. Introduced in 1780 by M. Thouin.

33. *Antirrhinum linaria*, or common yellow toad-flax: leaves lanceolate-linear, crowded; stem erect; spikes terminal, sessile; flowers imbricate. Root perennial, hard, woody, creeping. Stems several, from one to two feet high, full of leaves, round and smooth. Leaves pointed, smooth, bluish, growing without order. Flowers yellow, with the palate orange, villose; in a thick terminal spike. It grows wild in Europe on banks by road-sides, and in dry pastures; flowering from June to August. In Worcester-shire it is called *butter-and-eggs*. Gerard names it *wild-flaxe*, *toad-flaxe*, and *flaxe-weede*. It has these appellations from the similitude of the leaves to those of flax. It abounds in an acrid oil, that is almost empyreumatic. Given inwardly, it excites a nausea, purges, and provokes urine. It is recommended in hydropical cases, but Haller and others do not much approve of it. The juice, mixed with milk, is a poison to flies. The distilled water or juice of the plant, put into the eyes, is said to take away inflammations: but it is most approved, used as a cataplasm, with lard, in the piles.

34. *Antirrhinum linifolium*: leaves lanceolate, three-nerved, flowers racemed, peduncles distant shorter than the bracte. This species is found on the sea-coasts of Italy. Perennial.

35. *Antirrhinum chalapense*, or white-flowered toad-flax: leaves linear-lanceolate, alternate; flowers in racemes; calyxes longer than the corolla; stem erect. This is an annual plant, which rises with a branching stalk, two feet high, having very narrow lanceolate leaves placed alternately. The flowers are small, white, and have very long spurs. This flowers in July, and the seeds ripen in

autumn. Grows naturally in Sicily, Italy, and near Montpellier. It was cultivated in 1680, in the Oxford garden.

36. *Antirrhinum reflexum*: leaves ovate, smooth; peduncles axillary, fruit-bearing, elongate, recurved; stem procumbent. Root annual. Common in vineyards and gardens about Messina, flowering in May and June; and was found in Barbary by Bander.

37. *Antirrhinum pedunculatum*: leaves linear, remote; flowers paniced; peduncles longer than the leaf, stiff and upright. Observed in Spain by Alstromer.

38. *Antirrhinum lagopodioides*: leaves scattered, soft, recurved at the tip; spikes ovate, villose. A native of Siberia.

IV. Leaves none. 39. *Antirrhinum aphyllum*: a capillary scape. This is a very singular plant, and has no appearance of an herb, but would rather be taken for a kind of moss, and is not bigger than that. It has not even any radical leaves. Found near the Cape by Thunberg.

V. Corollas gaping or tailfe. 40. *Antirrhinum majus*, or great toad-flax or snap-dragon: corollas tailfe, flowers in spikes, calyxes rounded. There are several varieties of this species. The differences in the colour of the flowers are endless: the most known are red, yellow purple, white; red with white or yellow mouths, white and red, yellow and red, yellow and white, purple and white, purple with yellow mouths, scarlet dotted with gold colour, &c. The flowers are also sometimes double; and there is a variety with variegated leaves. Native of the southern countries of Europe, in hedges and on rocks and ruins. With us on walls, on Dover cliffs, between Northfleet and Gravesend, &c. but not originally of this country. It flowers in June and July. In Russia they express an oil from the seeds, little inferior to oil of olives.

41. *Antirrhinum orontium*, or small toad-flax or calves-snout: corollas tailfe, flowers subspiked, calyxes longer than the corolla. This resembles the great snap-dragon in many respects. It is a poisonous plant: and is sufficiently distinguished from the great snap-dragon in being smaller and annual, and by having long pointed leaves to the calyx. A native of England, and most parts of Europe, growing in corn-fields and vineyards, especially in a light soil. Flowers in July and August.

42. *Antirrhinum papilionaceum*: corollas tailfe, flowers axillary, calyxes papilionaceous, leaves fleshy. Native of Persia.

43. *Antirrhinum asarina*, or heart-leaved toad-flax: corollas tailfe, leaves opposite, heart-shaped, crenate; stems procumbent. This is a low, trailing, annual, plant; the branches extend little more than a foot each way, and are weak, so that, unless they are supported, they lie on the ground; these have leaves like those of ground-ivy, which grow by pairs: at the wings of the leaves the flowers come out singly on each side the stalk; they are shaped like those of snap-dragon, but have a long tube; are of a worn-out purple colour at the top, but below of an herbaceous colour. These come out in June, and the seeds ripen in September. It is a native of Italy and the south of France, and was cultivated in 1699 by Jacob Bobart.

44. *Antirrhinum molle*, or woolly-leaved toad-flax or snap-dragon: corollas tailfe, leaves opposite, ovate, tomentose, stems procumbent. Native of Spain.

45. *Antirrhinum unilabiatum*: corollas tailfe, with two calluses; leaves alternate, pinnate; stem paniced. Found near the Cape by Thunberg.

VI. Corollas gaping. 46. *Antirrhinum bellidifolium*, or daisy-leaved toad-flax: root-leaves tongue-shaped, toothed, marked with lines; stem-leaves parted, quite entire. This is a biennial, or at most a triennial, plant, which frequently perishes soon after the seeds are ripe. A native of Spain, Italy, and the south of France: also found near Geneva by M. de Saussure. It was cultivated in 1629.

47. *Antirrhinum Canadense*, or Canada toad-flax: leaves linear, alternate, lower lip spreading out flat. Root fibrose, annual. Native of Virginia and Canada.

New species. 48. *Antirrhinum micranthum*, or small flowered

flowered toad-flax: stem herbaceous upright, lower leaves in fours, upper ones alternate, flowers very small, spur short interior. Root annual. Native of Spain near Madrid; flowering there in March and April.

49. *Antirrhinum reticulatum*, or reticulate toad-flax: leaves linear channelled scattered, those on the radical shoots generally in fives, calyx hairy, flower-stalks shorter than the bractes. Root perennial, branched. It was discovered in Algiers by professor Desfontaines, of Paris, who sent it to the royal garden, whence the seeds were communicated to Dr. Smith, by M. Thouin.

50. *Antirrhinum pygmaeum*, or dwarf toad-flax: leaves sagittate, peduncles capillaceous. This has the appearance of *convolvulus arvensis*, but is much smaller.

51. *Antirrhinum ærugineum*: lower leaves in fours linear, flowers in racemes, the upper leaflet of the calyx twice as long as the rest. This is an annual plant. Native of Spain.

52. *Antirrhinum hexandrum*: leaves opposite cordate-ovate serrate, peduncles axillary one-flowered. Native of the island of Otaheite in the South Seas.

Propagation and Culture. Ivy-leaved toad-flax will thrive in any soil or situation, so that, where it is once established, it will be difficult to root it out, for the seeds will get into any joints of walls, &c. and there grow and propagate themselves plentifully. The stalks also put out roots at their joints, and thus spread themselves to a great distance. The seeds of the third and fourth sorts ripen in autumn, and should be sown, or permitted to scatter, at that time: if they are sown in the spring, they seldom grow the same year. They are weeds in corn-fields, but are rarely seen among spring-sown corn, in those lands where they commonly grow. If some of the seeds of the three-leaved toad-flax are sown in autumn upon a warm dry border, the plants will live through the winter, unless the frost proves very severe; and will grow larger, flower earlier, and afford good seeds. Such of the plants as are not natives of Britain may be easily propagated, for they require but little care, except the fifteenth and twenty-ninth sorts; which should be placed under a common hot-bed frame during the winter, letting them enjoy as much free air as possible in mild weather: the twenty-third also succeeds best in a pot or on rock-work; and it is apt to be lost, like other small Alpine plants, for want of proper treatment and care. Common toad-flax is seldom cultivated in gardens; for it is a very troublesome plant to keep within bounds, the roots being very apt to spread. The flowers however make a pretty appearance; a few plants therefore might be allowed a place, especially if the roots were confined in pots. All the varieties of snapdragon are raised from seeds, which should be sown in a dry soil, not too rich, either in April or May; and in July the plants may be planted out into large borders, where they will flower the spring following; or they may be sown early in the spring, for flowering the same autumn, but then they are not so likely to endure the winter; and, if the autumn prove bad, they will not perfect their seeds. Any of the sorts may be continued, by planting cuttings in the summer months, which will easily take root. They are all pretty ornaments in a garden, and, requiring very little culture, are rendered more acceptable. They are hardy plants, and will resist the cold of our winters extremely well, especially if they are planted on a dry, gravelly, or sandy, soil: for, when they are planted in a rich moist soil, they will grow very luxuriant for a time, but are very subject to rot in autumn or winter; and are much more susceptible of cold, than when they are in a dry, hungry, rocky, soil; these plants will grow amongst stones, or the joints of old walls, where they may be placed so as to render some object part of a garden very agreeable, for they will continue in flower several months; and, if the seeds are permitted to shed, there will be a continual supply of young plants, without any trouble. Wherever these plants are designed to grow on walls, or on a rocky barren soil, the seeds should be sown the beginning of

March, where they are designed to remain; for if the plants are first raised in a better soil, and afterward transplanted into those places, they seldom succeed well. When the plants are come up, they will require no other culture but to keep them clear from weeds; and, where they come up too thick, to pull some of them out, so as to give them room to grow. In July they will begin to flower, and will continue flowering till the frost prevents them. Those plants which grow on walls will have strong woody stems, which will continue two or three years or more, and are rarely hurt by frost.

ANTIRRHINIUM, a promontory at the mouth of the Corinthian bay, where it is scarcely a mile broad, and where it separates the Ætolians from the Peloponnesus; so called from its opposite situation to Rhium in Peloponnesus: both are now called the *Dardanelles of Lepanto*.

ANTISABBATARIANS, a modern religious sect, who oppose the observance of the Christian sabbath. The great principle of the Antisabbatarians is, that the Jewish sabbath was only of ceremonial, not moral, obligation; and consequently is abolished by the coming of Christ.

ANTISAGOGE, *f.* in rhetoric, a figure differing little from that called *concession*. The following passage from Cicero is an instance of it: *Difficilis ratio belli gerendi; at plena fidei, plena pietatis: et si dicas, magnus labor, multa pericula proponuntur; at gloria ex his immortalis est consecutura.*

ANTISCII, *f.* [from *anti* and *σκια*, Gr.] In geography, the people who inhabit on different sides of the equator, who consequently at noon have their shadows projected opposite ways. Thus the people of the north are *antiscii* to those of the south; the one projecting their shadows at noon toward the north pole, and the other toward the south pole. The word has no singular.

ANTISCIANS, *f.* in astrology, certain degrees in the zodiac, answering one to the other.

ANTISCORBU'TIC, *adj.* [from *anti*, and *scorbutum*, Lat. the scurvy.] Good against the scurvy.—The warm *antiscorbutics*, animal diet, and animal salts, are proper. *Arbutus*.

ANTISCORBU'TICAL, *adj.* [from *anti*, and *scorbutum*, Lat. the scurvy.] Good against the scurvy.—The warm *antiscorbutical* plants, in quantities, will occasion stinking breath, and corrupt the blood. *Arbutus*.

ANTISEPTICS, *f.* [from *anti*, against, and *σηπτικα*, Gr. *septica*, or purifiers.] Such things as resist or correct putrefaction. A complete putrefaction is not a complaint of the human machine that can be an object of practice, because it cannot take place in any considerable portion of the body without extinguishing life: it is therefore a tendency to it in any considerable degree, which, producing various morbid disorders, requires the utmost aid of the medical art to prevent. Now, as this tendency may be brought on by excess of heat and motion, as well as receiving any ferment into the vascular system; and as, when once fixed, and begun to exert its deleterious action, it induces languor and great debility in the moving powers: the reason may be observed, why our antiseptic class of medicines exhibit, according to the conception received of their action, such apparently contradictory views; for we find both volatile and neutral salts in the same arrangement; the former considered as highly heating, and strongly stimulant of the moving powers; the other, cooling the system, and mitigating vascular action. Hence then it is apparent, that they are only applicable in different states of putrescent action, or in different constitutions affected with putrescency. And not unlikely the same may hold good with acids and alkalies; for they are both enumerated under antiseptics. They have been properly divided into four heads: 1. *Such as are cooling*: acid salines, neutral salts. 2. *Stimulant*: wine, alcohol, oil of turpentine. 3. *Tonic*: Peruvian bark, wormwood, chamomile. 4. *Antispasmodic*: camphor, assafoetida, musk. All which furnish examples of the particular divisions. From the nature of these, we readily know in what particular states each is inapplicable: where there is peculiar sensibility of

the stomach, the *tonic* are to be avoided; the *refrigerant*, where a debility of the vital powers is manifest; the *stimulant*, when there is too great a degree of irritability, the circulation too highly accelerated, and strong disposition to profuse bleeding; the *sedative antispasmodics*, when there is too languid a circulation, a lethargic disposition, or a considerable degree of torpor in the system. See Machride's Essay on the respective Powers of Antiseptics, &c. Remarks on Mr. Alexander's Essays on Putrid Diseases; Cullen's *Materia Medica*; Wallis on Health and Disease.

ANTISO'PHIST, *f.* [*antisophistes*, Lat. *antisophistes*, Gr. of *anti*, against, and *sophistes*, a sophister.] A counter-sophister, one that disputes on the contrary.

ANTISPA'SIS, *f.* [from *anti*, against, and *σπασω*, to draw. Gr.] A revulsion. The turning the course of the humours whilst they are actually in motion. The doctrine of revulsion is the invention of Hippocrates.

ANTISPASMODICS, *f.* [from *anti*, against, and *σπασμος*, Gr. a convulsion.] Medicines suited to cure spasmodic affections. Some remove spasms by immediate contact, as asses milk, cream, oil of almonds, &c. others by repelling animal heat, as the gas sulphuris, nitre, sal ammoniac, &c. and where the strictures are produced by inanition, or defective vital heat, spasms are removed by those means that restore the vis vitæ, such as valerian, castor, musk, &c. Opium, balsam. Peruv. and the essential oils of many vegetables, are the most powerful of this kind. Opium, for its immediate effects, excels; balf. of Peru, in many instances, produces more lasting benefit than opium, and indeed it sometimes succeeds where opium hath failed; the essential oils differ as *antispasmodics* from opium; in this, they act more upon a particular part than upon the system in general, and have no soporific effect.

Antispasmodics are a very uncertain species of medicines in their effect on the disorders for which they are generally esteemed useful. They are best adapted for those spasmodic affections which are attended with great mobility, and which are usually known by the name of spasmodic diseases. They are more useful in preventing the approach, and in removing spasms which are more immediately present in weaker habits; and in preventing the returns of spasms when given in the remission of the spasm in strong habits: on the contrary, they are less useful in preventing the return of spasms in weak habits than in stronger ones; nay, they rather increase the tendency to spasmodic complaints in weakly people, if given in the interval of those disorders; and are less useful in removing the present fit, in strong habits, than they are in weak ones. Sometimes, indeed, in strong habits, they both remove the present fit and prevent returns. Cullen's *Mat. Medica*.

ANTISPAS'TIC, *adj.* [from *anti*, and *σπασμος*, Gr.] Medicines which cause a revulsion of the humours.

ANTISPLENE'TIC, *adj.* [from *anti* and *splenetic*.] Efficacious in diseases of the spleen.—*Antisplenetics* open the obstructions of the spleen. *Floyer*.

ANTISTA'SIS, *f.* in oratory, a defence of an action from the consideration that had it been omitted worse would have ensued. This is called by Latin writers *comparativum argumentum*; such, *e. gr.* would be the general's defence who had made an inglorious capitulation. That, without it, the whole army must have perished.

ANTIS'THENES, a Greek philosopher, and founder of the Cynics. He was born at Athens, and passed the early part of his life as a soldier. Having afterwards been an attendant at the lectures of Socrates, he was principally charmed with those exhortations of that great philosopher, which persuaded to frugality, to temperance, and to moderation: these Antisthenes was resolved to practise by carrying every precept to its utmost extent. Permitting therefore his beard to grow, he went about the streets in a thread-bare coat, scarcely to be distinguished from a common beggar. He prided himself upon the most rigid virtue, and thought himself obliged to attack the vicious

wherever he found them. His philosophy consisted rather in action than speculation: it was therefore his constant maxim, That to be virtuous was to be happy, and that all virtue consisted in action; that the wise man should live for himself, contented in all situations, and happy alone in the consciousness of his own virtue. He acknowledged nothing to be good but what was honourable; and asserted, that virtue might be acquired by practice. Laertius tells us that his works consisted of ten volumes, and he has given us many of his apophthegms.

ANTISTOE'CHON, *f.* in grammar, the using one letter instead of another; as *olli* for *illi*.

ANTI'STROPHE, *f.* [*αντιστροφη*, from *anti*, the contrary way, and *στροφη*, Gr. turning.] In an ode supposed to be sung in parts, the second stanza of every three, or sometimes every second stanza; so called because the dance turns about. In prose, it is a figure by which two things mutually depending on one another are reciprocally converted; as, The servant of the master, the master of the servant.

ANTISTRUMA'TIC, *adj.* [from *anti*, and *struma*, a scrophulous swelling.] Good against the king's evil.—I prescribed him distilled milk, with *antistrumatics*, and purged him. *Wiseman*.

ANTITACTÆ, *f.* in church history, a branch of Gnostics, who held, that God was good and just, but that a creature had created evil; and consequently that it is our duty to oppose this author of evil, in order to avenge God of his adversary.

ANTI'THESIS, *f.* in the plural *antitheses*. [*αντιθεσις*, Gr. placing in opposition.] Opposition of words or sentiments; contrast:

I see a chief, who leads my chosen sons,
All arm'd with points, *antitheses*, and puns.

Pope.

Such also is that of Cicero, in the second *Catilinarian*: "On one side stands modesty, on the other impudence; on one fidelity, on the other deceit; here piety, there sacrilege; here continency, there lust, &c." Such also is that of Augustus to some seditious young men: *Audite, juvenes, senem, quem juvenem senes audire.* Such again is that of Seneca: *Cura laves loquunter, ingentes stupent.* Many ancient writers seem greatly to affect antitheses; but among the moderns they are generally decried. The following, however, is an example of modern antithesis:

Though gentle, yet not dull;
Strong, without rage; without o'erflowing, full. *Denham.*

ANTI'THESIS, is sometimes used for controversy. In this sense, we meet with *antithetic* method, *antithetic* discourses; &c. Marcion composed a volume of *Antitheses*, or contrarieties and oppositions between the law and the gospel.

ANTITRINITA'RIANS, *f.* those who deny the Trinity, and teach that there are not three persons in the God-head. Thus the Samosatrenians, who do not believe the distinction of persons in God; the Arians, who deny the divinity of the Word; and the Macedonians, who deny that of the Holy Spirit; are all properly antitrinitarians. Among the moderns, antitrinitarians are particularly understood of Socinians, called also Unitarians.

ANTI'TYPE, *f.* [*αντιτυπος*, Gr.] That which is resembled or shadowed out by the type; that of which the type is the representation. It is a term of theology.—When once upon the wing, he soars to an higher pitch, from the type to the *antitype*, to the days of the Messiah, the ascension of our Saviour, and, at length, to his kingdom and dominion over all the earth. *Burnet*. The word *antitype* occurs twice in the New Testament; viz. in the Epistle to the Hebrews, ix. 24. and in St. Peter, i Eph. iii. 21. where its genuine import has been much controverted. The former says, that "Christ is not entered into the holy places made with hands, which are *αντιτυπα*, the figures or antitypes of the true—now to appear in the presence of God for us," Now *τυπος*, signifies the pater-
by

by which another thing is made; and as Moses was obliged to make the tabernacle, and all things in it, according to the pattern shewed him in the mount; the tabernacle so formed was the antitype of what was shewn to Moses: any thing, therefore, formed to a model or pattern, is an antitype.

AN'TITYPE, among the ancient Greek fathers, and in the Greek liturgy, is also applied to the symbols of bread and wine in the sacrament.

ANTI'TYPICAL, *adj.* that which relates to an antitype; that which explains the type.

AN'TIUM, anciently a city of the Volsci, situated on the Tuscan sea. The Romans gained their first reputation in naval affairs against the Antiates; part of whose ships they conveyed into the arsenal of Rome, and part they burnt; and with their beaks or rostra adorned the pulpit erected in the forum, thence called *rostra*. Here stood a famous temple of Fortune. Addison says, there were two Fortunes worshipped at Antium.—It is now extinct, but the name still remains in the *Capo d'Anzo*.

ANTI'VARI, a strong town of Turkey, in Europe, in Dalmatia, a Greek archbishop's see, and subject to the Turks. Lat. 43. 0. N. lon. 29. 15. E.

ANTIVENE'REAL, *adj.* [from *anti* and *venereal*.] Good against the venereal disease.—If the lues be joined with it, you will scarcely cure your patient without exhibiting *antivenereal* remedies. *Wifman*.

ANTLER, *f.* [andouillier, Fr.] Properly the first branches of a stag's horns; but, popularly and generally, any of his branches. BROW-ANTLER, denotes the branch next the head; and, BES-ANTLER, the branch next above the brow-antler.

ANT'LIA, *f.* an ancient machine, supposed to be the fame with our pump. Hence the phrase in *antliam condemnari*, according to the critics, denotes a kind of punishment, whereby criminals were condemned to drain ponds, ditches, or the like.

ANTOE'CI, *f.* It has no singular. [Lat. from *αντι*, and *οικω*, Gr. to inhabit.] In geography, those inhabitants of the earth who live under the same meridian, and at the same distance from the equator; the one toward the north, and the other to the south. Hence they have they same longitude, and their latitude is also the same, but of a different denomination. They are in the same semicircle of the meridian, but opposite parallels. They have precisely the same hours of the day and night, but opposite seasons; and the night of the one is always equal to the day of the other.

ANTO'INE (St.), a small town of France, in the department of Here, and late province of Dauphiny; 13 miles E. of Lyons. Lat. 45. 43. N. lon. 5. 20. E.

ANTONA, a river of Britain, which Camden supposes to be a faulty reading for Avuona, or Aufona, the Avon.

ANTON'ACUM, or ANTUN'NACUM, *f.* a town of the Treveri; now *Andernach*, below Coblenz. Lat. 50. 25. N. lon. 7. 5. E.

ANTON'IA, *f.* a citadel of Jerusalem, the origin of which we have in Josephus; who says, that Hyrcanus, the first high-priest of that name, built Baris near the temple, a house with turrets, where he generally resided. Herod afterwards made it stronger, for the security and defence of the temple; and in honour of Marc Antony, who then commanded in the east, called it *Antonia*.

ANTONIAN WATERS, *f.* medicinal waters of Germany, very pleasant to the taste, and esteemed good in many chronic and hypochondriac cases.

ANTONIA'NO (Silvio), a man of great learning, who raised himself from a low condition by his merit, was born at Rome in the year 1540. When only ten years old, he could make verses upon any subject proposed to him. The duke of Ferrara, coming to Rome, was so charmed with his genius, that he carried him to Ferrara, and provided able masters to instruct him in all the sciences. From thence he was sent for by Pius IV. who made him professor of the belles lettres in the college at Rome. Antoniano filled this place with so much reputation, that, on

the day of his oration *pro Marco Marcello*, he had a vast crowd of auditors, and among them no less than twenty-five cardinals. He was then chosen rector of the college; and, after the death of Pius IV. he joined himself to Philip Neri, and accepted the office of secretary to the sacred college, offered him by Pius V. which he executed for 25 years with the reputation of an honest and able man. He refused a bishopric which Gregory XIV. would have given him; but he accepted the office of secretary to the briefs, offered him by Clement VIII. who made him his chamberlain, and afterwards a cardinal. Antoniano is said to have died of fatigue: for he spent whole nights in study, which brought on his death, in the 63d year of his age.

ANTONI'DES VANDER GOES (John), an eminent Dutch poet, born at Goes in Zealand, the 3d of April, 1647. His parents were people of good character, but of low circumstances. They went to live at Amsterdam when Antonides was about four years old; and in the ninth year of his age he began his studies, under the direction of Hadrian Junius and James Coccius. Antonides took great pleasure in reading the Latin poets, and carefully compared them with Grotius, Heinsius, &c. By this means he acquired a taste for poetry, and enriched his mind with elegant ideas. He undertook one of the most difficult tasks in poetry, to write a tragedy: this was *Tragizil*, or *The invasion of China*. Antonides, however, was so modest, as not to permit it to be published. Vondel, who was then engaged in a dramatic piece, which was taken also from some event that happened in China, read Antonides's tragedy; and was so well pleased with it, that he declared, if the author would not print it, he would take some passages out of it, and make use of them in his own tragedy. He accordingly did so; and it was reckoned much to the honour of Antonides, to have written what might be adopted by so great a poet as Vondel. Upon the conclusion of the peace between Great Britain and Holland, in the year 1674, Antonides wrote a piece, intitled *Bellona aan band*, i. e. "Bellona chained;" a very elegant performance. He next wrote an ingenious heroic poem, intitled *The River Y*, (the river on which Amsterdam is built.) Antonides soon gained the esteem and friendship of several persons of distinction; particularly of Mr. Buifero, one of the lords of the admiralty at Amsterdam, who sent him at his own expence to the university of Leyden, where he remained till he took his degree of doctor of physic, and then his patron gave him a place in the admiralty. In 1678, Antonides married Susanna Bermans, a minister's daughter, who had also a talent for poetry. After marriage, he did not much indulge his poetic genius; and within a few years he fell into a consumption, of which he died on the 18th of September, 1684, being but thirty-seven years and a few months old. He is esteemed the most eminent Dutch poet after Vondel. His works were collected by father Anthony Tanfz. The best edition was printed by Nicholas Ten Hoom, at Amsterdam, in 1714, in 4to.

ANTONIN'US PIUS, the Roman emperor, was born at Lanuvium in Italy, A. C. 86, of a family originally from Nifnes in Languedoc. His character was in all respects one of the most amiable that can be imagined; and he had the title of *Pius* given him by the senate. We have no regular account of the transactions of his reign, since Capitolinus has written in a very confused manner, and we have only an abridgment of Dion Cassius's history by Xiphilin now extant. He managed the public revenues with great frugality, yet was extremely generous; was fond of peace, and in war preferred the reputation of justice to all the advantage which might be gained by victory. He was more intent upon preserving the bounds of his empire than extending them; and he often made use of Scipio's expression, That he chose rather to save one citizen than kill a thousand enemies. By this conduct he made himself universally esteemed and revered in that age, and admired by posterity. This great and good emperor died in 161, aged 75 years, having reigned 23.

ANTONINUS

ANTONINUS PIUS

Published as the Act. decret. Jun 7th 1797 by J. Wilkes

ANTONINUS PHILOSOPHUS (Marcus Aurelius), the Roman emperor, born at Rome, the 26th of April, in the 121st year of the Christian æra. He was called by several names till he was admitted into the Aurelian family, when he took that of Marcus Aurelius Antoninus. Adrian, upon the death of Cejonius Commodus, turned his eyes upon Marcus Aurelius; but, as he was not then 18 years of age, and consequently too young for so important a station, he fixed upon Antoninus Pius, whom he adopted, upon condition that he should likewise adopt Marcus Aurelius. The year after this adoption, Adrian appointed him questor, though he had not yet attained the age prescribed by the law. After the death of Adrian, Aurelius married Faustina, the daughter of Antoninus Pius, by whom he had several children. In the year 139, he was invested with new honours by the emperor Pius, in which he behaved in such a manner as endeared him both to the prince and the people.

Upon the death of Pius, which happened in the year 161, he was obliged by the senate to assume the government; in the management of which he took Lucius Verus as his colleague. Dion Cassius says, that the reason of this was, that he might have leisure to pursue his studies, and on account of his ill state of health; Lucius being of a strong vigorous constitution, and consequently more fit for the fatigues of war. The same day he took upon him the name of Antoninus, which he gave likewise to Verus his colleague, and betrothed his daughter Lucilla to him. The two emperors discharged the government in a very amicable manner; but the happiness Rome enjoyed under them was interrupted, in the year 162, by a dreadful inundation of the Tiber, which destroyed a vast number of cattle, and occasioned a famine. The calamity was followed by the Parthian war; and at the same time the Catti ravaged Germany and Rhetia. Lucius Verus went in person to oppose the Parthians; and Antoninus continued at Rome, where his presence was necessary. The Romans having gained a victory over the Parthians, who were obliged to abandon Mesopotamia, the two emperors triumphed over them at Rome in the year 166; and were honoured with the title of *Fathers of their country*. This year was fatal, on account of a famine under which Rome laboured: it was now that the Marcomanni, and many other people of Germany, took up arms against the Romans; but the two emperors, having marched in person against them, obliged the Germans to sue for peace. The war, however, was renewed the year following, and the two emperors marched again in person; but Lucius Verus was seized with an apoplectic fit, and died at Altinum. The Romans were now defeated with great slaughter; and the emperor, not choosing to burden his subjects with new taxes, exposed to public sale the furniture of the palace, the gold and silver plate belonging to the crown, and his wife's rich garments embroidered with gold, and a curious collection of pearls, which Adrian had purchased during his long progress through the provinces of the empire, and was called *Adrian's cabinet*. In 175, Antoninus made a treaty with several nations of Germany. Soon after, Avidius Cassius, governor of Syria, revolted; but this insurrection was put an end to by the death of Cassius, who was killed by a centurion named *Anthony*. In this affair Antoninus behaved with great lenity: he would not put to death, nor imprison, nor even sit in judgment himself upon, any of the senators engaged in this revolt. He wrote also to the senate, desiring them to act with indulgence rather than severity; not to shed the blood of any person whatsoever, but to allow this honour to his reign, that, even under the misfortune of a rebellion, none had lost their lives, except in the first heat of the tumult. In 176, Antoninus visited Syria and Egypt. He staid several days at Smyrna; and, after he had settled the affairs of the east, went to Athens, on which city he conferred several honours. From thence he returned to Rome with his son Commodus; and on the 23d of December, he entered Rome in triumph, with Commodus, on account of the

VOL. I. No. 49.

victories gained over the Germans. Dion Cassius tells us, that he remitted all the debts which were due to himself and the public treasury during 46 years, and burnt all the writings relating to those debts. He applied himself likewise to correct many enormities, and introduced several excellent regulations. In the year 179, he left Rome to go against the Marcomanni, and other barbarous nations; and the year following gained a considerable victory over them; after which he was seized with an illness, which carried him off on the 17th of March, 180, in the 59th year of his age, and 19th of his reign. The whole empire regretted the loss of so valuable a prince, and paid the greatest honour to his memory: he was ranked amongst the gods, and almost every person had a statue of him in their houses. His book of meditations is much admired.

ANTONINUS'S WALL, the name of the third rampart or defence built by the Romans against the incursions of the North Britons. It is called by the people in the neighbourhood, *Graham's Dyke*; from the notion that one Graham, or Grimus, first made a breach in it after the retreat of the Romans out of Britain. The great number of inscriptions which have been found in or near the ruins of this wall, to the honour of Antoninus Pius, leave us no room to doubt its having been built by his direction and command. It reached, as some imagine, from Caer-riden on the frith of Forth to Old Kirkpatrick on the Clyde; or, as others think, from Kinniel on the east, to Dunglass on the west. These different suppositions hardly make a mile of difference in its length, which, from several actual mensurations, appears to have been 37 English or 40 Roman miles. It is not a little surprising, that though it is now more than 1600 years since this work was finished, and more than 1300 since it was slighted, we can yet discover, from authentic monuments which are still remaining, by what particular bodies of Roman troops almost every part of it was executed. This discovery was made from inscriptions upon stones, which were originally built into the face of the wall, and have been found in or near its ruins. And, though we cannot discover exactly how many years this wall continued to be the boundary of the Roman territories in Britain, yet we know with certainty that it was not very long. For we are told by an author of undoubted credit, that, in the reign of Commodus, A. D. 180, "he had wars with several foreign nations, but none so dangerous as that of Britain. For the people of the island, having passed the wall which divided them from the Romans, attacked them, and cut them in pieces."

ANTONIO (Nicholas), knight of the order of St. James, and canon of Seville, did great honour to the Spanish nation by his *Bibliothèque* of their writers. He was born at Seville in 1617, being the son of a president of the admiralty established in that city in 1626. After having gone through a course of philosophy and divinity, he went to study the law at Salamanca; where he closely attended the lectures of Francisco Ramos del Manzano, afterwards counsellor to the king and preceptor to Charles II. In the year 1659, he was sent to Rome by Philip IV. in the character of agent-general from this prince, and from the inquisition of Spain. The cardinal of Arragon procured him, from pope Alexander VII. a canonry in the church of Seville, the income whereof he employed in purchasing books: he had above 30,000 volumes in his library. By this help, joined to continual labour, and indefatigable application, he at last finished his *Bibliotheca Hispan.* in 4 vols. folio, two of which he published at Rome in the year 1672. The work consists of two parts; the one containing the Spanish writers who flourished before the 15th century, and the other those since the end of that century. After the publication of this work, he was recalled to Madrid by Charles II. to take upon him the office of counsellor to the crusade; which he discharged with great integrity till his death, which happened in 1684.

ANTONIO (St.), one of the Cape de Verd islands, 15 miles from St. Vincent's, from which it is separated by a navigable channel two leagues in breadth. On the north

side, it has a good road for shipping, with a collection of fresh water rising from springs. The island stretches from north-east to south-west, and is filled with mountains; one of which is of so extraordinary a height, as to be compared with the Peak of Teneriffe: its top is constantly covered with snow, and, notwithstanding the clearness of the sky, is generally hid in clouds. Here are produced a variety of fruits; oranges, lemons, palms, melons, &c. and sugar-canes: but, notwithstanding all this plenty, the inhabitants live in the most wretched poverty. They are chiefly negroes, under the protection of the Portuguese, whose language they speak, and imitate their manners. Lat. 18. 10. N. lon. o. 26. E.

ANTONIO (St.), a Dutch fort in Axim, on the gold coast of Africa. It stands on a high rock, which projects into the sea in form of a peninsula; and is so environed by rocks and dangerous shoals, as to be inaccessible to an enemy but by land, where it is fortified by a parapet, draw-bridge, and two batteries of heavy cannon. This settlement was first founded by the Portuguese, during the reign of Emanuel. They fixed it first upon a small point; where, finding themselves insecure, they built the fort where it now stands. They were driven out by the Dutch in 1642; and, upon the conclusion of a peace with the States General, the fort remained by treaty in the hands of the Dutch West-India Company. This place lies in lat. 17. 0. N. lon. 25. 0. W.

ANTONIUS (Marcus), a celebrated Roman orator. He was made consul with A. Posthumius Albinus, in the year of Rome 653; when he opposed the turbulent designs of Sextus Titus, tribune of the people, with great resolution and success. Some time after, he was made governor of Cilicia, in quality of proconsul; where he performed so many great exploits, that he obtained the honour of a triumph. He was one of the most able orators of the forum; and it was owing to him, according to the testimony of Cicero, that Rome might boast herself a rival to Greece in the art of eloquence. He defended Marcus Aquilius; and moved the judges in so sensible a manner, by the tears he shed, and the scars he shewed upon the breast of his client, that he carried his cause. He never would publish any of his pleadings, that he might not be proved to say in one cause what might be contrary to his argument in another. He was unfortunately killed during those bloody contentions, raised at Rome by Marius and Cinna. He was discovered in the place where he hid himself, and soldiers were sent to dispatch him; but his manner of addressing them had such an effect, that none but he who commanded them, and had not heard his discourse, had the cruelty to kill him. His head was exposed before the rostra, a place which he had adorned with his triumphal spoils. This happened ninety years before the Christian era.

ANTONIUS (Marcus), Marc Antony, the triumvir, grandson to the above, was very handsome in his youth; for which reason he was greatly beloved by Curio, a senator, who carried him about in all his debaucheries, in so much that his own father forbade him his house. When the civil war broke out, Curio took Cæsar's party, and prevailed with Marc Antony to do the same; for which he was made a tribune of the people, and in that office did Cæsar great service. At the battle of Pharsalia, Cæsar gave him the command of the left wing of his army, whilst he himself led the right. After Cæsar was elected dictator, he made Marc Antony general of the horse; and he was also made consul in the last year of that usurper's life. On Cæsar's death, he harangued the people with great art, and raised their fury against his murderers; flattering himself that he should easily get into the place which Cæsar had filled; but his haughty behaviour occasioned him to lose all the advantages his affected concern had gained him. His ill treatment of Octavius produced another civil war; which ended in an accommodation between him, Octavius, and Lepidus, fatal to the peace of Rome. They agreed to share the supreme power among them; and many

of the most illustrious Romans were sacrificed by proscription to cement this bloody league, which is known by the name of the *Second Triumvirate*. But the triumvirs were too ambitious, and hated one another too much, to be long united. Marc Antony went into Asia, to raise money for his soldiers; and during his absence Fulvia his wife quarrelled with Octavius. While he was in Asia, indulging in all manner of luxury, the famous Cleopatra inspired him with the most violent passion. Finding Octavius was become publicly his enemy, he entered into a confederacy with Sextus Pompeius, who was still master of Sicily. He then went into Italy to fight Octavius; but Fulvia, who had been the author of this war, dying, Octavius and Marc Antony came to a compromise. One of the conditions of this new peace was, that they should together attack Pompey, though the latter had lately made an alliance with him. Marc Antony then married Octavia, sister to Octavius, as a pledge of their renewed friendship; but returned soon after to his beloved Cleopatra, and again lived with her in Alexandria. Octavius made this a pretence to begin the war again. At last they engaged in a sea-fight at Actium, and Octavius gained a complete victory: upon which Marc Antony fell upon his own sword; and Cleopatra stung herself to death with an asp, to avoid gracing the victor's triumph at Rome.

ANTONOMASIA, *f.* [from *anti*, and *νομα*, a name.] A form of speech, in which, for a proper name, is put the name of some dignity, office, profession, science, or trade; or when a proper name is put in the room of an appellative. Thus a king is called his majesty; a nobleman, his lordship. We say the philosopher instead of Aristotle, and the orator for Cicero: thus a man is called by the name of his country, a German, an Italian; and a grave man is called a Cato, and a wise man a Solomon.

ANTOSIAN'DRIANS, *f.* a sect of rigid Lutherans, who oppose the doctrine of Osiander relating to justification. They are otherwise denominated *Osiandromastixes*. The Antosians deny that man is made just, with that justice wherewith God himself is just; that is, they assert, that he is not made essentially, but only imputatively, just; or, that he is not really made just, but only pronounced so.

AN'TRE, *f.* [*antre*, Fr. *antrum*, Lat.] A cavern; a cave; a den: *not now in use*.

With all my travels history:
Wherein of *antres* vast, and deserts wild,
It was my hent to speak.

Shakespeare.

AN'TRIM, the most northerly county in Ireland, is bounded by that of Down on the south-east, that of Londonderry on the west, from which it is separated by the river Bann, part of Armagh on the south, St. George's channel on the east, and the Deucaledonian ocean on the north. It greatest length is about forty-six miles, its greatest breadth about twenty-seven; and the number of acres it contains, plantation-measure, are computed at 383,000. Though the country is much incumbered with bogs and marshes, yet it enjoys a pretty good air, and is well peopled, chiefly with protestants. Where it is free from bogs, the soil is fruitful. It sends two members for the shire, and two for each of the following towns, viz. Lisburn, Belfast, Antrim, and Randalstown. Antrim contains two great natural curiosities: Lough Neagh, a large lake, the waters of which are of a petrifying quality; and the Giant's Causeway, a very large and curious basalt.

ANTRIM, the capital of the above county, situated at the north end of Lough Neagh, about six miles from the mouth of the bay, having a good road, within which vessels lie dry at low water. It is thirteen miles west of Carrickfergus, and about eighty-four miles north of Dublin; and gives title of earl to the noble family of M'Donnell. At Antrim is a seat, with noble demesnes, and beautiful and highly-cultivated lands, of the earl of Massarene. Lat. 54. 45. N. lon. 6. 26. W.

AN'TRUM, *f.* among anatomists, a term used to denote several cavities of the body: as the *antrum highmoreanum*,
or

or that in the maxillary or jaw-bone; *antrum pylori*, or that at the bottom of the pylorus, &c.

ANTWERP, a large handsome town of Brabant, with a strong citadel, seated on the Scheldt. About 200 years ago it was the greatest emporium of trade in Europe; but the civil wars, that were the consequence of the tyranny of Philip II. diminished that commerce, which was almost annihilated in 1648, when, by the treaty of Munster, between Spain and the United Provinces, the navigation of the Scheldt, to large ships, was shut. Upon the seven United States of Holland being thus declared a free state, and the navigation of the Scheldt yielded to them, the Dutch built forts upon the river, to hinder all ships from coming up, except such as paid them custom; and after that time the trade was principally removed from Antwerp to Amsterdam, till then an inconsiderable town; but, by the late revolution, all these restrictions are done away. The streets of Antwerp are large and regular, their number 212, besides twenty-two public squares: the harbour is very commodious, the river being 400 yards wide, and, at the time of high water, twenty-two feet deep; so that large vessels may come up to the quay; and, by the canals, from the river to the doors of the houses. The public buildings are very handsome, and at least 200 in number. The church of Notre Dame, which is the cathedral, is allowed to be one of the most admirable pieces of architecture in all Europe. It is more than 500 feet long, 240 broad, and 340 high, and contains sixty-six chapels, enriched with columns of marble, all different, and ornamented with the most beautiful and masterly paintings. The high and elegant tower contains thirty-three large bells. It has three principal doors of marble, embellished with gold. Its spire is 466 feet high, with a cross on the top 151. The diameter of the clock is thirty feet, and its circumference ninety. It has also two sets of chimes. The fine paintings of the altar are most of them by Rubens. That of taking our Saviour down from the cross, where the figures are as large as life, is deemed his master-piece. Quintin Maffey, the famous blacksmith of Antwerp, has also enriched this cathedral with some curious pieces. The anecdote of his becoming a painter, deserves here particularly to be recorded. Falling in love with a painter's daughter, and her father saying that he should marry none but a painter, Quintin Maffey went to Italy, entered in the Lombard School, and, in a few years, returned a greater painter than the father of her he admired, which obtained him the hand of his mistress. He is interred at the entrance into this cathedral, where his effigy has this inscription: *Connubialis amore de Mulibre fecit Apellem*; i.e. Connubial love made Vulcan an Apelles. In this cathedral, Henry VIII. of England, with the then kings of France, the Romans, Denmark, Portugal, Poland, and Bohemia, were all, on the 25th of January, 1555, made by Philip II. of Spain, knights of the order of the Golden Fleece. The exchange cost 300,000 crowns. From this building Sir Thomas Gresham took the model of the Royal Exchange in London, as did the burghers of Amsterdam for that city. The town-house is a grand piece of architecture, and stands in the great market-place. The house of the Hanse-Towns, built for the accommodation of the oosteringers, or eastern merchants from the Baltic, is a square building of stone. In the middle story, which has a gallery quite round the square, there are 300 lodging-rooms: the cellars serve for stables. It is twenty-two miles north of Brussels, twenty-two north-east of Ghent, and sixty-five south of Amsterdam; situated in lat. 51. 12. N. lon. 4. 15. E.

In 1585, Antwerp underwent a remarkable siege by the duke of Parma. In order to succeed, he was obliged to cut off the communication of the city with Holland, Ghent, and all places both above and below the town. To effect this, he laid siege to Lissenhouk and Tillo, places of the utmost consequence to the security and commerce of Antwerp: both were obstinately defended; and the siege of Tillo was raised, after it had been carried on for three

months: however, the duke gained several other posts on the river, where he built forts, and greatly annoyed the shipping and trade of the besieged. Finding, however, this method of hemming in the city was ineffectual, while an opening to the mouth of the river remained, he formed a design of building a bridge across the Scheldt, to shut up the navigation. He began with collecting great quantities of wood at Callo and Fort St. Philip, where he intended the bridge should be built; but his project was for some time retarded by the Antwerpers, who broke down the dykes, overflowed the whole country, and carried off his magazines by the inundation. Not discouraged by this loss, he applied himself diligently to repair it, and with incredible expedition cut a canal from Steken to Callo, by which he carried off the waters. He then set to work upon the bridge, and finished it in seven months, without the least interruption from the Zealanders. During the building of this bridge, Aldegonde, governor of Antwerp, proposed to build a fort on Couvensteyn dyke, in order to secure that important post, and to break down the dyke when the bridge was nearly finished: but he was violently opposed by certain citizens, who apprehended that their lands and villas would be destroyed by the inundation. When the magistrates were afterwards deliberating on means for destroying the bridge, which they might have prevented from being completed, Ginebelli, a Mantuan engineer, offered his service, undertaking at a certain expence to blow it into the air. Even in this extremity the expence was grudging: but necessity at last overcame this obstacle; Ginebelli was furnished with two large vessels, a number of small boats, and every thing necessary. He formed the two large vessels into fire-ships, which he set adrift with the stream, deceiving the enemy by means of false fires lighted up in the fleet of small boats. The train of one of the fire-ships was expended before the time expected, and she blew up with a terrible explosion, but with little damage to the bridge. The other was more successful, carrying off all the out-works, setting fire to the whole bridge, and burying above 500 soldiers in the ruins. The fire, however, was soon extinguished, and the bridge repaired by the duke of Parma, while the Antwerpers were prevented by avarice from repeating the experiment; so that they were soon reduced to the utmost distress, and obliged to surrender. It is said that the city of Amsterdam had obstructed every measure for the relief of Antwerp, hoping to profit by its destruction. After the battle of Ramillies, the city of Antwerp surrendered to the duke of Marlborough. It was taken by the French in 1746, but restored to the house of Austria at the treaty of Aix-la-Chapelle.

ANUBIS, a symbolical deity of the Egyptians, was regarded as the faithful companion of Osiris and of Isis. Temples and priests were consecrated to him, and his image was borne in all religious ceremonies. Cynopolis, the present Minich, situated in the lower Thebais, was built in honour of Anubis. The temple wherein he was worshipped no longer subsists. The priests celebrated his festivals there with great pomp, and consecrated the dog to him as his living representation. "Anubis (says Strabo) is the city of dogs, the capital of the Cynopolitan prefecture. These animals are fed there on sacred aliments, and religion has decreed them a worship." An event, however, related by Plutarch, brought them into considerable discredit with the people. Cambyfes having slain the god Apis, and thrown his body into a field, all animals respected it except the dogs, which alone ate of his flesh. This impicity diminished the popular veneration for them.

The signification of this emblematical deity is thus explained by Plutarch. "The circle which touches and separates the two hemispheres, and which is the cause of this division, receiving the name of *horizon*, is called *Anubis*. He is represented under the form of a dog, because that animal watches day and night." St. Clemens of Alexandria, who was well informed of the mystic theology of the Egyptians, favours this explanation. The two dogs, says

he, (the two Anubis,) are the symbols of two hemispheres which environ the terrestrial globe. He adds in another place: Others pretend that these animals, the faithful guardians of men, indicate the tropics, which guard the sun on the south and on the north like porters. It is however, reasonable to imagine, that Anubis at first was only a symbolical image, invented by astronomers to give a sensible expression of their discoveries; that afterwards, the people, accustomed to see it in their temples, which were the depositories of science, adored it as a deity; and that the priests favoured their ignorance by connecting it with their religion. The worship of Anubis being introduced, that of the dog became his emblem. Almost all the gods of the Gentiles have originated in this manner.

ANUS, *f.* in anatomy, the lower extremity of the intestinum rectum, or orifice of the fundament.

ANUS, in botany, signifies the posterior opening of a monopetalous flower.

ANVIL, *f.* [*anvil*, Sax.] The iron block on which the smith lays his metal to be forged. Any thing on which blows are laid. Figuratively, *to be upon the anvil*, is to be in a state of formation or preparation.—Several members of our house knowing what was upon the *anvil*, went to the clergy, and desired their judgment. *Swift*.

ANXICO or ANRICO, a kingdom of Lower Guinea, the country of the Jagas. The inhabitants are strong, nimble, and very intrepid; rather fierce, but very sincere. They do not till the ground, but, like the Arabs, wander from place to place. They seem to pay some reverence to the sun and moon, and have other idols; and they carry off slaves from their own country and Nubia, to barter at Angola for the toys and trifles of Europe.

ANXIETY, *f.* [*anxietas*, Lat.] Trouble of mind about some future event; suspense with uneasiness; perplexity; solicitude.—To be happy, is not only to be freed from the pains and diseases of the body, but from *anxiety* and vexation of spirit; not only to enjoy the pleasures of sense, but peace of conscience, and tranquillity of mind. *Tillotson*.—In the medical language, lowness of spirits, with uneasiness of the stomach.—In *anxieties* which attend fevers, when the cold fit is over, a warmer regimen may be allowed; and, because *anxieties* often happen by spasms from wind, spices are useful. *Arbutnot*.

ANXIOUS, *adj.* [*anxius*, Lat.] Disturbed about some uncertain event; solicitous; being in painful suspense; painfully uncertain:

With beating hearts the dire event they wait,
Anxious, and trembling for the birth of fate. *Pope*.

Careful; full of inquietude; unquiet:

In youth alone unhappy mortals live;
But, ah! the mighty bliss is fugitive;
Discolour'd sickness, *anxious* labour, come,
And age, and death's inexorable doom. *Dryden*.

Careful, as of a thing of great importance.—No writings we need to be solicitous about the meaning of, but those that contain truths we are to believe, or laws we are to obey: we may be less *anxious* about the sense of other authors. *Locke*.—It has generally *for* or *about* before the object, but sometimes *of*; less properly.

ANXIOUSLY, *adv.* In an anxious manner; solicitously; uneasily; carefully; with painful uncertainty.

ANXIOUSNESS, *f.* The quality of being anxious; susceptibility of anxiety.

ANXUR, anciently a city of the Volsci, in Latium; called Tarracina by the Greeks and Latins: now *Terracina*; situated on an eminence. Lat. 41. 18. lon. 14. 5. E.

ANY, *adj.* [*anig*, *enig*, Sax.] Every; whoever he be; whatever it be. It is, in all its senses, applied indifferently to persons or things.—How fit is this retreat for uninterrupted study! Any one that sees it will own, I could not have chosen a more likely place to converse with the dead in. *Pope*.—Whosoever; whatsoever; as distinguished from some other.—What warmth is there in your affection

towards any of these princely suitors that are already come? *Shakespeare*.—It is used in opposition to *none*.—I wound and I heal: neither is there any that can deliver out of my hand. *Deut.* xxxii. 39.

ANZERMA, a town and province of Popayan, on the river Coca, in South America, where there are mines of gold. Lat. 4. 58. N. lon. 75. 25. W.

A'ON, a son of Neptune, who came from Apulia to Bœotia, where he collected the inhabitants, and reigned over them. They were called Aones, and the country Aonia, from him.

AO'NIDES, a name of the Muses, because the country Aonia was more particularly frequented by them.

AORA'SIA, *f.* [*αορασια*, Gr. from *α* priv. and *οραω*, to see.] In antiquity, the invisibility of the gods. The opinion of the ancients with regard to the appearance of the gods to men, was, that they never shewed themselves face to face, but were known from their backs as they withdrew. Neptune assumed the form of Calchas to speak to the two Ajaxes; but they knew him not till he turned his back to leave them, and discovered the god by his majestic step as he went from them. Venus appeared to Æneas in the character of a huntress: but her son knew her not till she departed from him; her divinity was then betrayed by her radiant head, her flowing robe, and her majestic pace.

A'ORIST, *f.* [*αοριστος*, Gr.] A tense peculiar to the Greek language, comprehending all the tenses; or rather, expressing an action in an indeterminate manner, without any regard to past, present, or future.

AORIS'TIA, *f.* in the sceptic philosophy, denotes that state of the mind wherein we neither assert nor deny any thing positively, but only speak of things as seeming or appearing to us in such a manner. The aoristia is one of the great points or terms of scepticism, to which the philosophers of that denomination had continual recourse by way of explication, or subterfuge. Their adversaries, the *dogmatists*, charged them with dogmatizing, and asserting the principles and positions of their sect to be true and certain.

AOR'NUS, a very high rock of India, having its name from its extraordinary height, as being above the flight of a bird. Its circuit is about twenty-five miles, its height eleven furlongs, and the way leading up to the top artificial and narrow; the bottom washed by the river Indus; and on the top a fine plain, part of which was covered with a thick wood; the rest arable land, with a fountain furnishing abundance of excellent water. This rock was taken by Alexander the Great, in whose time there was a report that Hercules had attempted it in vain: however, according to Arrian, this was a mere report, raised to magnify Alexander's exploit. While the Macedonian monarch was preparing for the siege, an old man, who had long lived in a cave near the summit, came and offered to shew him a private way up. This being readily accepted, Ptolemy, with a considerable body of light-armed troops, was dispatched, with orders, in case they succeeded, to entrench themselves strongly upon the rock, and to give notice, by a lighted torch, that he had got safely up. Upon this, Alexander gave orders for a body of troops to attempt the passage by which the rock was commonly ascended; but they were repulsed with great slaughter. He then sent an Indian to Ptolemy, desiring him, in the next attack, to fall upon the enemy behind. But in the mean time, those who defended the rock attacked Ptolemy with great vigour; but were repulsed, though with much difficulty. The next day Alexander renewed the attack; and, though Ptolemy attacked the Indians in the rear, the Macedonians were repulsed on both sides. At last, the king perceiving that the strength of the Indians lay in the straitness and declivity of the way, he caused a great quantity of trees to be felled, and with them filled the cavities between the plain on which the Indians were encamped and the highest of his own advanced posts. The Indians at first derided his undertaking; but at length perceiving the

the ardour with which the work was carried on, and having felt the effects of the missile weapons of the Macedonians, they sent deputies to propose terms of capitulation. Alexander, suspecting that their design was only to amuse him till they made their escape, withdrew his guards from the avenues. As soon as he knew the enemy were defended, he took possession of the deserted rock, and then made a signal for his forces to fall upon the flying Indians, the greatest part whom were killed in the roads.

AORTA, *f.* [of *αἶμα*, Gr. to lift up.] In anatomy, the great artery which rises immediately from the left ventricle of the heart, and is from thence distributed to all parts of the body. It is divided into two grand trunks, distinguished by the terms *ascending* and *descending*. See **ANATOMY**, p. 624.

AOUSTA, a town and district of Piedmont. Here are several antiquities of the Romans, who, under their general, Terentius Varro, reduced its ancient and hardy inhabitants, the Salassii, a people of Celtic extraction. It is seated at the foot of the Alps, on the river Doria, fifty miles north-west of Turin. Lat. 45. 48. N. lon. 7. 30. E. The valley of Aousta is thirty miles in length, and abounds in pastures and all sorts of fruits. The present inhabitants have mostly the *krope* (swollen throats), and are accounted the most simple people among the Piedmontese.

AOUTA, the name of the paper mulberry-tree at Otaheite, in the South Sea, from which a cloth is manufactured, that is worn by the principal inhabitants. See **BARK**.

APA'CE, *adv.* [from *a* and *pace*; that is, with a great pace.] Quick; speedily: used of things in motion.—Is not he imprudent, who, seeing the tide making haste towards him *apace*, will sleep till the sea overwhelm him. *Tillotson*.

ay, quoth my uncle Glo'ster,
Small herbs have grace, great weeds do grow *apace*.
And since, methinks, I would not grow so fast,
Because sweet flow'rs are slow, and weeds make haste.
Shakespeare.

With haste; applied to some action. Hastily; with speed: spoken of any kind of progression from one state to another.—If sensible pleasure, or real grandeur, be our end, we shall proceed *apace* to real misery. *Watts*.

This second course of men,
With some regard to what is just and right,
Shall lead their lives, and multiply *apace*. *Milton*.

APA'CHES, or **APA'CI**, a people of New Mexico in North America. They are brave, resolute, and warlike, fond of liberty, and the inveterate enemies of tyranny and oppression. Of this disposition the Spaniards found them towards the end of the last century, when they revolted against the Catholic king, massacred several of his officers, and committed the greatest devastations. Ever since, they have remained the allies, not the subjects, of the Spaniards; and the viceroy of Mexico has been obliged to maintain a more formidable garrison, and a greater number of troops. They have several strong holds in the mountains, and live under the government of their own cacique.

APAC'TIS, *f.* [απακτῆς, Gr. *abductus*, from *απαγω*.] In botany, a genus of the dodecapandria monogynia class. The generic characters are—Corolla: four-petalled; petals roundish, crenate, concave, unequal; two opposite broader. Stamina: filaments from sixteen to twenty. Pistillum: germ superior; style one.—*Essential Character*. Corolla, four-petalled.

There is but one species, known by the name of *apactis Japonica*. It is a tree erect and very branching; the branches are alternate, round, scabrous with dots, erect; branchlets similar, the last frequent. Leaves on the branchlets alternate, petiolate, ovate, acute, serrate, entire at the base, nerved, smooth, paler underneath, an inch long. Petioles half round, furrowed, a quarter of an inch in length. The flowers in racemes at the end of the branch.

lets. Racemes usually ovate, as they advance becoming more oblong. Peduncle and pedicels villose-scabrous.

AP'EDU'SIA, *f.* denotes ignorance or unskilfulness in what relates to learning and the sciences. Hence also persons uninstrued and illiterate are called *apadeute*. The term *apadeute* was particularly used among the French in the time of Huet; when the men of wit at Paris were divided into two factions, one called by way of reproach *apadeute*, and the others *eruditi*. The *apadeute* in effect were the men of pleasure; the *eruditi* those of study.

APAGO'GE, *f.* in logic. See **ABDUCTION**.

APAGOGE, in the Athenian law, the carrying a criminal taken in the fact to the magistrate. If the accuser was not able to bring him to the magistrate, it was usual to take the magistrate along with him to the house where the criminal lay concealed, or defended himself.

APAGOGE, in mathematics, is sometimes used to denote a progress or passage from one proposition to another; when the first, having been once demonstrated, is afterwards employed in the proving of others.

APAGO'GICAL, *adj.* [from *απαγω*, Gr. compound of *απο*, from, and *αγω*, to bring or draw.] An apagogical demonstration is such as does not prove the thing directly; but shews the impossibility, or absurdity, which arises from denying it; and is also called *reductio ad impossibile*, or *ad absurdum*.

APALA'CHIAN MOUNTAINS, more properly called the **ALLEGANY MOUNTAINS**, which see.

APALATO'A, *f.* in botany. See **CYCLAS**.

APAMEA, or **APA'MIA**, the name of several ancient cities. One of Bithynia, formerly called *Myrlea*, from Myrtilus, general of the Colophonians: destroyed by Philip, father of Perseus; and given to his ally Prusias, who rebuilt it, and called it Apamea, from the name of his queen Apama. Another Apamea, called *Cibotos*, of Phrygia, on the Meander. The name is from Apame, mother of Antiochus Soter, the founder, and the daughter of Artabazus. The rise, or at least the increase, of Apamea, was owing to the ruins of Celenæ. A third, on the confines of Parthia and Media, surname *Raphane*. A fourth Apamea, a town of Mesene, an island in the Tigris; where a branch of the Euphrates, called the *Royal River*, falls into the Tigris. A fifth in Mesopotamia, on the other side the Euphrates, opposite to Zeugma, both founded by Seleucus, and joined by a bridge, from which the latter takes its name. A sixth Apamea, now *Famia*, in Syria, below the confluence of the Orontes and Marfyas; a strong city, and situated in a peninsula, formed by the Orontes and a lake. "It was here (says Strabo) that the Seleucids had established the school and nursery of their cavalry." The soil of the neighbourhood, abounding in pasturage, fed no less than 30,000 mares, 300 stallions, and 500 elephants; instead of which, the marshes of Famia at present scarcely afford a few buffaloes and sheep. To the veteran soldiers of Alexander, who here reposed after their victories, have succeeded wretched peasants, who live in perpetual dread of the oppressions of the Turks and the inroads of the Arabs. Apamea was also the ancient name of *Pella*, in the Decapolis.

APANA'GE, or **APPEN'NAGE**, *f.* in the French customs, were lands assigned by the sovereign for the subsistence of his younger sons, which were to revert to the crown upon the failure of male issue in that branch to which the lands were granted.

APANO'MIA, a town of Santorin, an island in the Mediterranean Sea, called by some the Sea of Candia. It has a spacious harbour, in the form of a crescent. Lat. 36. 18. N. lon. 25. 59. E.

APAN'THROPY, *f.* [from *απο*, from, and *ανθρωπος*, Gr. a man.] A love of solitude, and aversion from the company of mankind. It is by some reckoned among the symptoms, by others among the species or degrees, of melancholy.

APAR'GIA, *f.* [αργῆς, Gr. white.] In botany, a genus of the syngenesia polygamia æqualis class, ranking in

the natural order of compositæ semisfculosæ. The generic characters are—Calyx: common imbricate, oblong; scales feveral, linear, parallel, unequal, longitudinal, incumbent. Corolla: compound, imbricate, uniform; corolllets hermaphrodite, numerous, equal; proper monopetalous, ligulate, linear, truncate, five-toothed. Stamina: filaments five, capillary, very short; antheræ cylindric, tubular. Pistillum: germ subovate; style filiform, length of the stamens; stigmas two, recurved. Pericarpium: none; calyx oblong, straight. Seeds: solitary, oblong, striated; down sessile, (in the central seeds somewhat stippled,) plumose; rays chafly beneath. Receptaculum: naked, subvillose.—*Essential Character.* Calyx, subimbricate, with linear, parallel, unequal, scales; down plumose, subfessile; receptacle naked, subvillose.

Species. 1. *Apargia hispida*: the whole calyx upright; leaves lanceolate toothed, hispid with forked bristles; scape one-flowered, naked. Linnæus says that this plant has a linear bractæ below the flower, which is not in the next species. Our English plant has the root end-bitten; the stem from six to sixteen inches high; the leaves petioled, lanceolate, toothed, rough and somewhat hoary with hairs, which sometimes have two or three points, and sometimes are simple. It is very common in meadows and pastures, where it flowers earlier than the other hawkweeds, namely, in May. The old writers call it *rough dandelion* or *dandelion hawkweed*. M. Villars has taken much pains to settle the synonyms of this and the other species, and to extricate them from the confusion under which they labour; but with what success we have not leisure to determine. The flowers open at four in the morning, and close at three in the afternoon.

2. *Apargia hirta*: the whole calyx upright, smoothish; leaves toothed, rough with hairs which are undivided; scape smooth, without any floral leaf; outer seeds without down. This very much resembles the foregoing, but yet it is different. According to Linnæus this is a native of Germany, Switzerland, France, Spain, &c. Villars confines it to the south of Europe, in hot, dry, rocky, places; and Leers affirms that he found it in marshy meadows, flowering in July. Mr. Curtis informs us that it is frequent on Hampstead-heath, Barnes-common, and other commons about London.

3. *Apargia Danubialis*: the whole calyx upright, smooth; leaves toothed, smooth; scape one-flowered, almost naked. It is found in meadows in the islands on the Danube, and flowers in June.

4. *Apargia tuberosa*: calyx acute hirsute, leaves runcinate scabrous. Native of Tuscany and the south of France, in meadows.

5. *Apargia autumnalis*: stem branched almost naked, peduncles scaly, leaves lanceolate toothed quite entire smooth. Root perennial, the second or third year dying at the end, and thus appearing as if bitten off. Linnæus remarks, that the flowers open at seven in the morning, and close at three in the afternoon. It is difficult, he says, to determine, under what genus it should be placed; since it differs from *scorzonera* in its sessile egret, from *crepis* in its simple imbricate calyx, from *leontodon* in its sessile plumose egret. This species is subject to many variations: having the leaves smooth, or hairy; toothed, sinuate-toothed, or pinnatifid, with the teeth quite entire; the calyx smooth or hirsute; the stem simple or branched, with one, two, three, or more, flowers, naked or scaly. It is common in pastures, flowering from July to October. According to the observations in the *Amenitates Academicæ*, horses, goats, and swine, eat it, but cows and sheep refuse it. Our old English writers name it *yellow devil's bit*, *small hare's hawkweed*, or *small hawkweed with bitten roots*.

6. *Apargia Pyrenaica*: peduncles scaly, leaves lanceolate with very few teeth, calyxes villose, root end-bitten. Native of the south of Europe. Perennial.

7. *Apargia taraxaci*: peduncles somewhat scaly at the top, leaves entire or pinnatifid smooth, calyx woolly, root end-bitten. Root perennial, oblique, almost creeping,

end-bitten, large, with strong fibres, longer than the plant itself. Linnæus, who placed it in the genus *hieracium*, doubts whether it be a mile plant, or a new species. This plant was gathered in 1573, in the mountains of Lapland, by Dan. Ch. Solander, LL. D. It has since been observed in several parts of the south of Europe, in mountainous situations; and with us both in Wales and Scotland. It flowers in July. Perhaps there may be other species which belong properly to this genus; but they are mostly common weeds in pasture, and not of much known use.

A'PARINE, *f.* in botany. See *ASPERUGO*, *GALUM*, *SHERARDIA*, *VALANTIA*, and *UTRICULARIA*.

APARINES. See *AMMANIA*.

APARITHME/SIS, *f.* in rhetoric, denotes the answer to the protasis or proposition itself. Thus, if the protasis be, *Apellandi tempus non erat*, the aparithmesis is, *At tecum anno plus vixi*.

APART, *adv.* [*à part*, Fr.] Separately from the rest in place.—Since I enter into that question, it behoveth me to give reason for my opinion, with circumspection; because I walk aside, and in a way *apart* from the multitude. *Raleigh*.—In a state of distinction; as, To set *apart* for any use:

The tyrant shall demand yon sacred load,
And gold and vessels set *apart* for God.

Prior.

Distinctly.—Moses first nameth heaven and earth, putting waters but in the third place, as comprehending waters in the word earth; but afterwards he nameth them *apart*. *Raleigh*.

APARTMENT, *f.* [*appartement*, Fr.] A part of the house allotted to the use of any particular person; a room; a set of rooms:

He, pale as death, despoil'd of his array,
Into the queen's *apartment* takes his way.

Dryden.

APARITHMENUS, *f.* in the ancient poetry, an appellation given to a verse, which comprehended an entire sense or sentence in itself. This is sometimes also written *apartemenus*, i. e. suspended, as not needing any following verse.

APA'TE, *f.* in botany. See *LATUCA*.

APA'THES, *f.* [*α priv.* and *παθος*, Gr. an affection or passion.] Those who seem to be void of human passions. This temper is also carried to that inflexible sternness which extinguishes the affections of humanity, as was instanced in Diogenes the Cynic, and Timon.

AP'ATHY, *f.* [*α, not*, and *παθος*, Gr. feeling.] The quality of not feeling; exemption from passion; freedom from mental perturbation:

In lazy *apathy* let stoics boast
Their virtue fix'd; 'tis fixed as in frost,
Contracted all, retiring to the breast;
But strength of mind is exercise, not rest.

Pope.

The stoics affected an entire apathy: they considered it as the highest wisdom to enjoy a perfect calmness or tranquillity of mind, incapable of being ruffled by either pleasure or pain. In the first ages of the church, the Christians adopted the term apathy to express a contempt of all earthly concerns; a state of mortification, such as the gospel prescribes. Clemens Alexandrinus, in particular, brought it exceedingly in vogue; thinking hereby to draw the philosophers to Christianity, who aspired after such a sublime pitch of virtue. Quietism is only apathy disguised under the appearance of devotion.

APATU'RIA, *f.* [*from απατη*, Gr. fraud.] A solemn feast celebrated by the Athenians in honour of Bacchus. It is said to have been instituted in memory of a fraudulent victory obtained by Melanthus king of Athens over Xanthus king of Bœotia, in a single combat, which they agreed upon, to put an end to a dispute between them relating to the frontiers of their countries. Hence Budæus calls it *sestum deceptionis*, "the feast of deceit." But other authors give a different etymology of this feast.

APAU'LIA, *f.* in antiquity, the third day of a marriage solemnity. It was thus called, because the bride, returning

turning to her father's house, did *απαυλιζεσθαι* *τυ νυμφίω*, lodge apart from the bridegroom. Some will have the *απαυλια* to have been the second day of the marriage, viz. that whereon the chief ceremony was performed; thus called by way of contradistinction from the first day, which was called *προαυλια*. On the day called *απαυλια* (when-ever that was), the bride presented her bridegroom with a garment called *απαυλητηρια*.

A'PE, *f.* [*ape*, Icelandic.] In zoology, that species of the *Simia* tribe which approaches nearest to the form of man. See *SIMIA*.

"An *ape* is an *ape*, a varlet's a varlet, though he be cloathed in silk or scarlet." Or, according to another proverb, "The higher the *ape* goes, the more he shews his tail." *Plus le singe s'eleve, plus il decouvre son cul pelé*, Fr. That is, dignities serve but to make persons ridiculous, who are not worthy of them, or don't know how to behave themselves in them.

Sea-APE, a name given by Steller to a marine animal which he saw on the coast of America, but which is neither known nor classed in any system of natural history by this appellation.

To *APE*, *v. a.* To imitate or mimic, as an *ape* imitates or mimics human actions:

Aping the foreigners in every dress,
Which, bought at greater cost, becomes us less. *Dryden*.

APE'AK, *adv.* [probably from *à pique*.] In a posture to pierce; formed with a point. It is mostly used as a sea-term: the anchor is said to be *apeak* when in a posture presently to pierce the ground.

APEI'BA, *f.* in botany. See *AURLETIA*.

APEL'LA, *f.* among the old physicians, was a name given to those whose prepuce is either wanting or shrunk, so as no longer to cover the glans. But, according to Salmasius and others, it was the proper name of a Jew.

APEL'LES, one of the most celebrated painters of antiquity. He was born in the isle of Cos, and flourished in the time of Alexander the Great, with whom he was in high favour. He executed a picture of this prince, holding in a thunderbolt in his hand: a piece, finished with so much skill and dexterity, that it used to be said there were two Alexanders: one invincible, the son of Philip; the other inimitable, the production of Apelles. Alexander gave him a remarkable proof of his regard: for, when he employed Apelles to draw Campaspe, one of his mistresses, having found that he had conceived an affection for her, he resigned her to him; and it was from her that Apelles is said to have drawn his *Venus Anadyomene*. What is called *grace*, was the characteristic of this artist. His pencil was so famous for drawing fine lines, that Protogenes discovered by a single line that Apelles had been at his house. Protogenes lived at Rhodes: Apelles sailed thither, and went to his house with great eagerness, to see the works of an artist who was known to him only by name. Protogenes was from home; but an old woman was left watching a large piece of canvas, fitted in a frame for painting. She told Apelles that Protogenes was gone out; and asked his name, that she might inform her master who had inquired for him. "Tell him (says Apelles) he was inquired for by this person;" at the same time, taking up a pencil, he drew on the canvass a line of great delicacy. When Protogenes returned, the old woman acquainted him with what had happened. That artist, upon contemplating the fine stroke of the line, immediately pronounced that Apelles had been there; for so finished a stroke could be produced by no other person. Protogenes, however, himself drew a finer line of another colour; and, as he was going away, ordered the old woman to shew that line to Apelles if he came again; and to say, "This is the person for whom you are enquiring." Apelles returned, and saw the line: he would not for shame be overcome; and therefore, in a colour different from either of the former, he drew some lines so exquisitely delicate, that it was utterly impossible for finer strokes to be made. Protogenes

now confessed the superiority of Apelles, flew to the harbour in search of him, and resolved to leave the canvas with the lines upon it for the admiration of future artists.

Apelles afterwards shewed great liberality of mind towards Protogenes. With ideas enlarged by education and literature, he was incapable of harbouring the little jealousies of competitors; on the contrary, he was the first who made the works of Protogenes to be valued as they deserved among the Rhodians. There are two stories related of Apelles, which shew him to be at once an artist of modesty in amending even trifling improprieties, and yet of self-confidence sufficient to make him know the perfection and value of his own paintings. It was customary with Apelles to expose to public view the works which he had finished, and to hide himself behind the picture, to hear the remarks passed on it by persons who came to view it. He once heard himself blamed by a shoemaker for a fault in the slippers of some picture: he corrected the fault which the man had noticed: but on the day following the shoemaker began to animadvert on the leg; upon which Apelles with some anger looked from behind the canvas, and bade him keep to his own province, "*Ne futor ultra crepidam*." It is well known, that Alexander forbade any one besides Apelles to paint his portrait. We are not, however, to conclude from this, that Alexander was a more skilful judge of painting than he was of poetry. Like Augustus, he cherished the fine arts more from vanity than taste. A remarkable proof is given of this prince's inability to discern merit, and of the painter's freedom in expressing the mortification he felt, when a work of his was not sufficiently commended. "Alexander (says *Zelian*, lib. ii. c. 3. Var. Hist.) having viewed the picture of himself which was at Ephesus, did not praise it as it deserved; but, when a horse was brought in, and neighed at seeing the figure of a horse in the picture, as though it had been a real horse, "O king," said Apelles, "this horse seems to be by far a better judge of painting than you." It happened more than once that the horses drawn by him were mistaken for real ones, by living horses which saw and neighed at the pictures. The works of Apelles were all admired; but the most celebrated were the picture of Alexander above-mentioned, and that of Venus emerging from the sea, which was esteemed the most exquisite figure the pencil could create.

APELLI'TÆ, heretics in the primitive church, so called from their head Apelles, who taught that Christ's body was only an elementary composition, which he again left in the world at his ascension into heaven; that there is a good and bad principle; that the prophets contradicted each other; and that there is no resurrection of the dead.

APE'NE, *f.* in antiquity, a chariot whereon the images of the gods were carried in procession on certain days, attended with a solemn pomp, songs, hymns, dancing, &c. It was very rich, made sometimes of ivory, or even of silver, and variously decorated.

APENIN'NUS, or AP'PENINES, a ridge of mountains, running through the middle of Italy, from north-west to the south-west, for 700 miles, in the form of a crescent, beginning at the Alps in Liguria, or the Riviera di Genoa; and terminating at the strait of Messina, or at Reggio, and the promontory Leucopetra; and separating, as by a back or ridge, the Adriatic from the Tuscan sea.

AP'ENRADE, a town of Denmark, in the duchy of Selswick, seated at the bottom of a gulph in the Baltic sea, between Flenboürg and Hadachleben. It is twenty-five miles north from Selswick. Lat. 54. 4. N. lon. 9. 28. E.

AP'ENZEL, a town of Switzerland, in the canton of the same name, seated on the river Chuz, lat. 47. 31. N. lon. 9. 1. E. The canton itself was received into the Helvetic league in 1513. Its greatest length is about thirty miles, and its breadth about twenty. It yields good pasturage, and consequently is not destitute of cattle, milk, butter, or cheese. Considerable quantities also of wheat, rye, barley, oats, beans, pease, flax, and wine, are produced in it; besides a good deal of fruit, wood, and turf; with mineral

mineral waters and warm baths. There are many mountains in the canton, the highest of which is called the *Hohelantis*, or the *Hohemefner*, which commands a prospect of a prodigious extent. There are also several lakes and rivers. The inhabitants, who are partly protestants, and partly Roman catholics, subsist chiefly by their manufactures of linen, crape, fustian, and thread, or by bleaching, and the sale of their cattle, butter, cheese, horses, wood, and coal. In spiritual affairs, the Romanists are subject to the bishop of Constance, but the protestants to their own consistory. The militia of the former does not exceed 3000, whereas those of the latter amount to 10,000.

APEP'SIA, *f.* [from α priv. and $\pi\epsilon\pi\sigma\iota$, to digest.] That genus of disease which Dr. Cullen names *dyspepsia*, or indigestion. See **MEDICINE**.

A'PER, *f.* A ridiculous imitator or mimic.

APE'RIENT, *adj.* [*aperio*, Lat. to open.] That which has the quality of opening.—Of the stems of plants, some contain a fine *aperient* salt, and are diuretic and saponaceous. *Arbutnot*.

APE'RIENTS, *f.* Medicines which have the power of opening the mouths of vessels, hence clearing obstructions of the vascular and glandular kind, as well as the pores of the skin. In this sense they are synonymous with the *anastomatica*, *deobstruents*, and *deopplatives*. But those medicines which render the bowels gently laxative, are now generally called *aperients*; the removal of other obstructions is more confined to the term *deobstruents*.

APE'RITIVE, *adj.* That which has the quality of opening the excrementitious passages of the body.—They may make broth, with the addition of *aperitive* herbs. *Harvey*.

APERIT'TOS, *f.* [from α priv. and $\pi\epsilon\pi\tau\iota\sigma$, redundant.] Such aliment as generates but little excrement. The opposite quality is called *perittomaticos*.

APE'RT, *adj.* [*apertus*, Lat.] Open.

APER'TION, *f.* [from *apertus*, Lat.] An opening; a passage through any thing; a gap.—The next now in order are the *aperitions*; under which term I do comprehend doors, windows, staircases, chimneys, or other conduits: in short, all inlets or outlets. *Wotton*. The act of opening; or state of being opened.—The plenitude of vessels, otherwise called the *plethora*, when it happens, causeth an extravasation of blood, either by rupture or *aperition* of them. *Wifeman*.

APERT'LY, *adv.* [*apertè*, Lat.] Openly; without covert.

APERT'NESS, *f.* Openness.—The freedom, or *apertness* and vigour of pronouncing, and the closeness of muzzling, and laziness of speaking, render the sound different. *Holder*.

APERTURE, *f.* [from *apertus*, Lat. open.] The act of opening.—Hence ariseth the facility of joining a consonant to a vowel, because from an appulse to an *aperture* is easier than from one appulse to another. *Holder*. An open place.—If memory be made by the easy motion of the spirits through the open passages, images, without doubt, pass through the same *apertures*. *Glanville*. In optics, the hole next the object-glass of a telescope or microscope.—The concave metal bore an *aperture* of an inch: but the *aperture* was limited by an opaque circle, perforated in the middle. *Newton*. Enlargement; explanation: a sense seldom used.—It is too much untwisted by the doctors, and, like philosophy, made intricate by explications, and difficult by the *aperture* and dissolution of distinctions. *Taylor*.

APE'TALOUS, *adj.* [of α priv. and $\pi\epsilon\tau\alpha\lambda\omicron\nu$, a leaf.] Without petala or flower-leaves.

APE'TALOUSNESS, *f.* Being without leaves.

APEX, *f.* [*apices*, plur. Lat.] The tip or point of any thing.—The *apex*, or lesser end of it, is broken off. *Woodward*.

APEX, in antiquity, the crest of a helmet, but more especially a kind of cap worn by the flamens.

APEX, among grammarians, denotes the mark of a long syllable, falsely called a *long accent*.

APHA'CA, a place in Syria, situated between Heliopolis and Byblus, near Lebanon; infamous for a temple of Venus, called *Aphacitis*. Near it was a lake, round which fire usually burst forth, and its waters were so heavy, that bodies floated on them. The temple was destroyed by Constantine, as being a school of incontinence. The name is of Syriac origin, signifying *embraces*.

APHACA, *f.* in botany. See **LATHYRUS**.

APHÆRE'SIS, *f.* [*ἀφαίρεσις*, Gr. of *ἀφαιρέω*, to take away.] In grammar, a figure by which a letter or syllable is cut off from the beginning of a word. Thus *ciconia*, by *aphæresis*, is written *conia*; *contemnere*, *temnere*; *omittere*, *mittere*, &c. A similar retrenchment at the end of a word is called *apocope*.

APHÆRESIS, in medicine, denotes a necessary taking away or removal of something that is noxious. In surgery, it signifies an operation whereby something superfluous is taken away.

APHA'NES, *f.* [*ἀφανς*, Gr. not apparent; from its diminutive size.] In botany, a genus of the *tétrandria digynia* or *monandria monogynia* class, ranking in the natural order of *fenticosæ*. The generic characters are—*Calyx*: perianthium one-leaved, tubular, permanent; mouth flat, eight-parted. *Stamina*: filaments four, or one, erect, subulate, very small, placed on the mouth of the calyx; anthera roundish, or one twin. *Pistillum*: germ ovate; style filiform, the length of the stamens, inserted into the base of the germ; stigma headed. *Pericarpium*: none; calyx containing the seeds in the bottom, converging at the mouth. *Seeds*: ovate, acuminate, compressed, the length of the style.—*Essential Character*. *Calyx*, eight-cleft. *Seeds* two, or one, naked.

There is only one species, called *aphanes arvensis*, or *parsley-piert*: stems many, slender, leafy, four inches long, round. Leaves roundish, three-parted, deeply lacinate; the lower ones petiolate; the upper ones sessile, hoary beneath; flowers herbaceous, axillary; calyx cut into eight segments. It varies with one pistil and seed; some botanists say it is always so. *Hudson* gives it one pistil and two seeds. *Haller* says it has often two seeds; and *Leers*, that it never has that number. According to *Gærtner*, it has only one seed, in the garden usually, but in the wild plant constantly: and therefore does not deserve to be separated from the genus *alchemilla*. *Villars* affirms, that the calyx is only four-cleft, and that there is one pistil and one seed. It is a native of Europe, growing in fallow-fields and dry pastures. Annual; flowering from May to August. *Parsley-piert* is a strange corruption from the French *perceperrière*, which name it acquired from its supposed lithontriptic qualities.

APHA'SIA, *f.* [from α priv. and $\phi\eta\mu\iota$, Gr. I speak.] In the sceptic philosophy, denotes a state of doubt, wherein, a person not knowing how to determine, it is best for him to be silent. In this sense, *aphasia* stands opposite to *phasis*, under which are included both assertion and negation.

APHE'A, a deity worshipped by the Cretans. *Pindar* composed an ode to her honour, who had a temple in the Isle of Crete.

A'PHEK, the name of several cities mentioned in scripture. 1. *Aphek* in the tribe of Judah, where the Philistines encamped when the ark was brought from Shiloh; 1 Sam. iv. 1, 2, &c. It is supposed to be the same with *Aphekah*, mentioned in Josh. xv. 53. 2. *Aphek* in Jezreel, where the Philistines encamped while Saul and his army were upon the mountains of Gilboa; 1 Sam. xxix. 1, &c. 3. *Aphek* a city of the tribe of Asher, near the country of the Sidonians; Josh. xix. 30. and xiii. 4. 4. *Aphek* in Syria, near which the battle was fought between Ahab and Benhadad, wherein the Syrians were worsted; and, as they retreated into the city, the walls fell upon them, and crushed in pieces 27,000; 1 Kings, xx. 26, &c.

APHE'LION, or **APHE'LUM**, *f.* [*ἀφελιον*, Gr. of *ἀπο*, from, and *ἡλιος*, the sun.] In astronomy, that point in the orbit of the earth, or a planet, in which it is at the greatest

greatest distance from the sun; which is the point A (in the fig. to the art. ANOMALY, p. 741,) or extremity of the transverse axis of the elliptic orbit, farthest from the focus S, where the sun is placed; and diametrically opposite to the perihelion B, or nearer extremity of the same axis. In the Ptolemaic system, or in the supposition that the sun moves about the earth, the aphelion becomes the *apogee*. The times of the aphelia of the primary planets may be known by their apparent diameter appearing the smallest, and also by their moving slowest in a given time. Calculations and methods of finding them have been given by many astronomers, as Riccioli, Wolfius, Halley, sir Isaac Newton, Euler, d'Alembert, Clairaut, &c.

The aphelia of the planets are not fixed: for their mutual actions upon one another keep those points of their orbits in a continual motion, which is greater or less in the different planets. This motion is made in consequentia, or according to the order of the signs; and sir Isaac Newton shows that it is in the sesquuplicate ratio of the distance of the planet from the sun, that is, as the square root of the cube of the distance. The quantities of this motion, as well as the place of the aphelion for a given time, are variously given by different authors. Kepler states them, for the year 1700, as in the following table:

Planets.	Aphelion.	Annual Motion.
Mercury	♊ 8° 25' 30"	1' 45"
Venus	♊ 3 24 27	1 18
Mars	♊ 0 51 29	1 7
Jupiter	♊ 8 10 40	0 47
Saturn	♊ 28 3 48	1 10
The Earth	♊ 8 25 30	

By De la Hire, they are given as follows, for the same year 1700:

Planets.	Aphelion.	Annual Motion.
Mercury	♊ 13° 3' 40"	1' 39"
Venus	♊ 6 56 10	1 26
Mars	♊ 0 35 25	1 7
Jupiter	♊ 10 17 14	1 34
Saturn	♊ 29 14 41	1 22

And De la Lande states them as follows, for 1750:

Planets.	Aphelion.	Secular Motion.
Mercury	8s 13° 33'	1° 57' 40"
Venus	10 8 13	4 10 0
Mars	5 1 28	1 51 40
Jupiter	6 10 22	1 43 20
Saturn	8 29 53	2 23 20
The Earth	9 8 38	1 49 10

Of the new planet, Herschel or Georgium Sidus, the aphelion for 1790 was 11s 23° 29' 42", and its annual motion 50" 3.

APH'EREMA, the name of a city. 1 Mac. ii. 34.

APH'E'TA, *f.* in astrology, the name of the planet which is imagined to be the giver or disposer of life in a nativity.

APHET'ICAL, *adj.* Relating to the apheta.

A'PHIOM KA'RA-HIS'SAK, a town of Asiatic Turkey, in Natolia, situated on the Mandra, defended by a castle, on an eminence: fifty-six miles south of Kutaia. Lat. 37. 21. N. lon. 41. 13. E. Ferro.

A'PHIS, *f.* in entomology, the *puceron*, *vine-fretter*, or *plant-louse*; a genus of insects belonging to the order of hemiptera. The rostrum or beak of the aphid is inflexed; the antennæ or feelers are longer than the thorax; the wings are four, and erect, or they are wanting; the feet are of the ambulatory kind; and the belly often ends in two horns, from which is ejected that most delicate juice called *honey-dew*. Gmelin's Linnæus enumerates seventy-

five species of the aphid, all of them inhabitants of particular plants from which their trivial names are taken: as *aphis ribis*, *ulmi*, *rosæ*, &c.

The extraordinary nature of these insects for some time justly excited the wonder and attention of naturalists. They were long ranked among the animals which had been classed with the true androgynes spoken of by Mr. Breynius: for, having never been seen in coitu, it was hastily concluded that they multiplied without copulation. This, however, was but a surmise; but this surmise was believed and adopted by Mr. Reaumur: and, though he supported it by some observations peculiar to himself, the question remained still undecided, until Mr. Bonnet cleared it up in the affirmative, by shutting up a young aphid at the instant of its birth, in the most perfect solitude, which yet brought forth in his sight ninety-five young ones. The same experiment being made on one of the individuals of this family, that had been tried with its chief, the new hermit soon multiplied like its parent; and one of this third generation, in like manner brought up in solitude, proved no less fruitful than the former. Repeated experiments, in this respect, as far as the fifth or sixth generation, all uniformly presenting the observer with fecund virgins, were communicated to the Royal Academy of Sciences; when an unforeseen and very strange suspicion, imparted by Mr. Trembley to Mr. Bonnet, namely, that one copulation of these insects might serve for several generations, engaged him anew in a series of still more painful experiments than the foregoing. Mr. Bonnet now reared to the amount of the tenth generation of solitary aphides, and had the patience to keep an account of the days and hours of the births of each generation. In short, it was discovered, that they are really distinguished by sexes: that there are males and females amongst them, whose amours are the least equivocal of any in the world: that the males are produced only in the tenth generation, and are but few in number: that these, soon arriving at their full growth, copulate with the females: that the virtue of this copulation serves for ten generations: that all these generations except the first (from the fecundated eggs), are produced viviparous; and all the individuals are females, except those of the last generations, among whom some males make their appearance, to lay the foundation of a fresh series. These circumstances have been confirmed by other naturalists. In particular, we have a curious and accurate detail of them by Dr. Richardson of Rippon, in the Philosophical Transactions, vol. xi. art. 22.

The young, immediately after being protruded from the mother, are always of a paler colour than the parent: they have then the entire use of their limbs, and go in quest of food. All the different kinds cast their skin; and it is after these developments that such of them as have wings obtain these parts. It is not the males only that are winged, as we have seen in some other genera; many of the plant-lice of both sexes are deprived of these instruments in their most perfect state; for many of the females without them are seen producing young. As the larvae of these insects possess all the activity peculiar to their genus in its last stage of growth, so they are equally distinguished by voracity. They are furnished with a small trunk, which pierces the leaves, and enables the animal to extract the juices proper for its nourishment. Many plants grow deformed by the number of punctures thus made upon their leaves, and decay from the want of their usual sap. Some thrive even when covered with these insects, while others rise up into small hollow tubercles, which, on being broken open, disclose the numberless families that inhabit them. The galls or excrescences formed by the plant-louse, which often disfigure the shrubs upon which they grow, are in China, Persia, and the Levant, applied successfully in dying. Some species formed in these more northerly climes might probably be turned to the same useful purpose, were their virtues understood.

The plant-lice void from the anus that clear liquid sub-

rance called *honey-dew*, as well as from the two horny appendices that terminate the abdomen. It is in pursuit of this fluid that the ants are seen to frequent those plants upon which the plant-lice settle. From this circumstance, the former animals have been supposed hostile to the latter; while other naturalists have deemed it an indication of the friendship of the two genera for each other: but it is neither from motives of love nor of hatred that the ants repair in such numbers to these haunts; they seek only to gratify their appetite by devouring this delicious excrement.

The most effectual method of preventing the depredations of plant-lice upon flowers and the leaves of plants, is suggested by those insects which live by preying upon them. The plant-louse-lion, or aphidivorous fly, either by instinct or foresight, deposits her eggs in the midst of these animals; and, as soon as the larvæ are produced, they devour hundreds around them, without the necessity of any other movement than turning to the right side or the left. This formidable insect is furnished with two tubercular horns, with which it pierces the plant-louse, and sucks its juice. A few of its eggs placed upon the leaves frequented by the lice, would soon produce a number sufficient to suppress or destroy them.

APHLASTUM, *f.* in the ancient navigation, a wooden ornament, shaped like a plume of feathers, fastened on the goose's or swan's neck used by the ancient Greeks in the heads of their ships. The aphlastum had much the same office and effect in a ship that the crest had on the helmet. It also had this farther use, that, by waving a party-coloured riband fastened to it, it showed from what quarter the wind blew.

APHONIA, *f.* [Gr. from α priv. and $\phi\omega\nu\eta$, a voice.] One who hath lost his voice, called also by some *anaudia*. For the treatment of this disease, see **PATHOLOGY**.

APHORISM, *f.* A maxim or principle of a science; or a sentence which comprehends a great deal in a few words. The word comes from $\alpha\phi\omicron\rho\iota\varsigma\omega$, Gr. I separate; q. d. a choice or select sentence. The term is chiefly used in medicine and law. We say the aphorisms of Hippocrates, of Sanctorius, of Boerhaave, &c. aphorisms of the civil law, &c.

APHORISTICAL, *adj.* In the form of an aphorism; in separate and unconnected sentences.

APHORISTICALLY, *adv.* In the form of an aphorism.—These, being carried down, seldom miss a cure, as Hippocrates doth likewise *aphoristically* tell us. *Harvey*.

APHRACTI, *f.* in the ancient military art, denotes open vessels, without decks or hatches, furnished only at head and stern with cross planks, whereon the men stood to fight.

APHRADITA'RIMUM, *f.* in physic, a dry medicine made of equal parts of frankincense, pomegranate, meal, and scales of brass. *Scott*.

APHRODISIA, *f.* in antiquity, festivals kept in honour of Venus, the most remarkable of which was that celebrated by the Cyprians. At this solemnity several mysterious rites were practised: all who were initiated to them offered a piece of money to Venus as an harlot; and received as a token of the goddess's favour a measure of salt, and a $\phi\alpha\lambda\lambda\omicron\varsigma$; the former, because salt is a concretion of sea-water, to which Venus was thought to owe her birth; the latter, because she was the goddess of wantonness.

APHRODISIACAL, *adj.* in medicine, relating to the venereal disease.

APHRODISIACS, *f.* Medicines said to increase the quantity of semen, and create an inclination to venery.

APHRODISIASMUS, [from $\alpha\phi\omicron\rho\delta\iota\varsigma\mu\omicron\varsigma$, Venus.] An immoderate desire of venery.

APHRODISIUS, *f.* in chronology, denotes the eleventh month in the Bithynian year, commencing on the 25th of July in ours.

APHRODITA, *f.* in helminthology, a genus of worms of the order of mollusca. The generic characters are—

Body creeping, oblong, covered with scales, and furnished with numerous bristly fasciculate feet on each side; mouth terminal, cylindrical, retractile; feelers two, setaceous, annulate; eyes four. There are nine species.

1. *Aphrodita aculeata*, the aculeated aphrodite, or sea-mouse: body oval, brown, beneath flesh-colour; with long silky changeable hair on each side the body, which is convex above and covered with short brown fur, the sides with long rich green-gold hair mixed with sharp spines; vent covered with two scales; belly covered with a naked pale skin; the mouth is placed beneath. Feet from thirty to thirty-six on each side, each consisting of a tuft of five or six strong black spines. Inhabits the European Seas, and is often found in the belly of the cod-fish; it is from four to seven inches long. In the annexed Plate, fig. 1, 2, 3, 4, exhibit upper and under views of two varieties of this species.

2. *Aphrodita scabra*, the rough aphrodite: body oblong, with two rows of alternate scales; mouth projecting, cylindrical. Much smaller than the last, with twenty alternate scales; legs about twenty on each side.

3. *Aphrodita squamata*, the squamose aphrodite. This is also a small species: body oblong, covered with two rows of uniformly-coloured scales dotted with black. Middle of the back and belly smooth; the other part covered with large opposite rigid ochre-yellow scales resembling those of a fish, twenty-four in number. Inhabits the European and Asiatic Seas; about an inch long. This species is shown on the Plate at fig. 5.—The other species are the *imbricata*, *plana*, *lepidota*, *cirrosa*, *violacea*, and *longa*.

APHRODITE, in mythology, a name of Venus, derived from $\alpha\phi\omicron\varsigma$, froth; because, according to the poets, Venus is supposed to have been produced from the froth or foam of the sea.

APHROGA'LA, *f.* [Greek; of $\alpha\phi\omicron\varsigma$, froth, and $\gamma\alpha\lambda\alpha$, milk.] Milk beat into an entire froth; a syllabub.

APHTHÆ, *f.* [from $\alpha\pi\tau\omega$, Gr. to inflame.] In medicine, small round superficial ulcers arising in the mouth, called the *thrush*.

APHTHONIUS, a rhetorician of the third century, who wrote a work entitled *Progymnasmata Rhetorica*, or Rhetorical Exercises; first published in Greek by Aldus, at Venice, in 1508; afterwards with Hermogenes and Longinus, in 8vo. at Geneva, in 1569; and at Upsal, in 1670, by Scheffer, with a translation and notes. To the same author are ascribed Fables, printed with those of Æsop, at Frankfort, in 1610.

APHYLLANTES, *f.* in botany. See **GLOBULARIA**.

APHYLLANTHES, *f.* [$\alpha\phi\upsilon\lambda\lambda\omicron\varsigma$ $\alpha\nu\theta\epsilon\varsigma$, Gr. a flower without leaves.] In botany, a genus of the class hexandria, order monogynia, natural order of tripetaloidææ. The generic characters are—Calyx: glumes univalve, lanceolate, several imbricate. Corolla: petals six, ovate, spreading into the border; claws slender, erect, converging into a tube. Stamina: filaments setaceous, shorter than the corolla, inserted into the throat; antheræ oblong. Pistillum: germ superior, three-cornered, turbinate; style filiform, the length of the stamens; stigma three, oblong. Pericarpium: capsule turbinate, triangular, trilocular. Seeds: ovate.—*Essential Character*. Corolla six-petalled; filaments inserted into the throat of the corolla. Capsule superior. Glume of the calyx univalve, imbricate.

There is but one species, known by the name of *Aphyllanthes Monspeliensis*: root creeping; culms naked, simple, surrounded at the base with sheaths, like the rush. Glume two-valved, two-flowered; the proper glume also two-valved. Were it not for the corolla, it would be a rush. It grows wild about Montpellier and Nice, in barren pastures and rocky places.

APHYLLANT'IA AFFINIS. See **GLOBULARIA**.

APHYL'LO, *f.* in botany. See **OROBANCHE**.

APHYTE'IA, *f.* [α , and $\phi\upsilon\tau\epsilon\iota\alpha$, Gr. plantless; having neither root, stem, nor leaves.] In botany, a genus of the class monadelphia, order triandria. The generic characters

APHRODITA.

J. Ross sculp.

Two varieties of the aculeated Aphrodite, shewing the upper and under Parts.
Fig. 5. the squamese Aphrodite.

ters are.—Calyx: perianthium monophyllous, semitrifid, funnel-shaped, large, fleshy, erect, permanent. Corolla: rudiments of three petals, growing to the divisions of the calyx; or rather none. Stamina: filaments connate at bottom, short; antheræ convex, cordate, striated. Pistillum: germ inferior; style thickish, short; stigma three-cornered, channelled. Pericarpium: berry one-celled. Seeds: numerous, nestling.—*Essential Character.* Calyx large, funnel-shaped, semitrifid; petals three, inserted into the throat of the tube in the calyx, and shorter than it.

There is only one species, which is called *Aphyteia hydronora*. This is a vegetable without leaves, stem, or root. Parasitical, terrestrial, consisting of a fructification only, which has but one flower, four inches over, sessile, coriaceous, succulent. Calyx large, with an erect trifid border, as it were of double licinias; the inside painted of a white scutiform figure. Smell of the flower and ripe fruit not unpleasant. Very agreeable to foxes and weasels, and eaten both raw and roasted by the Hottentots. First observed at the Cape of Good Hope by Thunberg.

A'PIAN, or A'PIAN (Peter), called in German *Biene-witz*, a celebrated astronomer and mathematician, was born at Leisnig, or Leipzig, in Misnia, in 1495, and made professor of mathematics at Ingolstadt in 1524, where he died in the year 1552, at fifty-seven years of age. Apian wrote treatises upon many of the mathematical sciences, and greatly improved them; particularly astronomy and astrology, which in that age were much the same thing; also geometry, geography, arithmetic, &c. He particularly enriched astronomy with many instruments, and observations of eclipses, comets, &c. His principal work was the *Astronomicum Cesarium*, published in folio at Ingolstadt in 1540, and which contains a number of interesting observations, with the descriptions and divisions of instruments. In this work he predicts eclipses, and constructs the figures of them in plano. In the second part of this work, or the *Meteoroscopium Planum*, he gives the description of the most accurate astronomical quadrant, and its uses. To it are added observations of five different comets, viz. in the years 1531, 1532, 1533, 1538, and 1539; where he first shows that the tails of comets are always projected in a direction from the sun. Apian also wrote a treatise on Cosmography, or Geographical Instruction. In 1533 he made, at Nuremberg, a curious instrument, which from its figure he called *Folium Populi*; which, by the sun's rays, showed the hour in all parts of the earth, and even the unequal hours of the Jews. In 1534, he published his *Inferionis Orbis*. In 1540, his *Instrumentum Sinuum, sive Primi Mobilis*, with 100 problems.

A'PIARY, *f.* [from *apis*, Lat. a bee.] A house or place where bees are kept.—Those who are skilled in bees, when they see a foreign swarm approaching to plunder their hives, have a trick to divert them into some neighbouring *apiary*, there to make what havoc they please. *Swift*.

A'PICE, a town of Italy, in the kingdom of Naples, and Principato Citra: seven miles east-south-east of Benevento.

APICES, *f. plu.* in botany, the little knobs that grow on the tops of the stamina or chives of flowers.

AP'CIAN, *adj.* [from *Apicius*, the subject of the next article.] High-seasoned, voluptuous.

AP'CIUS. There were at Rome three persons of that name, famous for their gluttony: the second is the most celebrated of the three. He lived under Tiberius, spent immense sums on his belly, and invented divers sorts of cakes, which bore his name. After having spent a hundred millions of sesterces in entertainments, about 853,601 l. sterling, he examined into the state of his affairs; and finding that he had but a tenth part of that sum remaining, he poisoned himself, under an apprehension of starving.

APIDANO, a river of European Turkey, which runs into the Peneus, near Larissa.

APIE'CE, *adv.* [from *a*, for each, and *piece*, or share.] To the part or share of each.—Men in whose mouths at first founded nothing but mortification, were come to think that they might lawfully have six or seven wives *apiece*. *Hooker*.

APIE'CES, *adv.* Tombs were hackt and hewn *apieces*. *Weever*.

APIFAC'TURE, *f.* [from *apis*, Lat. a bee, and *facio*, to do.] The curious work of bees.

AP'INA, or APINÆ, a town of Apulia, built by Diomedes, as was also Tricæ. *Apinæ et Tricæ* is a proverbial saying for things trifling and of no value; and *Apinari* was the appellation for triflers or buffoons.

A'PINEL, *f.* An American root, poisonous to serpents, and called by the natives *yabcani*. It has its name from a captain Apiuel, who first made the Europeans acquainted with it.

AP'OLZE, an ancient city of Italy, which was taken by Lucinus Tarquinius the elder; and with the plunder of it, according to Pliny, he founded the capitol of Rome.

A'PION, a famous grammarian, born in Egypt, was a professor at Rome in the reign of Tiberius. He had all the arrogance of a mere pedant, and amused himself with difficult and insignificant inquiries. One of his principal works was his *Antiquities of Egypt*. He wrote also against the Jews, and was answered by Josephus.

APION'TA, *f.* [from *απο*, and *επι*, to go from.] The natural excretions which proceed from the body.

A'PIOS, *f.* in botany. See GLYCINE and EUPHORBIA.

APIOSCOR'ODON, *f.* in botany. See CRATEVA.

A'PIS, the son of Phoroneus, and king of the Argives, who received divine honours after death. Some have imagined that he went into Egypt with a colony of Greeks, and that after death he was worshipped under the name of Seraphis; but others think it was his nephew and successor Argus that went there, and took the name of Osiris.

A'PIS, in the heathen mythology, a divinity worshipped by the ancient Egyptians at Memphis. It was an ox having certain exterior marks, in which the soul of the great Osiris was supposed to subsist. This animal had the preference to all others, as being the symbol of agriculture, the improvement of which that prince had so much at heart. Several learned writers on the Egyptian religion consider Apis as the only symbolical deity. "Amongst the animals consecrated to ancient rites, (says Ammianus Marcellinus,) Mnevis and Apis are the most celebrated: the first is an emblem of the sun, the second of the moon." Porphyry tells us, that Apis bore the characteristic signs of the two stars; and Macrobius, who confirms this opinion, adds, that he was equally consecrated to them both. According to Plutarch, the term of the life of Apis was limited to twenty-five years; which number marked a period of the sun and of the moon, and the bull was consecrated to these two bodies. Syncellius, in his Chronography, when he comes down to the thirty-second Pharaoh, called *Aseth*, says, "Before Aseth, the solar year consisted of 360 days. This prince added five to complete its course. In his reign a calf was placed amongst the gods, and named *Apis*." And in the Bibliotheca of Fabricius we have the following passage: "It was customary to inaugurate the kings of Egypt at Memphis, in the temple of Apis. They were here first initiated in the mysteries, and were obliged to swear, that they would neither insert months nor days in the year, and that it should remain composed of 365 days, as had been established by the ancients." From these facts Mr. Savary, in his letters on Egypt, infers that Apis was the tutelary divinity of the new form given to the solar year, and of the cycle of twenty-five years discovered at the same time. This deity, besides, had a marked relation to the swelling of the Nile, as is testified by a great number of historians. The new moon which followed the summer solstice was the era of this phenomenon, on which the eyes of every body was fixed; and Pliny speaks as follows on this subject: "Apis had on his right side a white mark, representing the crescent. This mark (continues Elian) indicated the commencement of the inundation." If Apis possessed the characteristic signs which proved his divine origin, he promised fertility and abundance of the fruits of the earth. It seems demonstrated, therefore, Mr. Savary adds, that this sacred bull, the guardian of the so-

lar year of 365 days, was also regarded as the genius who presided over the overflowing of the river. The priests, by fixing the course of his life to 25 years, and by making the installment of a new Apis concur with the renewal of the period above-mentioned, had probably perceived, as the result of long meteorological observations, that this revolution always brought about abundant seasons. Nothing was better calculated to procure a favourable reception of this emblematical deity from the people, since his birth was a preface to them of a happy inundation, and of all the treasures of teeming nature. The solemnity of this inauguration was called *Apparition*. That which was renewed every year towards the 12th or 13th of the month *Payn*, which corresponds with the 17th or 18th of June, was called *the birth of Apis*. It was a time of rejoicing, which Ælian describes in the following manner: "What festivals! what sacrifices take place in Egypt at the commencement of the inundation! It is then that all the people celebrate the birth of Apis. It would be tedious to describe the dances, the rejoicings, the shows, the banquets, to which the Egyptians abandon themselves on this occasion, and impossible to express the intoxication of joy which breaks forth in all the towns of the kingdom."

Dr. Bryant, however, apprehends, that the name of *Apis* was an Egyptian term for a father; that it referred to the patriarch Noah; and that the crescent which was usually marked on the side of the animal was a representation of the ark.

A'PIS [from *α*, priv. and *πες*, a foot, because they are born without feet; or from *apis*, to knit together, because they collect together in swarms; or from *οφις*, a serpent, on account of their stings. *Ape*, Ital. *abeja*, Span. *abelha*, Portuguese.] The BEE; in entomology, a genus belonging to the order of hymenoptera. The mouth is furnished with two jaws, and a proboscis infolded in a double sheath; the wings are four in number, the two foremost covering those behind when at rest: in the anus or tail of the females and working bees there is a hidden sting. These insects are distinguished into several species, each of which has its peculiar genius, talent, manners, and disposition. Variety prevails in the order of their architecture, and in the nature of their materials. Some live in society, and share the toils; such are the common bee and the drone. Others dwell and work in solitude, building the cradles of their families; as the leaf-cutter bee does with the rose-tree leaf, the upholsterer with the gaudy tapestry of the corn-rose, the mason-bee with a plaster, the wood-piercer with saw-dust. All are employed in their little hermitage, with the care of providing for the wants of their posterity. The species enumerated by Gmelin are 212; of which the following are the most remarkable:

1. *Apis floriformis*, the black bee, with a cylindrical incurvated belly, having two toothed-like protuberances at the anus, and a kind of prickles on the hind-legs. This bee sleeps in flowers.

2. *Apis dentata*, the shining green bee, with black wings, and a kind of teeth on the hind thighs. The tongue of this bee is almost as long as its body.

3. *Apis variegata*: the breast and belly are variegated with white and black spots; the legs are of an iron colour. It is a native of Europe. This species sleeps in the geranium phæum, or spotted crane's-bill.

4. *Apis rostrata*: the upper lip inflected and of a conical shape, and the belly invested with bluish belts. They build their nests in high sandy grounds, and there is but one young in each nest.

5. *Apis ferruginea*, the smooth black bee, with the feelers, mouth, belly, and feet, of an iron colour. This is a small bee, and supposed to be of an intermediate kind between the bee and wasp. It is a native of Europe.

6. *Apis cariosa*, the yellowish hairy bee: feet and front of a bright yellow colour. It builds in the rotten trees of Europe.

7. *Apis basiliatorum*, the pale-red hairy bee, with the

basis of the thighs black. This is a very large bee, every where covered with a testaceous skin. It is a native of America.

8. *Apis lapidaria*, the red hairy bee, with a yellow anus, builds in holes of rocks.

9. *Apis terrestris*, the humble bee: black and hairy, with a white belt round the breast, and a white anus; it builds its nest very deep in the earth.

10. *Apis violacea*, is a red bee, and very hairy, with bluish wings. It is a native of Europe; it is said to perforate trees, and hollow them out in a longitudinal direction; they begin to build their cells at the bottom of these holes, and deposit an egg in each cell, which is composed of the farina of plants and honey, or a kind of gluten.

11. *Apis muscorum*, a yellow hairy bee with a white belly, builds in mossy grounds.

12. *Apis centuncularis*, the leaf-cutter, or black bee, having its belly covered with yellow down. The nests of this species are made of leaves curiously plaited in the form of a mat or quilt. There are several varieties, all equally industrious.

13. *Apis mellifica*, the domestic honey-bee, an insect whose history has been the subject of many volumes. Almost every writer on entomology has made the manners and economy of these animals a considerable part of his work; and many authors have treated of them, who have entered into no other department of natural history. The celebrated Reaumur, in detailing the economy of these animals, an object to which he applied himself with a perseverance superior to all mankind, has abstracted much of the marvellous from their history; but in return he has enlarged it with many facts and observations formerly unknown, and which succeeding experiments have seldom contradicted.

There are, of the domestic bee, at certain seasons of the year, three kinds in every hive; the males, the females, and the bees without sex. The latter every person is acquainted with; their number is beyond comparison greater than that of the other two kinds. Nature seems to have destined them solely for the purpose of labour; and the whole drudgery of the hive lies upon them; hence they have properly been termed *working bees*. It is only during one or two months of the summer, when the hive is most crowded, that males are found in it; and even then, they do not amount to a tenth part of the whole: but they are of a superior size. During the whole course of the season, except a few days, there is only a single female to be discovered in the most numerous hive. Her fecundity, however, is so prodigious, that she is soon capable of multiplying her family to such a degree, that the hive can no longer contain it. To her the whole swarm, amounting from twenty to forty thousand, owe their birth. Her residence is generally in the interior apartments of the lodging; when she shows herself, she is readily known by her size, being longer than even the male bees, but inferior in thickness. It is this female whom the ancients dignified with the title of *king of the bees*, and whom, with more propriety, the moderns have denominated their *queen*. From a number of well-attested experiments and observations, it appears that her life is more precious than any of the rest; for she is the soul of all their operations. If a hive is deprived of her, however numerous, it will undertake no labour; and the individuals will hardly give themselves the trouble of collecting their daily subsistence. A swarm, busily employed from morning to night constructing cells and collecting wax, immediately upon this accident seem to forget that the flowers contain their food; they scarcely stir from the hive, construct no new cells, nor even finish what was begun; but, the moment she is restored, their wonted spirit and activity is resumed by the whole swarm.

The external parts of bees are happily accommodated, by their structure, to the delicate operations they are destined to perform. Each of them is furnished with a trunk or proboscis, commonly folded up, but capable of being extended

extended at pleasure. It is with this instrument that they collect their food; not by pumping or sucking, but by licking it from the nectaria of flowers. The teeth with which these insects are provided, serve another purpose equally important; they are the instruments by which they fashion and give a proper consistency to the wax. That valuable commodity is not found in a perfect state upon the flowers, as many have imagined; it is there scattered upon the surface in the form of a fine powder or dust, and swept off by the hairy legs of the bee, and deposited in a hollow part of each thigh, prepared for its reception. After being carried in that form into the hive, it is all eaten up by the bee; and by the action of the stomach is brought into the state of genuine wax. From the stomach, the working bee brings it back in small parcels to the mouth like a ruminating animal; and, by chewing it there, fashions it into pieces proper for the construction of the cell to which it is applied, and afterwards polished as the situation requires.

That small scaly spine, commonly termed the *sting* of the bee, is only the case of two needles or darts, extremely fine, and each denuded and united at the point. The wounds made by these slender arms would be little to be apprehended, were their points not impoisoned by a small drop of acrid liquor. This liquor, which, when tasted, burns the tongue, is conveyed along a small canal to the case of the sting, on the tip of which it appears in small drops, when the bee intends to make use of her offensive weapons. However disagreeable this instrument may sometimes prove to us, it is absolutely necessary to the bee, surrounded as that animal continually is with many enemies, whose hostilities are constantly provoked by the honey and wax. The sting of the bee is also used for another purpose, the propriety of which we are not so well able to vindicate. At a certain time, they are busy from morning till night in no other employment than mauling their associates. The males, after the female is fecundated, become useless, and even offensive to the rest of the hive. The working bees, who had formerly been their nurses, and hitherto had lived with them in the best understanding, all at once break loose upon them with unrelenting fury, and in two or three days destroy the whole in one general carnage. Of the reasons alleged by the working bees for this massacre, we are altogether ignorant; we know not upon what claim their power of life and death over the males is founded, farther than that nature seems to have granted such a right, by giving them power to exercise it. These, however, are not the only combats in which the bees are engaged: the working bees of the same hive often quarrel, and challenge each other to battle; the one endeavouring to find a place in the scaly body of his adversary into which he may thrust his sting, and the other as studiously warding off the blow. The first wound that takes place puts an end to the engagement; and the victorious bee walks off, leaving his adversary to expire in the dust. Sometimes three or four attack a single bee, without any design upon his life, but with a view to force him to disgorge his honey; and, as soon as they have succeeded, they lick it up, allowing the former proprietor to walk away. Battles are also occasioned when a neighbouring swarm, from poverty, or a principle of injustice, invade a hive already occupied. Scarcely have they entered the walls of the city, when a general engagement ensues: those who have the right of possession oppose their invaders with all their force, and with undaunted courage; not a minute passes that you do not observe a victorious bee dragging to the door of the hive a dead adversary, or one who is yet struggling in all the agonies of death. These engagements do not close but with the day; and, before victory declares for either party, they often cost thousands their lives; for very often the one who has stung its opponent leaves its weapon in the wound, an accident which proves fatal to itself. Insects of their own species are far from being the only enemies which the bees have to fear;

worms, wasps, hornets, and insects of different kinds, never fail to make their way into the hive, whenever any rent or crevice is left open. When attacked by these robbers, they perish in the unequal combat; and, when dead, their bodies are ripped up, in order to extract from them the honey they contain. Apprised of the fatal consequences of admitting them into the hive, the bees carefully fill up every chink and crevice, not with wax, but with the glutinous matter that exudes from certain trees, a substance still more tenacious. When a bee enters the hive loaded with a quantity of this stuff, it is met by others, who take small particles of it, and apply it to the sides of the part to be stopped up, till they are entirely closed.

A swarm of bees, however numerous, as we have already seen, all owe their birth to a single female. This queen, which Virgil, and the other writers of antiquity have charged with all the cares of government, is indeed busily occupied, but in functions of a different kind; and these are, the production of a vast number of eggs, which she continues to drop, one after another, into the empty cells, during a considerable part of the summer. This animal, which is so amazingly productive, on being opened, has been found to contain upwards of five thousand eggs, all of a size sufficient to be perceptible. If we make allowance for those that were already dropped, and many more not yet formed, so as to become perceptible; we shall no longer deem it incredible, that this animal should in one season become the mother of so many thousands. The most numerous hive is far inferior to the number of spawn that have been taken from the belly of a small fish. During the whole time that the female goes from cell to cell depositing her eggs, she is accompanied by the working bees, who attend her with the most officious care. And, as the males and females are produced by her of a superior size to the rest, the working bees, as if apprised of the circumstance, construct a few cells larger than the rest; and, what is still more remarkable, the female herself knows which of the embryos are to become of her own sex, and accordingly deposits them in cells of a suitable capacity. The cell which is to contain the future queen-bee is of a structure different from all the rest; and in building it, the labourers abandon the hexagonal shape which is best adapted to the saving of labour, and of wax; nothing, in this instance, seems to cost them too dear. The cradle of their future queen consumes as much as a hundred or a hundred and fifty of the ordinary cells.

From the great number of males in each hive to a single female, the ancients were induced to believe, that fecundation among these insects was not accomplished by any act of copulation, but that it was performed by a vivifying liquor shed upon the ova in the cells. But this opinion was overthrown, as soon as it was observed, that for nine or ten months in the year there was no male in the hive. Swammerdam, who could not observe that in these animals there were any parts of generation, therefore supposed, that the female was impregnated solely by the effluvia of the male bees. The observations made by Reaumur have removed those difficulties with which this part of the history of bees seemed to be attended. The female, who is surrounded by so many males, instead of being fatigued and persecuted by their importunities, is obliged to carefs and inflame the passions of these drones, who are the most cold and indifferent of all their sex. She mounts upon their backs, and pushes her gallantry to what may be deemed indecency; at length her allurements produce the desired effect, and copulation is performed. The female thus impregnated proceeds to lay her eggs, which are round and oblong, rather thicker at the one end than the other. Each is deposited in a separate cell, except upon some occasions, when the industry of the working bees has not been sufficient for the fertility of the mother: she then lays two or three in a single cell; the supernumeraries being afterwards carried away and placed by themselves, as soon as new cells are provided. The single egg which remains is fastened to the

bottom of the cell by the small end, the only part which seems to touch it. In a day or two after being placed there, it produces a worm, which the working bees take care to supply with suitable food, consisting of a whitish liquor, which serves it at once for subsistence and a bed; for it lies upon it, folded up like a ring. In the space of six or seven days more, the whole of its growth is completed; and the bees, who know the time at which it no longer needs to be supplied with food, cease to carry it any more. The last office which they render it, is closing up the mouth of the cell, which is done with wax. In the mean time, the young animal within, which hitherto was almost entirely inactive, begins to spin silk, and line the inside of its habitation, as a preparative to its entering into the chrysalis state, in which, for a while, it remains. Thus, in the space of about three weeks after it was first dropped into the cell, the young bee is ready to make its appearance as a winged animal. The first employment, after it has arrived at that period, is to gnaw off the wax with which the mouth of its cell had been stopped up. On its first issuing from the cell, the whole body is wet with the humid substance of the cell; but the affectionate bees flock around, and with their trunks assist in wiping off the moisture. The wings grow dry, and the limbs firm; and, in the course of the same day, it issues forth with the labourers to collect wax and honey, and thereby to make returns to the society for the care with which it has been reared.

Thus, after the commencement of summer, the number of bees daily continues to increase, till, by the month of June, they have become so numerous, that the same hive can no longer contain them. The only measure which then remains to be adopted, is to divide; and in an instant, a large colony prepares to abandon for ever the place of their nativity, and to follow a young queen in forming a new establishment for themselves. It is not merely the number of bees in a hive that determines them to swarm; that event depends upon the young female, who must not only be sufficiently strong to lead the colony, but must also be impregnated; for upon that circumstance depends the whole hopes of the future progeny. But no sooner do all these predisposing circumstances concur in a hive, than it prepares immediately for colonisation. In the evening before that eventful period, indication of their intention is given, by an unusual noise and hurry within the hive. All the morning of the next day passes without hardly a single bee going to collect honey. Those who are to leave the hive are preparing to take their departure; while those that remain behind defer their operations, till their companions, by their leaving them, have afforded sufficient room. It is in the great enterprise of colonisation that the influence of the queen bee is most clearly seen. Wherever she alights, there the whole swarm take up their abode, and all cling round her body. If she is removed, they all fly in quest of her: if put into a hive where she is not placed, they either forsake it or die. Hence the art of those persons is explained, who go about shewing bees, making them alight on different parts of their body, and follow them for any length of time. They have possession of the queen-bee; and by that means can influence the movements of all the others. When a swarm thus migrates from the parent hive, it frequently happens that more than one female accompanies it. The prosperity, however, of the new colony requires that there should be but one; one only is accordingly preserved. In a single day, all the rest are put to death; and it is found that the one which is spared is the best entitled to reign, because she is most fertile, or nearest her period of giving a new progeny to the society. The young females in the old hive, if any remain there, share not a more happy destiny; all the supernumeraries, like those in the swarm, are put to death.

When the bees begin to work in their hives, they divide themselves into four companies: one of which roves in the fields in search of materials; another employs itself

in laying out the bottom and partitions of the cells; a third is employed in making the inside smooth, from the corners and angles; and the fourth company brings food for the rest, or relieves those who return with their respective burdens. But they are not kept constant to one employment; they often change the tasks assigned them: those that have been at work, being permitted to go abroad; and those that have been in the fields already, take their places. They seem even to have signs, by which they understand each other: for, when any of them want food, it bends down its trunk to the bee from whom it is expected, which then opens its honey-bag, and lets some drops fall into the other's mouth, which is at that time open to receive it. Their diligence and labour is so great, that, in a day's time, they are able to make cells which lie upon each other numerous enough to contain 3000 bees. In the plan and formation of these cells they discover a most wonderful sagacity. In constructing habitations within a limited compass, an architect would have three objects in view: first, to use the smallest quantity that can be of materials; next, to give to the edifice the greatest capacity in a determined space; and thirdly, to employ the spot in such a manner that none of it may be lost. On examination, it will be found that the bees have obtained all these advantages in the hexagonal form of their cells: for, first, there is an economy of wax, as the circumference of one cell makes part of the circumferences of those contiguous to it; secondly, the economy of the spot, as those cells which join to one another leave no void between them; and thirdly, the greatest capacity or space; as, of all the figures which can be contiguous, that with six sides gives the largest area. This thriftiness prompts them to make the partitions of their cells thin; yet they are constructed so as that the solidity may compensate for the scantiness of materials. The parts most liable to injury are the entrance of the cells. These the bees take care to strengthen, by adding quite round the circumference of the apertures a fillet of wax, by which means this mouth is three or four times thicker than the sides: and they are strengthened at the bottom by the angle formed by the bottom of three cells falling in the middle of an opposite cell. The combs lie parallel to each other; and there is left between every one of them a space which serves as a street, broad enough for two bees to pass by each other. There are holes which go quite through the combs, and serve as lanes for the bees to pass from one comb to another, without being obliged to go a great way about. When they begin their combs, they form at the top of the hive a root or stay to the whole edifice, which is to hang from it.

It is not easy to discover the particular manner of their working; for, notwithstanding the many contrivances used for this purpose, there are such numbers in continual motion, and succeed one another with such rapidity, that nothing but confusion appears to the sight. Some of them, however, have been observed carrying pieces of wax in their talons, and running to the places where they are at work upon the combs. These they fasten to the work by means of the same talons. Each bee is employed but a very short time in this way: but there is so great a number of them that go on in constant succession, that the comb increases very perceptibly. Besides these, there are others that run about beating the work with their wings and the hinder part of their body, probably with a view to make it more firm and solid.

The crude wax, when brought home by the bees to form their cells, is of as different colours as are the flowers from which it is collected: but the new combs are always of a white colour, which is afterwards changed only by the impurities arising from the steam, &c. of the bees. They likewise collect crude wax for food; for, if this were not the case, there would be no want of wax after the combs are made: but they are observed, even in old hives, to return in great numbers loaded with such matter, which is deposited in particular cells, and is known by the name

of *bee-bread*. We may guess that they consume a great deal of this substance in food by the quantity collected; which, by computation, may in some hives, amount to an hundred weight in a season, whilst the real wax in such an hive does not perhaps exceed two pounds.

Honey is originally a juice digested in plants, which sweats through their pores, and chiefly in their flowers, or is contained in reservoirs in which nature stores it. The bees sometimes penetrate into these stores, and at other times find the liquor exuded. This they collect in their stomachs; so that, when loaded with it, they seem, to an inattentive eye, to come home without any booty at all.

When the bees have collected their honey, the instant they return home, they seek the cells in which they may disgorge and deposit their loads. They have two sorts of stores: one which consists of honey laid up for the winter; and the other of honey intended for accidental use in case of bad weather, and for such bees as do not go abroad in search of it. Their method of securing each of these is different. They have in each cell a thicker substance, which is placed over the honey, to prevent its running out of the cell; and that substance is raised gradually as the cell is filled, till the bees, finding that the cell cannot contain any more, close it with a covering of wax, not to be opened till times of want, or during the winter.

When the bees first settle in swarming, indeed when they at any time rest themselves, there is something very particular in their method of taking their repose. It is done by collecting themselves together in a heap, and hanging to each other by their feet. They sometimes extend these heaps to a considerable length. It would seem probable to us, that the bees from which the others hang must have a considerable weight suspended to them. All that can be said is, that the bees must find this to be a situation agreeable to themselves. They may perhaps have a method of distending themselves with air, thereby to lessen their specific gravity; in the same manner as fishes do, in order to alter their gravity compared with water. Their vigilance to counteract depredation or surprise from a foreign enemy, is highly deserving our admiration. Even during their repose, they plant centinels at the mouth of the hive, to prevent insects of any kind from getting in. But if a snail, or other large insect, should get in, notwithstanding all resistance they sting it to death; and then cover it over with a coat of *propolis*, to prevent the bad smell or maggots which might proceed from the putrefaction of such a large animal. Bees seem also to be forewarned of the appearance of bad weather by some particular feeling. It sometimes happens, even when they are assiduous and busy, that they on a sudden cease from their work; not a single one stirs out; and those that are abroad hurry home in such prodigious crowds, that the doors of their habitations are too small to admit them. It is alleged, that no bee is ever caught even in what we call a sudden shower, unless it has been at a very great distance from the hive, or has been before injured by some accident, or be sickly and unable to fly so fast as the rest. As to the age of bees, the large drones live but a little while, being destroyed without mercy so soon as the office of impregnating the queen bee is performed. Writers are not agreed as to the age of the working bees. Some maintain that they are annual, and others suppose that they live many years.

It has been generally supposed, that the queen-bee is the only female contained in the hive; and that the working bees are neutral, or of neither sex. But M. Schirach has lately established a different doctrine, which has been also confirmed by the later observations of Mr. Debray, of Cambridge. According to M. Schirach, all the working or common bees are females in disguise; and the queen bee lays only two kinds of eggs, viz. those which are to produce the drones, and those from which the working bees are to proceed: and from any one or more of these, one or more queens may be produced; so that every worm of the latter or common kind, which has been hatched about three days, is capable, under certain circumstances,

of becoming the queen, or mother, of a hive. In proof of this doctrine, new and singular as it may seem, he alleges a number of satisfactory and decisive experiments, which have been since verified by those of Mr. Debray. In the early months of the spring, and in any preceding month, even so late as November, he cut off from an old hive a piece of that part of the comb which contains the eggs of the working bees; taking care, however, that it contained likewise worms which had been hatched about three days. He fixed this in an empty hive, or box, together with a portion of honey-comb, &c. or, in other words, with a sufficiency of food and building materials, or wax, for the use of the intended colony. He then put into, and confined within, the same box, a sufficient number of common working bees, taken from the same or any other hive. As soon as the members of this small community found themselves deprived of their liberty, and without a queen, a dreadful uproar ensued, which continued generally, with some short intervals of silence, for the space of about twenty-four hours; during which time it is to be supposed they were alternately meditating and holding council on the future support of the new republic. On the final cessation of this tumult, the general and almost constant result was, that they betook themselves to work; first proceeding to the construction of a royal cell, and then taking the proper measures for hatching and feeding the brood inclosed within them. Sometimes, even on the second day the foundations of one or more royal cells were to be perceived; the view of which furnished certain indications that they had elected one of the inclosed worms to the sovereignty. The final result of this experiment is, that the colony of working bees thus shut up, with a morsel of common brood, not only hatch it, but are found, at the end of eighteen or twenty days, to have produced from thence one or two queens; which have apparently proceeded from worms of the common sort, pitched upon by them for that purpose; and which, under other circumstances, that is, if they had remained in the old hive, there is reason to suppose would have been changed into common working bees. In the present instance, the common worm appears to be converted by them into a queen bee, merely because the hive was in want of one. Hence we may justly infer, that the kingdom of the bees is not, if the expression may be used, a *jure divino*, or hereditary monarchy, but an elective kingdom; in which the choice of their future ruler is made by the body of the people, while she is yet in the cradle, or in embryo; and who are determined by motives of preference which will perhaps for ever elude the penetration of the most sagacious naturalists.

The conclusions drawn by M. Schirach, from experiments of the preceding kind, often repeated by himself and others with the same success, are, that all the common or working bees were originally of the female sex; but that, when they have undergone their last metamorphosis, they are condemned to a state of perpetual virginity, and the organs of generation are obliterated; merely because they have not been lodged, fed, and brought up, in a particular manner, while they were in the worm state. He supposes that the worm, designed by the community to be a queen, or mother, owes its metamorphosis into a queen, partly to the extraordinary size of its cell, and its peculiar position in it; but principally to a certain appropriate nourishment found there, and carefully administered to it by the working bees while it was in the worm state; by which, and possibly other means unknown, the development and extension of the germ of the female organs, previously existing in the embryo, is effected; and those differences in its form and size are produced, which afterwards so remarkably distinguish it from the common working bees. This discovery is capable of being applied towards forming artificial swarms, or new colonies of bees, by which means their number might be increased, and their produce in honey and wax proportionably augmented.

The annexed Plate will in some measure exhibit the structure

structure and economy of the bee. *Fig. 1.* is the queen bee. 2. The drone. 3. The working bee. 4. Represents the bees hanging to each other by the feet, taking their repose. 5. The proboscis or trunk magnified, wherewith they gather the honey and take their nourishment. 6. One of the hind legs of a working bee loaded with wax. 7. A comb in which the working bees are bred: the cells are the smallest of any: a royal cell is suspended on one side. 8. A comb in which the drones are bred, being larger than the former; the young-drones being included in several of them; with two royal cells suspended on the side. 9. A similar comb, in which the royal cell is fixed in the middle, and several common cells are sacrificed to serve as a basis and support to it: in general, the royal cells are suspended on the side of a comb, as in *fig. 7, 8.* At the side of *fig. 9.* two royal cells are begun; they resemble pretty much the cup in which an acorn lies: the other royal cells have the young queens included in them. *Fig. 10.* exhibits the sting and all its parts, magnified: the sting is composed of a sheath or case, and two shanks, united to each other, and terminating in a sharp point, so as to look like a single part; *b*, the poisonous bag; *c*, the tube that conveys the poison to the sting; *dd*, the two shanks of the sting; *ee*, the sheath of the sting; *ff*, the thickest end of the sheath, where the tube opens into it with the poison; *g*, the point of the sting; *h*, the beards or jags with which the sting is armed; *i*, the tube that secretes the poison; *kk*, extremities of the tube; *lll*, cartilages which are articulated with the shanks of the sting; *mm*, two other cartilages, less than the former; *nnnn*, places where the foregoing cartilages are articulated; *oooo*, four muscles serving to move the sting different ways; *pp*, two muscles which draw the shanks of the sting into its sheath; *qq*, two appendages of the sting which are moved along with it, and seem to answer no other purpose but that of ornament. *Fig. 11.* The ovary. 12. Six eggs drawn after nature, and placed on their ends. 13. An egg viewed with a microscope: it resembles the skin of a fish, divested of its scale, but still retaining the marks of their insertion. 14. Worms of bees of different sizes, drawn after nature; *a*, a worm newly hatched; *bcd*, four worms that received more nourishment, and are more grown; *fg*, two worms still larger than the former, having had more nourishment provided for them: they are represented as they lie doubled in their cells; *h*, a worm placed on its belly, so as to shew on its back a black line, which denotes the stomach; *i*, a worm lying on its back, beginning to draw in the hinder part of its body, and move its head. *Fig. 15.* A full-grown worm, viewed with a microscope; *aa*, its fourteen annular incisions or divisions; *b*, the head and eyes, &c. *ccc*, ten breathing-holes. 16. The worm forming its web; *aa*, the sides of the cell that contain it; *b*, bottom of the cell; *c*, entrance or door of the cell: the worm is here represented as making its web to shut up this entrance. *Fig. 17.* A worm taken out of the web, and just ready to cast its skin. 18. A cell containing the worm changed into a nymph, and perfectly lined with the worm's web: likewise the web entire, with the nymph contained in it, as they appear on opening the cell; *aa*, the sides of the cell, lined with the worm's web; *b*, the mouth of the cell, closed by the web; *c*, the bottom of the cell; *d*, the web entire, as it appears on opening the cell, which it greatly resembles in form; *e*, the upper part of the web of a convex form: this part shews its filaments pretty distinctly; *f*, the inclosed nymph appearing through the transparent sides of the web; *g*, the bottom of the web answering to that of the wax-cell. *Fig. 19.* Is a worm changed to a nymph, of its natural size and form, yet so as to exhibit its limbs, which are folded up in a curious manner. 20. The nymph of the bee viewed with the microscope, displaying all the parts of the inclosed insect, and the beautiful manner in which they are laid up; *a*, the head, bloated with humours; *bb*, the eyes, projecting considerably; *cc*, the horns, or antennæ; *d*, the lip; *ee*, the teeth, or jaw-bones; *ff*, the first pair of joints belonging to the pro-

boscis; *h*, the proboscis itself; *ii*, the first pair of legs; *hh*, two transparent little parts, lying against the lowest joints of the first pair of legs; *ll*, the second pair of legs; *mm*, the wings; *nn*, the blade bones; *oo*, the last pair of legs; *pp*, the abdominal rings; *q*, the hinder part of the body; *r*, two little parts accompanying the sting; *s*, the anus. *Fig. 21. a*, A cell full of bee-bread, placed in layers; *b*, little grains, of which the said substance, viewed with a microscope, appears to consist.

Of the MANAGEMENT of BEES.

OF THE APIARY, and HIVES. Columella directs that the apiary face the south, and be situated in a place neither too hot nor too much exposed to the cold: that it be in a valley, in order that the loaded bees may with greater ease descend to their homes: that it be near the mansion-house, on account of the convenience of watching them; but so situated as not to be exposed to noisome smells, or to the din of men or cattle: that it be surrounded with a wall, which however should not rise above three feet high: that, if possible, a running stream be near them: or, if that cannot be, that water be brought near them in troughs, with pebbles or small stones in the water, for the bees to rest on while they drink; or that the water be confined within gently-declining banks, in order that the bees may have safe access to it; they not being able to produce either combs, honey, or food for their maggots, without water; and that the garden in which the apiary stands, be well furnished with such plants as afford the bees plenty of good pasture. Columella mentions thyme, the oak, the pine, the sweet-smelling cedar, and all fruit-trees. Experience has taught us, that furze, broom, mustard, clover, heath, &c. are excellent for this purpose. Pliny recommends broom, in particular, as a plant exceedingly grateful and very profitable to bees.

With regard to hives, those made of straw are generally preferred on several accounts: they are not liable to be over-heated by the rays of the sun; they keep out cold better than wood or any other materials; and the cheapness renders the purchase of them easy. Those who intend to erect an apiary, should purchase a proper number of hives at the latter part of the year, when they are cheapest. The hives should be full of combs, and well stored with bees. The purchaser should examine the combs, in order to know the age of the hives. The combs of that season are white, those of the former year are of a darkish yellow; and, where the combs are black, the hive should be rejected, because old hives are most liable to vermin and other accidents. The summer is an improper time for buying bees, because the heat of the weather softens the wax, and thereby renders the combs liable to break, if they are not very well secured. The honey, too, being then thinner than at other times, is more apt to run out of the cells; which is attended with a double disadvantage, namely, the loss of the honey, and the daubing of the bees, whereby many of them may be destroyed. A first and strong swarm may indeed be purchased; but leave should be obtained for them to stand in the same garden till the autumn.

OF HIVING. Bees begin to swarm in May, or in the end of April, but earlier or later according to the warmth of the season. They seldom swarm before ten in the morning, and seldom later than three in the afternoon. When the bees of a swarm fly too high, they are made to descend lower, by throwing handfuls of sand or dust among them, which they probably mistake for rain. For the same purpose, it is usual to beat on a kettle or frying-pan: this practice may have taken its rise from observing that thunder or any great noise prompts such bees as are in the fields to return home. As soon as the swarm is settled, the bees which compose it should be got into a hive with all convenient speed, to prevent their taking wing again. If they settle on a small branch of a tree, easy to come at, it may be cut off and laid upon a cloth; the hive being ready immediately to put over them. If the branch cannot

not be conveniently cut, the bees may be swept off into a hive. The hive should not be immediately set on the stool where it is to remain; but should be kept near the place at which the bees settled, till the evening, lest some stragglers should be lost. It should be shaded either with boughs or with a cloth, that the too great heat of the sun may not annoy the bees.

OF FEEDING BEES IN WINTER. Providence has ordained, that insects which feed on leaves, flowers, and green succulent plants, are in an insensible or torpid state from the time that the winter's cold has deprived them of the means of subsistence. Thus the bees during the winter are in so lethargic a state, that little food supports them: but, as the weather is very changeable, and every warm or sunny day revives them, and prompts them to return to exercise, food becomes necessary on these occasions. Many hives of bees which are thought to die of cold in the winter, in truth die of famine; when a rainy summer has hindered the bees from laying in a sufficient store of provisions. The hives should therefore be carefully examined in the autumn, and should then weigh at least eighteen pounds. There is still, however, a want of experiments to ascertain both the time and the manner in which bees should be fed.

The following directions given in the *Maison Rustique* seem to be very judicious. Replenish the weak hives in September with such a portion of combs full of honey taken from other hives as shall be judged to be a sufficient supply for them. In order to do this, turn up the weak hive, after taking the precaution of defending yourself with the smoke of rags, cut out the empty combs, and put the full ones in their place; where secure them with pieces of wood run across, in such manner that they may not fall down when the hive is returned to its place. The bees will soon fix them more effectually. If this method be thought too troublesome, set under the hive a plate of liquid honey, unmixed with water, with straws laid across it, and over these a paper pierced full of holes, through which the bees will suck the honey without daubing themselves. This should be done in cloudy or rainy weather, when the bees stir least abroad; and the hive should be covered, to protect the bees from robbers, who might be allured to it by the smell of the honey. Another circumstance which may render it very necessary to feed the bees is, when several days of bad weather ensue immediately after they have swarmed; for then, being destitute of every supply beyond what they carried with them, they may be in great danger of starving. In this case, honey should be given them in proportion to the duration of the bad weather.

OF TAKING THE HONEY AND WAX. In this country it is usual, in seizing the stores of these little animals, to rob them also of their lives. The common method is, That when those which are doomed for slaughter have been marked out (which is generally done in September), a hole is dug near the hive, and a stick, at the end of which is a rag that has been dipped in melted brimstone, being stuck in that hole, the rag is set on fire, the hive is immediately set over it, and the earth is instantly thrown up all around, so that none of the smoke can escape. In a quarter of an hour, all the bees are seemingly dead; and they will soon after be irrecoverably so, by being buried in the earth that is returned back into the hole. By this last means it is that they are absolutely killed; for it has been found by experiment, that all the bees which have been affected only by the fume of the brimstone, recover again, excepting such as have been singed or hurt by the flame. Hence it is evident, that fume of brimstone might be used for intoxicating the bees, with some few precautions. The heaviest and the lightest hives are alike treated in this manner: the former, because they yield the most profit, with an immediate return; and the latter, because they would not be able to survive the winter. Those hives which weigh from fifteen to twenty pounds are thought to be the fittest for keeping. More humane and judicious methods were practised by the ancients; and successful attempts

have lately been made in our own country, to attain the desirable end of getting the honey and wax without destroying the bees.

Mr. Thorley, in his Inquiry into the Nature, Order, and Government, of Bees, has this object principally in view; and he thinks colonies in boxes preferable to hives, for the following reasons: 1st, The more certain preservation of very many thousands of these useful creatures. 2dly, Their greater strength, which consists in numbers, and consequently their greater safety from robbers. 3dly, Their greater wealth, arising from the united labours of their greater number. He tells us, that he has in some summers taken two boxes filled with honey from one colony; and yet sufficient store has been left for their maintenance during the winter; each box weighing forty pounds. Add to these advantages, the pleasure of viewing them, with the greatest safety, at all seasons, even in their busiest time of gathering, and their requiring a much less attendance in swarming time. The bees thus managed are also more effectually secured from wet and cold, from mice and other vermin. For this purpose boxes are made of deal, which, being spongy, sucks up the breath of the bees sooner than a more solid wood would do. Yellow dram-deal thoroughly seasoned is the best. An octagon, being nearer to a sphere, is better than a square form; for as the bees, in winter, lie in a round body near the centre of the hive, a due heat is then conveyed to all the out-parts, and the honey is kept from candying. The dimensions which Mr. Thorley recommends for the boxes, are ten inches depth, and twelve or fourteen breadth in the inside. There should be a glass-window behind, fixed in a frame, with a thin deal cover, two small brass hinges, and a button to fasten it. This window will be sufficient for inspecting the progress of the bees.

The London Society of Arts, having, among their premiums for the year 1790, proposed a reward for the most satisfactory mode of managing and preserving bees, and for collecting honey and wax, the same was adjudged to Mr. Thomas Morris, of Isleworth, for the following Paper, addressed to that society:

"My Lords and Gentlemen,—Were it the custom to ornament your gardens with that useful piece of furniture, an apiary, properly situated, and carefully managed, the public might be furnished with the valuable article of honey without adulteration, and your cellars be furnished with excellent mead, little inferior to foreign white wines. Hoping that such a fashion may yet prevail in the future allotment and disposal of garden and pleasure grounds, permit me to lay before you the construction of my own apiary, and the management of my bees.

"My hives are made in the following manner: nine inches deep, and fourteen diameter, containing each about five Winchester gallons, with a flat top made of well-seasoned deal, an inch thick; four holes at the top, one exactly over the mouth of the hive, the other three in a right angle, viz. take an inch centre-bit; make three holes as near as possible, so that you have but a small partition of wood between them; let them be made smooth and neat; then take a circular piece of half-inch board, tack it over those holes which are made in the hive, and let them be made to fit so close that no moth can get in among the young bees: so that, when a swarm is put in one of these hives in May, or the beginning of June, and begins to fill the hive with combs, brood, &c. which you may easily perceive by means of small pieces of glass, three inches square, put in the back of the hive, to observe their operations, and when the bees have filled their hive, and appear very busy at the mouth, open gently the hole on the top next the mouth, or rather right over the mouth, and place a glass or small hive over the hole, with proper sticks in the glass for the bees to hang their work upon; otherwise they would be a long time filling their glass, which, if they kindly take to, they will fill in twelve or fourteen days. But if your stock increases, and, perhaps, lies out at the mouth of the hive, you must open a second hole at

the top, and then a third, and so on to the fourth, if the bees increase, and continue to lie out at the mouth: and yet many of my hives have swarmed, and left their glasses only half full of honey, in order to follow the mother bee, to settle a new colony. What I call a *mother*, most writers on bees call a *queen*; but I am satisfied she is the real mother of the whole empire and stock; and hence may be deduced that filial affection and love so conspicuous in the whole community for the mother bee, which has been vaguely and erroneously compared to the mere loyalty of subjects for their sovereign. Those stocks, the mothers of which do not breed so fast as others, of course cannot swarm so early; therefore I put on them glasses, or small hives: if the stocks so glassed keep swarming without swarming, you most likely will get sixteen or seventeen pounds of honey in a month's time, and save all the bees alive; and such a stock will, except by accident, make a good stock next season.

"My hives, made as before described, have a board at the top, seventeen inches wide, that is a full inch wider than the outside of the hive, that one may stand on another; and thus you may make complete colonies of bees with a small expence, for three hives make a complete colony. When hives are made in this manner, they cost but 12s. but, in octagon boxes, 1l. 10s. I much prefer straw hives, well made, to wooden ones, because the joints of the wood often give way, by being exposed to the weather and the sweat of the bees; and the moth-fly (the greatest enemy they have) gets in and lays her eggs in the comb, and the warmth of the bees hatches them to their own destruction; therefore straw hives are preferable, as well as cheaper than wood. My method of managing straw hives is thus: when I make use of an old straw hive, I dip it into a copper of boiling water, so that, if there should be any moth's eggs, they must be destroyed; but I let the hive be perfectly dry before I use it.

"The best situation for an apiary is a little to the west of the fourth; for the sun, shining into the mouth of the hive too early, calls the bees abroad before the cold steam is exhaled from the flowers, and the vernal juice turned into honey: but in this situation the sun will reach the front of your apiary about nine o'clock. I would have the front leaning a little inwards, that the mouth of the hive may fit close to the mouth made in the boards, which should be three inches long in summer, and one in winter, and about one-fourth of an inch high, the better to keep out cold and the bevering moth, which you may often see, at the latter end of August, (when the working of the bees begins to decline,) standing at the mouth of the hive, bevering their wings, as if just flying in among the bees: they are then laying their eggs, and with the wind of their wings fan them within the hive; and the warmth of the bees hatches them. In October every stock should be well examined, and all the maggots brushed out, to prevent danger: for the grub or maggot forms a chrysalis, with a covering so strong, that the bees cannot displace them; and in the spring they creep out of their little sepulchres, and spin a thin web before them, as they march up into the hive among the combs; and the bees, endeavouring to dislodge them, are entangled in the web, and there die: and thus, for the want of a little trouble, many stocks are destroyed.

"To cleanse the hive of these maggots, it must be turned up, and the dust and vermin picked out, and then gently set down in its place. If your bees are well, and in a condition to stand the winter, and have a mother with them, they will sting, otherwise not, unless you hurt them: however, a yard and a half of Scotch gauze, sewed round the brim of your hat, and then tied round the waist, having holes for your arms, will completely secure your face. The hive should also be brushed on the outside very clean, and washed all over with a sponge dipped in brine made with clean salt; a small quantity of lime and hair, made fine, should be put round the bottom, and the hives be covered with hay or hay-bands.

"I come now to my method of feeding them, which, I think, is new. Sink a cavity in the middle of the floor, about six inches diameter, like a trencher, deep enough to hold a quarter of a pint of honey, and no more: if the cavity be too deep, the bees may be suffocated. A channel must be made from the outside of the floor, to communicate with the cavity; and a piece of wood to fit close into it, to keep out the vermin. If your bees do not weigh sixteen or seventeen pounds, exclusive of the hive, they must be fed in September, October, March, and April, and sometimes in May: they must not be fed in cold weather, for that calls them from sleep, and they then never return to the hive again: nor must they be fed in the sunshine; for, when the honey smells strong, it sets them quarrelling and fretting, and the strong injure the weak. The best time is evening, when I take the piece of wood out of the channel, and gently pour a quarter of a pint of honey into the cavity: if the honey will not run freely, I boil up four or five pounds with a quart of strong sweet-wort, which brings it to a proper liquid. This food will be of great service to the mothers, and make them lay eggs in abundance in the spring.

"If a stock has been glassed two summers, it should not be worked a third; but, if it increase, take a new hive, or a clean old one, and take off all the covers from the top of the hive: let it be stuck the same as if you were to have a new swarm; place it on one of the floors; and, having opened the hole on the top nearest the back, place a piece of lath diagonally from that hole to the side of the mouth; let it be made fast with pegs, not nails, lest the honey be stained; then place the old hive upon the new one, and stop the old mouth close; and the bees will then gradually work down the new hive: that will give them sufficient room for the summer. And, next spring, take another clean hive, and place the two upon it, in the same manner as before: this will serve for the next year. Now, having had no honey for two years, the upper hive will most likely be full, and may be taken away as follows: With a strong chisel separate the top hive from the other two; and in a fine day take it away, twenty or thirty yards, and place it on the ground bottom upwards; and secure the holes on the top of the second hive. The bees no doubt will rage; but you must secure yourself with gauze, as before directed, and wear black stockings, for that colour is least observed. Place a table even with the mouth of the lowest hive, and spread a cloth over it, near the mouth, and by this time the greater part of the bees that were out will come home: the middle hive being the breeding-place, it is most likely the mother is in that; but, if she was in the top, she may yet be safe. Place a clean hive, of the same diameter as that you have taken away, upon it; then tie a cloth over both, (glasses and all, if there be any,) so tight, that the bees within may be in darkness: let them remain thus half an hour; then, with a stick, rap the bottom hive, but not so hard as to injure the combs; continue rapping half an hour; then untie the cloth, and take away the upper hive, into which the noise has driven the bees, and place it on the table and cloth from whence you took them, and shake them out on the cloth, and they will run into the mouth of their proper hive. If necessary, repeat this operation, and all the bees will be preserved: this saves the trouble and loss of smothering them with sulphur, as is the custom; and the bees, in one day, will forget the injury, and work as usual. But, in case little honey is left in their two hives, they must be fed; thus, in two hours, your honey may be taken, and the bees preserved: the honey you have obtained in this way may be dark, but will make excellent meat; but better and brighter will be produced by those which work in glasses.

"Apiaries will not be beneficial in barren countries; but should be near gardens, shrubberies, orchards of cherries, or farms where clover, beans, fainfoin, or French wheat, grow. Lime-trees, or green-house plants, set out in the spring, and orange or lemon trees, are useful, and produce excellent

excellent honey: where there is room, it is worth while to plant gooseberries, currants, sweet marjoram, peppermint, or the like. Though I am not for preventing bees from swarming when they are inclined, yet I acknowledge that it is sometimes necessary to destroy some stocks. If they have lost their mother, and neither swarm nor work much, they should not be kept. The moth, or other accident, will sometimes spoil them, and then they should be destroyed. If bees continue in one hive for four or five years, they always degenerate, and become both fewer and weaker: the reason is, the combs for breeding are generally made on purpose, and larger than the rest; every time a bee is hatched in one, a skin or coat is left behind, which reduces the size; and in time it becomes too small to produce a bee of its proper dimensions, and occasions a necessity for their having frequently new habitations, which they will always accept, if you provide them a good situation and clean hives."

A'PISH, adj. Having the qualities of an ape; imitative. Foppish; affected. Silly; trifling, insignificant.—All this is but *apish* fopphistry; and to give it a name divine and excellent, is abusive and unjust. *Glanville.* Wanton; playful.

Gloomy fits the queen,
Till happy chance reverts the cruel scene;
And *apish* folly, with her wild resort
Of wit and jest, disturbs the solemn court.

Prior.

A'PISHLY, adv. In an apish manner; foppishly; conceitedly.

A'PISHNESS, f. Mimickry; foppery; insignificance; playfulness.

APIT'PAT, adv. [a word formed from the motion.] With quick palpitation.—O there he comes. Welcome my bully, my back: agad, my heart has gone *apitpat* for you. *Congreve.*

A'PIUM, [from *apes*, bees, because these insects are said to delight in it; or from *apex*, the head, which on some occasions was crowned with this herb.] In botany, a genus of the pentandria digynia class, ranking in the natural order of umbellatæ or umbellifere. The generic characters are—Calyx: umbel universal of fewer rays; partial of more. Involucre universal small, of one or more leaflets; partial similar: proper perianth obsolete. Corolla: universal uniform; floscules almost all fertile; proper, petals roundish, inflex, equal. Stamen: filaments simple; anthers roundish. Pistillum: germ inferior; styles reflex; stigmas obtuse. Pericarpium: none; fruit ovate, striated, splitting in two. Seeds: two, ovate, striated on one side, plane on the other.—*Essential Character.* Fruit ovate, striated; involucre one leaved; petals equal.

Species. 1. *Apium petrocelinum*, or parsley: Stem-leaves wedge-shaped. Of this there are the following varieties: 1. *Apium sativum*, or common parsley. The stems of parsley are round, smooth, striated. Usually there is one leaflet at the origin of the universal umbel, and an involucre of six or eight short folioles fine almost as hairs to the partial umbel. Flowers pale yellow, regular; petals small, long, narrow, acuminate, inflex. Seed short, turgid. The common parsley, which is generally cultivated for culinary use, is a biennial plant, and is said by Linnæus to be found wild in Sardinia, by brooks. The roots of parsley are sometimes used in apozems, and supposed to be aperient and diuretic, but liable to produce flatulencies. When large quantities are distilled, two or three drams of essential oil separate from 200 pounds. The leaves are warmer, but less sweet than the roots; they yield about ten drams of essential oil from 200 pounds. The seeds are warmer and more aromatic than any other part, and are accompanied with a considerable bitterness; they are accounted carminative, resolvent, and diuretic, and are recommended in the German ephemerides for destroying cutaneous insects in children. In distillation, three pounds yield above an ounce of essential oil. Parsley is said to be fatal to small birds.

It has sometimes been accused of causing epileptic symptoms, and of aggravating that complaint where it already exists: it has been said also to injure the eyes. A cataplasin of the leaves is reported to be resolvent and discent, if applied to glandular tumours: and also to be an efficacious remedy in curing the bites or stings of poisonous insects. According to some, the human calculus in a decoction of the leaves becomes friable; and hence the plant has been considered as of great efficacy in cases of the stone. For the distinction between this and fool's-parsley, see *ÆTHUSA*. ii. *Apium crispum*, curled parsley. The surest way to avoid any hazard, is to cultivate the curled parsley; which Mr. Miller affirms will remain constant, provided care be taken to separate all the plants which have thin leaves, when seed is to be saved from them. Columna informs us, that this variety is a native of Sardinia, and has been distributed from that island into the rest of Europe. iii. *Apium latifolium*, large-rooted parsley or Hamburgh parsley, is chiefly cultivated for its roots, which are now pretty commonly sold in the London markets; the leaves have much longer footstalks, and their subdivisions are not so numerous as in the common parsley; the leaflets are much larger, and of a darker green, so that it is easily distinguished from the common the common sort by its leaves, but the roots are six times as large as the common parsley can be brought to with the utmost culture. This sort was many years cultivated in Holland before the English gardeners could be prevailed upon to sow it. It is now however more familiar to us, and the roots are much esteemed in soups: in Holland they have long brought the roots to market in bunches, as we do young carrots. It is in season with us from July to Christmas, or March, according to the season.

2. *Apium graveolens*, or smallage: stem-leaves wedge-shaped. Of this there are also three varieties. This species grows in ditches and marshes, flowering from July to September. Biennial. The fresh roots, especially in their native watery places, are fetid, acrid, and supposed to be noxious. By drying, they lose the greatest part of their ill flavour, and become sweetish. In this state they have been employed in apozems, as aperients and diuretics. The seeds have been sometimes used as carminatives and aperients. They have a moderately strong grateful smell, and a warm bitterish taste. Mr. Miller affirms that he cultivated smallage forty years, to try if by art it could be brought to the same goodness as *celeri*; but all that he could do was to bring it to a larger size, and by earthing to give it a whiteness: it would not grow tall, nor rise with a straight stem, but sent out many suckers near the root, and after it was blanched, retained its strong, rank, taste. In more southern climates, however, this change has been effected with success; and Ray affirms that *celeri*, left to itself, will return after some years to smallage. i. *Apium dulce*, or upright *celeri*. Smallage, as improved by culture, has taken the Italian name of *celeri*, and in this state is reckoned not only wholesome, but serviceable for strengthening the stomach and assisting digestion. It is a good antiscorbutic, but said to be hurtful to persons predisposed to epileptic complaints. The expressed juice, taken to the quantity of six ounces, in the beginning of the shaking fit, it is said to conquer an intermittent by exciting sweat. The juice is also esteemed efficacious in calculous cases, like that of parsley. The blanched stalks have a sweetish warm taste, without any of the bad flavour of the wild plant. It is scarcely necessary to mention, that they are in great request in soups, for stewing, and as a raw salad herb, from August to Christmas, or even March, if the winter be not too severe, or if the beds be covered with stable muck or haulm in case of hard frost. The London gardeners cultivate two varieties; 1. the hollow *celeri*, which has been long known; and 2. the solid, which is of later introduction, and is preferred by some, for soups and stewing; but is not so proper for the main winter crop, because it

will

will not endure the frost so well as the other; nor for the market-gardener, because it is very brittle, and easily breaks in washing and bunching up for the market. Celeris, though a biennial, will run to seed the same year if sown very early. The seeds of this are much inferior in aromatic flavour to those of smallage. ii. *Apium rapaceum*, celeriac, or turnip-rooted celeri. iii. *Apium lufitanum*, or Portngal celeri.

Propagation and Culture. The common and curled parsley must be sown early in the spring, for the seeds remain a long time in the earth, the plants seldom appearing in less than four or six weeks after the seeds are sown. This sort is generally sown in drills by the edges of borders in the kitchen-gardens near London, because it is much easier to keep it clear from the weeds than if the seeds are sown promiscuously on a border, and the parsley is much sooner cut for use: but, when the roots are desired for medicinal use, then the seeds must be sown thin: and, when the plants are come up, they should be hoed out single, as is practised for carrots, onions, &c. observing also to cut up the weeds: if this be observed, the roots will become fit for use by July or August, and continue so till the spring. The common parsley is, by some skilful persons, cultivated in fields for the use of sheep, it being a sovereign remedy to preserve them from the rot, provided they are fed twice a-week for two or three hours each time with this herb; but hares and rabbits are so fond of it, that they will come from a great distance to feed upon it; and, in countries where these animals abound, they will destroy it, if it is not very securely fenced against them. The best time for sowing it in the fields is about the middle or latter end of February: the ground should be made fine, and the seeds sown pretty thick, in drills drawn at about a foot asunder, that the ground may be kept hoed between the drills, to destroy the weeds, which, if permitted to grow, will soon overrun the parsley. One bushel of seed will sow an acre of land. Large-rooted parsley may be cultivated by sowing the seeds in good ground early in the spring; and in April, when the plants are up, cut them out with a hoe (as is practised for young carrots) to about five or six inches square, and keep them constantly clean from weeds; and in July the roots will be fit to draw for use, and may be boiled and eaten as young carrots; and are very palatable and wholesome, especially for those who are troubled with the gravel. But if these plants are cut out, to allow them more room, if the soil is good, the roots will grow to the size of a middling parsnep by September.

Smallage, being a common weed by the side of ditches and brooks of water, in many parts of England, is seldom cultivated in gardens; but, if any person is willing to propagate it, the seeds should be sown soon after they are ripe, on a moist spot of ground; and, when the plants come up, they may be either transplanted in a moist soil, or hoed out, and left six or eight inches asunder, where they may remain for good. The seeds of the upright and turnip-rooted celeri should be sown at two or three different times, the better to continue it for use through the whole season, without running up to seed. The first sowing should be in the beginning of March, upon a gentle hot-bed; the second may be a fortnight or three weeks after, which ought to be in an open spot of light earth, where it may enjoy the benefit of the sun; the third time of sowing should be the end of April, or beginning of May, which ought to be in a moist soil: and, if exposed to the morning sun only, it will be so much the better, but it should not be under the drip of trees. The seeds which are sown in the hot-bed will come up in about three weeks or a month after sowing, when the plants should be carefully cleared from weeds; and, if the season prove dry, they must be frequently watered; and, in about a month or five weeks after it is up, the plants will be fit to transplant: you must therefore prepare some beds of moist rich earth, in a warm situation; in which you should prick these young plants, at about

three inches square, that they may grow strong; and, if the season should prove cold, the beds must be covered with mats to screen the plants from morning frosts, which would retard their growth: you must also observe, in drawing these plants out of the seed-beds, to thin them where they grow too thick, leaving the small plants to get more strength before they are transplanted; by which means one and the same seed-bed will afford three different plantings, which will accordingly succeed each other for use. You must observe, if the season prove dry, to keep the plants diligently watered after they are transplanted, as also to clear the seed-beds from weeds; and after every drawing keep them duly watered to encourage the small plants left therein. The middle of May some of the plants of the first sowing will be fit to transplant for blanching; they should be planted in a moist, rich, light, soil, upon which the first planted celeri will often grow to be twenty inches long in the clean blanched parts, which upon a poor or dry soil seldom rises to be ten inches. The manner of transplanting it is as follows: after having cleared the ground of weeds, you must dig a trench by a line about ten inches wide, and six or seven inches deep, loosening the earth in the bottom, and laying it level; the earth that comes out of the trench should be equally laid on each side the trench to be ready to draw in again, to earth the celeri as it advances in height. These trenches should be made at three feet distance from each other; then place the plants in the middle of the trench, at about four or five inches distance, in one straight row, having before trimmed the plants, and cut off the tops of the long leaves; when they are planted, you must observe to close the earth well to their roots, and to water them plentifully until they have taken fresh root; after which it will be needless, except in dry soils, or very dry seasons: as these plants advance in height, you must observe to draw the earth on each side close to them, being careful not to bury their hearts, nor ever to do it but in dry weather, otherwise the plants will rot. When the plants have advanced a considerable height above the trenches, and all the earth which was laid on the sides has been employed in earthing them up, you must then make use of a spade to dig up the earth between the trenches, which must also be made use of for the same purpose, continuing from time to time to earth it up until it is fit for use. The first of your planting out will, perhaps, be fit for use by the beginning of July, and will be succeeded by the after plantations; and, if the latter sowings are rightly managed, there will be a succession of celeri for use till April; but you should observe to plant the last crop in a drier soil, to prevent its being rotted with too much wet in winter; and also if the weather should prove extremely sharp, you will do well to cover your ridges of celeri with some pease-haulm, or some light covering which will admit the air to the plants; for, if they are covered too close, they will be very subject to rot; by this means you may preserve your celeri in season a long time, but you must remember to take off the covering whenever the weather will permit. By this method of covering the celeri, the frost being kept out of the ground, it may be always taken up for use when it is wanted. The celeri, when fully blanched, will not continue good above three weeks or a month before it will rot or pipe: therefore, in order to continue it good, you should have at least six or seven different seasons of planting; and if it be only intended to supply a family, there need not be much planted at each time. The best method to save seed of upright celeri, is to make choice of some long good roots, which have not been too much blanched, and plant them out at about a foot asunder in a moist soil, early in the spring; and, when they run up to seed, keep them supported with stakes, to prevent their being broken down by the winds: and in July, when the seed begins to be formed, if the season should prove very dry, it will be proper to give some water to the plants, which will greatly

ly help their producing good seeds. In August these seeds will be ripe, at which time the plants should be cut up, in a dry time, and spread upon cloths in the sun to dry; then beat out the seeds, and preserve them dry in bags for use.

A'PIUM MACEDO'NICUM. See BUBON.

A'PIUM PETRÆ'UM and MON'TANUM. See ATHAMANTA.

A'PIUM PYRENA'ICUM. See CRITHMUM.

APLA'NES, [απλανής, Gr. not wandering.] The fixed stars, so called in opposition to the planets; also the spheres themselves in which they are placed.

APLU'DA, *f.* [The name of the chaff, &c. that flies off from grain.] In botany, a genus of the polygamia monoecia class, of the natural order of gramina or grasses. The generic characters are—I. Calyx: involucre common univalve; valve ovate, concave, terminated by a very short point or leaflet, two-flowered, the inferior flower sessile in the short, ovate, truncate, hollow, base, which is continued into opposite, glumaceous, linear, flat, vertical, footstalks, (one at each side of the flower;) on one of these sits the superior flower; on the other a very short rudiment of a flower; flower inferior hermaphrodite, almost entirely lying hid between the footstalks. Calyx: involucre proper univalvate; valvelet lanceolate, compressed, rigid, double-toothed at the tip, smooth, embracing the flower with its margins beneath; opposite to the common involucre. Glume one-flowered, two-valved; valvelets membranaceous, transparent, shorter than the involucre; the exterior navicular, gibbous on the back, keeled, contracted towards the tip, acuminate; the interior ventricose, somewhat sharp, smaller. Corolla: glume bivalve, membranaceous, extremely thin, transparent; valve exterior navicular, compressed, smooth, hyaline; gibbous on the back, bifid, acute, awned below the tip, hid within the exterior valve of the calyx, and shorter than it; the interior lanceolate, flat, acute, doubled together at each margin, the exterior rather longer. Nectary very small, two-leaved, truncate-rounded, hyaline. Stamen: filaments three, capillary. Anthers linear, bifid on each side. Pistillum: germ oblong, small. Styles two, capillary upright, longer than the germ. Stigmas oblong, villose, spreading, protruded on each side from the flower. Pericarpium: none. Corolla cherishes the seed, gapes and drops it. Seed: ovate-oblong, compressed, smooth. II. Flower superior smaller. Calyx: glume two-flowered, two-valved; valves lanceolate, broadish, flat, sharp, nervose, nearly equal. One floscule female, (within the inner valve of the calyx;) the other male or neuter. Corolla: of the female; glume bivalve; valves membranaceous, hyaline; the exterior ventricose, cornered, sharp-pointed; the interior lanceolate, narrower, shorter, obtuse. Of the male; glume bivalve; valves lanceolate, membranaceous, hyaline; the exterior somewhat ventricose, sharp; the interior narrower, shorter. Nectary in both as in the inferior flower. Stamen: of the male as in the inferior flower. Pistillum: of the female as in the inferior flower. Pericarpium and seed of the female as in the inferior flower.—*Essential Characters.* Calyx: glume common; bivalve, female floret sessile, males peduncled. Male: calyx, none; corolla, bivalve; stamina, three. Female: calyx, none; corolla, bivalve; style, one; seed, one, covered.

Species. 1. *Apluda mutica*; leaves lanceolate, all the flowers awnless. 2. *Apluda aristata*: leaves lanceolate; male flowers, awnless, one at the end sessile and awned. Natives of India.

3. *Apluda zeugites*, or mountain reed-grass: leaves ovate; male flowers awnless, one at the end sessile and awned. Native of Jamaica. Browne says, that he found this curious little plant at the cold spring, in the mountains of New Liguanea, growing in a rich shady soil. He calls it *mountain reed-grass*.

4. *Apluda digitata*; spikes digitate, flowers pointing one way. A lofty East-Indian grass discovered by Thunberg.

VOL. I. No. 51.

APLUS'TRE, *f.* [Lat.] The ancient ensiga carried in sea vessels.—The one holds a sword in her hand, to represent the Iliad; as the other has an *aplustre*, to represent the Odyssey, or voyage of Ulysses. Addison.

APNOE'A [απνοια, of α privative, and πναι, to breathe, Gr.] want of breath, an entire suppression of breathing, or at least as to sense, as it happens to persons in a swoon.

APOBATA'NA, anciently the metropolis of Media, where the kings kept their treasures; supposed to be the same with Ecbatana.

APOBATE'RION, in antiquity, a valedictory speech or poem made by a person on departing out of his own country, and addressed to his friends or relations.

APOBA'THRA, a place near Sestos; the landing place where Xerxes's ships were frozen and stuck in the ice.

APO'CALYPSE, *f.* [from ἀποκαλυπτω, Gr. to reveal or discover.] Revelation; discovery: a word used only of sacred writings; and in general means the revelation of St. John.

O for that warning voice, which he who saw

Th' *apocalypse* heard cry in heav'n aloud. Milton.

The book of Revelation, according to Irenæus, was written about the year 99 of Christ, in the Patmos, whether St. John had been banished by the emperor Domitian. But Sir Isaac Newton places the writing of it earlier, viz. in the time of Nero. Some attribute this book to the arch-heretic Cerinthus: but the ancients unanimously ascribed it to John, the son of Zebedee, and brother of James; whom the Greek fathers call the *Divine*, by way of eminence, to distinguish him from the other evangelists. This book has not, at all times, been esteemed canonical. There were many churches in Greece, as St. Jerome informs us, which did not receive it; neither is it in the catalogue of canonical books prepared by the council of Laodicea, nor in that of St. Cyril of Jerusalem: but Justin, Irenæus, Origen, Cyprian, Clemens of Alexandria, Tertullian, and all the fathers of the fourth, fifth, and the following, centuries, quote the Revelations as a book then acknowledged to be canonical. The Alogians, Marcionites, Cerdonians, and Luther himself, rejected this book: but the Protestants have forsaken Luther in this particular; and Beza has strongly maintained, against his objections, that the apocalypse is authentic and canonical. It consists of twenty-two chapters. The three first are an instruction to the bishops of the seven churches of Asia Minor. The fifteen following chapters contain the persecutions which the church was to suffer from the Jews, heretics, and Roman emperors.

It is proper to mention that there have been several other works published under the title of *Apocalypses*. Sozomen speaks of a book used in the churches of Palestine, called the *Apocalypse* or *Revelation of St. Peter*. He also mentions an apocalypse of St. Paul: which the Coptæ retain to this day. Eusebius also speaks of both these apocalypses. St. Epiphanius mentions an apocalypse of Adam; Nicephorus, an apocalypse of Esdras; Gratian and Cedrenus, an apocalypse of Moses, another of St. Thomas, and another of St. Stephen; St. Jerom, an apocalypse of Elias. Porphyry, in his life of Plotin, makes mention of the apocalypse or revelations of Zoroaster, Zostrian, Nicothæus, Allogenes, &c.

APOCALYP'TICAL, *adj.* Concerning revelation; containing revelation.—If we could understand that scene, at the opening of this *apocalypitical* theatre, we should find it a representation of the majesty of our Saviour. Burnet.

APOCALYP'TICALLY, *adv.* In such a manner as to reveal something secret.

APO'COPE, *f.* [ἀποκοπή, Gr. of απο, and κοπή, to cut off.] A figure in grammar, when the last letter or syllable of a word is taken away; as, *ingeni*, for *ingenii*; *apoplex*, for *apoplexy*.

APOCRISA'RIOUS, [from ἀποκριναι, G. to answer.] In ecclesiastical antiquity, a sort of resident in an imperial city,

city, in the name of a foreign church or bishop, whose office was to negotiate, as proctor at the emperor's court, in all ecclesiastical causes in which his principals might be concerned. The institution of the office seems to have been in the time of Constantine, when, the emperors being become Christians, foreign churches had more occasions to promote their suits at court than formerly. However, we find it established by law in the time of Justinian. In imitation of this officer, almost every monastery had its apocrifarius, or resident, in the imperial city. The title and quality of apocrifary became at length appropriated to the pope's agent, or *nuncio*, as he is now called; who resided at Constantinople, to receive the pope's dispatches, and the emperor's answers.

APOCRUS'TIC, *adj.* [*αποκρυφικα*, Gr. from *αποκρυφω*, to drive.] Remedies endued with a repelling and astringent power, by which they prevent the too great afflux of humours.

APO'CRYPHA, *f.* [from *αποκρυφω*, Gr. to put out of sight.] Books not publicly communicated; books whose authors are not known. It is used for the books appended to the sacred writings, which, being of doubtful authors, are not admitted into the canon of scriptures. —We hold not the *apocrypha* for sacred, as we do the holy scripture, but for human compositions. *Hooker.*

When the Jews published their sacred books, they gave the appellations of *canonical* and *divine* only to such as they then made public: such as were still retained in their archives they called *apocryphal*, for no other reason but because they were not public; so that they might be really sacred and divine, though not promulgated as such. Thus, in respect of the Bible, all books were called *apocryphal* which were not inserted in the Jewish canon of scripture. The Protestants acknowledge such books of scripture only to be canonical as were so esteemed to be in the first ages of the church; such as are cited by the earliest writers among the Christians as of divine authority, and after the most diligent enquiry were received and so judged to be by the council of Laodicea. The several epistles above mentioned, and the book of Revelations, whatever the sentiments of some particular persons are or may have been of them, are allowed by all the reformed churches to be parts of the canon of the New Testament. The apocryphal books, however, according to the sixth article of the church of England, are to be read for example of life and instruction of manners; but it doth not apply them to establish any doctrine.

APOCY'MA, *f.* [*αποκος* and *κυμα*, Gr. a wave.] In the materia medica of the ancients, a name given by the Greek authors to a sort of cement used to daub over the bottoms of their ships, to preserve them from the injuries of the water: they called this also by the name of *zopiffa*; and Avicenna and Serapion call it *ketram*, *ketran*, or *alketran*. It was mixture of bees-wax and pitch melted together; and, after it had been soaked some time in seawater, it was supposed to have peculiar virtues, and was used in many compositions.

APO'CRYPHAL, *adj.* Not canonical; of uncertain authority. Contained in the apocrypha.—To speak of her in the words of the *apocryphal* writers, wisdom is glorious, and never fadeth away. *Addison*.—It is sometimes used for any account of uncertain credit.

APO'CRYPHALLY, *adv.* Uncertainly; not indisputably.

APO'CRYPHALNESS, *f.* Uncertainty; doubtfulness of credit.

APO'CYLISM, *f.* in medicine, the inspissated juice of vegetables.

APOCY'NUM, *f.* [*απο κυνος*, because the ancients supposed this plant was fatal to dogs.] In botany, a genus of the pentandria digynia class, ranking in the natural order of contortæ. The generic characters are—Calyx: perianth one-leaved, five-parted, acute, short, permanent. Corolla: monopetalous, bell-shaped, semiquinquefid; divisions revolute. Nectary of five glandular o-

val corpuscles, surrounding the germ. Stamina: filaments very short; antheræ oblong, erect, acute, bifid at the base, converging. Pistillum: germs two, ovate; styles short; stigma roundish, bifid at the tip, mucate, glued to the antheræ. Pericarpium: follicles two, long, acuminate, one-valved, one-celled. Seeds: numerous, very small, crowned with a long down. Receptacle subulate, very long, rough, free.—*Essential Character.* Corolla, bell-shaped; nectaries 5, alternate with the stamens.

Species. 1. *Apocynum androsæmifolium*, or tuttle-leaved dog's-bane: stem straightish, herbaceous; leaves ovate, smooth on both sides; cymes terminating. Baccæ as firms, that flies are destroyed if they light on the flowers of this plant. The French inhabitants of Canada call it *herbe à la puce*; and say, that it is noxious to some persons, but harmless to others. Kalm relates, that he saw a soldier whose hands were blistered all over merely from plucking it; whereas he frequently rubbed his own hands with the juice without feeling any inconvenience. It is a native of Virginia, as well as Canada; and flowers from July to September. It was cultivated in 1731, by Mr. Miller; but was in the Chelsea garden much earlier, for Mr. Ray mentions its being there in 1688, under the name of *apocynum flore lilii convallium purpurascente*.

2. *Apocynum cannabinum*, or hemp dog's-bane: stem straightish, herbaceous, leaves oblong, cymes lateral longer than the leaf. Roots perennial, creeping. Stems brown, about two feet high. Leaves smooth, in pairs, abounding with a milky juice, like the former. Towards the upper part of the stem, the flowers come out from the wings of the leaves in small bunches; they are of an herbaceous white colour, and, being small, make no great appearance; this therefore is seldom admitted into gardens, except for the sake of variety. It flowers with the foregoing; and is a native of the same countries. The Indians of North America prepare the stalks of this species as we do hemp, and make twine, bags, fishing nets and lines, and linen for their own wear. It was cultivated here in 1699, by the dukes of Beaufort.

3. *Apocynum hypericifolium*, or St. John's-wort-leaved dog's-bane: stem straightish herbaceous, leaves oblong cordate smooth, cymes shorter than the leaf. Root perennial creeping. The whole plant is smooth, and abounds in milk. It is a native of North America; was cultivated in 1756, by Mr. Miller; and flowers in June and July.

4. *Apocynum venetum*, or spear-leaved dog's-bane: stem straightish herbaceous, leaves ovate-lanceolate. Root perennial, creeping. Stems about two feet high. Leaves opposite, smooth. The flowers grow erect, at the top of the stems in small umbels, and are much larger than the former sorts. It varies with purple, and with white, flowers, and they shew themselves in July and August. It is a native of the islands in the Adriatic sea, near Venice; but is supposed to have been originally brought from some other country. It was cultivated in 1690, in the royal garden at Hampton-court.

5. *Apocynum minutum*, or petty dog's-bane: stem prostrate, leaves hastate. Found at the Cape by Montin.

6. *Apocynum filiforme*, or thread-leaved dog's-bane: stem prostrate herbaceous, leaves filiform, flowers umbelled. Found at the Cape by Thunberg.

7. *Apocynum frutescens*, or shrubby dog's-bane: stem erect shrubby, leaves lanceolate-oval, corollas acute villose at the throat. Native of the East-Indies, Ceylon, and the coast of Guinea.

8. *Apocynum reticulatum*, or net-leaved dog's-bane: stem twining perennial, leaves ovate veined. This plant has a twining stem, by which it rises to a considerable height. The leaves are dark green, very shining, with a beautiful net of milky veins. Native of the East Indies and Cochinchina. Mr. Miller cultivated it by seeds from professor Van Royen.

9. *Apocynum lineare*, or linear-leaved dog's-bane: stem twining herbaceous, leaves linear flat, umbels axillary compound. 10. *Apocynum triflorum*, or three-flowered dog's-bane: stem twining herbaceous, leaves lanceolate, umbels

umbels axillary two or three flowered. Found at the Cape of Good Hope by Thunberg.

11. *Apocynum juvenas*, or renovating dog's-bane: stem twining shrubby, leaves ovate hairy, racemes dichotomous. Native of Cochinchina. The physicians of the country fancy the root of this plant to refresh the animal spirits to such a degree, as by a long use of it to endow old age with all the strength and vigour of youth. The Chinese have the same opinion with respect to their *ho xeu u*, which they suppose to be the same plant, but that is not certain.

12. *Apocynum alterniflorum*, or alternate-flowered dog's-bane: stem climbing shrubby, leaves ovate acuminate smooth, axils alternate umbelliferous. Native of the islands near Canton in China.

13. *Apocynum Africanum*, or African dog's-bane: stem suberect shrubby, leaves ovate-oblong, peduncles two or three flowered. Native of the coast of Zanguebar, in Africa, on a sandy plain.

14. *Apocynum scandens*, or climbing dog's-bane: leaves oblong-cordate stiff, flowers lateral, stem shrubby twining. Was discovered by father Plumier, in some of the French islands in America. It was afterwards found by the late Mr. Robert Millar, surgeon, growing plentifully near Carthage, in New Spain, from whence he sent the seeds, which succeeded in several gardens. This plant has twining stalks, by which it mounts to the top of very tall trees, and stiff, oblong, heart-shaped, leaves, which are smooth, and of a shining green colour, being of the same thickness with those of the citron-tree. The flowers are produced in small clusters from the sides of the branches, and are of an herbaceous colour, so that they do not make any great appearance: these appear in August and September, but are not succeeded by pods in this country.

15. *Apocynum nervosum*, or nerved-leaved dog's-bane: leaves ovate, nerved; cymes lateral; flowers yellow, large; tube very long; stem shrubby, climbing. Has a climbing woody stalk, and rises to a considerable height, by the support of neighbouring trees. The leaves grow by pairs opposite; they are ovate, ending in a sharp point, and have many transverse nerves from the midrib. The flowers come out from the wings of the leaves, each standing upon a separate long foot-stalk; they are large, of a bright yellow colour, with very long tubes, spreading open wide at the top; these are succeeded by long compressed pods, which have borders on one side filled with long channelled seeds, which are crowned with long plumes of soft down. This sort grows naturally at Carthage, in New Spain, from whence Miller received the seeds.

16. *Apocynum cordatum*, or heart-leaved dog's-bane: leaves oblong-cordate pointed sessile, flowers lateral, stem climbing. 17. *Apocynum villosum*, or villose-flowered dog's-bane: leaves cordate smooth, flowers villose lateral, on long peduncles, stem climbing. These were discovered at La Vera Cruz, in New Spain, in the year 1729, by the late Dr. William Houston, who sent their seeds to England. These plants have both climbing stalks, by which they mount to the tops of the tallest trees. In England they have climbed over the plants in the stoves, and risen to upwards of twenty feet high. The sixteenth sort has produced flowers in England several times; but the seventeenth, which grows more luxuriantly than the other, never had any appearance of flowers. The down of these plants is in great esteem in France, for stuffing easy chairs, and making quilts, which, being warm, and extremely light, are very proper covering for persons afflicted with the gout. The French call it *delawad*; and, in the southern parts of France, where some of the sorts will thrive in the open air, and perfect their seeds, there are many plantations made of these plants for the sake of the down. As many of these sorts grow plentifully in the uncultivated lands in Jamaica, this cottony down might be easily procured from thence in plenty, and might probably become a vendible commodity in England, if once it were to become a fashionable furniture: especially as the plants require no cultivation, and the only trouble is to collect the

down, which, in some of the sorts with large pods, is produced in great quantity, and may be collected with little trouble.

Propagation and Culture. They are propagated by parting the roots in March, before they put out new stems. They are hardy enough to thrive in the open ground, but the soil should be light and dry, otherwise the roots are apt to rot in winter. They flower in July, and their stems decay to the root in autumn, seldom ripening their seeds. The second sort spreads so much by its creeping roots as to be troublesome in a garden. The first four species will live in the open air, provided they be planted in a warm situation. The other species are tender, and must be constantly kept in the hot-house, plunged in the tan-bed. They may be propagated by cuttings during the summer months; these should be laid in the stove three or four days to dry, before they are planted: or by seeds, procured from their native places, for they rarely produce any in England. These should be sown in pots filled with light sandy earth, and plunged into the tan-bed: they will appear in a month or six weeks, and should then be watered sparingly. They must be kept constantly in the tan-bed; and, as they advance in height, will require larger pots; but care must be taken not to overpot them; for, unless their roots are confined, the plants will not thrive. The second year, the plants will generally flower, if they have been skilfully managed, in July or August. Some of these make a fine appearance; and the leaves, being of a beautiful green, and keeping on the plant all the year, are an ornament to the stove at all seasons. See *ASCLEPIAS*, *CEROPEGIA*, *CYNANCHUM*, and *ECHITES*.

APODACRYTICS, *f.* [from *απο*, signifying negatively, and *δαρυ*, Gr. a tear.] Medicines which first excite, and then evacuate, the superfluous moisture of the eyes, thus preventing preternatural moisture there. Such are onions, celandine, hellebore, &c.

APODEC'TÆ, *f.* in antiquity, a name given to ten general receivers appointed by the Athenians to receive the public revenues, taxes, debts, &c. The apodectæ had also a power to decide controversies arising in relation to money and taxes, all but those of the most difficult nature and highest concern, which were reserved to the courts of judicature.

APODECTÆI, *f.* in the Athenian government, officers appointed to see that the measures of corn were just.

APODE'MICA, *f.* [*αποδημια*, Gr. I travel.] The doctrine or science of travelling, whether for knowledge, devotion, or other purposes. Jo. Meraker has published an *Apodemica*; Ranzovius a *Methodus Apodemica*.

A'PODES, *f.* in a general sense, denotes things without feet. Zoologists apply the name to a fabulous sort of birds, said to be found in some of the islands of the New World, which, being entirely without feet, support themselves on the branches of trees by their crooked bills.

Aropes, in the Linnæan system, the name of the first order of fishes, or those which have no belly-fins. See *ZOOLOGY*.

APODIC'TICAL, *adj.* [from *αποδειξις*, Gr. evident truth; demonstration.] Demonstrative; evident beyond contradiction.

APODIX'IS, *f.* [*αποδειξις*, *αποδεινω*, Gr. to demonstrate.] A plain proof or evident demonstration.

APODO'SIS, *f.* [*αποδοσις*, Gr. of *απο*, and *διδωμι*, to restore.] A recompensing or giving again.

Apodosis, in rhetoric, makes the third part of a complete exordium, being properly the application, or restriction of the *protasis*. The apodosis is the same with what is otherwise called *axiōsis*; and stands opposed to *protasis*: e. gr. *protasis*, all branches of history are necessary for a student; *catēscue*, so that, without these, he can never make any considerable figure; *apadōsis*, but literally history is of a more especial use, which recommends it, &c.

APODYTE'RIUM, *f.* [from *αποδοριαι*, Gr. to undress.] A private room before the entrance into the baths, where

where the bathers undressed themselves. It is also called *consilium* and *spoliarium*.

APOGEE, *f.* [*apogæum*, Lat.] In astronomy, that point in the orbit of the sun, moon, &c. which is farthest distant from the earth. It is at the extremity of the line of the apsidæ; and the point opposite to it is called the *perigee*, where the distance from the earth is the least. The ancient astronomers, considering the earth as the centre of the system, chiefly regarded the apogee and perigee; but the moderns, placing the sun in the centre, change these terms for the *aphelion* and *perihelion*. The apogee of the sun is the same thing as the aphelion of the earth; and the perigee of the sun is the same as the perihelion of the earth. The quantity of motion in the apogee may be found by comparing two observations of it made at a great distance of time; converting the difference into minutes, and dividing them by the number of years elapsed between the two observations; the quotient gives the annual motion of the apogee. Thus, from an observation made by Hipparchus in the year before Christ 140, by which the sun's apogee was found $5^{\circ} 30'$ of Π ; and another made by Ricciolus, in the year of Christ 1646, by which it was found $7^{\circ} 26'$ of Θ ; the annual motion of the apogee is found to be $1''$. And the annual motion of the moon's apogee is about $1^{\circ} 10' 39'' 52''$. But the moon's apogee moves unequally. When she is in syzygy with the sun, it moves forwards; but, in the quadratures, backwards; and these progressions and regressions are not equable, but it goes forward slower when the moon is in the quadratures, or perhaps goes retrograde; and, when the moon is in the syzygy, it goes forward the fastest of all.

APOGRA'PHON, *f.* [*απογραφον*, Gr. of *απο*, and *γραφω*, to write.] An inventory of goods, a copy or transcript of some book or writing, a pattern or draught.

APO'RIDES, *f.* in antiquity, those condemned for life to the public works, or exiled into some island, and thus divested of the privileges of Roman citizens.

APOLLINARIAN GAMES, were instituted in the year of Rome 542. The occasion was a kind of oracle delivered by the prophet Marcus after the fatal battle at Cannæ, declaring, that to expel the enemy, and cure the people of an infectious disease which then prevailed, sacred games were to be annually performed in honour of Apollo; the prætor to have the direction of them, and the decemviri to offer sacrifices after the Grecian rite. The first prætor by whom they were held was P. Cornelius Sylla. For some time they were moveable or indistinct; but at length were fixed, under P. Licinius Varus, to the fifth of July, and made perpetual. The men, who were spectators at these games, wore garlands on their heads; the women performed their devotions in the temples at the same time. The Apollinarian games were merely scenical; no chariot races, wrestling, or laborious exercises of the body, being ever practised at them.

APOLLINARIANS, or **APOLLINARISTS**, called by Epiphanius *Dimarita*, ancient heretics, who denied the proper humanity of Christ, and maintained that the body which he assumed was endowed with a sensitive, and not a rational, soul, but that the Divine Nature supplied the place of the intellectual principle in man. This sect derived its name from Apollinaris, bishop of Laodicea, in the 4th century. Their doctrine was first condemned by a council of Alexandria in the year 362, and afterwards in a more formal manner by a council at Rome in 375; and by another council in 378, which deposed Apollinaris from his bishopric. Notwithstanding all, his doctrine spread through most of the churches of the east; and his followers were sub-divided into various sects. In 388, the emperor Theodosius enacted a law, forbidding them to hold assemblies, to have any ecclesiastics or bishops, or to dwell in cities. The rigorous execution of this law, in concurrence with the decrees of different councils, reduced them to a very small number, and their doctrine had no long duration.

APOLLINARIS (Caius Sulpicius), a learned gram-

marian, born at Carthage, lived in the second century, under the Antonines; he is supposed to be the author of the verses which are prefixed to the comedies of Terence, and contain the arguments of them. He had for his successor in the profession of grammar Helvius Pertinax, who had been his scholar, and was afterwards emperor.

APOLLINARIS SIDONIUS (Caius Lollius), an eminent Christian writer and bishop in the 5th century, was born of a noble family in France. He made a prodigious progress in the arts and sciences, but particularly in poetry and polite literature. After he had left the schools, he applied himself to the profession of war. He married Papianilla, the daughter of Avitus, who was consul, and afterwards emperor, by whom he had three children. But Majorianus in the year 457 having deprived Avitus of the empire, and taken the city of Lyons, in which Apollinaris resided, he fell into the hands of the enemy. However, the reputation of his learning softened Majorianus's resentments, so that he treated him with the utmost civility, in return for which Apollinaris composed a panegyric to his honour; which was so highly applauded, that he had a statue erected to him at Rome, and was honoured with the title of *count*. In the year 467 the emperor Anthemius rewarded him farther, by raising him to the post of governor of Rome, and afterwards to the dignity of a patrician and senator. But he soon quitted these secular employments for the service of the church. The bishopric of Clermont being vacant in 472, Apollinaris was chosen to succeed him, in which he acted with the greatest integrity. Clermont being besieged by the Goths, he animated the people to the defence of that city, and would never consent to the surrender of it; so that, when it was taken about the year 480, he was obliged to retire; but was soon restored by Evariges king of the Goths, and continued to govern the church as he had done before. He died the 21st of August, 487; and his festival is still observed in the church of Clermont, where his memory is held in great veneration. His chief pieces in poetry are the three panegyrics upon the emperors Avitus, Majorianus, and Anthemius. His nine books of Letters contain a variety of particulars relating to polite literature, and profane history.

APOLLINARIUS (Claudius), a learned bishop of Hierapolis, who, about the year 170, presented to Marcus Aurelius an excellent Apology in Behalf of the Christians.

APOLLINARIUS the YOUNGER, thus called to distinguish him from his father, called *Apollinarius the Elder*, was first lecturer or reader of Laodicea, and afterwards bishop of that city. He was esteemed the greatest man of his age, both for learning and piety, and a most accurate and nervous defender of the Christian faith; but notwithstanding this, on his advancing some opinions that were not approved, he was anathematized as an heretic by the second general council of Constantinople in 381.

APOL'LO, in mythology, a Pagan deity worshipped by the Greeks and Romans. Cicero mentions four of his name: the most ancient of whom was the son of Vulcan; the second a son of Corybas, and born in Crete; the third an Arcadian, called *Nomian*, from his being a great legislator; and the last, to whom the greatest honour is ascribed, the son of Jupiter and Latona. Apollo had a variety of other names, either derived from his principal attributes, or from the places where he was worshipped. He was called the *Healer*, from his enlivening warmth and cheering influence; *Pæan*, from the pestilential heats: to signify the former, the ancients placed the Graces in his right hand; and, for the latter, a bow and arrows in his left: *Nomius*, or the shepherd, from his fertilizing the earth, and thence sustaining the animal creation: *Delius*, from his rendering all things manifest: *Pythius*, from his victory over Python; *Lycias*, *Phæbus*, and *Phaneta*, from his purity and splendour. As Apollo is almost always confounded by the Greeks with the sun, it is no wonder that he should be dignified with so many attributes. It was natural for the most glorious object in nature, whose influence is felt

by all the creation, and seen by every animated part of it, to be adored as the fountain of light, heat, and life. The power of healing diseases being chiefly given by the ancients to medicinal plants and vegetable productions, it was natural to exalt into a divinity the visible cause of their growth. Hence he was also styled the *God of Physic*; and that external heat which cheers and invigorates all nature, being transferred from the human body to the mind, gave rise to the idea of all mental effervescence coming from this god; hence, likewise, poets, prophets, and musicians, are said to be *Numine afflati*, inspired by Apollo.

Whether Apollo represented a real personage, or only the great luminary, many have doubted. Indeed, Vossius has taken great pains to prove this god to be only a metaphorical being, and that there never was any other Apollo than the sun: "He was styled the *son of Jupiter* (says this author), because that god was reckoned by the ancients the author of the world. His mother was called *Latona*, a name which signifies 'hidden;' because, before the sun was created, all things were wrapped up in the obscurity of chaos. He is always represented as beardless and youthful, because the sun never grows old or decays. And what else can his bow and arrows imply, but his piercing beams?" And adds, "that all the ceremonies which were performed to his honour had a manifest relation to the great source of light which he represented. Whence (he concludes) it is vain to seek for any other divinity than the sun, which was adored under the name of Apollo." However, though this be in general true, yet it appears, from many passages in ancient authors, that there was some illustrious personage named *Apollo*, who, after his apotheosis, was taken for the sun; as Osiris and Orus in Egypt, whose existence cannot be called in question, were, after their death, confounded with the sun, of which they became the symbols, either from the glory and splendour of their reigns, or from a belief that their souls had taken up their residence in that luminary.

Of the four Apollos mentioned by Cicero, it appears that the three last were Greeks, and the first an Egyptian; who, according to Herodotus, was the son of Osiris and Isis, and called *Orus*. Pausanias is of the same opinion as Herodotus, and ranks Apollo among the Egyptian divinities. The testimony of Diodorus Siculus is still more express; for, in speaking of Isis, after saying he had invented the practice of medicine, he adds, that she taught this art to her son Orus, named *Apollo*, who was the last of the gods that reigned in Egypt. It is easy to trace almost all the Grecian fables and mythologies from Egypt. If the Apollo of the Greeks was said to be the son of Jupiter, it was because Orus the Apollo of the Egyptians had Osiris for his father, whom the Greeks confounded with Jupiter. If the Greek Apollo was reckoned the god of eloquence, music, medicine, and poetry, the reason was, that Osiris, who was the symbol of the sun among the Egyptians, as well as his son Orus, had there taught those liberal arts. If the Greek Apollo was the god and conductor of the Muses, it was because Osiris carried with him in his expedition to the Indies singing women and musicians. This parallel might be carried on still further; but enough has been said to prove that the true Apollo was that of Egypt. To the other perfections of this divinity the poets have added beauty, grace, and the art of captivating the ear and the heart, no less by the sweetness of his eloquence than by the melodious sounds of his lyre. But the most remarkable incident in the history of Apollo, is his defeat of the serpent Python. The waters of Deucalion's deluge, says Ovid, which had overflowed the earth, left a slime from whence sprung innumerable monsters; and among others the serpent Python, which made great havoc in the country about Parnassus. Apollo, armed with his darts, put him to death; which, physically explained, implies, that the heat of the sun having dissipated the noxious steams, those monsters soon disappeared; or, if this fable be referred to history, the serpent was a robber, who haunting the country about Delphos, and very

much infesting those who came thither to sacrifice; a prince, who bore the name of Apollo, or one of the priests of that god, put him to death. This event gave rise to the Pythian games, so frequently mentioned in the Grecian history; and it was from the legend of Apollo's victory over the Python, that the god himself acquired the name of *Pythius*, and his priests that of *Pythia*. The city of Delphos, where the famous oracles were so long delivered, was frequently styled *Pytho*.

As Apollo was the god of the fine arts, those who cultivated them were called *his sons*. Of this number was Philammon of Delphos, whom the poets and mythologists make the twin-brother of Autolychus, by the nymph Clione, and Apollo and Mercury. It is pretended that both these divinities were favoured by the nymph on the same day, and that their fires were known from their different talents. Philammon, a great poet and musician, was reported to be the offspring of the god who presides over those arts; and Autolychus, from the craftiness and subtilty of his disposition, was said to have sprung from Mercury, god of theft and fraud. Philammon is one of the first, after Apollo, upon fabulous record, as a vocal performer, who accompanied himself with the sound of the lyre: his son was the celebrated Thamyris.

There can be no doubt but that Apollo was more generally revered in the Pagan world than any other deity; having, in almost every region of it, temples, oracles, and festivals, as innumerable as his attributes: the wolf and hawk were consecrated to him, as symbols of his piercing eyes; the crow and the raven, because these birds were supposed to have by instinct the faculty of prediction; the laurel, from a persuasion that those who slept with some branches of that tree under their heads received certain vapours, which enabled them to prophesy. The cock was consecrated to him, because by his crowing he announces the rising of the sun; and the grasshopper on account of his singing faculty, which was supposed to do honour to the god of music. Most of the ancient poets have celebrated this tuneful insect, but none equal to Anacreon, Ode 43. Plato says that the grasshopper sings all summer without food, like those men who, dedicating themselves to the Muses, forget the common concerns of life. The swan was regarded by the ancients as a bird sacred to Apollo in two capacities; first, as being, like the crow and raven, gifted with the spirit of prediction; and, secondly, for his extraordinary vocal powers. The sweetness of his song, (see ANAS,) especially at the approach of death, was not only extolled by all the poets of antiquity, but by historians, philosophers, and sages; and to call a great writer the *swan* of his age and nation, was a full acknowledgment of his sovereignty; Horace calls Pindar the *Theban swan*.

Plutarch, who was himself a priest of Apollo, impressed with the highest respect and veneration for him and for music, in his dialogue upon that art, makes one of his interlocutors say, that an invention so useful and charming could never have been the work of man, but must have originated from some god, such as Apollo, the inventor of the flute and lyre, improperly attributed to Hyagnis, Marsyas, Olympus, and others; and the proofs he urges in support of this assertion, shew, if not its truth, at least that it was the common and received opinion of the age in which he lived.

APOLLO BELVIDERE, one in the first class of the ancient statues. The excellence of this statue consists in the expression of something divine, whereas the rest excel only in things that are common to men. This statue may perhaps justly claim the preference; even in the superior and distinguished class of the best remains of antiquity. There are about twenty ancient statues which the moderns have discovered that are referred to the first class, and considered each as the chief beauty in its kind.

APOLLODORUS, a celebrated architect, under Trajan and Adrian, was born at Damascus, and flourished about the year of Christ 100. He had the direction of the

stone bridge which Trajan ordered to be built over the Danube in the year 104, which was esteemed the most magnificent of all the works of that emperor. Adrian, one day as Trajan was discoursing with this architect upon the buildings he had raised at Rome, would needs give his judgment, in which he shewed that he knew nothing of the matter. Apollodorus turned upon him bluntly, and said to him, "Go paint citruls, for you are very ignorant of the subject we are talking upon." Adrian at this time boasted of his painting citruls well. This was the first step towards the ruin of Apollodorus; a slip which he was so far from attempting to retrieve, that he even added a new offence, and that too after Adrian was advanced to the empire, upon the following occasion: Adrian sent to him the plan of a temple of Venus; and, though he asked his opinion, yet to shew that he had no need of him, and that he did not mean to be directed by it, the temple was already built. Apollodorus wrote his opinion very freely, and remarked such essential faults in it, as the emperor could neither deny nor remedy. This put Adrian into a great passion, and prompted him to the destruction of Apollodorus. He banished him at first; then under the pretext of certain supposed crimes, of which he had him accused, he at last put him to death.

APOLLODORUS, a celebrated painter of Athens, about 408 years before the birth of Christ, was the first who invented the art of mingling the colours, and of expressing the lights and shades. He was admired also for his judicious choice of subjects, and for the beauty and strength of colouring surpassed all the masters that went before him. He excelled likewise in statuary.

APOLLODORUS the Athenian, a famous grammarian, the son of Asclepiades and disciple of Aristarchus. He wrote many works; but his most famous production was the *Bibliotheca*, concerning the origin of the gods. This work consisted of twenty-four books, but only three are now in being. Several other pieces of his are to be found in Fabricius's *Bibliotheca Græca*. There were various other persons of this name. Scipio Testi, a Neapolitan, has written a treatise of the Apollodoruses, which was printed at Rome in 1555; and Dr. Thomas Gale published a work of the same kind in 1675.

APOLLONIA, the name of several ancient cities, particularly a colony of the Milesians in Thrace, from which Lucullus took away a colossus of Apollo, and placed it in the capitol. The greatest part of the town was situated in a small island on the Euxine, in which was a temple of Apollo. Pliny says the colossus was thirty cubits high, and cost 300 talents. There was also an Apollonia at mount Parnassus, near Delphi. Troezen was formerly called *Apollonia*.

APOLLONIA, feasts sacred to Apollo, instituted upon the following occasion. Apollo, having vanquished Python, went with his sister Diana to Ægialeæ; but, being driven from thence, he removed to the island of Crete. The Ægialeans were soon after visited with a plague; upon which, consulting the soothsayers, they were ordered to send seven young men, and as many virgins, to appease those deities, and bring them back into their country. Apollo and Diana, being thus appeased, returned to Ægialeæ: in memory of which, they dedicated a temple to Pitho, the goddess of persuasion; whence a custom arose of choosing every year seven young men, and as many virgins, to go as it were in search of Apollo and Diana.

APOLLONIA, in geography, a promontory of Africa, on the coast of Guinea, near the mouth of the river Mancu.

APOLLO'NIUS, author of the *Argonautics*, surnamed *The Rhodian*, from the place of his residence, is supposed to have been a native of Alexandria, where he is said to have recited some portion of his poem while he was yet a youth. Finding it ill received by his countrymen, he retired to Rhodes; where he is conjectured to have published and completed his work, supporting himself by the profession of rhetoric, and receiving from the Rhodians the freedom of their city. He at length returned, with con-

siderable honour, to the place of his birth; succeeding Eratosthenes in the care of the Alexandrian library in the reign of Ptolemy Euergetes, who ascended the throne of Egypt the year before Christ 246. That prince had been educated by the famous Aristarchus, and rivalled the preceding sovereigns of his liberal family in the munificent encouragement of learning. Apollonius was a disciple of the poet Callimachus; but their connection ended in the most violent enmity. The learned have vainly endeavoured to discover the particulars of their quarrel. The only work of Apollonius which has descended to modern times is his poem above-mentioned, in four books, on the Argonautic expedition. The ancient scholia upon this work, still extant, are extremely useful, and full of learning.

APOLLONIUS, of Perga, in Pamphilia, was a celebrated geometrician, who flourished in the reign of Ptolemy Euergetes, about 240 years before Christ; being about sixty years after Euclid, and thirty years later than Archimedes. He studied a long time in Alexandria, under the disciples of Euclid; and afterwards he composed several curious and ingenious geometrical works, of which only his books of Conic Sections are now extant, and even these not perfect. For it appears from the author's dedicatory epistle to Eudemus, a geometrician in Pergamus, that this work consisted of eight books; only seven of which however have come down to us. His work upon Conics was doubtless the most perfect of the kind among the ancients; and in some respects among the moderns also.

APOLLONIUS, a Pythagorean philosopher, born at Tyana, in Cappadocia, about the beginning of the first century. At sixteen years of age he became a strict observer of Pythagoras's rules, renouncing wine, women, and all sorts of flesh; not wearing shoes, letting his hair grow, and wearing nothing but linen. He soon after set up for a reformer of mankind, and chose his habitation in a temple of Æsculapius, where he is said to have performed many wonderful cures. Philostratus has written the life of Apollonius, in which there are numberless fabulous stories recounted of him. We are told that he went five years without speaking; and yet, during this time that he stopped many seditions in Cilicia and Pamphylia; that he travelled, and set up for a legislator; and gave out, that he understood all languages, without having ever learned them; that he could tell the thoughts of men, and understood the oracles which birds gave by their singing. Apollonius wrote four books of judicial astrology; a treatise upon the sacrifices, shewing what was proper to be offered to each deity; and a great number of letters; all of which are now lost.

APOL'LOS, in scripture-history, a Jew of Alexandria, who came to Ephesus during the absence of St. Paul, who was gone to Jerusalem, Acts xviii. 24. Apollos was an eloquent man, and well versed in the scriptures; and, as he spoke with zeal and fervour, he taught diligently the things of God: but knowing only the baptism of John, he was no more than a catechumen, or one of the lowest order of Christians, and did not as yet distinctly know the mysteries of the Christian doctrine. Aquila and Priscilla having heard him, took him home with them; instructed him, and baptized him, probably in the name of Jesus Christ; after which he became the companion of St. Paul. The Greeks make him bishop of Duras; others say, he was bishop of Iconium, in Phrygia; and others, that he was bishop of Cæsarea.

APOL'LYON, [*Ἀπολλων*, of *ἄπο*, and *ἄλυν*, to destroy.] A name in the Revelations, which signifies *The Destroyer*, and answers to the Hebrew word *Abaddon*, which see.

APOLOGE'TIC, or APOLOGE'TICAL, *adj.* [from *ἀπολογεω*, to defend.] That which is said in defence of any thing or person.—I design to publish an essay, the greater part of which is *apologetical*, for one sort of chymists. *Boyle.*

APOLOGE'TICALLY, *adv.* In the way of defence or excuse.

APO'LOGIST,

APOLOGIST, *f.* He that makes an apology; a pleader in favour of another.

To APOLOGIZE, *v. n.* To plead in favour of any person or thing.—It will be much more seasonable to reform than *apologize* or *rhetoricate*; and therefore it imports those, who dwell secure, to look about them. *Decay of Piety.* It has the particle *for* before the subject of apology.—I ought to *apologize* for my indiscretion in the whole undertaking. *Wake.*—The translator needs not *apologize* for his choice of this piece, which was made in his childhood. *Pope.*

APOLOGUE, *f.* [*apologus*, Lat. of *απολογος*, of *απολογεω*, to utter.] An ingenious method of conveying instruction by means of a feigned relation, called a *moral fable*. The only difference between a parable and an *apologue* is, that the former, being drawn from what passes among mankind, requires probability in the narration; whereas the *apologue*, being taken from the supposed actions of brutes, or of things inanimate, is not tied down to the strict rules of probability. *Æsop's fables* are a model of this kind of writing.

APOLOGY, *f.* [*apologie*, Fr. *apologia*, Lat. of *απολογία*, of *απολογεω*, Gr. to reject, or not admit.] Defence; excuse. *Apology* generally signifies rather excuse than vindication, and tends rather to extenuate the fault than prove innocence. This is, however, sometimes unregarded by writers :

In her face excuse
Came prologue, and *apology* too prompt;
Which with bland words at will she thus address'd. *Milton.*
It has *for* before the object of excuse.—It is not my intention to make an *apology* for my poem: some will think it needs no excuse, and others will receive none. *Dryden.*

APOLY'SIS, *f.* among physicians, the exclusion of any thing; as of the birth, the fæces, or the like; a relaxation by which any part of the whole is weakened.

APOMAG'NA, *f.* [from *απομαρτο*, to absterge.] Any thing used to wipe away fordes, as a handkerchief, or a sponge, &c.

APOMECONOMETRY, *f.* [*απο*, from *μετρο*, distance, and *μετρεω*, to measure.] The art of measuring things at a distance.

APO'MELI, *f.* A sweet liquor made with honey-combs, diluted and boiled with water. Galen says, that Hippocrates, and others, called *apomeli* by the names of *oxygliei* and *oxygliticum*; and that some were made with, and others without, vinegar; some being sweet, and others sour and sweet. It is simple oxyinel.

APO'MYOS DEUS, [*απο*, and *μυια*, fly.] In the heathen mythology, a name under which Jupiter was worshipped at Elis; and Hercules, as well as Jupiter, at the Olympic games. These deities were supplicated under this name, to destroy or drive away the vast number of flies which always attended at the great sacrifices.

APONEURO'SIS, *f.* [of *απο*, from, and *νευρον*, a nerve.] Any tendinous expansion. The tendon or tail of a muscle, called by Hippocrates, *τενον*, a tendon or cord. These expansions of tendons, called *aponeuroses*, or *fasciæ*, grow thinner and thinner, till they are lost in the cellular membrane. Instances of these are frequently met with, e. g. the outward muscles of the thigh are bound down by one of these expansions, viz. the *fascia lata*. Dr. Hunter describes this aponeurosis as proceeding from the musculus *fasciæ latæ*, called *membranofus musculus*, on the external part of the thigh, and from the gluteus maximus on the posterior part. There are also other *fasciæ*, as those of the legs, which, like those of the thighs, cover the muscles. The soles of the feet are strong *fasciæ*, which prevent the flexor muscles of the toes being hurt, when we tread. The *fasciæ* on the thighs and legs bind down the muscles while in action, and also increase their strength by compressing them. When matter is formed immediately under any of the *fasciæ*, it cannot point where it was first formed, but runs under them to some distance, to gain

an exit: to prevent inconveniences from this cause, as soon as matter can be felt under a fascia, it is right to give it vent immediately, and not to wait for its pointing, as in other situations; when this happens under the temporal muscle, great difficulties attend.

APO'NIA, *f.* [*α* priv. and *πον*, labour.] Among physicians, a state of indolence, or the absence of pain; in which sense the word amounts to the same with *anodynia*. Hence also *apona* is used by some for medicines which do not excite pain.

APO'NO (Peter d'), one of the most famous philosophers and physicians of his age, born in the year 1259, in a village about four miles from Padua. He studied some time at Paris, and was there promoted to the degree of doctor in philosophy and physic. When he came to practice as a physician, he is said to have insisted on very large sums for his visits: we are not told what he demanded for the visits he made in the place of his residence; but it is affirmed, that he would not attend the sick in any other place under 150 florins a day; and, when he was sent for by pope Honorius IV. he demanded 400 ducats for each day's attendance. He was suspected of magic, and prosecuted by the Inquisition on that account. "The common opinion of almost all authors (says Naude) is, that he was the greatest magician of his age; that he had acquired the knowledge of the seven liberal arts, by means of the seven familiar spirits, which he kept inclosed in a crystal; and that he had the dexterity to make the money he had spent come back into his purse." The same author adds, that he died before the process against him was finished, being then in the eightieth year of his age; and that, after his death, they ordered him to be burnt in effigy, in the public place of the city of Padua; designing thereby to strike a fear into others of incurring the like punishment; and to suppress the reading of three books which he had wrote; the first being the *Heptameron*, which is printed at the end of the first volume of Agrippa's work; the second, that which is called by Trithemius, *Elucidarium Necromanticum Petri de Albano*; and the last, that which is intitled by the same author, *Liber experimentorum Mirabilium de Annulis Secundum xxviii. Manfones Luna*. His body, being secretly taken up by his friends, escaped the vigilance of the inquisitors, who would have burnt it. It was removed several times, and was at last placed in the church of St. Augustin, without an epitaph or any mark of honour. The most remarkable book which Apono wrote, was that which procured him the surname of *Conciliator*; he wrote also a piece intitled *De Medicina Omnimoda*.

APONOGE'TON, *f.* in botany, a genus of the dodecandria tetragynia class, in the natural order of *inunada*. The generic characters are—Calyx: none, except a spatheaceous scale surrounding the outer side of the flower, simple, sessile, ovate, obtuse, entire, upright, smooth, coloured. Stamina: filaments eleven to nineteen, in the upper flowers fewer, inserted between the spathe and the capsules, subulate, smooth, white, many times shorter than the spathe. Pistillum: germs usually four, seldom three or five; styles none; stigmas subulate, bent in. Pericarpium: capsules four, seldom three or five, ovate, subulate, acute, gibbous on the outside, flat on the inner side, smooth, one-celled. Seeds: in each capsule three, affixed to the base of it, sessile, obovate, very blunt, subcompressed, smooth.—*Essential Character.* Calyx, an ament; capsule three-seeded.

Species. 1. *Aponogeton monostachyon*, or single-spiked *aponogeton*: spike simple, leaves cordate-oval. Observed by Koenig to be common in the fields that are flooded for rice in the East Indies.

2. *Aponogeton distachyon*, or broad-leaved *aponogeton*: spike bifid, leaves linear-oblong, floating, bractes entire, flowers many-stamened. Found at the Cape of Good Hope, in brooks, by Thunberg. It flowers almost all the year, and was introduced in the year 1788 by Mr. Francis Masson.

3. *Aponogeton*

3. *Aponogeton angustifolium*, or narrow-leaved aponogeton: spike bifid, leaves linear-lanceolate, erect; bracts two-parted; flowers six-stamened. A native of the Cape of Good Hope; introduced in 1788 by Mr. Masson. It flowers almost all the year. These plants are inhabitants of the greenhouse or Cape stove; and may be increased by offsets from the bulbs.

APO'NUS, a hamlet near Patavium, with warm baths. It was the birth-place of Livy, and is now called *Albano*. Lat. 45. 15. lon. 10. 0. E.

APOPEM'PTIC, *f.* in the ancient poetry, a hymn addressed to a stranger on his departure from a place to his own country. The ancients had certain holidays, wherein they took leave of the gods with *apopemptic* songs, as supposing them returning each to his own country.

APO'PHASIS, *f.* [Lat. *αποφασις*, a denying.] A figure in rhetoric, by which the orator, speaking ironically, seems to wave what he would plainly insinuate; as, Neither will I mention those things; which if I should, you notwithstanding could neither confuse nor speak against them.

AOPHLEGMA'TICS, or **AOPHLEGMA'TIZANTS**, *f.* [of *απο*, from, and *φλεγμα*, phlegm.] Medicines suited to promote a discharge of mucus or phlegm, from the mouth and nose; and, according to the part from whence the discharge is made, so are they denominated. If from the mouth, *masicatories*; if from the Schneiderian membrane, *errhins*. Hence, pellitory of the wall, horse-radish, &c. Snuff also, and whatever occasions an excretion of mucus, or serum from the head and parts above the throat, come under this denomination. Any medicine possessed of this power, is called *masicatorium* and *commansum*.

AOPHRA'DES, *f.* [from the singular *αποφρας*, unfortunate.] Those days in which an acute distemper comes to a fatal crisis, or on which there is no crisis at all, when expected.

AOPH'THEGM, *f.* [*apophthegme*, Fr. *apoteigma*, It. *apophthegma*, Sp. *apophthegma*, Lat. *αποφθειγμα*, of *απο* and *φθειγγωμαι*, Gr. to pronounce.] A short, sententious, and instructive, remark, pronounced by a person of distinguished character. Such is that of Cyrus: "He is unworthy to be a magistrate, who is not better than his subjects." Or this: "He that will not take care of his own business, will be forced to take care of that of others." Or that of Artaxerxes Mnemon, when reduced to hunger: "How much pleasure have I hitherto lived a stranger to!" Or that of Cato: "*Homines nihil agendo discunt male agere.*"

AOPHTHORA, *f.* [*αποφθορα*, of *αποφθειρω*, to corrupt.] An abortion; the bringing forth a child putrefied in the womb.

AOPHYGE, *f.* in architecture, a concave part or ring of a column, lying above or below the flat member. The French call it *le conge d'en bas*, or *d'en haut*: the Italians, *cavo di basso*, or *di sopra*; and also *il vivo di basso*. The apophyge originally was no more than the ring, or ferril, at first fixed on the extremities of wooden pillars, to keep them from splitting; which afterwards was imitated in stone.

AOPHYSIS, *f.* [*αποφυσις*, of *απο*, from, and *φυω*, to grow.] The prominent parts of some bones; the same as process. It differs from an epiphysis, as it is a continuance of the bone itself; whereas the latter is somewhat adhering to a bone, and of which it is not properly a part.—It is the *apophysis*, or head, of the os tibiae, which makes the knee. *Wyseman*.

AOPLEC'TIC, *adj.* Relating to an apoplexy.—A lady was seized with an *apoplectic* fit, which afterward terminated in some kind of lethargy. *Wyseman*.

AOPLEC'TICAL, *adj.* Relating to an apoplexy.—We meet with the same complaints of gravity in living bodies, when the faculty locomotive seems abolished; as may be observed in supporting persons inebriated, *apoplectical*, or in lipothymies and swoonings. *Brown*.

APOPLEX, *f.* Apoplexy. The last syllable is cut away; but this is only in poetry:

Present punishment pursues his maw,
When surfeited and swell'd, the peacock raw
He bears into the bath; whence want of breath,
Repletions, *apoplex*, intestate death. *Dryden*.

APO'PLEXED, *adj.* Seized with an apoplexy:

Sense, sure, you have,
Else could you not have motion: but sure that sense
Is *apoplex'd*. *Shakespeare*.

A'POPLEXY, *f.* [from *αποπλησσω*, to strike or knock down, or smite suddenly; the Latins call it *attonitus morbus*.] A sudden deprivation of all internal and external sensation, and of all motion, unless of the heart and thorax. See **MEDICINE**.

APO'RIA, *f.* [*απορια*.] A figure in rhetoric, by which the speaker shews, that he doubts where to begin for the multitude of matter, or what to say in some strange and ambiguous thing; and doth, as it were, argue the case with himself. Thus Cicero says, "Whether he took them from his fellows more impudently, gave them to a harlot more lasciviously, removed them from the Roman people more wickedly, or altered them more presumptuously, I cannot well declare."

APO'RON, or **APO'RIME**, *f.* A problem difficult to resolve, and which has never been resolved, though it be not, in itself, impossible. The word is derived from *απορος*, which signifies something difficult, and impracticable; being formed from the privative *α* and *πορος*, passage. Such we conceive the quadrature of the circle; the duplicature of the tube; the trisection of an angle, &c. This word is also used by some law writers for an inexplicable speech or discourse.

APORRHOE'IA, *f.* [*απορροια*.] Effluvium; emanation; something emitted by another: not now in use.—The reason of this he endeavours to make out by atonical *aporrhoeas*, which passing from the cruentate weapon to the wound, and being incorporated with the particles of the salve, carry them to the affected part. *Glanville*.

APORRHOEA, *f.* in astrology, is when the moon separates from one planet and applies to another.

APOSCEPARNISMUS, *f.* [*σκειπαρνον*, an axe, or hatchet.] A species of fracture of the skull or other bone, wherein a piece is taken clearly off, as if cut out with a hatchet.

APOSIOPE'SIS, *f.* [*αποσιωπησις*, from *απο*, after, and *σιωπω*, to be silent.] A form of speech, by which the speaker, through some affection, as sorrow, bashfulness, fear, anger, or vehemency, breaks off his speech before it be all ended. A figure, when, speaking of a thing, we yet seem to conceal it, though indeed we aggravate it; or when the course of the sentence begun is so stayed, as thereby some part of the sentence, not being uttered, may be understood.

AOSPHRAGIS'MA, *f.* [from *απο* and *σφραγιζω*, I seal.] In antiquity, the figure or impression of a seal. It was forbid among the ancients to have the figure or image of God on their rings and seals; but in process of time it was usual enough to have the figures of Egyptian and other deities, as well as of heroes, monsters, friends, ancestors, &c. on their *dactyli*, or ring-seals.

AOSPONGIS'MUS, *f.* [*απο* and *σφογγιζω*, *spongia tergo*.] It is the using of a sponge either dry or moist, for the deterring of the filth from the skin, alleviating pains and itching, recovering the spirits, or for other purposes.

APOSTAG'MA, or **APOSTALAG'MA**, *f.* [*αποσταζω*, distilled.] The sweet liquor that distils from grapes before they are pressed.

APOSTA'SIS, *f.* [from *αφιστημι*, to abscede.] It is when a fragment of a bone comes away by a fracture; and is the same with *absciss*. Hippocrates uses the word also, first, when a distemper passes off by some outlet, and this is an *apostas* by excretion: secondly, when the morbid matter, by its own weight, falls and settles on every part; this is an *apostas* by settlement: thirdly, when one disease turns

turns to another; this is an *apostasis* metastasis. So Pliny calls the *apostema*.

APOSTASY, *f.* [*apostase*, Fr. *apostasia*, Lat. of *αποστασία*, of *ἀφίσταμαι*, Gr. to depart.] Departure from what a man has professed: it is generally applied to religion; sometimes with the particle *from*.—The canon law defines *apostasy* to be a wilful departure from that state of faith, which any person has professed himself to hold in the Christian church. *Ayliffe*.—Whoever do give different worships, must bring in more gods; which is an *apostasy* from one God. *Stillingfleet*. The primitive church distinguished several kinds of apostasy. The first, of those who went over entirely from Christianity to Judaism; the second, of those who mingled Judaism and Christianity together; and the third, of those who complied so far with the Jews, as to communicate with them in many of their ceremonies, without making a formal profession of their religion. But the fourth sort was of those who, after having been some time Christians, voluntarily relapsed into paganism. The apostasy of a Christian to Judaism, paganism, &c. was punished by the emperors Constantius and Julian with confiscation of goods; to which the emperors Theodosius and Valentinian added capital punishment, in case the apostate endeavoured to pervert others to the same iniquity. A punishment too severe for temporal laws to inflict; and yet the zeal of our ancestors imported it into this country; for we find by Bracton, that in his time apostates were burnt to death. Doubtless the preservation of Christianity, as a national religion, is, abstracted from its own intrinsic truth, of the utmost consequence to the civil state; which a single instance will sufficiently demonstrate. The belief of a future state of rewards and punishments, the entertaining just ideas of the moral attributes of the supreme Being, and a firm persuasion that he superintends, and will finally compensate, every action in human life, are the grand foundation of all judicial oaths; which call God to witness the truth of those facts, which perhaps may be only known to Him, and the party attesting: all moral evidence therefore, all confidence in human veracity, must be weakened by apostasy, and overthrown by total infidelity. But yet the loss of life is a heavier penalty than the offence, taken in a civil light, deserves; and, taken in a spiritual light, our laws have no jurisdiction over it. This punishment, therefore, has become obsolete; and the offence of apostasy was for a long time the object only of the ecclesiastical courts, which corrected the offender *pro salute animæ*. But about the close of the last century, the civil liberties to which we were then restored being used as a cloak of maliciousness, and the most horrid doctrine subversive of all religion being publicly avowed both in discourse and writings, it was thought necessary again for the civil power to interpose. To this end it was enacted by 9 and 10 W. III. c. 32. that if any person educated in, or having made profession of, the Christian religion, shall by writing, printing, teaching, or advised speaking, deny the Christian religion to be true, or the holy scriptures to be of divine authority, he shall upon the first offence be rendered incapable to hold any office or place of trust; and for the second be rendered incapable of bringing any action, or of being guardian, executor, legatee, or purchaser of lands, and shall suffer three years imprisonment without bail. To give room, however, for repentance, if, within four months after the first conviction, the delinquent will in open court publicly renounce his error, he is discharged for that once from all disabilities.

APOSTATA CAPIENDO, *f.* in the English law, a writ that formerly lay against a person who, having entered into some order of religion, broke out again, and wandered up and down the country.

APOSTATE, *f.* [*apostata*, Lat. *αποστατης*, Gr.] One that has forsaken his profession; generally applied to one that has left his religion.—The angels, for disobedience, thou hast reserved to a miserable immortality; but unto man, equally rebellious, equally *apostate* from thee and

goodness, thou hast given a Saviour. *Rogers*. Among the Romanists, it signifies a man who, without a legal dispensation, forsakes a religious order of which he had made profession.

APOSTATICAL, *adj.* After the manner of an apostate.

To APOSTATIZE, *v. n.* To forsake one's profession: it is commonly used of one who departs from his religion.

—None revolt from the faith, because they must not look upon a woman to lust after her, but because they are restrained from the perpetration of their lusts. If wanton glances, and libidinous thoughts, had been permitted by the gospel, they would have *apostatized* nevertheless. *Bentley*.

To APOSTEMATE, *v. n.* To become an aposteme; to swell and corrupt into matter.—There is care to be taken in abscesses of the breast and belly, in danger of breaking inwards; yet, by opening these too soon, they sometimes *apostemate* again, and become crude. *Wifeman*.

APOSTEMAT'ION, *f.* The formation of an aposteme; the gathering of a hollow purulent tumour.—Nothing can be more admirable than the many ways nature hath provided for preventing or curing of fevers; as vomitings, *apostemations*, salivations, &c. *Grew*.

APOSTEME, or **APOSTUME**, *f.* [*αποσυμα*, of *ἀφίσταμαι*, to depart.] A hollow swelling, filled with purulent matter; an abscess.—With equal propriety we may affirm, that ulcers of the lungs, or *apostemes* of the brain, do happen only in the left side. *Brown*.—The opening of *apostemes*, before the suppuration be perfected, weakeneth the heat, and renders them crude. *Wifeman*.

A POSTERIO'RI, *f.* or demonstration *à posteriori*. See **DEMONSTRATION**.

APOS'TIL, *f.* The same with a marginal note.

APOS'TLE, *f.* [*apotre*, Fr. *apostolus*, Lat. of *αποστολος*, of *αποστέλλω*, Gr. to send on a message.] In general signifies a messenger, a person sent upon some special errand, for the discharge of some peculiar affair of him that sent him; but is more particularly applied to the disciples whom our Saviour sent to preach the gospel to all nations. He selected only twelve of his disciples to be invested with the apostleship. Their names were Simon Peter, Andrew, James the greater, John, Philip, Bartholomew, Thomas, Matthew, James the less, Jude surnamed Lebbeus or Thaddeus, Simon the Canaanite, and Judas Iscariot. Of these Simon, Andrew, James the greater, and John, were fishermen; and Matthew a publican, or receiver of the public revenues: of what profession the rest were, we are not told in Scripture; though it is probable they were fishermen. There are various conjectures as to the reason of our Saviour's making choice of *twelve* apostles. The most probable is, that it might be in allusion to the twelve patriarchs, as the founders of their several tribes; or to the twelve chief heads or rulers of those tribes, of which the body of the Jewish nation consisted. This opinion seems to be countenanced by what our Saviour tells his apostles, that "when the Son of man shall sit in the throne of his glory, they also shall sit upon twelve thrones, judging the twelve tribes of Israel." The first commission of our Saviour to his apostles was in the third year of his public ministry, about eight months after their solemn election; at which time he sent them out by two and two. They were to make no provision of money for their subsistence, but to expect it from those to whom they preached. They were to declare, that the kingdom of heaven was at hand; and to confirm their doctrine by miracles. They were to avoid going either to the Gentiles or to the Samaritans, and to confine their preaching to the people of Israel. In obedience to their Master, the apostles went into all the parts of Palestine inhabited by the Jews, preaching the gospel, and working miracles. The evangelical history is silent as to the particular circumstances attending this first preaching of the apostles; and only informs us, that they returned, and told their Master of all that they had done. Their second commission was of a more extensive nature. They were not to confine their preaching to the Jews, but to "go and teach all nations, baptizing them in the name

of the Father, and of the Son, and of the Holy Ghost." Accordingly they began publicly, after the ascension, to exercise their ministry, working miracles, and making great numbers of converts to the Christian faith.

After the apostles had exercised their ministry for twelve years in Palestine, they resolved to disperse themselves in different parts of the world, and agreed to determine by lot what parts each should take. According to this division, St. Peter went into Pontus, Galatia, and other provinces of Lesser Asia. St. Andrew had the vast northern countries of Scythia and Sogdiana allotted to his portion. St. John's was partly the same with Peter's, namely, the Lesser Asia. St. Philip had the Upper Asia, with some parts of Scythia and Colchis. Arabia Felix fell to the lot of St. Bartholomew. St. Matthew preached in Chaldaea, Persia, and Parthia. St. Thomas preached likewise in Parthia; as also to the Hyrcanians, Bactrians, and Indians. St. James the less continued in Jerusalem, of which church he was bishop. St. Simon had Egypt, Cyrene, Libya, and Mauritania. St. Jude, Syria and Mesopotamia; and St. Matthias, who was chosen in the room of Judas Iscariot, Cappadocia and Colchis. Thus, by the dispersion of the apostles, Christianity was quickly planted in many parts of the world; yet we have but very short and imperfect accounts of their travels and actions. The appellation is given in like manner to those persons who first planted the Christian faith in any place. Thus, Dionysius of Corinth is called the *apostle of France*; Xavier, the *apostle of the Indies*, &c. In the East Indies the Jesuit missionaries are also called *apostles*.

APOSTLE is also used among the Jews for a kind of officer anciently sent into the several parts and provinces, in their jurisdiction, by way of visitor or commissary, to see that the laws were duly observed, and to receive the monies collected for the reparation of the temple, and the tribute payable to the Romans. The Theodosian code, lib. 14. *De Judæis*, calls those *apostoli, qui ad exigendum aurum atque argentum a patriarcha certo tempore diriguntur*. Julian the apostate remitted the Jews the *apostole, ἀποστολη*; that is, as he himself explains it, the tribute they had been accustomed to send him. These apostles were a degree below the officers of the synagogues called *patriarchs*, and received their commissions from them. Some authors observe, that St. Paul had borne this office; and that it is this he alludes to in the beginning of the epistle to the Galatians: as if he had said, Paul, no longer an apostle of the synagogue, nor sent thereby to maintain the law of Moses, but now an apostle and envoy of Jesus Christ, &c.

APOSTLE, in the Greek liturgy, is particularly used for a book containing the epistles of St. Paul, printed in the order wherein they are to be read in churches, through the course of the year. Another book of the like kind, containing the Gospels, is called *Εὐαγγέλιον, Gospel*. The apostle, of late days, has also contained the other canonical epistles, the Acts of the Apostles, and the Revelations. Hence it is also called *Acts of the Apostles*, *Πράξεις ἀποστόλων*: that being the first book in it.

APOSTLE is also thought by many to have been the original name for bishops, before the denomination *bishop* was appropriated to their order. Thus, Theodorus says expressly, the same persons were anciently called promiscuously both bishops and presbyters, whilst those who are now called bishops were called *apostles*.

APOSTLES' CREED: a *formula*, or summary of the Christian faith, drawn up, according to Rufinus, by the apostles themselves: who, during their stay at Jerusalem, agreed upon this *creed*, as a rule of faith, and as a *word of disinction* by which they were to know friends from foes. Baronius, and some other authors, conjecture, that they did not compose it till the second year of the reign of Claudius, a little before their dispersion. But there are reasons which may induce us to question whether the apostles composed any such creed as this. For, first, neither St. Luke, in the Acts, nor any other ecclesiastical writer before the fifth century, make any mention of an as-

sembly of the apostles in order to the composing of a creed. Secondly, the fathers of the three first centuries, in disputing against the heretics, endeavour to prove that the doctrine contained in this creed was the same which the apostles taught; but they never pretend that the apostles composed it. Thirdly, if the apostles had made this creed, it would have been the same in all churches, and in all ages; and all authors would have cited it after the same manner. But the case is quite otherwise. In the second and third ages of the church, there were as many creeds as authors, and one and the same author sets down the creed after a different manner in several places of his works: which is an evidence that there was not, at that time, any creed which was reputed to be the apostles'. In the fourth century, Rufinus compares together the three ancient creeds of the churches of Aquileia, Rome, and the East, which differ very considerably in the terms. From these reasons it may be gathered, that, though this creed may be said to be that of the apostles in regard to the doctrines contained therein, yet it is not to be referred to them as the authors and first composers of it. Who was the true author of it, is not easy to determine; though its great antiquity may be inferred from hence, that the whole form, as it now stands in the English liturgy, is to be found in the works of St. Ambrose and Rufinus, the former of whom flourished in the third century, and the latter in the fourth century. The primitive Christians, in regard they always concealed this and their other mysteries, did not publicly recite the creed, except at the times of baptism; which, unless in cases of necessity, were only at Easter and Whitsuntide. The constant repeating it was not introduced into the church till the end of the fifth century; about which time Petrus Gnephus, bishop of Antioch, prescribed the recital of it every time divine service was performed.

APOSTLES'HIP, *f.* The office or dignity of an apostle.—God hath ordered it, that St. Paul hath writ epistles; which are all confined within the business of his *apostleship*, and so contain nothing but points of Christian instruction. *Locke.*

APOSTOLA'RE, APOSTOLICA'RE, *apostolizing*, in some middle-age writers, denotes the being preferred to the dignity of pope.

APOSTOLATE, *f.* in a general sense, is used for mission. In this sense, Olearius has a discourse concerning the apostolate of Christ. But it more properly denotes the dignity or office of an apostle of Christ; but it is also used, in ancient writers, for the office of a bishop. In this sense we meet with several letters, petitions, requests, &c. directed to bishops, under the title of your *apostolate*, or *apostolatus vester*. But, as the title *apostolicus* had been appropriated to the pope, so that of *apostolate* became at length restrained to the sole dignity of the popedom. Every bishop's see was anciently dignified with the title of *sedes apostolica*, an apostolical see, which is now the peculiar denomination of the see of Rome.

APOSTOLI, *f.* in law, denote those letters missive which are demanded in cases of appeal.

APOSTOLIC, *adj.* [the accent is placed by Dryden on the antepenult.] Taught by the apostles; belonging to an apostle.—Their oppositions, in maintenance of public superstition against *apostolic* endeavours, were vain and frivolous. *Hooker.*

APOSTOLIC, in the primitive church, was an appellation given to all such churches as were founded by the apostles; and even to the bishops of those churches, as being the reputed successors of the apostles. These were confined to four, viz. Rome, Alexandria, Antioch, and Jerusalem. In after-times, however, other churches assumed the same quality, because all bishops held themselves successors of the apostles, or acted in their dioceses with similar authority. The first time the term *apostolical* is attributed to bishops, is in a letter of Clovis to the council of Orleans, held in 511, though that king does not there expressly denominate them *apostolical*, but (*apostolica*

foliâ fide digniffimi) highly worthy of the apostolical see. In 581, Guntram calls the bishops, met at the council of Maçon, *apostolical pontiffs, apostolici pontifices*.

APOSTO'LICAL, *adj.* Delivered or taught by the apostles; belonging to the apostles.—Declare yourself for that church which is founded upon scripture, reason, *apostolical* practice, and antiquity. *Hooker*.

APOSTOLICAL CONSTITUTIONS. See **CONSTITUTION**.

APOSTOLICAL TRADITIONS. See **TRADITION**.

APOSTOLICAL FATHERS, is an appellation usually given to the writers of the first century who employed their pens in the cause of Christianity.

APOSTO'LICALLY, *adv.* In the manner of the apostles.

APOSTO'LICALNESS, *f.* The quality of relating to the apostles; apostolical authority.

APOSTO'LICI, or **APOSTOLICS**, was a name assumed by three different sects, on account of their pretending to imitate the manners and practice of the apostles. The first apostolici rose out of the Encratitæ, and Cathari, in the third century. They made profession of abstaining from marriage, and the use of wine, flesh, money, &c. Gerhard Sagarelli was the founder of the second sect; he obliged his followers to go from place to place as the apostles did, to wander about clothed in white, with long beards, dishevelled hair, and bare heads, accompanied with women, whom they called their spiritual sisters. They likewise renounced all kinds of property and possessions, inveighed against the growing corruption of the church of Rome, predicted its overthrow, and the establishment of a purer church on its ruins. Sagarelli was burnt alive at Parma in the year 1300, and was afterwards succeeded by Dulcinus, who added to the character of an apostle those of a prophet and a general, and carried on a bloody and dreadful war for more than two years against Raynerius, bishop of Vercelli; he was at length defeated, and put to death, in the year 1307. Nevertheless, this sect subsisted in France, Germany, and in other countries, till the beginning of the fifteenth century, when it was totally extirpated under the pontificate of Boniface IX. The other branch of apostolici were of the twelfth century. These also condemned marriage, preferring celibacy, and calling themselves the chaste brethren and sisters; though each was allowed a spiritual sister, with whom he lived in a domestic relation; and on this account they have been charged with concubinage: they held it unlawful to take an oath; they set aside the use of baptism; and in many things imitated the Manichees. Bernard wrote vehemently against this sect.

APOSTO'LICUM, *f.* is a peculiar name given to a kind of song or hymn, anciently used in churches. Vossius understands it as spoken of the apostles' creed: Suicer thinks this impossible, for that this creed was then unknown in the churches of the east.

APOSTOO'LIANS, a sect of the Mennonites, which first sprung up in the year 1664, and derived its name from Apostool, one of the Mennonite ministers at Amsterdam. They concurred with them in doctrine, and admitted to their communion those only who professed to believe all the sentiments which are contained in their public confession of faith.

APOSTROPHE, *f.* [*αποτροπή*, from *απο*, from, and *τρέπω*, to turn.] In rhetoric, a figure by which a person who is either absent or dead is addressed as if he were present, and attentive to us. This figure, in boldness, is a degree lower than the address to personified objects, since it requires a less effort of imagination to suppose persons present who are dead or absent, than to animate insensible beings and direct our discourses to them. The poems of Ossian abound with the most beautiful instances of this figure. "Weep on the rocks of roaring winds, O Maid of Inishore! Bend thy fair head over the waves, thou fairer than the ghost of the hills when it moves in a sun-beam at

noon over the silence of Morven! He is fallen! Thy youth is low; pale beneath the sword of Cuchullin!"

APOSTROPHE, in grammar, the contraction of a word by the use of a comma: as *call'd* for *called*, *tho'* for *though*, &c.

To **APOS'TROPHIZE**, *v. n.* To address by an apostrophe.—There is a peculiarity in Homer's manner of *apostrophizing* Eumæus, and speaking of him in the second person: it is generally applied only to men of account. *Pope*.

A'POSTUME, *f.* [this word is properly *apostem*.] A hollow tumour filled with purulent matter.—How an *apostume* in the mesentery, breaking, causes a consumption in the parts, is apparent. *Harvey*. See **APOSTEME**.

To **APOSTUME**, *v. n.* To apostemate.

APOSYR'MA, *f.* [*αποσυρμα*, of *αποσυρω*, to draw, pull, or take off.] That which is drawn, shaved, or pared off.

APOTAC'TITÆ, or **APOTACTICI**, an ancient sect, who, affecting to follow the evangelical counsels of poverty, and the examples of the apostles and primitive Christians, renounced all their effects and possessions.

APOTEICHIS'MUS, *f.* in the ancient military art, a line of circumvallation drawn round a place in order to besiege it. This was also called *periteichismus*; which generally consisted of a double wall, or ramparts, raised of earth; the innermost to prevent sudden sallies from the town, the outermost to keep off foreign enemies from coming to the relief of the besieged. This answered to what are called *lines of contravallation* and *circumvallation* among the moderns.

APO'THECARY, *f.* [*apothecaire*, Fr. *apothecarius*, Lat. of *αποθήκη*, of *απο* τίθημι, to mix with, or add to, because of their compounding things together for medicine.] One who practises the art of pharmacy, keeps a physical shop, and sells medicines. In London, the apothecaries are one of the city-companies. They were incorporated by a charter of king James I. till which time they only made a part of the grocers' company; plumbs, sugar, spice, Venice treacle, mithridate, &c. were sold in the same shop and by the same person. The reason of separating them was that medicines might be better prepared, and in opposition to divers persons who imposed unwholesome drugs on the people. By an act which was made perpetual in the ninth year of George I. they are exempted from serving upon juries, or in ward and parish offices. They are obliged to make up their medicines according to the formulas prescribed in the college dispensatory; and are liable to have their shops visited by the censors of the college, who are empowered to destroy such medicines as they think not good. They have a noble hall in Water-lane, Blackfriars, which has been lately enriched with the curious and valuable museum of the late Dr. Hunter, presented to them by parliament. Here are also two fine laboratories, out of which all the surgeons' chests are supplied with medicines for the royal British navy.

The charitable dispensation of medicines by the Chinese is well deserving of notice. They have a stone, which is ten cubits high, erected in the public squares of their cities; on this stone are engraved the names of all sorts of medicines with the price of each; and, when the poor stand in need of any relief from physic, they go to the public treasury, where they receive the price each medicine is to cost.

APO'THECARY, or **APOTHECA'RIOUS**, is also used to denote a store-keeper, or officer appointed to have the direction of a magazine, granary, &c. In which sense *apothecarii* is sometimes rendered by *horarii* and *rationarii*.

A'POTHEGM, *f.* [properly *apophthegm*; which see.] A remarkable saying.—By frequent conversing with him, and scattering short *apothegms*, and little pleasant stories, and making useful applications of them, his son was, in his infancy, taught to abhor vanity and vice as monsters. *Walton*.

APOTHE'OSIS, *f.* [*apothecose*, Fr. of *απθειωσις*, Gr. of *αποθεω*, to reckon or place among the gods.] A consecration, or solemn enrolling, of great men deceased, in the

number of the gods; anciently practised by the Romans, first begun by Augustus for Julius Cæsar. After the ceremony was finished, the deified emperor was worshipped as a god, and with as much veneration as any of the rest of their gods; so that Minutius Felix says, that a person might more safely swear falsely by Jupiter himself than by the genius of the deified person; and this was continued in Christian Rome by the pope, by the name of canonization.

The doctrine of Pythagoras, which he borrowed from the Chaldees, taught that virtuous persons after their death were raised into the order of the gods. And hence the ancients deified all the inventors of things useful to mankind; and those who had done any important service to the commonwealth.

APOTHERA'PIA, *f.* [from ἀποθεραπεύω, I cure.] In physic, denotes a complete or finished cure.

APOTHERAPIA is also used in the gymnastic art, for the last part of all regular exercise, viz. friction or unction with oil, before as well as after bathing. The design of this was partly to cleanse the skin, and partly to remove weariness.

APOTHER'MUM, *f.* An acrimonious kind of pickle, as with mustard, vinegar, &c.

APOT'HESES, *f.* [from ἀποτίθημι, to reposit, or from ἀπο and τίθημι, to place.] The reduction of a dislocated bone.

APOT'OME, *f.* in geometry, the remainder or difference between two lines or quantities which are only commensurable in power. Such is the difference between 1 and $\sqrt{2}$, or the difference between the side of the square and its diagonal. The term is used by Euclid; and a full explanation of such quantities is given in the tenth book of his Elements, where he distinguishes six kinds of apotomes, and shews how to find them all geometrically.

The doctrine of apotomes, as delivered in the tenth book of Euclid, is a very curious subject, and has been much admired and cultivated by all mathematicians who have rightly understood this part of the elements; and therefore Peter Ramus has greatly exposed his judgment by censuring that book. The first algebraical writers in Europe have commonly employed a considerable portion of their works on an algebraical exposition of that book, which led them to the doctrine of surd quantities; as Lucas de Burgo, Cardan, Tartalea, Stifelius, Peletarius, &c. &c. See also Pappus, lib. 4, prop. 3, and the introduction to lib. 7. And Dr. Wallis's Algebra, p. 109.

APOTOME, in music, is the difference between a greater and less semitone, being expressed by the ratio of 128 to 125.

APOTROPÆ'A, *f.* [from ἀποτρέπω, I avert.] In the ancient poetry, verses composed for averting the wrath of incensed deities.

AP'OZEM, *f.* [apozeme, Fr. apozema, Lat. of ἀποζυμα, of ἀποζέω, to decoct.] A medicinal decoction of herbs, flowers, roots, barks, &c.

To **APPA'L**, *v. a.* [appallir, Fr. It might more properly have been written *appale*.] To fright; to strike with sudden fear; to depress; to discourage:

Give with thy trumpet a loud note to Troy,
Thou dreadful Ajax; that th' *appalled* air
May pierce the head of thy great combatant. *Shakespeare.*

The monster curls
His flaming crest, all other thirst *appall'd*,
Or shiv'ring flies, or choak'd at distance stands. *Thomson.*

APPA'LEMENT, *f.* Depression; discouragement; impression of fear.—The furious slaughter of them was a great discouragement and *appalement* to the rest. *Bacon.*

APPAMAT'TOX, a river of Virginia, in North America, navigable as far as Broadways, by vessels of any size that can cross the bar in James's river; it afterwards keeps eight or nine feet water up to Fisher's bar; and from four to five feet or upwards, from thence to Petersburg, where its navigation ceases.

AP'PANAGE, *f.* [appanagium, low Lat. probably from panis, bread.] Lands set apart by princes for the maintenance of their younger children:

Had he thought it fit
That wealth should be the *appanage* of wit,
The god of light could ne'er have been so blind,
To deal it to the worst of human kind. *Swift.*

APPARA'TUS, *f.* [Lat.] Things provided as means to any certain end, as a set of instruments for any art or science; the utensils or tools of a trade; the furniture of a house; ammunition for war; equipage; show.—Our-selves are easily provided for; it is nothing but the circumstances, the *apparatus* or equipage of human life, that costs so much. *Pope.*

APPARATUS, in chemistry. See **CHEMISTRY**.

APPARATUS, in surgery. See **SURGERY**.

APPA'REL, *f.* [appareil, Fr.] Dress; vesture. External habiliments.—At public devotion, his resigned carriage made religion appear in the natural *apparel* of simplicity. *Tatler.* It has no plural.

To **APPA'REL**, *v. a.* To dress; to clothe.—With such robes were the king's daughters that were virgins *apparelled*. 2 Sam. xiii. 18.—To adorn with dress.—She did *apparel* her apparel, and with the preciousness of her body made it most sumptuous. *Sidney.*—To cover, or deck, as with dress.—Shelves, and rocks, and precipices, and gulfs, being *apparelled* with a verdure of plants, would resemble mountains and valleys. *Bentley.*—To fit out; to furnish: (not in use).—It hath been agreed, that either of them should send ships to sea well manned and *apparelled* to fight. *Hayward.*

APPA'RENT, *adj.* [apparent, Fr. apparens, Lat.] Plain; indubitable; not doubtful.—The main principles of reason are in themselves *apparent*. For to make nothing evident of itself unto man's understanding, were to take away all possibility of knowing any thing. *Hooker.*—Seeming; in appearance; not real.—The perception intellectual often corrects the report of phantasy, as in the *apparent* bigness of the sun, the *apparent* crookedness of the staff in air and water, &c. *Hale.*—Visible; in opposition to *secret*.—The outward and *apparent* sanctity of actions should flow from purity of heart. *Rogers.*—Open; evident; known; not merely suspected. Certain; not presumptive:

He is the next of blood
And heir *apparent* to the English crown. *Shakespeare.*

APPARENT, *f.* Elliptically used for *heir apparent*:

Draw thy sword in right.—
—I'll draw it as *apparent* to the crown,
And in that quarrel use it. *Shakespeare.*

APPARENT, among mathematicians and astronomers, denotes things as they *appear* to us, in contradistinction from their *real* state, either as to distance, figure, magnitude, position, &c. &c. Thus,

APPARENT DIAMETER, or **MAGNITUDE**, as for example of the heavenly bodies, is not the real length of the diameter, but the angle which they subtend at the eye, or under which they appear. And hence, the angle, or apparent extent, diminishing with the distance of the object, a very small object, as AB, may have the same apparent diameter as a very large one FG; and indeed the objects have all the same apparent diameter that are contained in the same angle FEG. And, if these are parallel, the real magnitudes are directly proportional to their distances.

But the apparent magnitude varies not only by the distance, but also by the position of it. So, if the object
CD

CD be changed from the direct position to the oblique one CE, its apparent magnitude would then be only the angle CED, instead of the angle CED.

If the eye E be placed between two parallels AB, CD, these parallels will appear to converge or come nearer and nearer to each other the further they are continued out, and at last they will appear to coincide in that point where the sight terminates, which will happen when the optic angle BED becomes equal to about one minute of a degree, the smallest angle under which an object is visible. Also the apparent magnitudes of the same object FG or BD, seen at different distances, that is the angles FEG, BED, are in a less ratio than the reciprocal ratio of the distances, or the distance increases in a greater ratio than the angle or apparent magnitude diminishes. But when the object is very remote, or the optic angle is very small, as one degree or thereabouts, the angle then varies nearly as the distance reciprocally. But, although the optic angle be the usual or sensible measure of the apparent magnitude of an object, yet habit, and the frequent experience of looking at distant objects, by which we know that they are larger than they appear, has so far prevailed upon the imagination and judgment, as to cause this also to have some share in our estimation of apparent magnitudes; so that these will be judged to be more than in the ratio of the optic angles.

The apparent magnitude of the same object, at the same distance, is different to different persons, and different animals, and even to the same person, when viewed in different lights, all which may be occasioned by the different magnitudes of the eye, causing the optic angle to differ as that is greater or less: and since, in the same person, the more light there comes from an object, the less is the pupil of the eye, looking at that object; therefore the optic angle will also be less, and consequently the apparent magnitude of the object. Every one must have experienced the truth of this, by looking at another person in a room, and afterwards abroad in the sunshine, when he always appears smaller than in a room where the light is less. So also, objects up in the air, having more light coming from them than when they are upon the ground, or near it, may appear less in the former case than in the latter; as the ball of the cross on the top of St. Paul's church, which is six feet in diameter, appears less than an object of the same diameter seen at the same distance below, near the ground. And this may be the chief reason why the sun and moon appear so much larger when seen in the horizon, where their beams are weak, than when they are raised higher, and their light is more bright and glaring. Again, if the eye be placed in a rare medium, and view an object through a denser, as glass or water, having plane surfaces, the object will appear larger than it is: and contrariwise, smaller. And hence it is that fishes, and other objects, seen in the water, by an eye in the air, always appear larger than in the air. In like manner, an object will appear larger when viewed through a globe of glass or water, or any convex spherical segments of these; and, on the contrary, it will appear smaller when viewed through a concave of glass or water.

APPARENT DISTANCE, is that distance which we judge an object to be from us, when seen afar off. This is commonly very different from the true distance; because we are apt to think that all very remote objects, whose parts cannot well be distinguished, and which have no other visible objects near them, are at the same distance from us; though perhaps they may be thousands or millions of miles off; as in the case of the sun and moon. The apparent distance

of objects are also greatly altered by the refraction of the medium through which they are seen.

APPARENT FIGURE, is the figure or shape which an object appears under when viewed at a distance; and is often very different from the true figure. For a straight line, viewed at a distance, may appear but as a point; a surface, as a line; and a solid, as a surface. Also these may appear of different magnitudes, and the surface and solid of different figures, according to their situation with respect to the eye: thus, the arch of a circle may appear a straight line; a square, a trapezium, or even a triangle; a circle, an ellipsis; angular magnitudes, round; and a sphere, a circle. Also all objects have a tendency to roundness and smoothness, or appear less angular, as their distance is greater: for, as the distance is increased, the smaller angles and asperities first disappear, by subtending a less angle than one minute; after these, the next larger disappear, for the same reason; and so on continually, as the distance is more and more increased; the object seeming still more and more round and smooth. So, a triangle, or square, at a great distance, shews only as a round speck; and the edge of the moon appears round to the eye, notwithstanding the hills and valleys on her surface. And hence it is also, that near objects, as a range of lamps, or such like, seen at a great distance, appear to be contiguous, and to form one uniform continued magnitude, by the intervals between them disappearing, from the smallness of the angles subtended by them.

APPARENT MOTION, is either that motion which we perceive in a distant body that moves, the eye at the same time being either in motion or at rest; or that motion which an object at rest seems to have, while the eye itself only is in motion. The motions of bodies at a great distance, though really moving equally, or passing over equal spaces in equal times, may appear to be very unequal and irregular to the eye, which can only judge of them by the mutation of the angle at the eye. And motions, to be equally visible, or appear equal, must be directly proportional to the distances of the objects moving. Again, very swift motions, as those of the luminaries, may not appear to be any motions at all, but like that of the hour-hand of a clock, on account of the great distance of the objects: and this will always happen, when the space actually passed over in one second of time is less than about the 14000th part of its distance from the eye; for the hour-hand of a clock, and the stars about the earth, move at the rate of fifteen seconds of a degree in one second of time, which is only the 13751 part of the radius or distance from the eye. On the other hand, it is possible for the motion of a body to be so swift, as not to appear any motion at all; as when through the whole space it describes there constantly appears a continued surface or solid as it were generated by the motion of the object, as when any thing is whirled very swiftly round, describing a ring, &c.

Also, the more oblique the eye is to the line which a distant body moves in, the more will the apparent motion differ from the true one. So, if a body revolve with an equable motion in the circumference of the circle ABCD, &c. and the eye be at E in the plane of the circle; as the body moves from A to B and C, it seems to move slower and slower along the line ALK, till when the body arrives at C, it appears at rest at K; then when it really moves from C by D to F, it appears to move quicker and quicker from K by L to A, where its motion is quickest of all; after this it appears to move slower and slower from A to N while the body moves from F to H: there, becoming stationary again, it appears to return from N to A in the straight line, while it really moves from H by I to A in the circle. And thus it appears to move in the line KN

by a motion continually varying between the least, or nothing, at the extremes K and N, and the greatest of all at the middle point A. Or, if the motion be referred to the concave side of the circle, instead of the line KN, the appearances will be the same.

If an eye move directly forwards from E to Q, &c. any remote object at rest at P, will appear to move the contrary way, or from P to Q, with the same velocity. But, if the object P move the same way, and with the same velocity as the eye, it will seem to stand still. If the object have a less velocity than the eye, it will appear to move back towards Q with the difference of the velocities; and, if it moves faster than the eye, it will appear to move forwards from Q with the same difference of the velocities. And so likewise when the object P moves contrary to the motion of the eye, it appears to move backwards with the sum of the motions of the two. And the truth of all this is experienced by persons sitting in a boat moving on a river, or in a wheel-carriage when running fast, and viewing houses or trees, &c. on the shore or side of the road, or other boats or wheel-carriages also in motion.

APPARENT HEIR, in law. See HEIR.

APPARENTLY, *adv.* Evidently; openly.—Vices apparently tend to the impairing of men's health. *Tillotson.*

APPARITION, *f.* [from *apparco*, Lat. to appear.] Appearance; visibility.—My retirement tempted me to divert those melancholy thoughts which the new apparitions of foreign invasion and domestic discontent gave us. *Denham.* The thing appearing; a form; a visible object:

I have mark'd

A thousand blushing apparitions

To start into her face; a thousand innocent flames

In angel whiteness bear away those blushes. *Shakespeare.*

A spectre; a walking spirit.—Tender minds should not receive early impressions of goblins, spectres, and apparitions, wherewith maids fright them into compliance. *Locke.* See GHOST.

APPARITION, in astronomy, denotes a star's or other luminary's becoming visible, which before was hid. So, the heliacal rising is rather an apparition than a proper rising.

APPARITORS, *f.* [from *apparco*, Lat. to be at hand.] Such persons as are at hand to execute the proper orders of the magistrate or judge of any court of judicature. The lowest officer of the ecclesiastical court; a summoner.—They swallowed all the Roman hierarchy, from the pope to the apparitor. *Ayliffe.*

APPAUME'E, *f.* in heraldry, denotes one hand extended, with the full palm appearing, and the thumb and fingers at full length.

To APPA'Y, *v. a.* [appayer, old Fr. to satisfy.] To satisfy; to content: whence *well appayed*, is *pleased*; *ill appayed*, is *uneasy*. It is now obsolete.

To APPEA'CH, *v. a.* To accuse; to inform against any person. To censure; to reproach; to taint with accusation: Nor canst nor durst thou, traitor, on thy pain, Approach my honour, or thine own maintain. *Dryden.*

APPEACH'MENT, *f.* Charge exhibited against any man; accusation.

To APPE'AL, *v. n.* [appello, Lat.] To transfer a cause from one to another; with the particles *to* and *from*.—From the ordinary therefore they appeal to themselves. *Hooker.*—To refer to another as judge.—Force, or a declared sign of force, upon the person of another, where there is no common superior on earth to appeal to for relief, is the state of war; and it is the want of such an appeal gives a man the right of war, even against an aggressor, though he be in society, and a fellow-subject. *Locke.*—To call another as witness.—Whether this, that the soul always thinks, be a self-evident proposition, I appeal to mankind. *Locke.*—To charge with a crime; to accuse: a term of law:

One but flatters us,

As well appeareth by the cause you come,
Namely, t' appeal each other of high treason. *Shakespeare.*

APPEAL, *f.* An appeal is a provocation from an inferior to a superior judge, whereby the jurisdiction of the inferior judge is for a while suspended, in respect of the cause; the cognizance being devolved to the superior judge.

Appeals lie from all the ordinary courts of justice to the house of lords. In ecclesiastical cases, if an appeal is brought before a bishop, it may be removed to the archbishop; if before an archdeacon, to the court of arches, and thence to the archbishop; and from the archbishop's court to the king in chancery.

APPEAL, in common law, hath two significations; one is, the removing a cause from an inferior court, or judge, to a superior; as from one or more justices of the peace to the quarter sessions. The other kind of appeal is a prosecution against a supposed offender, by the party's own private action; prosecuting also for the crown, in respect of the offence against the public. 2 *Haw.* 155. In which latter sense, an appeal may be brought in three cases: 1. By a man for a wrong done to his ancestor. 2. By a wife for the death of her husband. 3. For wrong done to the appellants themselves; as in case of robbery, rape, or maihem. *Wood, b. 4. c. 5.*

By statute 6 Edw. I. c. 9. all appeals of death must be sued within a year and a day after the completion of the felony. And if a man be acquitted on an indictment of murder, or found guilty and pardoned by the king, yet he ought not (in strictness) to go at large, but be imprisoned or let to bail till the year and day be past, within which time an appeal may be brought. 3 Hen. VII. c. 1. If the appellee is convicted, the ancient usage was, so late as Henry the Fourth's time; that all the relations of the slain should drag the appellee to the place of execution. 4 *Bl.* 316.

Forasmuch as an appeal is the suit of the party, as well as of the king, hence it is that the king cannot pardon an offender found guilty upon an appeal, as he may when found guilty upon an indictment; for in such case he can only pardon for himself, but not for the party. 2 *Haw.* 155. However the punishment of the offender may be remitted and discharged by the concurrence of all parties interested; and, as the king by his pardon may frustrate an indictment, so the appellant by his release may discharge an appeal. 4 *Blackst.* 316. If the person appealed be acquitted on the appeal, the appellor shall be imprisoned for a year, and restore damages to the party, and be grievously fined to the king, 13 Edw. I. st. 1. c. 12. that is, if the appeal shall appear to the court to have been malicious. 2 *Haw.* 198. And, being acquitted on the appeal, he cannot afterwards be indicted for the same offence. 4 *Blackst.* 315. But appeal is now entirely disused, on account of the great nicety required in conducting it, and the charges of prosecution; and indictment is the only method now taken.

APPEAL'ANT, *f.* He that appeals:

Lords appellants,

Your differences shall all rest under gage,
Till we assign you to your days of trial. *Shakespeare.*

APPEAL'ER, *f.* One who makes an appeal.

To APPE'AR, *v. n.* [apparco, Lat.] To be in sight; to be visible.—As the leprosy appeareth in the skin of the flesh. *Lev.* xiii. 43.—To become visible as a spirit.—For I have appeared unto thee for this purpose, to make thee a minister and a witness. *Acts*, xxvi. 16.—To stand in the presence of another, generally used of standing before some superior; to offer himself to the judgment of a tribunal.—When shall I come and appear before God? *Psalms*, xlii. 2.—To be object of observation.—Let thy work appear unto thy servants, and thy glory unto their children. *Psalms*, xc. 16.—To exhibit one's self before a court of justice.—This morning see you do appear before them. *Shakespeare.*—To be made clear by evidence.—Egfrid did utterly waste and subdue it, as appears out of Beda's complaint against him; and Edgar brought it under his obedience,

dience, as *appears* by an ancient record. *Spenser*.—To seem, in opposition to reality.—His first and principal care being to *appear* unto his people such as he would have them be, and to be such as he *appeared*. *Sidney*.—To be plain beyond dispute.—From experiments, useful indications may be taken, as will *appear* by what follows. *Arbutnot*.

APPEAR'ANCE, f. The act of coming into sight; as, They were surprised by the sudden *appearance* of the enemy. The thing seen; as, The remarkable *appearances* in the sky. Phenomena; that quality of any thing which is visible.—The advancing day of experimental knowledge discloseth such *appearances*, as will not lie even in any model extant. *Glanville*.—Semblance; not reality.—The hypocrite would not put on the *appearance* of virtue, if it was not the most proper means to gain love. *Addison*.—Outside; show.—Under a fair and beautiful *appearance* there should ever be the real substance of good. *Rogers*.—Entry into a place or company.—Do the same justice to another, which will be done us hereafter by those, who shall make their *appearance* in the world, when this generation is no more. *Addison*.—Apparition; supernatural visibility.—I think a person terrified with the imagination of spectres, more reasonable than one who thinks the *appearance* of spirits fabulous. *Addison*.—Exhibition of the person to a court:

I will not tarry; no, nor ever more
Upon this business my *appearance* make
In any of their courts.

Shakespeare.

Presence; mein.—Health, wealth, victory, and honour, are introduced; wisdom enters the last, and so captivates with her *appearance*, that he gives himself up to her. *Addison*.—Probability; seeming; likelihood.—There is that which hath no *appearance*, that this priest being utterly unacquainted with the true person, according to whose pattern he should shape his counterfeit, should think it possible for him to instruct his player. *Bacon*.

APPEARANCE, in law, signifies the defendant's filing common or *special* bail, when he is arrested on any process out of the courts at Westminster. Anciently, the sheriff, on execution of the writ, was obliged to take the defendant into custody, in order to produce him in court upon the return, however small and minute the cause of action might be. For not having obeyed the original summons, he had shewn a contempt of the court, and was no longer to be trusted at large. But when the summons fell into disuse, and the *capias* became, in fact, the first process, it was thought hard to imprison a man for a contempt which was only supposed; and therefore in common cases, by the gradual indulgence of the courts, (at length authorized by the statutes 12 Geo. I. c. 9. and 5 Geo. II. c. 27.) the sheriff or his officer can now only personally serve the defendant with the copy of the writ or process, and with notice in writing to appear by his attorney in court to defend this action; which in effect reduces it to a mere summons. And, if the defendant thinks proper to appear upon this notice, his *appearance* is recorded, and he puts in sureties for his future attendance and obedience; which sureties are called *common bail*, being two imaginary persons, usually named *John Doe* and *Richard Roe*; or, if the defendant doth not appear upon the return of the writ, or within four (or in some cases eight) days after, the plaintiff may enter an *appearance* for him, as if he had really appeared; and may file common bail in the defendant's name, and proceed thereupon as if the defendant had done it himself. But, if the plaintiff will make affidavit that the cause of action amounts to 10l. or upwards, then the defendant upon the arrest must either go to prison, or put in *special* bail; which is done by entering into a bond to the sheriff, with one or more sureties, (not fictitious persons, as in the former case of common bail, but real, substantial, responsible, men,) to insure the defendant's *appearance* at the return of the writ, which is called the

bail bond; and, on the return of the writ, or within four days after, the defendant must appear according to the exigency of the writ. Which *appearance* is effected by putting in bail to the *action*, and is commonly called putting in bail *above*. This bail above, or bail to the action, must be put in either in open court, or before one of the judges thereof; or else, in the country, before a commissioner appointed for that purpose by virtue of the statute 4 Wm. c. 4. 3 Blackst. 287, 289. *Appearance* saves error in mesne process. 1 Vez. 386.

APPEARANCE, in perspective, is the representation or projection of a figure, body, or the like object, on the perspective plane. The *appearance* of an objective right line, is always a right line. See **PERSPECTIVE**.

APPEAR'ER, f. The person that appears.—That owls and ravens are ominous *appearers*, and presignify unlucky events, was an augurial conception. *Brown*.

APPEAS'ABLE, adj. That may be pacified; reconcilable.

APPEAS'ABLENESS, f. The quality of being easily appeased; reconcilableness.

To APPE'ASE, v. a. [*appaier*, Fr.] To quiet; to put in a state of peace.—By his counsel he *appeaseth* the deep, and planteth islands therein. *Ecclus.* xliii. 23.—To pacify; to reconcile; to still wrath.—So Simon was *appeased* towards them, and fought no more against them. 1 Mac. xiii. 47.

O God! if my deep prayers cannot *appease* thee,
Yet execute thy wrath on me alone. *Shakespeare.*

The rest shall hear me call, and oft be warn'd
Their sinful state, and to *appease* betimes
Th' incensed Deity.

Milton.

APPEASEMENT, f. A state of peace.—Being neither in numbers nor in courage great, partly by authority, partly by entreaty, they were reduced to some good *appeasements*. *Hayward*.

APPEAS'ER, f. He that pacifies others; he that quiets disturbances.

APPEL'LANT, f. [*appello*, Lat. to call.] A challenger; one that summons another to answer either in the lists or in a court of justice:

These shifts refuted, answer thy *appellant*,
Though by his blindness maim'd for high attempts,
Who now defies thee thrice to single fight. *Milton.*

One that appeals from a lower to a higher power.—An appeal transfers the cognizance of the cause to the superior judge; so that, pending the appeal, nothing can be attempted in prejudice of the *appellant*. *Ayliffe*.

APPEL'LATE, f. [*appellatus*, Lat.] The person appealed against.—An appellatory libel ought to contain the name of the party appellant; the name of him from whose sentence it is appealed; the name of him to whom it is appealed; from what sentence it is appealed; the day of the sentence pronounced, and appeal interposed; and the name of the party *appellee*, or person against whom the appeal is lodged. *Ayliffe*.

APPELLA'TION, f. [*appellatio*, Lat.] Name; word by which any thing is called.—Good and evil commonly operate upon the mind of man, by respective names or *appellations*, by which they are notified and conveyed to the mind. *South*.

APPEL'LATIVE, f. [*appellativum*, Lat.] Words and names are either common or proper. Common names are such as stand for universal ideas, or a whole rank of beings, whether general or special. These are called *appellatives*. So fish, bird, man, city, river, are common names; and so are trout, eel, lobster; for they all agree to many individuals, and some to many species. *Watts*.

APPEL'LATIVELY, adv. According to the manner of nouns appellative; as, This man is a Hercules. *Hercules* is used *appellatively* to signify a strong man.

APPEL'LATORY, adj. That which contains an appeal.

APPELLE'E,

APPELLE'E, f. One who is appealed against, and accused.

To APPEND, v. a. [*appendo*, Lat. to hang to any thing.] To hang any thing upon another; as, The inscription was *appended* to the column: the seal is *appended* to the record. To add to something, as an accessory, not a principal part.

APPENDAGE, f. [French.] Something added to another thing, without being necessary to its essence, as a portico to the house.—Modesty is the *appendage* of sobriety, and is to chastity, to temperance, and to humility, as the fringes are to a garment. *Taylor*.

APPENDANT, adj. [French.] Hanging to something else. Belonging to; annexed; concomitant.—Riches multiplied beyond the proportion of our character, and the wants *appendant* to it, naturally dispose men to forget God. *Rogers*.

APPENDANT, f. That which belongs to another thing, as an accidental or adventitious part.—A word, a look, a tread, will strike, as they are *appendants* to external symmetry, or indications of the beauty of the mind. *Grew*.

APPENDANT, [from *appendens*, Lat.] in law, is a thing of inheritance belonging to another that is more worthy. As an advowson may be appendant to a manor, land appendant to an office, a seat in a church appendant to an house. 1 *Inst.* 121. So there is common appendant; which differs from common appurtenant. Common appendant is a right belonging to the owners or occupiers of arable land, to put commonable beasts upon the lord's waste, and upon the lands of other persons within the same manor. Common appurtenant arises from no connexion of tenure, but may be annexed to lands in other lordships, or extended to other beasts besides such as are generally commonable, as to hogs, goats, and the like. 2 *Blackst.* 33. If a thing appendant to another be granted by itself, without the thing to which it is appendant, the appendancy is destroyed, and that which was appendant is become in gross: as if an advowson appendant be granted without the manor to which it is appendant; or the manor be granted, saving the advowson.

To APPENDICATE, v. a. [from *appendo*, Lat.] To add to another thing.—In a palace there is the case or fabric of the structure, and there are certain additions; as, various furniture, and curious notions of divers things *appendicated* to it. *Hale*.

APPENDICATION, f. Adjunct; appendage; annexion.—There are considerable parts and integrals, and *appendications*, unto the *mundus aspectabilis*, impossible to be eternal. *Hale*.

APPENDITIA, in law, the appendages or pertinencies of an estate. Hence the word *penthouse*, for the appendage of an house.

APPENDIX, f. [*appendices*, plur. Lat.] Something appended or added to another thing.—Normandy became an *appendix* to England, the nobler dominion, and received a greater conformity of their laws to the English, than they gave to it. *Hale*. An adjunct or concomitant.—All concurrent *appendices* of the action ought to be surveyed, in order to pronounce with truth concerning it. *Watts*.

To APPERTA'IN, v. n. [*appartenir*, Fr.] To belong to as of right: with *to*.—The honour of devising this doctrine, that religion ought to be enforced by the sword, would be found *appertaining* to Mahomed the false prophet. *Raleigh*.

The Father, & whom in heav'n supreme Kingdom, and power, and glory, *appertains*, Hath honour'd me, according to his will. *Milton*.

To belong to by nature or appointment.—If the soul of man did serve only to give him being in this life, then things *appertaining* to this life would content him, as we see they do other creatures. *Hooker*.

APPERTAINMENT, f. That which belongs to any rank or dignity.

APPERTENANCE, f. [*appartenance*, Fr.] That which belongs or relates to another thing.—Can they which be-

hold the controversy of divinity condemn our enquiries in the doubtful *appertenances* of arts, and receptaries of philosophy. *Brown*.

APPER'TINENT, adj. Belonging; relating.

You know how apt our love was to accord

To furnish him with all *appertinents*

Belonging to his honour.

Shakespeare.

APPETENCE, or AP'PETENCY, f. [*appetentia*, Lat.] Carnal desire; sensual appetite.

Bred only and completed to the taste

Of lustful *appetence*; to sing or dance,

To dress, to trouble the tongue, and roll the eye. *Milton*.

APPETIBILITY, f. The quality of being desirable.—That elicitation which the schools intend, is a deducing of the power of the will into act, merely from the *appetibility* of the object, as a man draws a child after him with the sight of a green bough. *Bramhall*.

APPETIBLE, adj. [*appetibilis*, Lat.] Desirable; that which may be the object of appetite.—Power both to slight the most *appetible* objects, and to controul the most unruly passions. *Bramhall*.

APPEN'SA, amulets, or things hanging about the necks of diseased persons, to free them from some distemper, as a dried toad to stop bleeding, &c.

APPETITE, f. [*appetitus*, Lat.] The natural desire of good; the instinct by which we are led to seek pleasure.—The will properly and strictly taken, as it is of things which are referred unto the end that man desireth, differeth greatly from that inferior natural desire which we call *appetite*. The object of *appetite* is whatsoever sensible good may be wished for: the object of will is that good which reason does lead us to seek. *Hooker*. The desire of sensual pleasure:

Why, she would hang on him,

As if increase of *appetite* had grown

By what it fed on.

Shakespeare.

Violent longing; eagerness after any thing.—Hopton had an extraordinary *appetite* to engage Waller in a battle. *Clarendon*. The thing eagerly desired.—Power being the natural *appetite* of princes, a limited monarch cannot gratify it. *Swiss*. Keenness of stomach; hunger; desire of food.—There be four principal causes of *appetite*; the refrigeration of the stomach, joined with some dryness: contraction; velleitation, and absterfion; besides hunger, which is an emptiness. *Bacon*. It has sometimes of before the object of desire.—The new officer's nature needed some restraint to his immoderate *appetite* of power. *Clarendon*. Sometimes *to*.—We have generally such an *appetite* to praise, that we greedily suck it in.

Appetites are passions directed to general objects, in contradistinction to passions directed to particular objects, which retain their proper name. Thus we say, an *appetite* for fame, for glory, for conquest, for riches; but we say the *passion* of love, of gratitude, of envy, &c. Appetite may be also distinguished from passion, since the latter has no existence till a proper object be presented: whereas the former exists first, and then is directed to an object. "A good *appetite* needs no sauce." Fr. *A bon appetit il ne faut point de sauce*. The Latins say, *Optimum cibi condimentum fames*. The Germans, *Hunger ist de ver best loch*. (Hunger is the best sauce or cook.) The meaning is, that a good appetite makes our food go down more favourably than the best sauces without it, and, where the former is, the latter ought to be avoided, as very destructive to our constitution.

APPETITION, f. [*appetitus*, Lat.] Desire.—We find in animals an estimative or judicial faculty, and *appetition* or averfation. *Hale*.

APPETITIVE, adj. [from *appetite*.] That which desires; that which has the quality of desiring.—The will is not a bare *appetitive* power, as that of the sensual appetite; but is a rational appetite. *Hale*.

APPIA VIA, or **APPIAN WAY**, an ancient paved highway of Italy. It began within the city of Rome, at the place where Constantine's triumphal arch is erected. The first projector of it, Appius Claudius Cæcus, at an immense expence from the public treasury, carried it as far as Capua; Julius Cæsar, from Capua to Benevento; and Augustus thence to Brundisium. The Appian Way, a great part of which remains entire till this day, was 350 miles in length, and about 15 feet in breadth. Caius Græchus placed stones along it, called cippi, for travellers to sit and rest on, and riders to mount at, who, in those days, had no stirrups; also mile-stones, called millaria, or lapides. It was laid with very hard stone, and was so wide, that several waggons could go abreast. Statius calls it *the queen of roads*. Its course is described by Horace, Strabo, and Antonine.

APPIADES, a name given to these five deities, Venus, Pallas, Vesta, Concord, and Peace; because they had a temple near the Appian waters, at Rome.

APPIAN, an eminent writer of the Roman history in Greek, under the reign of Trajan and Adrian. He was of a good family at Alexandria in Egypt; whence he went to Rome, and there distinguished himself so well as an advocate, that he was chosen one of the procurators of the empire, and the government of a province was committed to him. He did not complete the Roman history in a continued series; but wrote distinct histories of all nations that had been conquered by the Romans, in which he placed every thing relating to those nations in the proper order of time. His style is plain and simple: in the opinion of Phocius, he manifested the greatest knowledge of military affairs, and the happiest talent at describing them; for, while we read him, we in a manner see the battles he describes. Of all this voluminous work there remains only what treats of the Punic, Syrian, Parthian, Mithridatic, and Spanish, wars, with those against Hannibal, the civil wars, and the wars in Illyricum, and some fragments of the Celtic or Gallic wars.

APPIUS CLAUDIUS, a Sabine by birth, one of the principal inhabitants of Regillum. His shining merit having drawn the envy of his fellow-citizens upon him, he retired to Rome with all his family. Appius was admitted into the senate, and was made consul, with Publius Servilius Priscus, in 258 from the building of Rome: but he was hated by the plebeians, being an austere opposer of their clamours and seditions. The Claudian family continued long one of the most illustrious of the patrician families in Rome; and several in succession of the name of Appius supported the same stern character that distinguished their first founder.

To **APPLAUD**, *v. a.* [*applaudo*, Lat.] To praise by clapping the hands. To praise in general.

Nations unborn your mighty names shall sound,
And worlds *applaud* that must not yet be found. *Pope.*

APPLAUD'ER, *f.* [from *applaud*.] He that praises or commends.

APPLAU'SE, *f.* [*applausus*, Lat.] Approbation loudly expressed; praise: properly a clap with the hands, &c.

See their wide-streaming wounds; they neither came
For pride of empire, nor desire of fame;
Kings fight for kingdoms, madmen for *applause*,
But love for love alone, that crown the lover's cause. *Dryd.*

APPLAUSE, in antiquity, differed from *acclamation*, as the latter was articulate and performed with the voice, the former with the hands. Among the Romans, applause was an artificial musical kind of noise, made by the audience or spectators to express their satisfaction. There were three species of applause, viz. *Bembus*, *Imbrices*, and *Testæ*; the first a confused din, made either by the hands or the mouth; the second and third, by beating on a sort of sounding vessels placed in the theatres for this purpose. Persons were instructed to give applause with skill, and there were even masters who professed to teach the art.

VOL. I. No. 52.

The proficients in this way let themselves out for hire to the vain-glorious among the poets, actors, &c. on purpose to support a loud applause. These they called *Laudicani*, and *Σοφοκλεις*. At the end of the play, a loud peal of applause was expected, and even asked of the audience, either by the chorus or the person who spoke last. The formula was, *Spectatores plaudite*, or *Valite et plaudite*. The *plausores*, or applauders, were divided into chori, and disposed opposite to each other, like the choristers in cathedrals, so that there was a kind of concert of applauds.

APPLE, CUSTARD, *f.* in botany. See **ANNONA**.

APPLE of the EYE, a name not unfrequently given to the pupil.—He kept him as the *apple of his eye*. Deut. xxxii. 10.

APPLE, LOVE. See **SOLANUM**.

APPLE, MAD. See **SOLANUM**.

APPLE, PINE. See **BROMELIA**.

APPLE, PURPLE. See **ANNONA**.

APPLE, SOUR. See **ANNONA**.

APPLE, THORN. See **DATURA**.

APPLE-TREE. See **PYRUS**.

APPLE, WATER. See **ANNONA**.

APPLEBY, [called by the Romans *Ahallaba*,] is the county town of Westmoreland, and where the assizes are held. It was formerly of great extent; but, a great part of it having been destroyed by the Scots, it is now reduced to a small, but pleasant, town; it consists principally of one street, running about 40 yards wide, with three narrow streets running from it. The market is kept on Saturdays, and is generally well supplied, and very reasonable; fish are scarce, (being so far from the sea,) except trout, which are caught in great plenty in the river Eden, which runs close by the town, and divides the London road from it. The fairs are on Whitfun-eve, Whit-Monday, June 10, and August 10. It is the only borough in Westmoreland, and sends two members to parliament: it is a town-corporate, consisting of a mayor, recorder, 12 aldermen, 16 common council, two chamberlains, two serjeants, and two beades. Here is an excellent free-grammar-school, founded in the year 1507; the standing salary 120*l*. The church, which is very ancient, is dedicated to St. Lawrence, in the diocese of Carlisle. At the upper end of the town is the castle, formerly belonging to the countess of Pembroke, but now to the earl of Thanet. The steep, on whose brow this noble edifice is erected, is richly clothed with wood; save only where a rugged cliff of a red hue breaks through the trees, and gives an agreeable variety to the landscape. The front of the castle is irregular and antique. Over its front, the top of a fine square tower is discovered, whose corners rise in turrets; the landscape to the left is richly wooded: to the right it is divided by hanging gardens, which adjoin the town, overtopped with dwellings. The prospect from the terrace, which is under the eastern front of the castle, is very beautiful. To the right, the river Eden forms a winding lake, whose banks are clothed with lofty hanging woods, descending in a swift, but regular, sweep, to the brink of the stream. On the left, lofty cliffs and precipices arise perpendicular from the water, over whose brows, oaks and ashes hanging, render their aspect more romantic by the solemn shade. On the ground above, the public road leading to Appleby winds up the hill, on whose side some cottages are scattered; whilst all behind the distant ground is formed by mountains, shadowed with clouds. Here is an hospital for 13 poor widows, endowed by the countess of Pembroke.

APPLEDORE, a small town in Kent, situated on the south side of the county, nine miles from New Romney, and 54 from London, in the direct road to Tenterden, on the banks of the river Rother. It had anciently a market, which has long been disused, but has a fair in July. Here is a court-leet, which extends itself over Town-borough and Horse-borough. It is said, the sea formerly flowed up as far as this town.

APPLI'ABLE, *adj.* That which may be applied. For this word the moderns use *applicable*; which see.

APPLI'ANCE, *f.* The act of applying; the thing applied:

Diseases desperate grown
By desperate *appli'ance* are reliev'd. *Shakespeare.*

APPLICABILITY, *f.* The quality of being fit to be applied to something.—The action of cold is composed of two parts; the one pressing, the other penetration, which require *applicability*. *Digby.*

APPLICABLE, *adj.* That which may be applied, as properly relating to something.—What he says of the portrait of any particular person, is *applicable* to poetry. In the character, there is a better or a worse likeness; the better is a panegyric, and the worse a libel. *Dryden.*

APPLICABLENESS, *f.* Fitness to be applied.—The knowledge of faults may possibly, by that little part which we have already delivered of its *applicableness*, be of use in natural philosophy. *Boyle.*

APPLICABLY, *adv.* In such a manner as that it may be properly applied.

APPLICATE, *f.* A right line drawn across a curve, so as to bisect the diameter thereof.

APPLICATION, *f.* The act of applying any thing to another; as, he mitigated his pain by the *application* of emollients. The thing applied; as, he invented a new *application*, by which blood might be stanch'd. The act of applying to any person, as a solicitor or petitioner. The employment of means for a certain end.—If a right course be taken with children, there will not be much need of the *application* of the common rewards and punishments. *Locke.*—Intenseness of thought; close study.—I have discovered no other way to keep our thoughts close to their business, but by frequent attention and *application*, getting the habit of attention and *application*. *Locke.* Attention to some particular affair: with the particle *to*.—His continued *application* to such public affairs, as may benefit his kingdoms, diverts him from pleasures. *Addison.* Reference to some case or position; as The story was told, and the hearers made the *application*.

APPLICATION, in geometry, is used for the act or supposition of putting or placing one figure upon another, to find whether they be equal or unequal; which seems to be the primary way in which the mind first acquires both the idea and proof of equality. And in this way Euclid, and other geometers, demonstrate some of the first or leading properties in geometry. Thus, if two triangles have two sides in the one triangle equal to two sides in the other, and also the angle included by the same sides equal to each other; then are the two triangles equal in all respects: for, by conceiving the one triangle placed on the other, it is proved that they coincide or exactly agree in all their parts. And the same happens if, of two triangles, one side and the two adjacent angles of the one triangle, are equal, respectively, to one side and the two corresponding angles of the other. Thus also may be proved that the diameter of a circle divides it into two equal parts, as also that the diagonal of a square or parallelogram bisects or divides it into two equal parts.

APPLICATION, in astrology, the approaching of two planets to each other.

APPLICATION of one science to another, as of algebra to geometry, is said of the use made of the principles and properties of the one for augmenting and perfecting the other. Indeed all arts and sciences mutually receive aid from each other. But the application here meant, is of a more express and immediate nature. The first and principal applications of algebra were to arithmetical questions and computations, as being the first and most useful science in all the concerns of human life. Afterwards algebra was applied to geometry and all the other sciences in their turn.

APPLICATIVE, *adj.* That which applies.—The directive command for counsel is in the understanding, and the *applicative* command for putting in execution is in the will. *Bramhall.*

APPLICATORY, *adj.* That which comprehends the act of application.

APPLICATORY, *f.* That which applies.

To APPLY, *v. a.* [*applico*, Lat.] To put one thing to another.—He said, and to the sword his throat *applied*. *Dryden.* To lay medicaments upon a wound.—God has addressed every passion of our nature, *applied* remedies to every weakness, warned us of every enemy. *Rogers.* To make use of as relative or suitable to something.—This brought the death of your father into remembrance, and I repeated the verses which I formerly *applied* to him. *Dryden.* To put to a certain use.—The profits thereof might be *applied* towards the support of the year. *Clarendon.* To use as means to an end.—These glorious beings are instruments in the hand of God, who *applies* their services, and governs their actions, and disposes even their wills and affections. *Rogers.* To fix the mind upon; to study: with *to*. *Locke* uses *about*, less properly.—Every man is conscious to himself that he thinks; and that which his mind is *applied about*, whilst thinking, is the ideas that are there. *Locke.*—To have recourse to, as a solicitor or petitioner; with *to*: as, I *applied* myself to him for help. To address to:

Sacred vows and mystic song *apply'd*,
To grisly Pluto and his gloomy bride.

Pope.

To busy; to keep at work: an antiquated sense; for which we now use *ply*. To act upon; to ply.

To APPLY, *v. n.* To suit; to agree. To have recourse to, as a petitioner. To attach by way of influence.—God knows every faculty and passion, and in what manner they can be most successfully *applied*. *Rogers.*

APPOGIATU'RA, in music, a small note inserted by the practical musician, between two others, at some distance.

To APPOINT, *v. a.* [*appointer*, Fr.] To fix any thing, as to settle the exact time for some transaction.—Now there was an *appointed* sign between the men of Israel and the liars in wait. *Judges*, xx. 38. To establish any thing by decree.—It was before the Lord, which chose me before thy father, and before all his house, to *appoint* me ruler over the people of the Lord. *2 Sam.* vi. 21. To furnish in all points; to equip; to supply with all things necessary: used anciently in speaking of soldiers.—The English, being well *appointed*, did so entertain them, that their ships departed terribly torn. *Hayward.*

APPOINTEE, a foot-soldier, formerly in the French army, &c. who for his long service and bravery received pay above a private sentinel. Till the year 1670, they had also captains and lieutenants under the appellation of *appointees*, who, without residing in the regiment, received pay.

APPOINTEE, in heraldry, the same as *aguisee*: Thus we say, a cross *appointee*, to signify that with two angles at the end cut off, so as to terminate in points.

APPOINT'ER, *f.* He that settles or fixes any thing or place.

APPOINTMENT, *f.* [*appointment*, Fr.] Stipulation; the act of fixing something in which two or more are concerned. Decree; establishment.—The ways of death be only in his hands, who alone hath power over all flesh, and unto whose *appointment* we ought with patience meekly to submit ourselves. *Hooker.* Direction; order. Equipment; furniture:

Here art thou in *appointment* fresh and fair,
Anticipating time with starting courage. *Shakespeare.*

An allowance paid to any man, commonly used of allowances to public officers.

To APPORTION, *v. a.* [from *portio*, Lat.] To let out in just portions.—An office cannot be *apportioned* out like a common, and shared among distinct proprietors. *Collier.*

APPOR'TIONMENT, *f.* in law, signifies a division or partition of a rent, a common, or the like; that is, a making of it into parts or portions. If a man hath a rent-charge to him and his heirs issuing out of certain land, if he purchase any parcel of this to him and his heirs, all the rent-charge is extinct, because the rent is intire, and issuing out of every part of the land, and therefore,

fore, by purchase of part, it is extinct in the whole, and cannot be apportioned. *Lit.* 222. But if a man, which hath a rent service, purchase parcel of the land out of which the rent is issuing, this shall not extinguish all, but only the parcel. For a rent-service in such case may be apportioned according to the value of the land. *Id.* But if one holdeth his land of his lord by the service to render to his lord yearly at such a feast a horse, a spear, a rose, and such like; if in this case the lord purchase parcel of the land, such service is taken away, because such service cannot be severed nor apportioned. *Id.* If the tenant holdeth by fealty, and a bushel of wheat, or a pound of cummin, or of pepper, or such like, and the lord purchases part of the land, there shall be an apportionment, as well as if the rent were in money: and yet, if the rent were by one grain of wheat, or one seed of cummin, or one pepper corn; by the purchase of part, the whole shall be extinct. 1 *Inst.* 149. But if an entire service be for the public good, as castle-guard, cornage, and the like, or if it be for defence of the realm, or to repair a bridge or a way, or to keep a beacon, or for advancement of justice and peace, as to attend the sheriff in the execution of process; though the lord purchase part, the service remains. *Id.*

If a man hath common of pasture without number in twenty acres of land, and ten of those acres descend to another person, the common without number is intire and uncertain, and cannot be apportioned, but shall remain. But if it had been a common certain (as for ten beasts), in that case the common should be apportioned. And so it is of common of estovers, turbary, fishery, and the like. *Id.* But apportionment of rent or common is usually settled by covenant or special agreement.

APPOR'TUM, [*apport*, Fr.] signifies properly the revenue or profit which a thing brings in to the owner. It was commonly used for a corody or pension. It was also applied to the payment made by the alien priories here in England to the superior house abroad; or sometimes it was what remained over and above the sustenance of such alien priory.

APPO'SAL of sheriffs, is the charging them with money received upon their account in the exchequer.

To APPOSE, *v. a.* [*appono*, Lat.] To put questions to. This word is not now in use, except that, in some schools, to put grammatical questions to a boy is called to *pose* him; and we now use *pose* for puzzle. A Latinism. To apply to.—By malignant putrid vapours, the nutriment is rendered unapt of being *apposed* to the parts. *Harvey.*

APPO'SER, *f.* an examiner. In the court of exchequer, there is an officer called the *foreign apposer*. In the office of confirmation, in the first liturgy of Edward VI. the rubric directs the bishop, or such as he shall appoint, to appose a child; and a bishop's examining chaplain was anciently called his *posser*.

APPOSITE, *adj.* [*appositus*, Lat.] Proper; fit; well adapted to time, place, or circumstances.—The duke's delivery of his mind was not so sharp, as solid and grave, and *apposite* to the times and occasions. *Wotton.*

APPOSITELY, *adv.* Properly; fitly; suitably.—When we come into a government, and see this place of honour allotted to a murderer, another filled with an atheist or blasphemer, may we not *appositely* and properly ask, Whether there be any virtue, sobriety, or religion, among such a people? *South.*

APPOSITENESS, *f.* Fitness; propriety; suitability.—Judgment is either concerning things to be known, or of things done, of their congruity, fitness, rightness, *appositeness*. *Hale.*

APPOSITION, *f.* [*appositio*, Lat.] The addition of new matter, so as that it may touch the first mass.—Urine, inspected with a microscope, will discover a black sand; wherever this sand sticks, it grows still bigger, by the *apposition* of new matter. *Arbuthnot.* In grammar, the putting of two nouns in the same case; as *Liber Susanna matris*, the book of his mother Susan.

To APPRA'ISE, *v. a.* [*apprecier*, Fr.] To set a price upon any thing, in order to sale.

APPRAISER, *f.* A person appointed to set a price upon things to be sold. They are usually called *sworn appraisers*, from their taking an oath to do justice between party and party.

APPRAISEMENT, in law, see INVENTORY.

To APPREHEND', *v. a.* [*apprehendo*, Lat.] To take hold of. To lay hold on.—There is nothing but hath a double handle, or at least we have two hands to *apprehend* it. *Taylor.* To seize in order for trial or punishment.—It was the rabble, of which no body was named; and not one *apprehended*. *Clarendon.* To conceive by the mind.—The First Being is invisible and incorruptible, and can only be *apprehended* by our minds. *Stillingfleet.* To think on with terror; to fear.—From my grandfather's death I had reason to *apprehend* the stone; and from my father's life, the gout. *Temple.*

APPREHENDER, *f.* Conceiver; thinker.—Gross *apprehenders* may not think it any more strange, than that a bullet should be moved by the rarefied fire. *Glanville.*

APPREHENSIBLE, *adj.* That which may be apprehended, or conceived.—The north and southern poles are incommunicable and fixed points, whereof the one is not *apprehensible* in the other. *Brown.*

APPREHENSION, *f.* [*apprehensio*, Lat.] The mere contemplation of things, without affirming or denying any thing concerning them. So we think of a horse, high, swift, animal, time, matter, mind, death, &c.—Simple *apprehension* denotes no more than the soul's naked intellection of an object, without either composition or deduction. *Glanville.* Opinion; sentiments; conception.—To be false, and to be thought false, is all one in respect of men who act not according to truth, but *apprehension*. *South.* The faculty by which we conceive new ideas, or power of conceiving them:

I nam'd them as they pass'd, and understood
Their nature, with such knowledge God endu'd
My sudden *apprehension*.

Milton.

Fear.—After the death of his nephew Caligula, Claudius was in no small *apprehension* for his own life. *Addison.* Suspicion of something to happen, or be done.—That he might take away the *apprehension*, that he meant suddenly to depart, he sent out orders, which he was sure would come into the enemies hands, to two or three villages; that they should send portions of corn into Basinghouse. *Clarendon.* Seizure:

See that he be convey'd unto the Tower:
And go we brothers to the man that took him,
To question of his *apprehension*.

Shakespeare.

The power of seizing, catching, or holding.—A lobster hath the chely or great claw of one side longer than the other, but this is not their leg, but a part of *apprehension* whereby they seize upon their prey. *Brown.*

APPREHENSION, is painted as a young, sprightly, and active, damsel, clad in white, and in a listening posture, holding in one hand a camelion, and in the other a looking-glass. Youth denotes her aptness to apprehend and learn; in white because it is the ground of all colour; on tip-toe shews the readiness she is in to apprehend, learn, and understand; the glass, because the imprints on herself, and makes all she hears and sees her own.

APPREHENSIVE, *adj.* Quick to understand.—If conscience be naturally *apprehensive* and sagacious, certainly we should trust and rely upon the reports of it. *South.* Fearful.—The inhabitants of this country, when I passed through it, were extremely *apprehensive* of seeing it the seat of war. *Addison.* Perceptive feeling:

Thoughts, my tormentors, arm'd with deadly stings,
Mangle my *apprehensive* tend'rest parts.

Milton.

APPREHENSIVELY, *adv.* In an apprehensive manner.

APPRE-

APPREHENSIVENESS, *f.* The quality of being apprehensive.—Whereas the vowels are much more difficult to be taught, you will find, by falling upon them last, great help by the *apprehensiveness* already gained in learning the consonants. *Holder.*

APPRENTICE, *f.* [*apprentisse*, Fr. of *apprehendere*, Lat. to learn.] One who is bound by covenant to serve a tradesman or artificer a certain time, upon condition of the master's instructing him in his art or mystery. Apprentices are usually bound by deed *indented*, to serve their masters, and be maintained and instructed by them. 1 *Blackst.* 426. And hereby an infant is bound, though under age. Nevertheless they cannot bind themselves so as to intitle the master to an action of covenant, or other action, for departing the service, or other breaches of the indenture; therefore it is usual for the father or some friend of the apprentice to be bound with him for the faithful discharge of his office, according to the terms agreed on. 8 *Mod.* 190.

The churchwardens and overseers of the poor may bind any such poor children apprentices, whose parents they shall judge not able to maintain them; till such man child shall attain the age of twenty-one, and such woman child the age of twenty-one, or marriage. 43 *Eliz. c. 2.* 18 *Geo. III. c. 47.* Also they may, by the consent of two justices, bind out any boy, of the age of ten years, who shall be chargeable, or whose parents shall be chargeable, or who shall beg for alms, to be apprentice to the sea-service till he shall attain the age of 21 years. 2 & 3 *An. c. 6.*

A master may by law correct his apprentice, for negligence or other misbehaviour, so it be done with moderation. 1 *Blackst.* 428. Disputes between masters and apprentices are in most cases determinable before the justices of the peace.

Inticing an apprentice to depart from his master is not an offence for which an indictment will lie; but the party's remedy is by an action on the case, which he may well maintain. *Bur. Mansf.* 1306. An apprentice gains a settlement where he serves the last forty days of his time.

An apprenticeship, being a personal trust, becomes determined by the death of the master, unless there are special words in the indenture to the contrary. *Bur. Set. Cas.* 320. Persons, having served seven years as apprentices to any trade, have an exclusive right to set up that trade in any part of England, except where they are prohibited by the bye-laws or local privileges of divers corporations. And if a man shall in any town exercise a trade, without having served an apprenticeship for seven years, he shall forfeit 40s. a month. The whole law, with respect to apprentices, is as follows:

Who may take Apprentices.—Every person being an householder, and having and using half a plough-land in tillage, may take an apprentice above the age of ten years, and under eighteen, to serve in husbandry till twenty-one at the least, or till twenty-four, as the parties can agree. 5 *Eliz. c. 4. f. 25.*

Every person being an householder, and twenty-four years old at the least, dwelling in any city or town corporate, and exercising any art, mystery, or manual occupation, may retain the son of a freeman, not occupying husbandry, nor being a labourer, and inhabiting in the same, or in any other city or town corporate, to serve as an apprentice, after the custom and order of the city of London, for seven years at the least, so as such apprenticeship do not expire before the apprentice shall be twenty-four years of age. 5 *Eliz. c. 4. f. 26.* But no person dwelling in any city or town corporate, being a merchant, mercer, draper, goldsmith, ironmonger, embroiderer, or clothier, shall take any apprentice except he be his son, or else that the father and mother of such apprentices shall have an estate of inheritance or freehold of 40s. a year, to be certified under the hands and seals of three justices where the lands lie, to the mayor of that city or town corporate, and to be inrolled among the records there. *f. 27.* And the reason of this seems to be, for that such as are to be bound apprentices in towns corporate, if their parents be of a

competent livelihood, then their masters shall be not only better secured, but such apprentices also in likelihood shall have the better means to set up their trades after their times expired. And concerning such, whose parents have not 40s. a year, they are fitter to be bound apprentices to husbandry, and the like, in the country. *Dalt. c. 58.* But, by reason of the great alteration in the value of money since that time, this provision is become of little use; for an estate of 40s. a year then was equal to more than 10l. a year now. But the citizens of London and Norwich may take and have apprentices, as before this act. *f. 40.*

Every person being an householder, and twenty-four years old at the least, and not occupying husbandry, nor being a labourer, dwelling in any market-town not corporate, and exercising any art, mystery, or manual occupation, may have to apprentice the child or children of any other artificer, not occupying husbandry, nor being a labourer, inhabiting in the same or any other such market town in the same shire. 5 *Eliz. c. 4. f. 28.* But no person dwelling in any such market-town, being a merchant, mercer, draper, goldsmith, ironmonger, embroiderer, or clothier, shall take any apprentice except he be his son, or else that his father and mother shall have an estate of inheritance or freehold of 3l. a year, to be certified under the hands and seals of three justices of the shire where the lands lie, to the head officer of such market-town where such apprentice shall be taken, there to be inrolled of record. *f. 29.*

Any person using the art of a smith, wheelwright, ploughwright, millwright, carpenter, rough mason, plaisterer, sawyer, lineburner, brickmaker, bricklayer, tyler, slater, helier, tylemaker, linen-weaver, turner, cooper, miller, earthen-potter, woollen-weaver weaving household cloth only, fuller, otherwise called tucker or walker, burner of oare and woad ashes, thatcher or shingler, wheresoever he shall dwell, may take the son of any person as apprentice, albeit his parents have no land. 5 *Eliz. c. 4. f. 30.*

Every owner of a ship or vessel, and every householder exercising the trade of the seas by fishing or otherwise, and every gunner commonly called a cannoner, and every shipwright, may take apprentices for ten years or under; and every apprentice so taken, being above seven years of age, shall be by the same covenants bound, or ordered and used to all intents, according to the custom of London, so that the covenant or bond of apprenticeship be made by writing indented, and inrolled in the town where the apprentice shall be inhabiting, if it be a town corporate; if not, then in the next town corporate: for which inrollment shall be paid not above 12d. 5 *Eliz. c. 5. f. 12.*

Every person that shall have three apprentices in any the crafts of a clothmaker, fuller, sheerman, weaver, taylor, or shoemaker, shall keep one journeyman; and for every other apprentice above three, one other journeyman, on pain of 10l. half to the king, and half to him that shall sue in the sessions or other court of record; or, if it is in a town corporate, then to be applied as by the charter. 5 *Eliz. c. 4. f. 33.* No hatmaker shall have above two apprentices at one time, nor those for any less term than seven years, on pain of 5l. a month, half to the king, and half to him that shall sue in any court of record: but this not to extend to his own son, in his own house, so as he be bound by indenture for seven years, and his term not to expire before he be twenty-two years of age. 1 *Jac. c. 17. f. 3, 5.* Weavers of stuffs in Norfolk and Norwich, that shall employ two apprentices, shall also employ two journeymen; and no master shall have above two apprentices, or any week boy, to weave in the said trade; on pain of 5l. a month to the king. 13 and 14 *Car. II. c. 5. f. 18.*

Who are compellable to be bound Apprentices.—If any person shall be required by any householder using half a plough-land at least in tillage, to be an apprentice and to serve in husbandry, or in any other art, mystery, or science, before expressed, and shall refuse so to do, then on complaint of such housekeeper to one justice (or head officer) he shall send for the person refusing; and if he shall think the said person meet to serve, and such person refuse to be bound,

he may commit him to ward, there to remain until he be contented, and will be bound. 5 Eliz. c. 4. f. 35. But no person shall be bound to enter into any apprenticeship, other than such as be under the age of twenty-one years. Id. f. 46.

Although these laws are still in force, concerning the value of the parent's estate, and such like; yet, as they are become entirely obsolete, they had better be repealed. The restrictions were originally intended (as appears by the statute, 9 Hen. IV. c. 17.) for the encouragement of husbandry, by reason of the scarcity of labourers in ancient time. And this statute of the 5 Eliz. is only a re-enacting, as it were, of former statutes; and expresseth, that any person being a householder may take apprentice the son of any freeman, *not occupying husbandry, nor being a labourer.*

Of Binding.—No one can be bound an apprentice without deed. 1 *Salk.* 68. And, by the 5 Eliz. c. 4. it must be by deed *indented.* f. 25. M. 1 Geo. II. *Smith and Birch.* An action was brought against the defendant, for enticing away and detaining the plaintiff's apprentice, who had agreed by writing to serve for seven years. Upon evidence it appeared, that the style of the writing began, *This indenture, &c.* but in fact the parchment was not indented, but was a deed poll. On exception taken to the deed, it was insisted, that the young man was not an apprentice, because he was not bound by an indenture. An infant can be bound no other way than as the statute 5 Eliz. directs, which is by indenture, and nothing can make this good. The deed cannot now be indented, for that would be a forgery. Therefore unless the plaintiff shews the apprentice to be of full age at the time of signing such deed, he cannot be accounted his apprentice, and by consequence no action can lie for detaining the apprentice; neither can the plaintiff prove him to be his servant by his deed, for he has declared for an apprentice, and must prove him so to be. Therefore the plaintiff was nonsuited. 1 *Seff. Ca.* 222. But with respect to settlements, it is enacted by the 31 Geo. II. c. 11. that the apprentice may gain a settlement under such writing, although it shall not be indented. And an apprentice must be retained by the name of apprentice expressly, otherwise he is no apprentice though he be bound. *Dalt.* c. 58. And all indentures, covenants, promises, and bargains, for having or taking apprentices otherwise than by statute of 5 Eliz. shall be clearly void in the law to all intents and purposes; and every person that shall take any apprentice contrary to the said act shall forfeit *vol.* half to the king, and half to him that shall sue in the sessions, or other court of record; or, if it is in a town corporate, then to the use of such town as by the charter. 5 Eliz. c. 4. f. 41.

By the several stamp acts, the binding (except it be of parish apprentices) shall be on a 7s. stamp; and the same shall not be given in evidence in any court till it be stamped, and the duties paid. And by the 8 Anne, c. 9. beside the said stamps and duties, there shall be paid the duty of 6d. for every 20s. of every sum of 50l. or under; and the duty of 1s. for every 20s. of every sum above 50l. given with any apprentice; and proportionably for greater or lesser sums; to be paid by the master. f. 32. And where any thing, not being money, shall be given with such apprentice, the duties shall be answered for the value thereof. f. 45. But this shall not extend to any apprentice, put out at the common charge of any parish or township, or out of any public charity. f. 40. And the full sum shall be inserted in the indenture in words at length, and shall bear date on the day of the execution thereof; on pain that the master shall forfeit double, half to the king, and half with full costs to him that shall sue. f. 35. And no such indenture shall be given in evidence in any suit to be brought by any of the parties thereunto, unless such party, on whose behalf the same shall be given in evidence, do first make oath, that, to the best of his knowledge, the sum therein inserted was really and truly all that was directly or indirectly to be given with such apprentice. f. 43. The said indentures, within the bills, shall be

brought to the head office to be stamped with a stamp for that purpose, and the duties paid within one month after date. f. 36. And elsewhere shall be brought either to the head office within the bills, or to a collector of the stamp-duties out of the said limits, in two months after date, and the duties thereupon shall be paid, and the indenture stamped, if it be at the said head office; otherwise such collector shall indorse on the indenture a receipt for the duties in words at length, and subscribe his name thereto. f. 37. And, if it is within fifty miles of the limits of the bills of mortality, the indenture shall within three months after date, and elsewhere within six months, be brought to the head office to be stamped. f. 38. And all such indentures wherein shall not be inserted the full sum directly and indirectly given, or whereupon the duties shall not be paid, or which shall not be stamped within the time limited, shall be void, and not available in any court or place, or to any purpose whatsoever; and the apprentice shall be incapable of exercising the said trade. f. 39.

Moreover, by the 9 Anne, c. 21. If the master shall neglect to pay the duties within the time limited, he shall forfeit 50l. half to the king, and half with full costs to him who shall sue. f. 66. And by the 18 Geo. II. c. 22. If he shall neglect to pay the same as aforesaid, he shall, besides all other penalties, forfeit double duty. f. 23, 24. And by the 20 Geo. II. c. 45. If any master, having forfeited the double duty, shall pay the same, and tender the indenture to be stamped, within two years after the determination of the apprenticeship, and before suit hath been commenced for the penalties, the indenture shall be valid, and the penalties discharged. f. 5. And, if after the master shall have forfeited the double duty, the apprentice shall in the presence of, or by writing under his hand signed in the presence of, one witness, require his master to pay the same, and the master shall not do it in three months, and such apprentice shall at any time within two years after the determination of his apprenticeship, pay the double duty; he may in three months after such payment demand of his master double the sum contracted for in the indenture, and if not paid in three months after, may recover the same by action at law, with full costs. And the apprentice immediately after payment of the said double duties (if his apprenticeship shall not be then expired) and signifying by writing under his hand, that he desires to be discharged from his apprenticeship, shall be discharged accordingly, and shall have the same benefit of the time he hath served as he would have had in case he had been assigned, or turned over to a new master. f. 6, 7. And where any prosecution shall be commenced against the master for the penalties, if the apprentice shall pay the double duty at any time in two years after the end of his apprenticeship, he may thereupon exercise his trade, and the indenture shall be valid, and may be given in evidence. f. 8.

Finally, by the 5 Geo. III. c. 46. Every chamberlain and other proper officer of every city and corporate town, and company, where any clerk or apprentice or servant obtains his freedom by servitude, shall enter in a book to be kept for that purpose, the names of all such clerks, apprentices, and servants, as shall be put out within the jurisdiction of such city or town corporate, and also the names and places of abode of the masters or mistresses, and of the sums of money [but it is not said, or other things equivalent] given or contracted for, and the trade or profession which they are to learn; and the date of the indentures: on pain of 20l. half to the king, and half to him that shall sue in any court of record, with full costs. f. 18, 41. And all printed indentures shall have the following memorandum printed under the same; viz. *The indenture, covenant, article, or contract, must bear date the day it is executed; and what money or other thing is given or contracted for with the clerk or apprentice, must be inserted in words at length; and the duty paid to the stamp office, if in London, or within the weekly bills of mortality, within one month after the execution, and if in the country, and out of the said bills of mortality, within two months, to a distributor of the stamps, or his substitute; otherwise the indenture*

indenture will be void, the master or mistress forfeit 50*l.* and another penalty, and the apprentice be disabled to follow his trade, or to be made free. And if any printer, stationer, or other person, shall sell or cause to be sold any such indenture, without such memorandum being printed under the same, he shall forfeit 10*l.* in like manner. s. 19.

It seems clearly agreed, that by the common law infants, or persons under the age of twenty-one years, cannot bind themselves apprentices, in such a manner as to intitle their masters to an action of covenant, or other action, for departing the service, or other breaches of their indentures: which makes it necessary, according to the usual practice, to get some of their friends to be bound for the faithful discharge of their offices, according to the terms agreed on. *Bac. Abr.* Master and servant. But by the statute of 5 Eliz. c. 4. Forasmuch as there hath been some doubt, whether any person under twenty-one years of age, and bound to serve as an apprentice, in any other place than the city of London, shall be bound, accepted, and taken, as an apprentice; it is enacted, that every such person who shall be bound by indenture, to serve as an apprentice, in any art, science, occupation, or labour, according to this statute, albeit he be within the age of twenty-one years, shall be bound as amply to every intent, as if he were of full age at the time of making the indentures. s. 43, 43. But this is to be understood of a compulsion by the means prescribed by the statute; for although an infant may voluntarily bind himself apprentice, and if he continue apprentice for seven years, he may have the benefit to use his trade; yet neither at the common law, nor by any words of this statute, a covenant or obligation of an infant for his apprenticeship shall bind him, but, if he misbehave himself, the master may correct him in his service, or complain to a justice to have him punished, according to the statute. But no remedy lieth against an infant upon such covenant. *Co. Car.* 179.

T. 17 Geo. III. *K. and Evered.* Two justices committed Robert Collehall for running away from his master; the case was, he had been bound an apprentice when an infant for six years by indenture, and being now of age ran away, alleging afterwards that he did so with an intent to avoid the apprenticeship made when he was an infant, and to his prejudice: he had run away twice before. Two objections were taken; first, that the binding was only for six years, and the 5 Eliz. requires it to be for seven; the other was, that an infant could make no contract but such as was voidable, though for his benefit; and *K. v. St. Nicholas in Ipswich* was cited, where it was adjudged, that such an indenture was voidable by the parties; that in the present case, the apprentice had done every thing in his power to avoid the indenture, having left his master, and said he would live with him no longer. In answer thereto, it was insisted, that the apprentice who had submitted to the indenture as long as he had benefit from it, and till he had learned his trade, should not be permitted to desert his service as soon as he became useful in it; but that the contract at the time of its commencement, which was during infancy, (the time when almost all apprenticeships are entered into,) was beneficial to the infant, and might legally be made, and therefore could not be abandoned. L. Mansfield: it has been adjudged that an infant may bind himself for his own benefit, and it is settled in the case in 2 Str. 1066. S. C. that a binding for four years gives a settlement.—Aston J. Supposing the indentures voidable, I cannot conceive that the apprentice's running away can avoid them; had he served regularly, and during such service declared his intention to depart, it might have been different; here he would make use of his offence in order to avoid the punishment that attends it: but it is too late to do it before a justice when charged with a crime. Willes and Ashurst J. agreed. *Cal. Caf.* 26.

But if his father, or other person, doth covenant for him; such covenant shall bind the father, or such other person: as in the case of *Whitley and Loftus*, M. 10 Geo. II. In the indenture of apprenticeship, the father covenants

to pay the apprenticeship money; the son covenants to account for his master's goods; and, in the conclusion, the father and son each bind themselves for the true performance of all covenants and agreements therein. By the court: The end of binding the father was to answer wrongs done by the son, and he must answer for any; and the covenant that each did bind himself must be so, where the son is bound to perform the thing for which the covenant was made; and this clause is usually inserted, that the covenants may be taken distributively, to wit, that each of the covenantors should perform his part; and this makes the covenant of the son bind the father, who covenanted for him as well as for himself. 8 Mod. 190.

So in the case of *Branch and Ewington*, M. 21 Geo. III. On an action of covenant by the master against the father of the apprentice, the indenture was in the common form of the statute, the master covenanting to find the apprentice meat and lodging, the father to find him clothes and washing, and the apprentice that he would serve faithfully; and for the true performance of all and every the said covenants, each of the said parties bound himself to the other. The breach assigned was, that the apprentice had absented himself from the service. For the father it was contended, that the parties were only bound for the express covenants which they had severally entered into. That it would be absurd to construe the general words so as to render the father liable for breaches of such of the covenants as were to be performed only by the son. The same construction would render the father liable to the son, or the son to the father, for those which the master was to perform. In all covenants the intention is to govern. The master has other remedies besides an action of covenant against the apprentice if he absent himself: he may, by application to the justices, have him punished under the statute of Elizabeth; or, if he wants compensation for the loss of service, he may compel him to make it up by subsequent service under 6 Geo. III. c. 23. Lord Mansfield stopped the counsel who was to have argued on the other side, and said, nothing was clearer than that the father was bound for the performance of the covenants by the son. *Douglas*, 500.

And as an infant may be bound by indenture, so the apprenticeship may be determined by consent of all the parties concerned; which, in the case of parish poor children, includes the parish officers; in other cases, the father, (or guardian,) master, and infant. *Burr. Sett. Caf.* 362, 766: *K. v. Justices of Devonshire*. Where a master receives money of an apprentice of full age to vacate his indentures, the relation is dissolved, though the indentures remain uncanceled. T. 17 Geo. III. *K. v. Justices of Devonshire, Cal. Caf.* 32. But a covenant between the master and a third person, the infant not being party, maketh not an apprenticeship. 2 Salk. 479. If an apprentice is bound, it is not necessary to the validity of his indenture, that the master should sign a counterpart. T. 17 Geo. III. *Cal. Caf.* 31. This was the case of a poor apprentice.

Of binding Poor Apprentices.—The churchwardens and overseers, or the greater part of them, by the assent of two justices, (one of the *quorum*,) may bind any such children, whose parents they shall judge not able to maintain them, to be apprentices where they shall see convenient, till such man child shall come to the age of twenty-one, (18 Geo. III. c. 47.) and such woman child to the age of twenty-one or marriage; the same to be as effectual to all purposes, as if such child were of full age, and by indenture of covenant bound him or her self. 43 Eliz. c. 2. s. 5.

By the assent of two justices. T. 29 Geo. III. *K. v. Hamfall Ridware*. Anne Cradock was bound by indenture by the parish officers of Rudgeley apprentice to Susannah Cotton of the same place, who assigned her by deed to S. Walker of Hamfall Ridware, with whom she resided there under the indenture for more than forty days and until his death, when she was removed by two justices from Hamfall Ridware to Rudgeley. The indenture was separately assented to by two justices, by signing the same, but the two justices did not assent to or sign the same at the same time, or in the

the presence of each other. The sessions quashed the order of removal. Bearcroft and Sayer, in support of the order of sessions, admitted that wherever the magistrates are to exercise a judgment upon the subject, it is necessary they should meet, in order that their act may be the result of their joint opinion; as in making orders of removal, orders of filiation, and appointing of overseers; but contended that where the justices acted only *ministerially* as allowing a poor rate, they may act separately, and that the assent of the justices in the present case fell within the latter description. The words in 43 Eliz. c. 2. f. 1. by which the parish officers, *by and with the consent of two justices*, are directed to raise competent sums for the relief of the poor, are nearly similar to those in the fifth section of that act, on which the question arises. For the words in this clause are, "that it shall be lawful for the churchwardens and overseers, *by the assent of two justices*, to bind such children to be apprentices, &c." And as under the first clause the court said in *K. v. Justices of Dorchester*, "The two justices are necessary to sign the rate only by way of form;" so under the fifth clause they are not to exercise any discretion, it being left to the parish officers to judge of the propriety of binding out the apprentices. If indeed there be any difference between the penning of the two sections, it is rather in favour of the construction now contended for in this instance, namely, that the justices may assent to the indenture *separately*; for, as was said in *Billings v. Binn*, "Assent may be by individuals, *consent* by the body." And great inconveniences will ensue from determining this indenture to be void, because it will invalidate many indentures in different parts of the kingdom, that are now supposed to be binding; for, owing to the inconvenience of procuring a meeting of justices in many places, it has been found necessary to sign them separately.—*Leicester contra* was stopped by the court. L. Kenyon, Ch. J. Perhaps the rule requiring the concurrence of two magistrates at the same time, may be sometimes attended with inconvenience. But the rule has been long settled to be that the concurrence of justices together is not necessary where the act to be done is merely *ministerial*; but they must confer together and form a joint opinion, where the act is of a *judicial* nature. It has been held (whether rightly so or not we are not now to enquire), that the allowance of a poor rate is an act merely *ministerial*; and, that being once established, the consequence results that the two magistrates need not meet when they allow the rate. The words indeed of the section on which this question arises are nearly similar to those used in the first, under which the poor rate is to be allowed: but, when the nature of this case is considered, it appears to be one of the most serious subjects that fall within the decisions of the justices. For they are empowered by this act to take children out of the arms of their parents, and to bind them out as apprentices till they are twenty-one years of age. The law has made them the guardians for those children, who have no others to take care of them. And who ought to judge of the fitness of the persons, to whom the poor children are thus to be apprenticed? Not the overseers; they are frequently obscure people, and perhaps in managing the business of the parish are not always attentive to the feelings of parents. But the legislature intended that the magistrates should have a check and controul over the parish officers in this instance; and in my mind they are called upon to examine with the most minute and anxious attention the situations of the masters, to whom the apprentices are to be bound, and to exercise their judgment solemnly and soberly before they allow or disallow the act of the parish officers; for which purpose it is necessary that they should confer together.—*Ashhurst, J.* The act of the justices in this case is in its nature an act of judgment. They are the guardians of the morals of the people, and ought to take care that the apprentices are not placed with masters who may corrupt their morals. The justices therefore should enquire particularly whether or not they ought to allow the binding by the parish officers; and I

think they would be guilty of a breach of duty if they implicitly gave their assent without examining into the circumstances of the case.—*Buller, J.* It is not easily to be reconciled with any principle of common sense to say that an act, which is merely *ministerial*, must be done with the *consent of two justices*. And I much doubt whether the person who brought in the act (43 Eliz. c. 2.) requiring the consent of two magistrates to the allowance of a poor rate, intended that the act of allowing it should be only *ministerial*; for it seems absurd to require the assent of two justices, and yet not to give them the power of withholding it, if they see occasion. But the legislature has not given them any authority to exercise their judgment upon that subject; and therefore this court has said, on the construction of that statute, that their allowance of the rate is merely *ministerial*. But the act of assenting to the binding of parish apprentices is purely *judicial*; for, on appeal, the justices at the sessions are not only to consider the propriety of binding out the apprentice, but also whether the master be bound to take him.—*Grose, J.* This act is peculiarly of a judicial nature; for the magistrates are appointed the guardians of those who have no other guardians. They should therefore exercise their judgment in this case with great deliberation. Order of session quashed. *Durnf. and East, 3 V. 380.*

By the several stamp acts, the indenture must be on a sixpenny stamped piece of paper or parchment; but it is exempted from the additional stamps and duties for money given with the apprentice. And by 32 Geo. III. c. 57. after reciting, that in indentures of parish apprentices, it hath been usual to insert several agreements and covenants to be done and performed by the several parties thereto, and, amongst other things, that the master shall, during the term of such apprenticeship, find and allow to such apprentice, sufficient meat, drink, apparel, lodging, and all other things needful for an apprentice; it is enacted, that in all parish indentures which shall be made after 1st July 1792, where no more than 5l. shall be given with such apprentice, there shall be annexed to the covenant in such indentures for such maintenance as aforesaid, a proviso declaring, that such covenant shall not be made to continue and be in force longer than three calendar months next after the death of such master, in case he shall die during the term of such apprenticeship: and in case such proviso be omitted in such indenture, the covenant for maintenance shall be in force for no longer time than three calendar months next after the death of such master, any thing in any such covenant the contrary notwithstanding. f. 1. And, where any poor child shall be appointed to be bound apprentice by the 43 Eliz. the person to whom he is appointed to be bound shall receive and provide for him, and also execute the other part of the indentures; and if he shall refuse so to do, oath being thereof made by one of the churchwardens or overseers, before two justices, he shall forfeit 10l. by distress and sale, by warrant of such justices, to the use of the poor; saving always to the person to whom any poor child shall be appointed to be bound apprentice, if he shall think himself aggrieved thereby, his appeal to the next sessions, whose order therein shall be final. 8 and 9 Will. c. 30. f. 5. And, as the churchwardens and overseers have power to place out poor children, therefore they are proper judges of persons who are fit to be their masters; and those are, all persons, who by their profession or manner of living have occasion to keep servants; but the same are to be approved of by the justices, and, if such master is dissatisfied, he may appeal to the sessions. *Dalt. c. 58.*

T. 13 Will. *Minchamp's case.* Two justices bound an apprentice to a merchant; He appealed to the sessions, and the order was discharged. And now the court, in consideration of the matter, confirmed the order of sessions; because the act having made persons compellable to take apprentices, and given an appeal to the sessions, it was in the discretion of the justices at sessions to determine, whether it was or was not fitting to put an apprentice

upon any one; and therefore the court would not disturb what the sessions had done, but confirmed the order. 2 *Salk.* 491.

M. 12 Geo. III. K. and Botley. The parish officers of Botley appointed an apprentice to be bound to Edward Clowerley; who appealed to the sessions. The sessions discharge the appointment, and state the case specially: That it appears to them upon the evidence, that Edward Clowerley resides in the parish of Hound, but is owner and occupier of an estate in the parish of Botley, of the yearly value of 30*l.* upon which there is a house inhabited by a weekly labourer of the said Edward for the better managing the farm: that the said Edward did not reside or lodge in the said parish of Botley, but paid church and poor rates for the premises: that a very considerable part of the lands of Botley is occupied by persons residing in other parishes. In support of the order of sessions, it was contended, that the sessions have a discretionary power to judge of the fitness or unfitness of binding apprentices to particular persons, and having by their determination declared, that Clowerley ought to be relieved from the apprentice, they had determined the question, and the court could not entertain any question of law about it. It was suggested, that the only question agitated at the sessions and intended to be referred to this court was, whether occupiers of land, not living within the parish where the land lies, are bound by law to take apprentices. And it not appearing in the state of the case, whether the sessions had determined on the unfitness of that particular person, or on the point of law in general, of his not being liable in respect of his living out of the parish; *L. Mansfield* said that there was no coming at the point on that state of the case by the sessions; but he thought, if they had determined it on the latter ground, they had done very right. *Mr. J. Aston* was of the same opinion, and observed how hard it might be to bind an apprentice on a person occupying lands in one parish, and being a housekeeper in a very distant parish. *Mr. J. Willes* assented. And the rule for quashing the order of sessions was discharged, and the sessions order confirmed. *Bott.* 389. *Lofft.* 79.

H. 29 Geo. III. K. v. John Clapp. The parish officers of Sowton, Devon, having, with the assent of two justices, apprenticed Sarah Hellier, a poor child of Sowton, to the defendant according to the statute; he appealed to the sessions, who confirmed the order, subject to the opinion of the court on the following case.—The apprentice was bound (*prout* the indenture) to the appellant, who resided in the parish of Pinhoe, on an estate which he rented and occupied in the parish of Sowton of 20*l. per ann.* which was divided by the highway from the house in which he lived. There was no house on the estate of which he was the occupier. The indenture, together with the apprentice, was tendered to the appellant in the parish of Sowton, in the highway adjoining to the said estate lying in the parish of Sowton.—*East* argued in the support of the order of sessions: and *Fanshaw* and *Clapp contra.*—*L. Kenyon, Ch. J.* It is highly fit that this question should not remain any longer undecided. I remember a much older case than either of those mentioned at the bar, in which this question was discussed, but not decided. The question arises on the fifth section of 43 *Eliz. c. 2.* The general purview of that statute was to make a provision for the maintenance of the poor; and the first clause, in mentioning those who are to contribute to such maintenance, describes two sorts of persons, namely, *inhabitants* and *occupiers of lands, &c.* Amongst other provisions for the poor, the fifth section gives power to the parish officers, with the assent of two magistrates, to bind poor children apprentices *where they shall see convenient.* It is true indeed that those words cannot be taken so generally as they purport, because they cannot compel mere strangers, who stand in no relation to the parish, to take such apprentices. But I think that the context of the statute furnishes the means of circumscribing the general extent of those words; and that context I take from the first clause, which imposes other

burdens of the same nature on *occupiers of lands, &c.* as well as inhabitants. The general object of the act was to compel all those, who had any property in the parish, to contribute their due proportion towards the maintenance of the poor; and the receiving apprentices is one mode of contributing to their general relief. In construing these words, I see no reason for confining the power of binding to the *inhabitants* of the parish; they ought to be extended to persons *occupying lands in the parish, though residing out of it.* Then it is said that if this construction be put upon the statute, the party may be doubly charged; in the parish where he lives in respect of his inhabitancy; and in that in which he has lands, in respect of his occupation of them. But, if he find himself aggrieved, he may appeal to the sessions; and we must take it for granted that the justices will do what is right. They are to adapt the charge to the size of the property which the person charged possesses: and these are incidental charges which fall on him in respect of that property. I remember it was argued in a former case on this subject that, if this construction of the statute were to prevail, some parishes would disburthen themselves of many of their poor by apprenticing out their poor children to persons living out of the parish: but the answer to any such argument is that, at the time when the 43 *Eliz.* was passed, the 13 and 14 *Car. II.* was not in existence. However the ground of my decision here is, that this is one of the modes provided for the maintenance of the poor in this statute, which imposes the duty in respect of the property.—The other judges concurred. Order of sessions confirmed. *Dunf. and East,* 3 *V.* 107.

And by 32 *Geo. III. c. 57.* Where any parish apprentice shall have been discharged for misbehaviour in the master, and such master shall have been convicted of such offence on indictment, or action at law, the churchwardens and overseers shall not bind any other apprentice upon such person; but that, when he ought or would be compellable to take a parish apprentice, two justices, on application by such churchwardens and overseers, may order that such person shall pay into the hands of such churchwardens and overseers, any sum not exceeding 10*l.* nor less than 5*l.* for the purpose of binding out such child (intended to be bound) an apprentice, with the approbation of such justices; and on his refusing payment thereof, such justices may levy the same by distress, together with the reasonable expences of such distress. Provided that any such master, from whom any such apprentice shall be discharged by virtue of 20 *Geo. II. c. 19.* may appeal against such discharge, or order for the payment of any money in consequence thereof as aforesaid, or in lieu of a subsequent binding by virtue of this act, to the next sessions, who shall finally determine the same, and in their discretion allow to all parties their reasonable costs. And no such distress for enforcing the payment of such money last mentioned, shall be taken until after the next general quarter sessions next after such order shall be made, in case the person ordered to pay the same shall, within seven days after notice given to him of such order, give notice to such churchwardens and overseers or one of them, of such intended appeal; and if he shall not appear at such sessions in support of his appeal, then 40*s.* shall be added to the expences of distress before directed to be taken and levied accordingly. *f. 12.*

E. 13 Anne. Q. and Wagstaff. It was moved to quash an order to compel a person to take an apprentice, because in the close of the indenture it was said, that the master, at the end of the term, shall give his apprentice two suits of clothes. Upon debate, the court held this to be ill; for the justices during the term of his apprenticeship cannot order him wages, they must only order him a maintenance as an apprentice, and cannot order him any thing after the term is ended. So the order was quashed. *Foley* 205, 1 *Seff. C.* 43.

And by 32 *Geo. III. c. 57.* After reciting, that it frequently happens, that persons are compellable by 9 and 10 *Will.* to take a greater number of parish apprentices than it

it is convenient for them to maintain or employ in their own families, and are therefore forced to place out or assign over such apprentice to other persons, and it is proper that such assignment should be legally made, under the inspection and controul of the magistrates, as well for the benefit of the apprentice, as that the original master may be discharged from his covenants in respect of such apprentice; and it is fit that such apprentice and the person to whom he is so assigned, should be made subject to the ordinary jurisdiction of justices of the peace with respect to masters and parish apprentices; it is enacted, that any such master as aforesaid, by indorsement on the indenture, or by other instrument in writing, with the consent of two justices of the place where such master shall dwell, testified under their hands, to assign such apprentice for the residue of the term, to any person who is willing to take him. Provided, that such person shall, at the same time, by indorsement on the counter part of the indenture, or by writing under his hand stating the said indenture, and the indorsement and consent aforesaid, declare his acceptance of such apprentice, and acknowledge himself, his executors and administrators, to be bound by the agreements and covenants mentioned in such indenture; and in such case such apprentice shall be deemed and taken to be the apprentice of such subsequent master, and so from time to time as often as it shall be convenient for any such subsequent master to part with any such apprentice; and all justices shall have the like power with respect to such subsequent masters and apprentices as they shall then have by any law for the regulating parish apprentices. f. 7.

And whereas no express provision has been made for the discharge of any such parish apprentice from a master who is become insolvent, or so far reduced as to be unable to employ or maintain such apprentice; it shall be lawful for two justices where such master shall live, on request of such master that such apprentice may be discharged for the reasons aforesaid, to enquire into the matter of such allegations, and to discharge such apprentice, in case they shall find the same to be true. f. 8. Provided, that nothing herein shall extend to any parish apprentice with whom more than 5l. shall be given, but the same shall remain subject to the like rules and regulations as if this act had not been made. f. 9. Provided also, that no indorsement made in pursuance of this act, shall be chargeable with any stamp-duty; and no such other instrument or writing herein directed to be made, shall be chargeable with a higher stamp-duty than parish indentures of apprenticeship. f. 10.

In hundreds or other districts incorporated by particular acts of parliament for relief of the poor, where, by such acts, power is given to bind poor children apprentices; the respective persons, to whom they shall be appointed to be bound, shall receive and provide for them according to the indentures to be executed by the directors and acting guardians, and shall execute the counter part of such indentures; and if any person shall refuse to receive such apprentice, or to execute such counter part of the indenture; he shall, on conviction on the oath of one of the said directors or acting guardians, or other credible witnesses, before two justices, forfeit 10l. to the poor within such incorporated district, to be levied by distresses. Saving always to such person his appeal to the next sessions, whose order therein shall be final. And provided, that nothing herein shall extend to compel any person to take any such poor child apprentice, unless he be an inhabitant and occupier of lands in the parish to which such child belongs. 20 Geo. III. c. 36.

Unless he be an inhabitant and occupier. H. 30 Geo. III. K. against the directors and guardians of the poor within the hundreds of Tunstead and Happing in Norfolk. Incorporated by 25 Geo. III. c. 27. The directors, under the powers given them by that act, bound a poor male child apprentice to one Reynolds, who was an *occupier* of land, but not an *inhabitant*, within the said hundreds. He appealed to the sessions; who were of opinion that he was

not bound to receive the apprentice, because he was not an inhabitant as well as an occupier. But the court of K. B. said, that incorporated districts under particular statutes, were to be governed as to binding out apprentices, by the same rule as other places. That for some purposes, *inhabitants* and *occupiers* are synonymous terms; that where a person derives a benefit from property which he occupies in a parish, he is liable to contribute to the ease of it. If indeed the legislature had used imperative words, the court must have been bound by them, but there are none such in this statute. Order of sessions quashed. *Dunf. and East*, 3 V. 523.

Of Money given or bequeathed to bind out Poor Apprentices.—By the 7 Jac. c. 3. All money given by any person to be continually employed for the binding out apprentices, shall be employed in manner following, unless otherwise ordered by the givers; viz. All corporations of cities, boroughs, and towns corporate, and in places not corporate, the minister, constables, churchwardens, overseers, or the most part of them, shall have the nomination and placing of such apprentices, and ordering of such money; and, if they shall not employ the same accordingly, every person offending shall forfeit 3l. 6s. 8d. half to the poor, and half to him that shall sue. f. 2. And the master that shall receive the money, shall be bound with one or two sureties in double the sum, unto such corporation, or to the other persons appointed by this act in places not corporate, to take care of it, on condition to repay it at the end of seven years, or within three months thereof; and, if the apprentice shall happen to die within the seven years, then within one year after such death; and, if the master shall die, then within one year after such master's death. f. 3. And the said money shall always be put forth in three months after it shall come to the said parties hands; and, if there are not then fit persons to be bound apprentices, within the places where the money is given to be employed, it shall be disposed of for binding some of the poorest children of any adjoining parish. f. 4. And choice shall always be made of the poorest children; and no such apprentice shall be above fifteen years of age when bound. f. 5. And the said persons in places not corporate, shall yearly, within a month after Easter, account to their successors before two justices dwelling in or next to the place. f. 6. And if any of the trustees shall break their trust, or commit any offence for which no penalty is given by this act; any person may petition the lord-chancellor, who may issue a commission to hear and determine the same, and may levy the money misemployed upon such defaulters, or otherwise upon such able inhabitants of the place, as they shall think fittest; and persons aggrieved may appeal to the lord-chancellor. f. 7.

Of binding Poor Apprentices to the Sea-Service.—It shall be lawful for two justices, and for the head officers in corporations, and for the churchwardens and overseers of the several parishes or townships, with the consent of such justices or head officers, to bind and put out any boy at the age of ten years or upwards, or who shall be chargeable, or whose parents shall be chargeable, or who shall beg for alms, to be an apprentice to the sea-service, to any subject being master or owner of any ship or vessel, until he shall attain the age of twenty-one years. 2 and 3 Anne, c. 6. f. 1. And every person to whom any poor parish boy shall be put apprentice by the 43 Eliz. may, with the consent of two justices dwelling near the parish where such poor boy was bound, or with the like consent of the chief officer in a corporation, at the request of the master, his executors, administrators, or assigns, by indenture assign over such poor boy apprentice, to any master or owner of a ship or vessel using the sea-service, during the remaining time of his apprenticeship. f. 6. And every master or owner of a ship, from thirty to fifty tons burden, shall be obliged to take one such apprentice, and one more for the next fifty tons, and one more for every hundred tons such ship shall exceed the burden of an hundred tons; on pain of forfeiting 10l. to the poor of the parish from whence such boy was bound. f. 8. But no master shall be obliged

to take any such apprentice, under thirteen years of age, or who shall not appear to be fitly qualified both as to health and strength of body for that service. 4 Anne, c. 19. f. 16. The boy's age shall be inserted in the indenture, being truly taken from a copy of the entry in the register-book (where it can be had), which copy shall be given and attested by the minister without fee: and, where no such entry can be found, two such justices, and such head officers, shall as fully as they can inform themselves of such boy's age, and from such information shall insert the same in the indentures. 2 and 3 Anne, c. 6. f. 1. And the churchwardens and overseers shall pay down to the master, at the time of the binding, the sum of 50s. for clothing and bedding; and the charges by this act appointed shall be allowed on their accounts. 2 and 3 Anne, c. 6. f. 2.

The churchwardens and overseers shall send the indentures to the collector of the customs at the port whereunto the master belongeth; who shall enter the indenture in a book, and make an indorsement upon the indenture of the registry thereof, subscribed by him, without fee. And if he shall neglect or refuse to enter such indentures, and indorse the same, or make false entries, he shall forfeit 5l. to the poor of the parish from whence such boy was bound. 2 and 3 Anne, c. 6. f. 5. Such apprentice shall be conveyed to the port to which his master belongeth, by the churchwardens and overseers, or their agents; and the charges thereof shall be paid as by the vagrant act of 11 and 12 Will. 2 and 3 Anne, c. 6. f. 10. That is to say, out of the gaol and marshal's money; which, by the 12 Geo. II. c. 29. is directed to be paid out of the general county rate.

The counter part of the indenture shall be sealed and executed by the master, and attested by the collector of the port, and the constable or other officer who carries the apprentice; which officer shall transmit such counter part to the churchwardens and overseers of the place from whence the apprentice was bound. 2 and 3 Anne, c. 6. f. 11. And the collector or his deputy shall transmit a certificate under his hand, to the commissioners of the admiralty, containing the name and age of such apprentice, and to what ship he belongs; and on receipt of such certificate, a protection shall be made and given *gratis* to such apprentice, till he attain the age of eighteen years. Id. f. 5.

Also every person who shall voluntarily bind himself apprentice to the sea-service, shall not be impressed for three years from the date of his indentures; which indentures shall be registered, and certificates thereof given and transmitted by the collector as aforesaid; on receipt of which certificates, protections shall be made and given for the first three years without fee. Id. f. 15. But by 4 Anne, c. 19. No person of the age of eighteen years shall have any protection from being impressed, who shall have been in any sea-service before he bound himself apprentice. f. 17. But every person not having before used the sea, who shall bind himself apprentice to serve at sea, shall be exempted from being impressed for three years: and the commissioners of the admiralty, on due proof of the circumstances, shall grant a protection accordingly, without fee. 12 Geo. II. c. 17.

When such parish or voluntary apprentice shall be impressed, or voluntarily enter into the king's service, the owner or master, his executors, administrators, or assigns, shall be intitled to able seamen's wages for such of the apprentices as shall upon due examination be found qualified for the same, notwithstanding their indentures of apprenticeship. 2 and 3 Anne, c. 6. f. 17. Such poor boys bound out, or assigned over, to the sea service, until they shall attain to the age of eighteen years, shall be exempted from the payment of 6d. a month to Greenwich hospital. Id.

Every master so obliged to take such apprentice, shall after his arrival into any port aforesaid, and before he clears out of such port, give an account in writing under his hand, to the collector, containing the names and number of such apprentices as are there remaining in his service. f. 9. And every custom-house officer shall insert at

the bottom of their coquets, the number of men and boys on-board their respective ships at their going out, describing the apprentices by their names, ages, and dates of their indentures, for which no fee shall be taken. f. 14. And the collector in the port shall keep a register, containing the number and burden of all ships belonging to the port, together with the masters or owners names, and also the names of all such apprentices in such ships, and from what parishes and places they were sent; and shall transmit *gratis* true copies thereof signed by him, to the quarter sessions, or to such towns corporate, parishes, or places, when and so often as he shall be reasonably required so to do; and every collector refusing or neglecting to send such copy, shall forfeit 5l. to the poor of the parish from whence such boy was bound. f. 13.

Two justices near the port, and mayors of towns corporate, in or near adjoining to such port to which such ship or vessel shall at any time arrive, may determine all complaints of ill usage from the master to such apprentice, and also of all such as shall voluntarily put themselves apprentices to the sea-service, and make such order therein as they are now enabled by law to do in other cases between masters and apprentices. f. 12. All the penalties aforesaid shall, by warrant of two justices of the county, city, or town corporate, be levied by distress and sale. f. 18. If any master, who hath been obliged to take such parish boy an apprentice, shall die, during the term; his widow, or his executor or administrator, may assign over such apprentice to any other master who hath not his complement of apprentices. 4 Anne, c. 19. f. 16.

By the 2 Geo. III. c. 15. Masters, apprentices, mariners, and others, employed in fishing-vessels upon the coasts, are exempted, during such their employment, from being impressed. f. 22, 23, 24, 25.

Of Differences arising between the Master and Apprentice.—A master may by law correct and chastise his apprentice, for neglect or other misbehaviour, so it be done with moderation. The master may not of his own accord discharge his apprentice; but, if they cannot agree, they may proceed in one of these two ways: either upon the statute of the 5 Eliz. c. 4. or upon the statute of 20 Geo. II. c. 19.

By the 5 Eliz. c. 4. "If any such master shall misuse or evil intreat his apprentice, or the said apprentice shall have any just cause to complain, or the apprentice do not his duty to his master, then the said master or apprentice being grieved, and having cause to complain, shall repair unto one justice of the county, or to the mayor or other head officer of the city, town corporate, or market-town, or other place where the master dwelleth; who shall by his wisdom and discretion take such order and direction between the master and his apprentice as the equity of the cause shall require: and if, for want of good conformity in the master, the said justice (or head officer) cannot compound and agree the matter, he shall take bond of the said master to appear at the next sessions; and on his appearance, and hearing of the matter there, if it be thought meet to discharge the said apprentice, then the justices, or four of them at the least, (one of the quorum,) or the said mayor or other head officer, with the consent of three other of his brethren, or men of best reputation in such city, town corporate, or market-town, shall have power, in writing under their hands and seals, to pronounce and declare, that they have discharged the said apprentice of his apprenticeship, and the cause thereof: and the said writing, being enrolled by the clerk of the peace, or town-clerk, amongst the records, shall be a sufficient discharge for the apprentice against his master, his executors and administrators. And, if the default should be found to be in the apprentice, then the said justices, or the said mayor, or other head officer, with the assistance aforesaid, shall cause such due correction and punishment to be administered unto him, as by their wisdom and discretions shall be thought meet." f. 35.

If any such master. That is, any such master as is before mentioned in this statute, in the trades therein specified; and

and the former resolutions confined the sense of the statute to such trades only, but the latter adjudications seem to extend the equity thereof to other trades not mentioned in the statute; as in the following instances:

M. 7 Will. K. and *Gately*. On a certiorari it was moved to quash an order of sessions, for the discharge of one Edward Green from his apprenticeship to the defendant Gately. The fact was, that Gately was a mountebank, and being at a place in Yorkshire, where he kept a public stage, Green was by indenture bound apprentice to him in this manner, viz. to Robert Gately, surgeon, to learn the trade he now useth; and immediately he went upon the stage, and ever since continued in the employ. After which, being with his master Gately in Middlesex, he complained to the justices, that his master did not teach him the trade. Upon which they discharged him. This being done, Green set up the trade of mountebank himself. It was moved to quash the order, the justices being willing, because they were imposed upon. And the exception was, that the statute of the 5 Eliz. in discharging apprentices is confined, and extends only to apprentices mentioned in that clause, and there neither surgeon nor mountebank is mentioned: and though a surgeon may be a trade within the statute, which a man cannot exercise without serving an apprenticeship to, because that clause of the statute is general; yet this part of the statute, relating to the discharge of apprentices, extends only to trades there mentioned. By the court: The clause relating to the discharge of apprentices is general, and goes to all manner of apprentices, even to those of merchants; but afterwards the court were of opinion, that the power of discharging reaches only to the trades mentioned in the statute, among which a surgeon is not mentioned; for that, though as to the serving seven years apprenticeship, a surgeon comes under the general term of arts and mysteries, yet the power of discharging reaches only to the trades particularly mentioned. 2 *Salk.* 471, 2. And M. 12 Anne, Q. and *Furness*. It was held, that the statute extends only to the trades therein mentioned; and therefore not to a glass-bottle-maker. *Caf. of S.* 29. On the other hand, in the case of K. and *Collingbourn*, M. 12 Geo. Exception was taken to an order of discharge, that the justices could not discharge the apprentice, because the trade to which he was bound, viz. a glazier, was not within the statute: But not allowed; for though formerly it was held, that the trade ought to be a trade within the statute, yet the latter resolutions have been otherwise. *L. Raym.* 1410. *Str.* 663.

Shall misuse or evil intreat his Apprentice. An apprentice to a surgeon was sent by his master to the East Indies: It was adjudged, that the master cannot compel his apprentice to go beyond the sea, except the master go with him; but he may send him to any part of England. 13 Jac. *Coventry* and *Windall*. *Brownl.* 67. But otherwise, if it be expressly agreed, or the nature of the apprenticeship doth import it; as if the master be a merchant adventurer, or sailor. *Hobart*, 134.

Evil intreat. E. 8 Geo. II. K. and *Easman*. An apprentice was discharged, the master having *used him unkindly*, and refusing to provide for and entertain him: But by the court, this is not a good ground for the discharge: for there is a power to oblige the master to receive and entertain the apprentice, and *using him unkindly* is too loose. *Str.* 1014.

Or the Apprentice do not his duty to his Master. T. 4 Geo. K. and inhabitants of *Hales Owen*. An order reciting that Joseph Higgin was bound out by indenture, as the statute requires, to John Parks, and being lame, and having the king's evil, and in the opinion of surgeons incurable, therefore the justices discharge the master from his apprenticeship. It was moved to confirm the order, because the master cannot now have the end of the binding, which was, the service of his apprentice. But it was answered, that the statute only impowers the justices to discharge for misbehaviour, and not for sickness. And quashed by the court; for the master takes the apprentice for better

and worse, and is to provide for him in sickness and in health. *Str.* 99.

Shall repair unto one justice. Upon an order made at the sessions to discharge an apprentice, it did not appear, that he applied himself to a justice first. And Holt, Ch. J. was of opinion, that the justice hath power to make an order, and, if obeyed by the master, then the sessions can have no power; if disobeyed, then the justice upon complaint may bind the master to the sessions, and that the sessions have no power otherwise. 1 *Salk.* 67.

T. 13 Will. K. and *Johnson*. Exception was taken to an order for discharging an apprentice, that the complaint was made originally at sessions, without any previous application to a single justice out of sessions: Holt, Ch. J. delivered the opinion of the court, That the order was good; if it had been a new question, he should have held a prior application to some justice out of sessions necessary; but after so many orders affirmed in this court, which have been otherwise, it is too late to settle that now. 1 *Salk.* 68. So also in the case of K. and *Gill*, H. 5 Geo. It was said by the court, It hath been so often resolved, that the sessions hath an original jurisdiction, that we will not suffer it now to be made a question, though it might be doubtful upon the statute itself. *Str.* 143. And, T. 12 Geo. K. and *Davie*. The court agreed, that it is a point not now to be disputed, that the sessions hath an original jurisdiction to discharge apprentices. *Str.* 704. And by Lord Hardwicke, Ch. J. in the case of K. and *Easman*, E. 8 Geo. II. This determination is right; for the application which the act directs to be made to a private justice, seems to mean only to arbitrate and accommodate the dispute. The statute says, if he cannot compound the matter, he is to take bond for the parties appearance at the sessions, so that they are not to take it by appeal. *Cases in the time of Lord Hardwicke*, 101.

Or to the mayor or other head officer. M. 12 Geo. K. and *Collingbourn*. An order of sessions was made at Hicks's Hall, for the discharge of an apprentice to a freeman of the city of London, and who was bound and inrolled there. And, the order being removed into the king's bench, the question was, whether the court of sessions at Hicks's Hall hath any jurisdiction to discharge an apprentice to a freeman of London (especially as there is a saving in the act, of the custom of the city of London); or whether he ought not to be discharged by the mayor's court only. It appeared that the apprentice lived with his master out of the city of London, and within the jurisdiction of the justices of Middlesex. To this exception it was answered, that the statute doth not regard where the binding or inrolling is, but gives the jurisdiction expressly to the justices where the master lives; and if this did not belong to the justices of Middlesex, where the master lives, there would be a failure of justice: for neither the chamberlain, nor any other city magistrate, have power to compel the master's appearance before them. The court affirmed the order of discharge, and said they would not take away the jurisdiction of the mayor's court, but only give a concurrent jurisdiction to the justices for the county. And it would be very inconvenient, to have apprentices to a freeman of London, who are bound there, and who live in distant counties, obliged to come up to the mayor's court to get themselves discharged: and the words of the statute are very plain; for they give the jurisdiction to the justices where the master dwelleth. *Str.* 663.

Who shall by his wisdom and discretion take such order and direction between the Master and his Apprentice as the equity of the case shall require. Hereupon the justice, if he sees cause, may, by consent of the master, discharge the apprentice from his apprenticeship: but this must not be by a verbal discharge; for the apprentice being by deed, cannot be discharged but by deed, that is, by order under the hand and seal of the justice. *Dalt. c.* 58. 6 *Mod.* 182.

If for want of good conformity in the master. If the master is dissatisfied, he may have the matter transferred to the sessions: but here is not the like option given to the apprentice;

apprentice; and the reason seems to be, because, the apprentice being most commonly an infant, the law presumes that the justice is more capable of judging what is for the infant's benefit.

On his appearance. E. 13 Will. Ditton's case. It was moved to quash an order made for the discharge of an apprentice. The question arose upon the clause of the statute which directs, that upon appearance of the master, the apprentice may be discharged by four justices, after one justice out of sessions hath endeavoured to compose the matter in difference. And in this case it was objected, that Ditton the master was bound over to appear, and did not; and the justices have but a limited jurisdiction, and it is expressly directed by the act, that the discharge is to be made on the appearance of the master; besides, there is another remedy, to proceed on the recognizance which is forfeited by not appearing. By the court: The act must have a reasonable construction, so as not to permit the master to take advantage of his own obstinacy; and it would be very hard, that supposing the master is profligate, and runs away, the apprentice shall never be discharged. 2 Salk. 490.

H. 5 Geo. K. and Gill. An order of sessions for discharging an apprentice was quashed, because it did not set forth, that the master was summoned, or did appear. Str. 143. So also, E. 8 Geo. II. K. and Eastman. The order was quashed, because it did not appear that the master was present or summoned, which it is plain the act intended he should be. Str. 1013.

Inrolled by the clerk of the peace. T. 4 Geo. K. and inhabitants of Hales Owen. The order of discharge was not inrolled; and by the court for that reason held ill. Str. 99.

Shall be a sufficient discharge for the apprentice against his master. But as the justices may discharge the apprentice from his master, for ill usage; so also they may discharge the master from the apprentice for evil and disorderly behaviour. Read. Appr.

Discharge. T. 13 Will. K. and Johnson. Exception was taken to an order of discharge, that the justices had ordered money to be returned: But by the court, the order is good. And Holt, Ch. J. said he never doubted of that matter, for it is a power consequential upon their jurisdiction to discharge. 1 Salk. 68. But in the case of K. and Vandeleur, M. 4 Geo. The justices at the sessions did order an apprentice to be discharged, and that the master, having received 3l. with him, should refund 3l. as a further provision for him. This was moved to be quashed, because the statute, which gives the justices power to discharge, gives them no authority to order any money to be returned. By the court: It is very hard, that, if the master misuses the apprentice the next day after he is bound, he should pay back nothing if he is discharged: it will be an encouragement to masters to treat their apprentices ill; but, the statute being silent, the order must be quashed. Str. 69. Nevertheless, this doctrine of refunding seemeth now to be established, is founded on great reason, though not expressly mentioned in the act; for the justices being authorized to discharge according to their discretions; when the end of the apprenticeship cannot be attained with one person, it is but justice the master should return part of the money he has received with his apprentice, to place him out with a new master. 2 Bac. Abr.

In the chancery. Jan. 22, 1745. Ex parte Sanby. The petitioner, on the tenth of Jan. 1744, was put apprentice to Ward, a bookseller at York, and the sum of 80l. was given with him as an apprentice for seven years. In July following, a commission of bankruptcy was taken out against Ward; and, being declared a bankrupt, assignees were chosen, who fell off the bankrupt's effects, and he is now the supervisor of the press to the purchaser, and becomes incapable of performing his part of the contract, nor is the petitioner able to raise any money to put him out an apprentice to another master; and, the commission being a recent one, probably no dividend may be made in a year, or a year and a half; so that all this time will be lost to

the petitioner. Upon these circumstances, the petitioner prayed, that on deducting 10l. out of the 80l. for his board with the bankrupt during the six months he lived with him, the assignees should be ordered to pay him the sum of 70l. out of the effects of the bankrupt already come to their hands, and not oblige him to prove it as a debt under the commission. The lord-chancellor Hardwicke was at first doubtful, and seemed inclined to grant the petition; but on ordering search to be made for precedents, and several being produced wherein it was directed that apprentices should come in as creditors only, after deducting for the time they lived with the bankrupt, upon the remaining sum; it was ordered accordingly in this case, and that the petitioner should be admitted a creditor for 70l. only. 1 Atkyns, 149.

Shall cause due correction and punishment to be administered. This being left indefinite, it seemeth most apposite, that the justice commit the apprentice to the house of correction for a time, to be kept to hard labour, or otherwise corrected, as the nature of the offence may require.

By the 20 Geo. II. c. 19. "On complaint unto two justices, by any parish apprentice, or other apprentice upon whose binding out no larger a sum than 5l. was paid, concerning any misusage, refusal of necessary provision, cruelty, or other ill treatment, they may summon the master or mistress, to appear before them at a reasonable time to be named in such summons; and, on proof upon oath of the truth of the said complaint, (whether the master or mistress be present or not, if service of the summons be also upon oath proved,) the said justices may discharge the apprentice by warrant or certificate under their hands and seals, for which warrant or certificate no fee shall be paid." f. 3.

And by 32 Geo. III. c. 57. Where any parish apprentice shall be so discharged, such two justices may order such master to deliver up to such apprentice his clothes; and also to pay to the churchwardens or overseers of the place to which such apprentice shall belong, any sum not exceeding 10l. to be applied by them, under the order of such justices, for the again binding out such apprentice, or otherwise for his benefit, as to such justices shall seem meet; and also to pay any sum not exceeding 5l. in case such master shall refuse to deliver up such clothes; and on his refusal to pay the sum so ordered, or any part thereof, such justices may levy the same by distress, together with the reasonable expences of such distress. And such justices may, if they think fit, compel such churchwardens and overseers, or one of them, to enter into recognizance for the effectual prosecution, by indictment, of such master, for such ill treatment of any such apprentice so discharged as aforesaid; and may also order that the expences of such prosecution shall be paid or reimbursed to such person entering into such recognizance as aforesaid, one moiety thereof out of the poor rates of the parish or place to which such apprentice shall belong, and the other moiety out of the county rate in which such place shall lie. And, in case the churchwardens and overseers shall refuse to pay such their moiety as aforesaid, such justices may levy the same by distress on the goods and chattels of such churchwardens and overseers, or any of them, together with the reasonable charges of such distress. f. 11.

"And such justices on complaint on oath by any master or mistress, against any such apprentice, concerning any misdemeanor, miscarriage, or ill behaviour, may hear and determine the same, and punish the offender, by commitment to the house of correction, there to remain and be corrected, and held to hard labour for a reasonable time, not exceeding one calendar month, or otherwise by discharging such apprentice." 20 Geo. II. c. 19. f. 4.

And in all cases where any parish apprentice shall be discharged for misbehaviour as aforesaid, such two justices may commit such offender to the house of correction, to be corrected and kept to hard labour, for any time not exceeding three calendar months. 32 Geo. III. c. 57. f. 13. Persons aggrieved by any determination, order, or warrant, of such justices (except any order of commitment), may appeal

appeal to the next sessions, who may award costs to either party not exceeding 40s. to be levied by distress and sale. 20 Geo. II. c. 19. s. 5. And no certiorari shall issue to remove any the said proceedings. s. 6.

If any apprentice in husbandry, or in any art or occupation aforesaid, shall flee into any other shire, the justices, mayors, or other head officers being justices, may issue writs of capias to the sheriffs of the counties or other head officers of the places whither he shall so flee, to take his body, returnable before them at what time shall please them; so that if he come by such process he may be put in prison, till he find sufficient surety well and honestly to serve his master. 5 Eliz. c. 4. s. 47. And by the 24 Geo. II. c. 55. If a justice shall issue a warrant against such person, and he shall escape into another shire; the constable or other person, on having the warrant indorsed by a justice in such other shire, may arrest him there, and carry him before a justice in such other shire; if the offence is bailable, to find bail, or else shall carry him back before a justice in the shire from whence the warrant did first issue.

Feb. 3, 1747. *Hill and Allen*. In chancery. The bill was by an apprentice, who against his master's consent quitted his service of a shipwright, before his time was out, and went on-board a privateer, which took a very considerable prize, whose share thereof, being 1200l. the master claimed. By L. Hardwicke: In general, the master is intitled to all that the apprentice shall earn; consequently, if he runs away, and goes to a different business, the master is intitled at law to all his earnings. And in this case, his lordship said, there was nothing in equity to relieve. But he said he would send the case to be tried at law, unless they would agree to compound the matter, which he recommended to them, and thought, as the boy's share of the prize was so very large, the balance ought to be in his favour. And the master agreed to accept 450l. *Vezey*, 83.

By the 6 Geo. III. c. 25. If any apprentice shall absent himself from his master's service, before the term of his apprenticeship shall be expired; he shall, at any time thereafter, whenever he shall be found (so it be within seven years after the expiration of his term), be compelled to serve his said master, for so long a time as he shall have absented himself; unless he shall make satisfaction to his master for the loss he shall have sustained by such absence. And if he shall refuse so to serve, or to make satisfaction, the master may complain upon oath to one justice where he shall reside; who shall issue his warrant for apprehending such apprentice. And such justice, on hearing the complaint, may determine what satisfaction shall be made to such master by the apprentice. And if the said apprentice shall not give security to make satisfaction according to such determination; such justice may commit him to the house of correction for any time not exceeding three months. Persons aggrieved by such determination, order, or warrant of the justice (except any order of commitment), may appeal to the next sessions, giving six days notice to the justice and to the parties, and entering into recognizance, within three days after such notice, before a justice, with sufficient surety, to try the appeal at, and to abide the order or judgment of, and pay such costs as shall be awarded by the justices at, such sessions: which said justices, at their said sessions, on proof of such notice given, and of entering into such recognizance, shall hear and determine the appeal, and give such relief and costs to either party as they shall judge reasonable. And their determination shall be final and conclusive to all parties concerned. Provided, that nothing herein shall extend to the stauneries in Devon or Cornwall; or to impeach or lessen the jurisdiction of the chamberlain of London, or of any other court within the said city, touching apprentices; nor to any apprentice whose master shall have received with him the sum of 10l.

Apprentice stealing his Master's Goods.—By the 21 Hen. VIII. c. 7. Servants going away with their master's goods, with intent to steal them, shall be guilty of felony; but not to extend to apprentices. And by 12 Anne, st. 1. c. 7. Per-

sons stealing to the value of 40s. being in a dwelling-house, or out-house thereto belonging, though such house be not broken, and though no person be therein, are excluded from the benefit of clergy. But this not to extend to apprentices under fifteen years of age. But, if they be fifteen years of age, they shall be guilty as other persons.

The enticing of an apprentice to depart from his master, is not an offence of a public nature, for which an indictment will lie; but the party's remedy is by an action on the case, which he may well maintain. 6 Mod. 182. *Bur. Mansf.* 1306. *Reavely v. Mainwaring* and others.

Assigning or turning over Apprentices.—The master assigning, and the apprentice himself consenting, will not make him an apprentice to the assignee within the fifth of Eliz. But by the custom of London, he may be turned over to another. *Dalt.* c. 58. And an assignment to the sea-service is good by act of parliament, as is before mentioned.

E. 3 Geo. K. and *Barnes*. Order returned on a certiorari. It was resolved by the justices at the sessions, where a person was bound an apprentice to *Barnes* by the parish officers, and *Barnes* had assigned him to another, that the assignment is void, and they direct *Barnes* to take his apprentice again. But by the court: The sessions had no power to judge of the validity of a deed, or to hinder a man from assigning his apprentice. The covenant to provide for him is well performed, if the person to whom he is bound assigns him to another to provide for him. Wherefore the order was quashed. *Foley*, 155. *Str.* 48. For the jurisdiction of the justices extends no farther, than to compel the master to take care of his apprentice; but in what manner he does it, whether in his own house or otherwise, is nothing to them. But, if the assignee of the apprentice doth not provide for him, the first master may be compelled to do it, and he may take his remedy over. 1 *Seff.* C. 110.

Master dying.—It hath been said, that if the master dies, the apprentice goes to the executors or administrator to be maintained, if there are assets; but the executor or administrator may bind him to another master for the remaining part of his time. But in the case of *K. and Peck*, M. 10 Will. Eyre, J. held, that an apprenticeship is a personal trust between the master and servant, and determines by the death of either of them; and by the death of either of them the end and design of the apprenticeship cannot be obtained, and it may be the executor is of another trade; he admitted covenant would lie against the executor, but in that there is no inconvenience, because the executor may make his defence by pleading no assets, or debts of a higher nature. *Holt*, Ch. J. said, that by the custom of London, the executor shall put the apprentice to another master of the same trade; and that, in other places, it would be very hard to construe the death of a master to be a discharge of the covenants; he said, it had been held, that the covenant for instruction failed, but that he still continues an apprentice with the executor, as to maintenance. 1 *Salk.* 66.

E. 20 Geo. II. *Baxter* (widow and executrix) against *Burfield*. In debt on bond, conditioned for Matthias Anderson's performance of the covenants in an indenture of apprenticeship, whereby he was bound to the plaintiff's testator, who was a mariner; the defendant pleaded, that Anderson served faithfully to the death of the testator: the plaintiff replied, that since the death of the testator, Anderson had absented from her service: to which there was a demurrer. And after argument at bar, *Lee*, Ch. J. delivered the resolution of the court, viz. That they were all of opinion the defendant should have judgment, and that the executrix could maintain no such action. The binding was to the *man*, to learn his *art*, and serve *him*, without any mention of executors. And as the words are confined, so is the nature of the contract; for it is fiduciary, and the apprentice is bound from a personal knowledge of the integrity and ability of the master. H. 3 Anne, *Horne* and *Blake*; an award that an apprentice should be assigned, was held void; unless there was a custom, or the concurrence of the apprentice. And they

held, it was not material, that, according to Cro. Eliz. 553, the assets were liable on the master's covenant to maintain. Therefore judgment was given for the defendant. *Str.* 1266.

In the court of chancery. M. 30 Car. II. In the case of *Soam* against *Boroden and Eyles*. The master received with the apprentice 250*l.* and died within two years, the apprentice having for that time been employed only in inferior affairs. It was decreed, after debts on specialties paid, that the executors repay the 250*l.* as a debt due on simple contract: deducting after the rate of 20*l.* a year for the maintenance of the apprentice, during the time he lived with his master. *Cha. Ca. Finch.* 396.

And by 32 Geo. III. c. 57. after reciting, that in the event of the death of the master of any parish apprentice during the apprenticeship, the agreement for service on the part of the apprentice is at an end, but the covenant for maintenance on the part of the master still continues in force as far as his assets will extend; or doubts have arisen with respect thereto: it is enacted, that after the 1st July, 1792, in case of the death of the master of any parish apprentice during the apprenticeship, upon which binding no larger sum than 5*l.* shall be paid, any covenant for the maintenance of such apprentice inserted in the indenture, shall not be in force longer than three calendar months next after the death of such master; and that during such three months, such apprentice shall continue to live with and serve as an apprentice, the executors and administrators of such master, or such person as they, or some or one of them, shall appoint: and such master and apprentice, during such three months, shall be subject to all the laws in force for regulating masters and parish apprentices. *f.* 4.

And whereas it is reasonable that such apprentice as aforesaid, in case of his master's death, should be obliged to make some satisfaction by his labour to the family or representatives of his deceased master, for the advantages he has received in his childhood, when his service could not be equal to his maintenance: it is enacted, that within such three calendar months after the death of such master, two justices, on the application of such master, or by the husband of the mistress, or by any son or daughter, brother or sister, or executor or administrator, of such person deceased, by indorsement on such indenture or counter part thereof, or by any other instrument or writing, may order and direct that such apprentice shall serve as an apprentice any one of such persons so making application as aforesaid (such person having lived with, or been part of, such master's family at the time of his death), as they shall think fit, during the residue of the term mentioned in such indenture; and the person obtaining such order, shall declare his acceptance of such apprentice, by subscribing his name to such order: and, after such order shall be made, the executors and administrators, and the personal assets, estate, and effects, of the master so dying, shall be discharged from any covenant in such indenture; and the person obtaining the same shall be deemed the master of such apprentice in like manner as if he had been originally bound to such master; and such last-mentioned master, his executors and administrators, shall be bound by the covenants contained in such indenture in like manner as if he had executed the counter part thereof: and such master and apprentice shall be subject to the several penalties, provisions, and regulations, which shall then be in force for governing apprentices: and all justices shall have the like power and authority with respect thereto, as they shall then have by any act of parliament relating to parish apprentices. *f.* 2, 3. But in case no such application shall be made as aforesaid, within three calendar months as aforesaid; or in case such two justices shall not think fit that such apprenticeship should be continued, then such apprenticeship shall be determined; and the indenture, and covenants therein contained, shall be at an end, in like manner as they would have been at the expiration of the term. *f.* 4.

And whereas delays must happen in bringing an action upon such covenant for maintenance as aforesaid: it is

enacted, that in case any such original master, or master appointed by virtue of this act as aforesaid, shall, during the term of any such parish apprenticeship as aforesaid, or the executors or administrators of such master, or any of them, having assets, shall, during three calendar months as aforesaid, refuse or neglect to maintain and provide for any such apprentice according to the terms of such covenant; two justices, on complaint of such apprentice, or of the churchwardens and overseers of such place, may levy by distress of the personal estate or assets and effects of such master, such sum as shall be necessary for the maintenance and clothing of such apprentice; and as shall also be necessary to reimburse to the churchwardens and overseers any sum that shall have been reasonably expended by them for that purpose. *f.* 6.

Of Apprentices setting up their Trades.—By the common law, no man may be prohibited to work in any lawful trade, or in more trades than one, at his pleasure. *11 Co.* 53. So that without an act of parliament no man may be restrained, either to work in any lawful trade, or to use divers mysteries or trades; therefore an act of parliament made to restrain any person herein must be taken strictly, and not favourably as acts made in affirmance of the common law. The restraining clause in the statute of 5 Eliz. c. 4. is as follows: "It shall not be lawful to any person, to set up, use, or exercise, any craft, mystery, or occupation, now used or occupied within the realm of England or Wales, except he shall have been brought up therein seven years at the least as an apprentice by this statute, nor to set any person on work therein, except he shall have been apprentice as aforesaid, or else having served as an apprentice will become a journeyman, or hired by the year; on pain of 40*s.* a month, half to the king, and half to him that shall sue in the sessions, or other court of record; or, if it is in a town corporate, then to be disposed of as other fines by the charter." *f.* 31.

It shall not be lawful. This is a negative clause, and no one shall exercise a trade against it, unless by virtue of a custom, as the widows of tradesmen, who by custom carry on the trade of their husbands, which the court held not to be within this statute. *2 Salk.* 610.

To any person. But by the 15 Car. II. c. 15. Hemp workers of all kinds, net-makers, and makers of tapestry hangings, are excepted; who may set up without having served seven years. And, by 3 Geo. III. c. 8. All officers, mariners, and soldiers, who have been employed in his majesty's service, and not deserted, may exercise such trades as they are apt for, in any town or place. And, by 6 and 7 Will. c. 17. An apprentice discovering two offenders guilty of coining, so as they be convicted, shall be deemed a freeman, and may exercise his trade as if he had served out his time. *f.* 12.

To set up, occupy, use, or exercise. T. 9 Geo. III. *Beach and Turner.* On an action brought for exercising a trade, without having served an apprentice, it appeared that the defendant was only a journeyman. And the question was, whether the statute extends to journeymen, or only to masters? By the court: The statute was meant to prevent masters only from setting up trades, and did not intend to give a penalty against both. There is great difference between setting up a trade and working in it: a man may work in it, by doing a very trifling part. A journeyman doth not exercise the trade upon his own account, but for his master. *Burr. Mansf.* 2449. And it is not material, as to the master, that the journeyman hath served seven years; for, if the master himself hath not served seven years, he is restrained by the statute to work as a trader, either by himself or others; for the intent of the act is, to annex the benefit of trade to such as underwent the hardship of learning it, thereby to encourage labour in youth: and few would undergo the trouble of being apprentices, if they might employ others to work for them. T. 3 Will. *Hobbs and Young.* *2 Salk.* 610.

If a man use the trade of a tallow-chandler, baker, brewer, or any other lawful trade, or manual occupation, for his

his own use, or for the use of his family, without selling any for lucre and gain, he may lawfully do it; but he cannot retain an apprentice therein; but he may hire one to be his servant, who is skilful in that trade or occupation. 8 Co. 129. In like manner, a person brought up to the trade may take a *partner*, who hath not served an apprenticeship to the trade, provided the partner share only in the profits or loss of the business, and do not actually exercise the trade. As in the case of *Reynard and Chafe*, M. 30 Geo. II. An action of debt was brought against Chafe, for a penalty on the act, for exercising the trade of a brewer, without having served an apprenticeship. On a special verdict, it was stated, that the defendant Chafe and one Cox were partners in the trade; that the trade was carried on, and had been for four years carried on, in their joint names; that Cox did serve an apprenticeship to the trade, but Chafe never did; and that Cox is a working brewer, and was paid a salary for his labour, which salary was always deducted, and allowed to him, previous to a division of the profits; and the entries at the excise-office were in their joint names; but that the defendant John Chafe never exercised the trade himself, (which was wholly managed and carried on by Cox;) but only shared the profits, and stood the risks of the partnership. The question was, whether the defendant John Chafe is within the act, upon this special finding? By L. Mansfield, Ch. J. The defendant is to share the profits with Cox in moieties; and is liable to the debts of the partnership: but it is expressly found, that, during all the time charged, he never acted in or exercised the trade. He was not, by the terms of his agreement, to act in the trade. The other partner was to do the whole, and had a particular salary on that account. It is not found, that either Cox, or any servant under him, was set to work by Chafe; nor that Chafe did any act whatever of exercising the trade; he was only concerned in the profits. Now though this may be, to some purposes, exercising a trade, in respect of third persons who deal with the partnership as creditors, and within the meaning of the statutes concerning bankrupts; yet the present question is, whether it be exercising a trade contrary to this act? In the argument of this cause it hath been well observed, that this is a penal law; that it is in restraint of natural right; that it is contrary to the general right given by the common law of this kingdom. To which I will add, that the policy on which the act was made, is, from experience, become doubtful. Bad and unskilful workmen are rarely prosecuted. This act was made early in the reign of queen Elizabeth. Afterwards, when the great number of manufacturers, who took refuge in England from the duke of Alva's persecution, had brought trade and commerce with them, and enlarged our notions; the restraint introduced by this law was thought unfavourable, and the judges by a liberal interpretation have extended the qualifications for exercising the trade much beyond the letter of it, and confined the penalty and prohibition to cases precisely within the express letter. Let us consider whether the present case be within the letter, or even the meaning, of this act. The general policy of the act was, to have trades carried on by persons who had skill in them. Now here, the personal skill of the defendant makes no real difference in the case. For the person who is skilful acts every thing, and receives no direction from this man: he neither did, nor was to interfere. In many considerable undertakings, it is absolutely necessary to take in persons as partners, to share the profits and risk the loss. And the general usage and practice of mankind ought to have weight, in determinations of this sort, affecting trade and commerce, and the manner of carrying them on. It is notorious that many partnerships are entered into upon the foundation of one partner contributing industry and skill, and the other money. Many great breweries and other trades have been carried on for the benefit of infants and residuary legatees, under the direction of the court of chancery: now, if the plaintiff's construction was to hold, the whole direction and

decree of the court of chancery was contrary to law, and to an express act of parliament. So it is likewise practised in other great trades. The late Mr. Child directed his business of a banker to be carried on for the benefit of his children and other persons. Many other instances might be mentioned. It would introduce the utmost confusion in affairs of trade and commerce, if this construction should prevail. On the other hand, I see no inconvenience. It is exactly the same thing as to trade, in every particular, whether this partner has or has not served an apprenticeship. Therefore I think the defendant not liable to the penalty of the statute. The other three justices concurred. And judgment was given for the defendant. *Bur. Mansf. 2.*
Any craft, mystery, or occupation. T. 3 Geo. III. *French and Adams.* An action of debt was brought upon the statute against the defendant for exercising the trade of a *carpenter*, he not having served an apprenticeship to that trade. It appeared, that the defendant had worked or served as a servant for seven years in the trade of a *glazier*, and for some time afterwards exercised that trade as a master; that afterwards he exercised the trade of a *carpenter* for the space of nine years, and it was proved that he well understood that trade. It was objected, that the defendant being originally bred up to the trade of a *glazier*, he could not follow two trades, both *glazier* and *carpenter*; and whether he could or not, was the question reserved for the consideration of the court. By the court: All the judges of England at a meeting lately resolved, that, if any man as a master had exercised and followed any trade as a master without interruption or impediment for the term of seven years, he was not liable to be sued or prosecuted on the statute of 5 Eliz. also, if a man hath followed two or more different trades for the term of seven years or more, he shall not be liable to be prosecuted on this statute. There is no law against one man's following several trades at this day. There was an ancient statute, (37 Edw. III. c. 6.) that artificers or handicraftsmen should use but one mystery, and that none should use any mystery but that which he had before that time chosen and used. But this restraint of trade and traffic was immediately found prejudicial to the public, and therefore at the next parliament it was enacted, that all people should be as free as they were at any time before the said ordinance. And L. Coke observes, that acts of parliament made against the freedom of trade never live long. Without the least doubt, a man may follow twenty trades, if he has worked at or followed each trade seven years. Mr. Harrison of Red-lion-square served an apprenticeship to the trade of a *carpenter*; but for twenty-six years past he has been a *watchmaker*; and, though he never served as an apprentice to the trade of a watchmaker, is the best maker of time-pieces in the world, and the parliament has given him a large sum of money towards finding out the longitude by the help of his watches or time-measurers: and shall this man be hindered from making watches and exercising the trade of a carpenter also if he pleases? And by the whole court in the present case, judgment was given for the defendant. 2 *Wilson*, 168.

Now used. That is, on the 12th of Jan. 1562, when that parliament began; and this restraint shall not extend any further than the words do expressly direct, and therefore not to new arts and mysteries since invented. 1 *Roll. Rep.* 10. 1 *Ventr.* 326, 346.

Within the realm of England and Wales. M. 1 Geo. II. *K. and Lister.* Indictment for using the trade of a dry-salter, being a craft, mystery, or occupation, used in this kingdom on the 12th day of Jan. in the 5th year of Eliz. Which the court held to be ill; for that the words in this kingdom tie down the indictment to the kingdom of Great Britain, as it is at this day; whereas it should have been in England or in England and Wales. 2 *Seff. C.* 160. *Str.* 788.

H. 3 Geo. II. *K. and Monro.* It was moved to quash an indictment for exercising the trade of a *baker*, the defendant not having served a legal apprenticeship. The exception was, the trade was not laid to be used within the realm of England and Wales at the time of the act. But the

the court said, the trade of a *baker* is within the words of the act; and no averment of the trade's being used at the time of the act is necessary, but where the trade only falls within the general conclusion of the clause at last. 1 *Barnardist*. 277.

Except he shall have been brought up therein seven years. E. 11 Will. K. and Fox. Indictment for using the trade of a taylor, not having served seven years, was quashed, because it is said only, not having served as an apprentice within England or Wales; for it may be he did so beyond sea, and if it were any where it sufficeth. 1 *Salk*. 67.

As an apprentice. E. 5 Anne, Q. and Maddox. By the court: Upon indictment on this statute, in evidence we allow following the trade for seven years to be sufficient, without any binding, this being a hard law. 2 *Salk*. 613. T. 3 Geo. II. K. and Morrice. On an indictment for exercising a trade, without having served a legal apprenticeship; the defendant offered to give evidence of his having exercised his trade for seven years, as being tantamount to his having served an apprenticeship for that time. Eyre, Ch. J. said, that the cases indeed had gone so far, as to allow a wife's living in the shop with her husband for seven years to be equivalent to an apprenticeship; but he thought the present case not strong enough to come up to the meaning of the statute. Accordingly the evidence was disallowed. 1 *Barnard*. 367. But in the case of *Wallen and Holton*, at the assizes for Berkshire, T. 33 Geo. II. On an information against the defendant for exercising the trade of a baker contrary to the statute, it appeared in evidence that he had followed it twelve years, but never had been an apprentice, nor served with any person *as such*. On a case reserved, baron Adams, before whom it was tried, consulted the eleven judges; who all joined with him in opinion, that exercising a trade seven years, without any prosecution with effect, was a sufficient qualification. *Blackst. Rep.* 233.

Nor to set any person on work therein, except he shall have been apprentice as aforesaid. But by 17 Geo. III. c. 33. with respect to the counties of Middlesex, Essex, Surrey, and Kent, for want of a sufficient number of persons who have served apprenticeships to the trade of a *dyer*, it shall be lawful for any person exercising that trade within any of the said counties, to employ such number of journeymen, servants, and labourers, as he shall have occasion for, without incurring any penalty.

Or else having served as an apprentice, will become a journeyman. M. 26 Car. II. K. and Moor. The defendant was indicted for using the trade of a weaver, not having served as an apprentice seven years; the evidence was, he served six as an apprentice, and had since as journeyman in the same trade worked above that time. And, by the court, the serving of seven years is sufficient either way; and the defendant was found not guilty. 3 *Keb.* 400.

To APPRENTICE, v. a. To put out to a master as an apprentice:

Him portion'd maids, *apprentic'd* orphans, blest,
The young who labour, and the old who rest. *Pope.*

APPRENTICEHOOD, f. The years of an apprentice's servitude:

Must I not serve a long *apprenticehood*
To foreign passages, and in the end,
Having my freedom, boast of nothing else,
But that I was a journeyman to grief? *Shakespeare.*

APPRENTICESHIP, f. The years which an apprentice is to serve under a master.—In every art, the simplest hat is, there is an *apprenticeship* necessary, before it can be expected one should work. *Digby.*

To APPRI'ZE, v. a. [*apprendre*, Fr. part. *appris*.] To inform; to give the knowledge of any thing.—He considers the tendency of such a virtue or vice; he is well *apprized*, that the representation of some of these things may convince the understanding, and some may terrify the conscience. *Watts.*

To APPROACH, v. n. [*approcher*, Fr.] To draw near locally.—'Tis time to look about: the powers of the kingdom *approach* apace. *Shakespeare.*—To draw near, as time. To make progress towards, in the figurative sense, as mentally.—To have knowledge in all the objects of contemplation, is what the mind can hardly attain unto; the instances are few of those who have, in any measure, *approached* towards it. *Locke.*—To come near, by natural affinity, or resemblance; as, The cat *approaches* to the tiger.

To APPROACH, v. a. To bring near to. This sense is rather French than English.—By plunging paper thoroughly in weak spirit of wine, and *approaching* it to a candle, the spirituous parts will burn, without harming the paper. *Boyle.*—To come near to.—He was an admirable poet, and thought even to have *approached* Homer. *Temple.*

APPROACH, f. The act of drawing near:

'Tis with our souls
As with our eyes, that after a long darkness
Are dazzled at th' *approach* of sudden light. *Denham.*

Access.—Honour hath in it the vantage-ground to do good; the *approach* to kings and principal persons; and the raising of a man's own fortunes. *Bacon.*—Hostile advance. Means of advancing:

Hills pil'd on hills, on mountains mountains lie,
To make their mad *approaches* to the sky. *Dryden.*

APPROACH'ER, f. The person that approaches or draws near.

APPROACH'ES, f. in fortification, the works thrown up by the besiegers, in order to get nearer a fortress, without being exposed to the enemy's cannon. See *FORTIFICATION*.

APPROACH'ING, f. in fowling, a term used to express such devices as are contrived for the getting within shot of shy birds. The best method is by means of three hoops tied together at proper distances according to the height of the man that is to use it, and having boughs of trees tied all round it, with cords to hang it over his shoulders; a man, getting into this, conceals himself, and approaches by degrees towards his game in the form of a moving bush. Geese, ducks, and teal, quit the waters in the evening, and pass the night in the fields; but at the approach of morning they return to the water again, and even when on the water they will retire to great distances, on the approach even of a horse or cow, so that the business of the stalking horse is of little use; but this device of approaching by the moving bush succeeds tolerably well.

APPROACH'MENT, f. The act of coming near.—As for ice, it will not concrete but in the *approachment* of the air, as we have made trial in glasses of water, which will not easily freeze. *Brown.*

APPROBATION, f. [*approbatio*, Lat.] The act of approving, or expressing ourselves pleased or satisfied.

Moralists are divided on the principle of approbation or the motive which determines us to approve and disapprove. The Epicureans will have it to be only self-interest: according to them, that which determines any agent to approve his own action, is its apparent tendency to his private happiness; and even the approbation of another's action flows from no other cause but an opinion of its tendency to the happiness of the approver, either immediately or remotely. Others resolve approbation into a moral sense, or a principle of benevolence by which we are determined to approve every kind affection either in ourselves or others, and all publicly useful actions, which we imagine to flow from such affection, without any view therein to our own private happiness.

APPROOF, f. [*from approve*, as *proof* from *prove*.] Approbation; commendation: a word rightly derived, but old:

O most perilous mouths,
That bear in them one and the self-same tongue
Either of condemnation or *approof*! *Shakespeare.*

To APPROPERATE, v. a. [*appropriero*, Lat.] To hasten; to set forward.

To APPROPINQUATE, *v. n.* [*appropinquo*, Lat.] To draw nigh unto; to approach.

To APPROPINQUE, *v. n.* [*appropinquo*, Lat.] To approach; to draw near to. A ludicrous word:

The clotted blood within my hose,
That from my wounded body flows,
With mortal crisis doth portend
My days to *appropinque* an end.

Hudibras.

APPROPRIABLE, *adj.* That which may be appropriated; that which may be restrained to something particular.

APPROPRIARE COMMUNIAM, is to approve or to appropriate and inclose part of a common to a man's own separate use; and this may be done either by the lord of the manor, or by a tenant with the lord's permission; provided they leave sufficient common for the rest of the tenants.

To APPROPRIATE, *v. a.* [*appropriar*, Fr. *approprio*, low Lat.] To consign to some particular use or person.—Marks of honour are *appropriated* to the magistrate, that he might be invited to reverence justice. *Atterbury*.—To claim or exercise; to take to himself by an exclusive right.—Why should people engross and *appropriate* the common benefits of fire, air, and water, to themselves? *L'Esfrange*.—To make peculiar to something; to annex by combination.—We, by degrees, get ideas and names, and learn their *appropriated* connection one with another. *Locke*.—In law, to alienate a benefice.

APPROPRIATE, *adj.* Peculiar; consigned to some particular use or person; belonging peculiarly.—The heathens themselves had an apprehension of the necessity of some *appropriate* acts of divine worship. *Stillingfleet*.

APPROPRIATION, *f.* The application of something to a particular purpose. The claim of any thing as peculiar. The fixing a particular signification to a word.

APPROPRIATION, in law, is the annexing of a benefice to the proper and perpetual use of some religious house, bishopric, college, or spiritual person, to enjoy for ever. To make an appropriation, the king's licence was to be obtained in chancery, and also the consent of the ordinary, patron, and incumbent. And in this manner the religious houses of old time became possessed of that vast number of advowsons, which they had in this kingdom; when these churches, after the dissolution of the monasteries, came into lay hands, the church so possessed by a *layman* was called an *impropriation*, and himself the *impropriator*. But the words *appropriation* and *impropriation* are often confounded and used for each other.

The contrivance of appropriations seems to have sprung from the policy of the monastic orders, who have never been deficient in subtle inventions for the increase of their own power and emoluments. At the first establishment of parochial clergy, the tithes of the parish were distributed in a four-fold division; one for the use of the bishop, another for maintaining the fabric of the church, a third for the poor, and the fourth to provide for the incumbent. When the sees of the bishops became otherwise amply endowed, they were prohibited from demanding their usual share of these tithes, and the division was into three parts only. And hence it was inferred by the monasteries, that a small part was sufficient for the officiating priest, and that the remainder might well be applied to the use of their own fraternities, (the endowment of which was construed to be a work of the most exalted piety,) subject to the burden of repairing the church and providing for its constant supply. And therefore they begged and bought, for masses and obits, and sometimes even for money, all the advowsons within their reach, and then appropriated the benefices to the use of their own corporation. The appropriators and their successors, being perpetual parsons of the church, must sue and be sued, in all matters concerning the rights of the church, by the name of *parsons*.

This appropriation may be severed, and the church become disappropriate, two ways; as, first, if the patron or

appropriator presents a clerk, who is instituted and inducted to the parsonage: or the incumbent so instituted and inducted is to all intents and purposes a complete parson; and the appropriation, being once severed, can never be re-united again, unless by a repetition of the same solemnities. And, when the clerk so presented is distinct from the vicar, the rectory thus vested in him becomes what is called a *fine-cure*; because he hath no cure of souls, having a vicar under him to whom that cure is committed. Also, if the corporation which has the appropriation is dissolved, the parsonage becomes disappropriate at common law: because the perpetuity of person is gone, which is necessary to support the appropriation.

In this manner, and subject to these conditions, may appropriations be made at this day: and thus were most if not all of the appropriations at present existing originally made; being annexed to bishoprics, prebends, religious houses, nay, even to nunneries, and certain military orders, all of which were spiritual corporations. At the dissolution of monasteries, by statutes 27 Hen. VIII. c. 28. and 31, c. 13. the appropriations of several parsonages, which belonged to those respective religious houses (amounting to more than one-third of all the parishes in England), would have been by the rules of the common law disappropriated; had not a clause in those statutes intervened, to give them to the king in as ample a manner as the abbots, &c. formerly held the same at the time of their dissolution. This, though perhaps scarcely defensible, was not without example: for the same was done in former reigns, when the alien priories (that is, such as were filled by foreigners only) were dissolved and given to the crown. And from these two roots have sprung all the lay-appropriations or secular parsonages which we now see in the kingdom; they having been afterwards granted out from time to time by the crown.

APPROPRIATION, in the animal economy, that action of the natural heat or vital flame, by which the fluids are so united with the solids of our bodies, as to enable them to perform their functions. Medicines are said to be *appropriated*, which are believed to be destined for a particular part of the body.

APPROPRIATOR, *f.* He that is possessed of an appropriated benefice.—These *appropriators*, by reason of their perpetuities, are accounted owners of the fee simple; and therefore are called proprietors. *Ayliffe*.

APPROVABLE, *adj.* That which merits approbation.—The solid reason, or confirmed experience, of any men, is very *approvable* in what profession soever. *Brown*.

APPROVAL, *f.* Approbation: a word rarely found.—There is a censor of justice and manners, without whose *approval* no capital sentences are to be executed. *Temple*.

APPROVANCE, *f.* Approbation: a word not much used.—A man of his learning should not so lightly have been carried away with old wives' tales from *approvance* of his own reason. *Spenser*.

To APPROVE, *v. a.* [*approver*, Fr. *approbo*, Lat.] To like; to be pleased with.—There can be nothing possibly evil which God *approveth*, and that he *approveth* much more than he doth command. *Hooker*.—To express liking. To prove; to shew; to justify:

In religion,
What damned error, but some sober brow
Will bless it, and *approve* it with a text? *Shakespeare*.

—Refer all the actions of this short life to that state which will never end; and this will *approve* itself to be wisdom to the last, whatever the world judge of it now. *Tillotson*.
—To experience. Not in use:

Oh! 'tis the curse in love, and still *approv'd*,
When women cannot love, where they're belov'd.
Shakespeare.

To make, or show, to be worthy of approbation. It has of before the object, when it signifies to be pleased, but may

be used without a preposition; as, I *approve* your letter, or, of your letter.

APPROVEMENT, *f.* Approbation; liking.—It is certain that at the first you were all of my opinion, and that I did nothing without your *approvement*. *Hayward*.

APPROVEMENT, in law, by the statute of Merton, 20 Hen. III. c. 4. is where a man hath common in the lord's waste, and the lord makes an inclosure of part of the waste for himself, leaving sufficient common with egress and regress for the commoners. If there be not sufficient common left for the tenant, he may have a writ of assize, and by 3 & 4 Edw. VI. c. 3. shall recover treble damages, and a commoner may break down an inclosure, if the lord doth inclose part of the common, and not leave sufficient room in the residue; but if any, upon just title of approvement, do make a hedge or ditch for that purpose, which afterwards is thrown down in the night by persons unknown, the towns adjoining may be distrained to make such hedge at their own charges, for which there is a writ (*noctantur*) in the register. 13 Edw. I. c. 46. But in the case of *Durberley v. Page*. E. 28 Geo. III. it was determined, that the lord has no right under the statute of Merton to inclose and approve the wastes of a manor, where the tenants of the manor have a right to dig gravel on the wastes, or to take effovers there. Cases by Durnford and East. 2 V. 391.

APPROVER, *f.* He that approves; he that makes trial.

APPROVER, in law, is a person indicted of treason or felony, and in prison for the same, who, upon his arraignment, before any plea pleaded, doth confess the indictment, and takes a corporal oath to reveal all treasons and felonies that he knoweth of, and therefore prays a coroner, before whom he is to enter his appeal or accusation against those that are partners in the crime contained in the indictment, and this accusation of himself, and oath, makes the accusation of another person of the same crime to amount to an indictment; and if his partners are convicted he shall have his pardon of course. But as it is in the discretion of the court, whether they will suffer one to be an approver, this method is now out of use; but in many cases we have what amounts to the same thing by statute, where pardon is assured to offenders on discovering and convicting their accomplices. 3 Inst. 129.

APPROVER, is particularly used in ancient law writers, for a bailiff or land-steward, appointed to have the care of a manor, franchise, or the like, and improve and make the most of it for the benefit of his master. In this sense, the word is also written *appruare*.

APPROXIMATE, *adj.* [from *ad*, to, and *proximus*, Lat. near.] Near to.—These receive a quick conversion, containing *approximate* dispositions unto animation. *Brown*.

APPROXIMATION, *f.* Approach to any thing.—The fiery region gains upon the inferior elements; a necessary consequent of the sun's gradual *approximation* towards the earth. *Hale*.—In science, a continual approach nearer still, and nearer, to the quantity sought, though perhaps without a possibility of ever arriving at it exactly.

APPUI, [q. d. rest or stay upon the hand.] In the manege, is the reciprocal effort between the horse's mouth and the bridle-hand, or the sense of the action of the bridle on the hand of the horseman. A just appui of the hand, is the nice bearing up or stay of the bridle, so that the horse, being awed by the sensibility and tenderness of his mouth, dares not rest too much upon the bit, nor check or beat upon the hand to withstand it. A horse is said to have no appui, when he is too apprehensive of the hand, and cannot bear the bit; and too much appui, when he rests or throws himself hard upon the bit. Horses designed for the army ought to have a full appui upon the hand. To give a horse a good appui, he should be kept reined up, galloped, and put often back.

APPULSE, *f.* [appulsus, Lat.] The act of striking against any thing.—An hectic fever is the innate heat kindled into a destructive fire, through the *appulse* of saline streams. *Harvey*.—In vowels, the passage of the mouth is open and free, without any *appulse* of an organ of speech

to another: but, in all consonants, there is an *appulse* of the organs. *Holder*.

APPULSE, in astronomy, means the actual contact of two luminaries, according to some authors; but others describe it as their near approach to each other, so as to be seen, for instance, within the same telescope. The appulses of the planets to the fixed stars have always been very useful to astronomers, as serving to fix and determine the places of the former. The ancients, wanting an easy method of comparing the planets with the ecliptic, which is not visible, had scarcely any other way of fixing their situations, but by observing their track among the fixed stars, and marking their appulses to some of those visible points. Dr. Halley has published a map or planisphere of the starry zodiac, in which are accurately laid down all the stars to which the moon's appulse has ever been observed in any part of the world. See *Philos. Transf.* No. 369; or *Abridg.* vol. vi. p. 170.

APPURTENANCES, *f.* [*pertinentia*, Lat.] In law, signify things both corporeal and incorporeal, appertaining to some other thing as principal: as an hamlet to a chief manor, common of pasture to lands, common of effovers to an house, outhouses, yards, orchards; gardens are appurtenant to a messuage; but lands cannot properly be said to be appurtenant to a messuage. 1 *Lil. Abr.* 91. Turbary may be appurtenant to an house, but not to lands; a leet may be appurtenant to a manor, but not to an house, for the things must agree in nature and quality. 1 *Inst.* 121.

TO A'PRICATE, *v. n.* [*apricor*, Lat.] To bask in the sun.

APRICITY, *f.* [*apricitas*, Lat.] Warmth of the sun; sun-shine.

A'PRICOT, *f.* in botany. See *PRUNUS*.

A'PRIES, son of Psammis, king of Egypt; the same with Pharaoh Hophrah in Jeremiah and Ezekiel. He ruined Sidon, and some say he put Jeremiah to death. He thought neither God nor man could dethrone him; which yet was easily done by Amasis, and he himself was strangled by the Egyptians.

A'PRIL, [*Aprilis*, Lat. of *aperio*, I open; because the earth, in this month, begins to open her bosom for the production of vegetables.] The fourth month of the year according to the common computation, and the second from the vernal equinox. In this month the sun travels through part of the signs of Aries and Taurus.—*April* is represented by a young man in green, with a garland of myrtle and hawthorn buds; in one hand primroses and violets, in the other the sign Taurus. *Peacham*.—Men are *April* when they woo, December when they wed: Maids are May when they are maids, but the sky changes when they are wives. *Shakespeare*.

A PRIORI, a kind of demonstration. See *DEMONSTRATION*.

A'PRON, *f.* [a word of uncertain etymology, but supposed by some to be contracted from *afore one*.] A cloth hung before, to keep the other dress clean.—In these figures the vest is gathered up before them, like an *apron*, which you must suppose filled with fruits. *Addison*.

APRON, in naval architecture, a piece of curved timber fixed behind the lower part of the stern, immediately above the foremost end of the keel.

APRON is also a name given to a platform or flooring of plank, raised at the entrance of a dock, against which the dock-gates are shut.

APRON, in gunnery, a piece of lead which caps or covers the vent or touch-hole of a great gun.

A'PRONED, *adj.* Wearing an apron:

The cobbler *apron'd*, and the parson gown'd. *Pope*.

APSINTHA'TUM, *f.* [from *αψινθος*, wormwood.] A sort of drink accommodated to the stomach.

APSINTHIUM, *f.* in botany. See *ARTEMISIA*.

AP'SIS, *f.* [*apses*, or *apsides*, plural: from *αψις*, Gr.] In astronomy, are the points in the orbits of planets, where they are at their greatest and least distance from the sun or the earth. The point at the greatest distance being called the

the *higher* apsis, and that at the nearest distance the *lower* apsis. And the two apses are also called *auges*. Also the higher apsis is more particularly called the *aphelion*, or the *apogee*; and the lower apsis the *perihelion*, or the *perigee*. The diameter, which joins these two points, is called the *line of the apses* or of the *apsides*; and it passes through the centre of the orbit of the planet, and the centre of the sun or the earth; and in the modern astronomy this line makes the longer or transverse axis of the elliptical orbit of the planet. In this line is counted the excentricity of the orbit; being the distance between the centre of the orbit and the focus, where is placed the sun or the earth.

Different means have been employed to determine the motion of the apses. Dr. Keil explains, in his *Astronomy*, the method used by the ancients, who supposed the orbits of the planets to be perfectly circular, and the sun out of the centre. But since it has been discovered that they describe elliptical orbits, various other methods have been devised for determining it. Newton has given, in the *Principia*, an excellent method of determining this motion, on the supposition that the orbits of the planets differ but little from circles, which is the case nearly. That great philosopher shews, that if the sun be immovable, and all the planets gravitate towards him in the inverse ratio of the squares of their distances, then the apses will be fixed, or their motion nothing; that is, the lines of greatest and least distance will form one right line, and the apses will be directly opposite, or at 180 degrees distance from each other. But, because of the mutual tendency of the planets towards each other, their gravitation towards the sun is not precisely in that ratio; and hence it happens, that the apses are not always exactly in a right line with the sun. And Newton has given a very elegant method of determining the motion of the apses, on the supposition that we know the force which is thereby added to the gravitation of the planet towards the sun, and that this additional force is always in that direction.

APsis, in architecture, signifies the bowed or arched roof of a house, room, or oven, &c. as also the ring or compass of a wheel.

APsis, in ecclesiastical writers, denotes an inner part in the ancient churches, wherein the clergy sat, and where the altar was placed. It is more particularly used for the bishop's seat, or throne. This was peculiarly called *apsis gradata*, because raised on steps above the ordinary stalls. It was also denominated *exedra*, and in latter times, *tribune*.

APsis is also used for a reliquary, or case, wherein the relics of saints were anciently kept. It took the name apsis, from its being round, or arched, at the top; or perhaps from the place where it was kept. The apsis was commonly placed on the altar: it was usually of wood, sometimes also of gold and silver, with sculptures, &c.

APSY'CHY, *f.* [of *α* priv. and *ψυχη*, the soul.] A swooning or fainting away.

APT', *adj.* [*aptus*, Lat.] Fit. Having a natural tendency to; liable to; inclined to; led to; disposed to.—You may make her you love believe it; which, I warrant she is *apt* to do, than confess she does. *Shakespeare*.—Men are *apt* to think well of themselves, and of their nation, of their courage and strength. *Temple*.—What we have always seen to be done in one manner, we are *apt* to imagine there was but that one way. *Bentley*.—Ready; quick; as, An *apt* wit. Qualified for.—All that were strong and *apt* for war, even them the king of Babylon brought captive to Babylon. *2 Kings*.

APT, or **AP'TA**, an ancient town in the department of the mouths of the Rhone. Its commerce consists in prunes, coarse ferges, and wax chandlery, for which last there is a great demand. Here are many fine Roman antiquities, and it is seated on the river Calaron, twenty miles north of Aix, and twenty-five south-east of Orange. Lat. 43. 51. N. lon. 5. 30. E.

To **APT**, *v. a.* [*apto*, Lat.] To suit; to adapt; to fit; to qualify; to dispose; to prepare:

We need a man that knows the several graces
Of history, and how to *apt* their places;
Where brevity, where splendour, and where height,
Where sweetness is required, and where weight. *Ben Jonson*.

To **AP'TATE**, *v. a.* [*aptatum*, Lat.] To make fit.—To *apate* a planet, is to strengthen the planet in position of house and dignities to the greatest advantage, in order to bring about the desired end. *Bailey*.

APTE'NODYTES, *f.* [of *α* priv. and *πτενναι*, to fly.] The **PENGUIN**, so called by the Dutch navigators, who first discovered these birds, on a voyage to the South Sea, in 1598. Dr. Grew calls them *pinguins*, from *pinguis*, "fat;" and Messrs. Pennant and Latham have gone so far, to favour that conjecture, as to alter the usual spelling into pinguin. But is it in the smallest degree probable, that the illiterate Dutch sailors should think of bestowing a Latin generic term upon a newly-discovered object? But, even admitting that any on-board were capable of this, they would have called the bird *pingued*, and not *pinguin*; surely far less *penguin*, which is the original orthography, and the name by which the Indians described these birds to the Dutch adventurers, and by which they distinguished them at this day.

They are a genus belonging to the order of the anseres, and there are eleven species; the characters are these: Bill straight, smooth, flatish, and somewhat knife-shaped; the upper mandible marked longitudinally with oblique furrows; the lower truncated at the tip. Feet fettered and palmated. Wings consist of pinions, without shafts. The penguins, in many respects, appear analogous to the *alca*, or auks. The former fill up the same space among the fowls of the southern, that the latter do among those of the northern, hemispheres. As nature seems to have begun the feathered tribes with birds incapable of flight, and resembling quadrupeds more than birds, so she concludes the order with others, that appear more nearly allied to fishes than to fowls. The plumage of the penguins, especially that upon the wings, more resembles scales than feathers; and, while it renders these instruments serviceable to their owners as fins in swimming, it renders them altogether useless for flight. The whole body of the penguins is covered with oblong plumes, of a hard, thick, and shining, substance, and closely applied to each other, like the scales of a fish. These, together with a thick coat of fat, protect the birds of this order from the cold of those frozen regions which they inhabit. They prefer, as a residence, those bleak and deserted tracts, that border upon the south pole; tracts, condemned by nature to perpetual sterility and solitude. In the highest latitudes visited by captain Cook, who penetrated to the very borders of those countries that are locked up by perpetual ice and snow, he constantly observed the penguins and petrels, far beyond the precincts allotted to other animals, as if sent to rouse nature from that eternal silence and inactivity in which she is sunk in these horrid abodes. As the water is the natural and proper element of the penguins, they can rest upon it by night as well as by day. When the ice, upon which they perch, breaks off and floats, they still keep by it, till they are often carried to an immense distance from land. Their motions, upon land are as slow and awkward as upon the sea they are alert and rapid. Their short legs are situated far back in the abdomen; and, in order to support themselves upon them, their bodies are raised quite perpendicular; so that, when walking, they appear like so many children with white aprons. The food of the penguins is fish only; and, although they are seen, while on shore, frequenting the tufts of coarse grass, the only vegetable that grows on those lands which they visit, it is, probably, for shelter, and not for the sake of food. They lay from one to three eggs, a very small progeny, like that of the congenerous birds of the North Seas. They dig holes, like rabbits, in the sand, where they deposit their eggs, and rear their young. In walking over the fields, which they have dug in this manner, one often sinks to the knee

knee in their burrows. If the penguins be within, they take their revenge by biting the leg, which they do with wonderful effect. The eggs and young afford an excellent refreshment to sailors, in those countries where there is no other species of food. As the penguins visit the land but seldom, their colours are influenced by that circumstance. The belly, and other parts covered by the water, are white; while the back is of different colours, according to the diversity of the species, which are as follow:

1. *Aptenodytes Patagonica*, or Patagonian penguin: so named, not only because it is found on that coast, but also because it exceeds in bulk all the other penguins. It was brought into England by captain Macbride, from Falkland Islands, off the straits of Magellan. The length of the stuffed skin of this bird, which may be seen in the Leverian Museum, measured four feet three inches, and the bulk of the body seemed to exceed that of a swan. The bill was four inches and a half long, slender, straight, bending on the end of the upper mandible, with no nostrils. The tongue half the length of the bill, and singularly armed with strong sharp spikes pointing backwards. Its bill and legs are black. The plumage is most remarkable, the feathers lying over one another with the compactness of the scales of a fish; the shafts are broad and very thin; the vanes unwebbed; the head, throat, and hind part of the neck, are of a deep brown colour; from each side of the head to the middle of the fore part of the neck are two spots of a gold colour, broad above, narrow beneath, and uniting half way down; from thence the same colour widens towards the breast, fading away till it is lost in pure white, of which colour is the whole under side of the body, a dusky line dividing it from the colour of the upper part. The back is of a deep ash-colour, almost dusky; but the end of each feather is marked with a blue spot, those about the junction of the wings larger and paler than the others. The wings are extremely short in respect to the size of the bird; hang down, and have the appearance of fins, whose office they perform; their length is only fourteen inches; on the outside they are dusky, and covered with feathers, whose shafts are so broad and flat as scarcely to be distinguished from scales; those on the ridge of the wings consisting entirely of shaft; the larger or quill feathers have some very short webs. The tail consists of thirty brown feathers, or rather thin shafts, resembling split whale-bone; flat on the upper side, concave on the under, and the webs short, unconnected, and bristly. From the knees to the end of the claws is about six inches, covered with strong pentangular black scales; the fore toe scarcely an inch long, and the others so remarkably short, as to evince the necessity of that strength of the tail, which seems intended as a support to the bird in its erect attitude; between the toes is a strong semilunar membrane, continued up even part of the claws; the middle claw is near an inch long, and the inner edge very sharp and thin; the interior toe is small, and placed very high. This species inhabits Falkland Islands, Kerguelen's Land, New Georgia, and New Guinea. M. Bougainville caught one, which soon became so tame as to follow and know the person who had the care of it: it fed on flesh, fish, and bread; but, after a time grew lean, pined away, and died. This is rather a scarce species. They lay in the end of September or the beginning of October. They are very full of blood, so that in killing them their head should be severed, to allow it to flow.

2. *Aptenodytes Magellanica*, or Magellanic penguin: is about two feet, and sometimes two feet and a half, long, and weighs eleven pounds. The bill is black, having a transverse band across near its tip; the head and neck are black, except a few markings here and there; the upper parts of the body and wings are of the same colour; the under parts of both are white from the breast, except a narrow band of black passing at a little distance within the white on the breast, and downwards on each side, beneath the wings, quite to the thighs; the legs are of a reddish colour, irregularly spotted on the thighs; and the

claws are black. This species, which is very numerous, inhabits the Straits of Magellan, Staten Land, Terra del Fuego, and Falkland Islands. As food they are not at all unpalatable. They often mix with sea-wolves among the rushes, burrowing in holes like a fox. They swim with prodigious swiftness. They lay their eggs in collective bodies, resorting in incredible numbers to certain spots, which their long residence has freed from grass, and to which were given the name of towns. Penrose observes, that they composed their nests of mud, a foot in height, and placed as near one another as may be. It is possible that they may have different ways of nestling, according to the places they inhabit; or perhaps the manners of this may be blended with those of another. "Here, (says he,) during the breeding-season, we were presented with a sight which conveyed a most dreary, and I may say awful, idea of the desertion of these islands by the human species. A general stillness prevailed in these towns; and, whenever we took our walks among them, in order to provide ourselves with eggs, we were regarded indeed with side-long glances, but we carried no terror with us. The eggs are rather larger than those of a goose, and laid in pairs. We took them once, and sometimes twice, in a season; but they were as often replaced by the birds. The eggs were palatable food, and were preserved good for three or four months."

3. *Aptenodytes demersa*, or Cape penguin: so called from being found in such vast numbers all around the Cape of Good Hope, where they nestle on the small islands in the vicinity of the continent; one of which is named *Penguin Isle*, from the multitudes there are of these birds always upon it. The male of this species is distinguished by a black collar, which crosses the back, and falls over the breast; the head, neck, and back, are of a brown colour, spotted with black. The bill is black, having a yellow band across near its tip. The legs and feet are black; and the back toe, which is not included in the membrane by which the others are connected, is very short, and turned about to one side. The fin, which supplies the place of the wing, is small and flat; and the small pointed feathers that rise out of it give it the appearance of rough leather, rather than of the wing of a bird. Their brood consists of two eggs only, of a white colour. When the young are excluded, the old birds defend them with great courage. Penguins of this species are about the size of a goose; and, though altogether incapable of flight, they sometimes build on these little islands, at the distance of a mile and a half from the shore. As these birds are capable of fasting for several days, it is probable, that they do not repair every day to feed upon the water, during the time they rear their young. This is the *diomedea demersa* of Linnæus, and the *black-footed* penguin of Edwards.

4. *Aptenodytes chrysolome*, the hopping or crested penguin: the birds of this species are twenty-three inches long; the bill is three inches long, and of a red colour, with a dark furrow running along on each side to the tip; the upper mandible is curved at the end, the under is obtuse; the irides are of a dull red; the head, neck, back, and sides, are black. Over each eye there is a stripe of pale yellow feathers, which lengthens into a crest behind, nearly four inches long; the feathers on each side of the head, above this stripe, are longer than the rest, and stand upward, while those of the crest are decumbent, but can be erected on each side at pleasure; the wings, or rather fins, are black on the outside, edged with white; on the inside they are white; the breast and all the under parts are also white; the legs are orange, and the claws are dusky. The female has a streak of pale yellow over the eye, but it is not prolonged into a crest behind as in the male. This species inhabits Falkland Islands, and was likewise met with in Kerguelen's Land, or Isle of Desolation, as well as at Van Diemen's Land, and New Holland, particularly in Adventure-bay. They are called *hopping penguins*, and *jumping jacks*, from their action of leaping quite out of the water, on meeting with the least obstacle,

for three or four feet at least; and indeed, without any seeming cause, they often do the same, appearing chiefly to advance by that means. This species seems to have a greater air of liveliness in its countenance than others, yet is in fact a very stupid bird, so much so as to suffer itself to be knocked on the head with a stick when on land. On one of the islands touched at by captain Cooke, vast numbers of these birds were found, in a sleep so profound, that they allowed themselves to be tumbled over several times before they awoke. The sailors were obliged to give a few of them smart cuffs, with their hands, before they could rouse them from this astonishing lethargy. By and by, however, the whole crowd awoke; and, seeing themselves surrounded by an enemy, they assumed courage, and fell upon the crew in close battle. The ship's company, finding their clothes and their legs torn, beat down vast numbers of them; and, leaving these dead, as they supposed, they went in pursuit of the main body of the flying army. While thus employed, they were surprised by finding that those which they had left upon the field had suddenly got up, and had already attacked their rear, tearing their legs and clothes with redoubled fury. Happy had it been for the human race, and much to the honour of adventurers, had the discovery of unknown countries never led to hostilities of a more mischievous nature!

5. *Aptenodytes catarractes*, or thick-billed penguin: the bill of this species is its distinguishing character; the lower mandible being thick, and apparently broken off, before it reaches the full length of the upper one. Brisson has given this bird the name of *catarracta*, an appellation applied by Aristotle to an aquatic bird of the predatory kind. It is certain, however, that neither he, nor any of the ancient naturalists, ever were acquainted with the penguins; because they are found to reside in regions far beyond the limits of ancient navigation. The bill and legs of this species are red; the face, dark brown; all the fore parts of the body, white; and the hind part of the head, neck, and back, purple, and covered with short stiff feathers, more resembling the scales of a serpent than the plumage of a bird. This is the *phæton demursus* of Linnæus.

6. *Aptenodytes Papua*, or Papuan penguin: it is about two feet and a half long, being a little larger than that which is called the *Cape penguin*. This species inhabits the Isle of Papos, or New Guinea; and has been met with at Falkland Isles and Kerguelen's Land. It is often found among the Patagonian penguins.

7. *Aptenodytes antarctica*, or antarctic penguin: is about twenty-five inches long, and weighs about eleven pounds and a half. The bill is upwards of two inches and three-quarters long; the upper parts of the body are black, the under are glossy white; beneath the chin there is a narrow streak of a blackish colour, passing backwards towards the hind head, a little bent about the region of the ears; the wings are much the same as in the other species; the tail is cuneiform; the feathers, or rather bristles, of which it is composed, are black, and in number thirty-two; the legs are of a flesh-colour, and the soles of the feet are black. This species inhabits the South Sea, from forty-eight degrees to the antarctic circle; and is frequently found on the ice mountains and islands; it is a very numerous species. Our last voyagers found them in plenty in the Isle of Desolation. And it was observed, that in an island they touched at, not greatly distant, the rocks were almost covered with penguins of this sort.

8. *Aptenodytes torquata*, or collared penguin: is a little less than the Papuan, being eighteen inches long. The bill, which is black, is similar to that of the Patagonian penguin; the irides are black; the eye is surrounded with a bare skin of a blood-colour, of an oval shape, and three times as large as the eye itself; the head, throat, hind part of the neck, the sides, back, wings, and tail, are all black; the fore part of the neck, breast, belly, and thighs, are white, extending round the neck, where the white begins, like a collar, except that it does not quite meet at the back part; the legs are black. This species inhabits New Gui-

nea. It was also seen by Forster, the companion of Capt. Cook, near Kerguelen's Land; and again on two isles adjoining to the island of South Georgia.

9. *Aptenodytes minor*, or little penguin: is about the size of a teal, being fifteen inches long. The bill, which is of a dusky colour, is about an inch and a half long, and shaped like that of the *phæton demursus*; the upper parts of the bird from the head to the tail appear to be of a cinereous blue colour, of which colour are the ends of the feathers; the base of them is brown black, and the shafts of each of the same colour; the under parts from chin to vent are white; the wings are dusky above and white beneath; the tail, which is exceedingly short, consists of sixteen stiff feathers, which are scarcely perceptible; the legs are of a dull red colour; the webs are dusky, and the claws are black. This species is commonly found among the rocks on the southern parts of New Zealand, but they are most frequent at Dusky-bay. They make deep burrows on the sides of the hills, in which they lay their eggs. The inhabitants of Queen Charlotte's Sound kill them with sticks, and, after skinning them, esteem the flesh as good food. They are known at New Zealand by the name of *korora*. The legs in these two last are marked with black at the end of the toes; and the claws are black.

10. *Aptenodytes chilensis*, or woolly-cinereous penguin: found very common in the archipelago of Chiloe, and is about the size of a goose.

11. *Aptenodytes Chilensis*, or three-toed penguin: is found in Chili, and is about the size of the former species, but hath a longer neck. It lays in the sand, about six or seven eggs, white, dotted with black.

APT'ERA, or AP'TERON, an inland town of Crete, whose port was Cifamus, on the west side of the island, twelve miles to the south of Sydonia, towards the Montes Leuci, and as many from the Sinus Amphimales. So called from the Sirens, who, being there vanquished in song by the Muses, stripped themselves of their wings, and out of grief leaped into the sea. *Stephanus*. There was a town of Lycia of the same name. Lat. 35.50. lon. 25.0. E.

APT'ERA, a term used by Linnæus for his seventh order of insects, comprehending such as have no wings.

APT'HA, *f.* [αῖμα, Gr.] Certain ulcers which breed in the uppermost part of the mouth.

APT'HANE, a title anciently given to the higher degrees of nobility in Scotland. See THANE.

APTITUDE, *f.* [from *aptus*, Lat. fit.] The natural disposition any thing hath to serve for any particular purpose. Thus, oil hath an *aptitude* to burn, and water to extinguish fire. It is often used, in speaking of the faculties of the mind, for a promptitude or disposition to learn things with ease and expedition. In which sense *aptitude* amounts to the same with what the Greeks call *εὐαδία*, *bona indoles*, and *docility*. Charlton divides *aptitude* into three parts, viz. *acuteness*, *sagacity*, and *memory*.—He that is about children, should study their natures and *aptitudes*, what turns they easily take, and what becomes them; what their native stock is, and what it is fit for. *Locke*.

APT'LY, *adv.* Properly; with just connection, or correspondence: fitly:

But what the mass nutritious does divide?
What makes them *aptly* to the limbs adhere,
In youth increase them, and in age repair? *Blackmore*.

Justly; pertinently. Readily; acutely: as, He learned his business very *aptly*.

APT'NESS, *f.* Fitness; suitability.—The nature of every law must be judged of by the *aptness* of things therein prescribed. *Hooker*.—Disposition to any thing; of persons. Quickness of apprehension; readiness to learn. Tendency; of things.—Some seeds of goodness give a relish of such reflections, as have an *aptness* to improve the mind. *Addison*.

APTOTE, *f.* [απρωτος, of a and πρωτος, a case.] A noun which is not declined with cases.

APTYS'TOS, *f.* [from α priv. and πτω, to spit.] A denomination for disorders in which spitting, though an

usual symptom, is yet wanting, as in what is called a dry asthma, a dry pleurisy, &c.

APULEIUS (Lucius), a Platonic philosopher, universally known as the author of the *Golden Ass*. He lived in the second century, under the Antonines; and was born at Madaura, a Roman colony in Africa. He was a man of a curious and inquisitive disposition, especially in religious matters, which prompted him to take several journeys, and to enter into several societies of religion. He spent his fortune in travelling; so that, at his return to Rome, when he was about to dedicate himself to the service of Osiris, he had not money sufficient to defray the expence attending the ceremonies of his admission, and was obliged to pawn his clothes to raise the necessary sum. He supported himself afterwards by pleading causes; but he raised himself more by a good marriage, than by his pleadings: a widow named *Pudentilla*, who was very rich, fell in love with him. This marriage drew upon him a troublesome law-suit. The lady's relations, pretending he made use of sorcery to gain her heart and money, accused him of being a magician. Apuleius was under no great difficulty of making his defence. He said *Pudentilla* was neither handsome nor young, nor such as could tempt him to have recourse to enchantments. He also took notice of many inconveniences which attend the marrying of widows, and spoke highly of the advantages of a maid above a widow. "A handsome virgin (said he), let her be ever so poor, is abundantly portioned; she brings to her husband a heart quite new, together with the flower and first-fruits of her beauty. It is with great reason that all husbands set so great a value upon the flower of virginity: all the other goods which a woman brings her husband are of such a nature, that he may return them again, if he has a mind to be under no obligation to her: but, virginity cannot be restored, it remains in the possession of the first husband. If you marry a widow, and she leaves you, she carries away all that she brought you." This apology is still extant, and is reckoned a very fine piece. Apuleius was extremely indefatigable in his studies; and composed several books. He took great pleasure in declaiming, and was generally heard with applause.

APULIA, the east side of the kingdom of Naples, on the gulf of Venice. It is divided into three territories, Capitanata, Terra di Bari, and Otranto.

APURIMA, or **APORAMAC'**, a rapid river of Peru, in South America.

A'PUS, *Avis Indica*, in astronomy, a constellation of the southern hemisphere, placed near the pole, between the *triangulum australe* and the *chamelion*, supposed to represent the bird of paradise.

APYCNISUONI, *f.* in music, sounds distant one or more octaves, and yet concord.

APYCNOS, *f.* in music, is said of the diatonic genus, on account of its having spacious intervals, in comparison of the chromatic and enharmonic.

APYE'TOS, *f.* [from α priv. and $\pi\upsilon\omicron\varsigma$, *pus*.] An epithet for a tumour that will not suppurate.

APY'REXY, *f.* [$\alpha\pi\upsilon\sigma\epsilon\lambda\gamma\alpha$, Gr.] The abating or slackening of a fever.

APY'ROUS, *f.* a word applied to denote that property of some bodies, by which they resist the most violent fire without any sensible alteration. Apyrous bodies ought to be distinguished from those which are refractory. Refractory substances are those which cannot by violent heat be fused, whatever other alteration they may sustain. But a body, properly apyrous, can neither be fused by heat, nor can undergo any other change. Diamonds were long thought to be possessed of this property. But some late experiments have shewn, that diamonds may be entirely dissipated or evaporated by heat, and are therefore not intitled to be ranked among apyrous substances. Perhaps there is no body in nature essentially and rigorously apyrous; but it is sufficient that there be bodies apyrous relatively to the degree of fire which art can produce, to intitle them to that name.

A'QUA, *f.* [Lat.] A word signifying *water*, very much used in chemical writings.

AQUA FORTIS, a name given to an impure nitrous acid, commonly used by dyers, brass-founders, &c. and serves as a menstruum for dissolving of silver, and all other metals, except gold. It is usually contaminated with a small quantity of marine acid. The artists who use nitrous acid distinguish the common and less pure acid by the name of *aqua fortis*, and call the more concentrated acid *spirit of nitre*. This distinction appears to be of some utility, and is therefore not improperly retained by chemical writers. The manufacturers of soap in France and elsewhere call their *lixivium* or soap-les by the name of *strong water*; and this name, *eau forte*, being consequently used to denote the caustic alkali in recipes for dyeing and other processes, has given rise to several mistakes.

AQUA MARINA, or **AUGITES**, a precious stone of a transparent green-blue colour, fusible by the blow-pipe; it is nearly the same both in form and specific gravity with the *Peru emerald*, and the *chrysolite*. Its specific gravity is about 2.72, and its hardness nearly the same as that of quartz.

AQUA MIRABILIS. The wonderful water is prepared of cloves, galangals, cubebs, mace, cardomums, nutmegs, ginger, and spirit of wine, digested twenty-four hours, then distilled.

AQUA REGIA, or **REGIS**, an acid compounded of a mixture of the nitrous and marine acids, the bases of which, together with a certain portion of vital air different from what originally existed in the two acids, become combined in a manner which has not been clearly explained. When one or two parts of pale concentrated nitrous acid are mixed with four of marine acid, an effervescence soon takes place, and dephlogisticated marine acid flies off in the elastic form, at the same time that the mixture becomes of a deep red colour: it has obtained its name from its property of dissolving gold, the royal metal of the alchemists, which is not perceptibly acted upon by either of the acids which compose it. *Aqua regia* may be made by adding to nitrous acid any alkaline or earthy salt which contains the marine acid; for the affinity of the nitrous acid to the base being in most cases stronger than the marine, this last is set at liberty, and consequently the mixture, if the salt be not excessive in quantity, so as to engage the whole of the nitrous acid, will contain a certain portion of both acids at liberty. An *aqua regia* will therefore be produced, which is not essentially impaired with respect to common uses by the portion of neutral salt suspended in it. It is usual to make *aqua regia* by dissolving sal ammoniac in about four times its weight of strong nitrous acid; but the results of experiments must vary considerably according to the nature and proportions of the ingredients made use of.

The opinions and inferences of chemical writers respecting the nature of this mixed acid, are various. After the discovery of the dephlogisticated marine acid, it was concluded, that the nitrous acid performs the same office with respect to the marine as the manganese does; that is, in fact, that it either deprives the marine acid of phlogiston, or affords vital air to combine with it, or answers both these purposes. This general supposition is not however without several difficulties. If the marine acid be enabled to calcine and dissolve gold, because it has been dephlogisticated or aerated by the nitrous, it should follow much more strongly that the nitrous acid itself should dissolve that metal; whereas, in fact, it does not. And again, it has not been shewn how this dephlogisticated acid, which is so volatile, and so sparingly soluble in water, is retained in the solution; not to mention that no component part of the nitrous acid is found to escape during the effervescence, except the vital air which enters into the composition of the gas which flies off. When the two acids are in due proportion, *aqua regia* must therefore consist of marine acid and nitrous acid, which has an under-proportion of vital air, or is in the most fuming state; or, in other words, it contains the two bases of the acids, together with a less proportion

proportion of vital air than they possessed before mixture. But whether these principles combine, and form a compound acid, or in what other order they may be arranged, has not been experimentally determined, though the writings of chemists abound with conjectures upon this subject. The combinations of earths and alkalies, and even of metals, with aqua regia, have not been well examined. It is not known whether two different kinds of salts are formed apart from each other, or whether a triple combination takes place, consisting of two acids united to one base. It appears, however, that in some cases the result is one entire compound, and in others two separate ones.

AQUA SECUNDA, is a name sometimes given to an exceedingly-diluted aqua fortis, used in the arts for cleaning the surface of metals, and some other bodies.

AQUA-TETRACHYMAGO'CON, *f.* [of aqua, Lat. *τρίψα*, in compounds, four, *χυμῶς*, humour, and *αγωγός*, Gr. a leader.] A medicine purging the four humours of the body.

AQUA VITÆ, is commonly understood of what is otherwise called brandy, or spirit of wine, either simple, or prepared with aromatics. Some, however, distinguish between them; appropriating the term *brandy* to what is drawn from wine, or the grape; and *aqua vitæ* to that drawn after the same manner from malt, &c. For medicated and aromatic waters, see PHARMACY.

AQUÆ AUGUSTÆ, AQUÆ TARBEL'LICÆ, or AQUEN'SIS CIVITAS, in the Notitia, now *Aqs*, or *Dax*, a town in Gascony, on the river Adour, famous for its baths. Lat. 43. 56. N. lon. 1. 40. W.

AQUÆ BILBILITANÆ, baths twenty-four miles to the west of Bilbilis. Now *Banos de Alhama* in Arragon. *Antonine*.

AQUÆ CALIDÆ, or AQUÆ SOLIS, a place of the Belgæ in Britain, famous for its hot waters. Now *Bath*, in Somersetshire.

AQUÆ CALIDÆ, or AQUICALDEN'SIS, formerly a place in great repute, and a public bath; whose ruins still remain testimonies of the Roman grandeur. Now *Orense*, in Gallicia, still famous for its baths; on the river Minho, fifty-four miles south-east of Compostella. Lat. 42. 30. lon. 8. 30. W. Also a place in the bay of Carthage, *Strabo*. There are other Aquacaldenses, to the north of Gerunda, in Catalonia. *Ptolemy*.

AQUÆ CALIDÆ, a colony between the rivers Serbetes and Savus, in Mauretania Cæsariensis. *Ptolemy*.

AQUÆ CELEN'IE, or CI'LINÆ, now *Caldas*, a hamlet on the Minho, in Gallicia.

AQUÆ CONVENARUM, a hamlet of Gaul, in Aquitaine, and on the borders of the Convenæ, or le Cominge, at the foot of the Pyrenees, near the source of the Garonne; now *Bagnères*. Lat. 42. 20. lon. 3. 39. W.

AQUÆ CUTILÆ, a lake of the Sabines, in the territory of Reate, with a moveable island in it, supposed to be the centre of Italy. The waters were medicinal, and extremely cold, good for a weak stomach and weak nerves; they seemed to act by a kind of suction, which approached to a bite. *Pliny*. Vespasian used them every summer, and there he died. *Suetonius*.

AQUÆ FLAVIÆ, a town on the confines of Gallicia and Portugal, so called from Vespasian and Titus. The inhabitants called *Aquiflavienfes*. Now *Chaves*, a mean hamlet: but the ruins of its bridge testify its former grandeur. Lat. 41. 40. lon. 6. 6. W.

AQUÆ HELVETIÆ, described by Tacitus as a municipal town, and much frequented for its excellent waters; and, though he does not mention its name, Cluverius supposes it to be Baden, in Switzerland, or the river Limat, which falls into the Aar. It is called the Upper, to distinguish it from another called the Lower Baden, in Alsace. Lat. 47. 55. lon. 8. 49. E.

AQUÆ ME'ROM, famous for the defeat of Jabin: supposed to be the lake called *Samachonitis*, or *Semechonitis*, by Josephus; into which the river Jordan falls, before it comes to the sea of Genesareth, or Galilee.

AQUÆ PANNO'NIÆ, celebrated baths of Austria, now

called *Baden*, twenty-eight miles to the south of the city of Vienna.

AQUÆ PATAVINÆ, baths in the territory of Venice, near Padua, called *Fontes Aponi*; now *Bagni d'Abano*. Lat. 45. 15. lon. 13. 48. E.

AQUÆ QUINTIANÆ, now supposed to be *Sarria*, a town of Gallicia, on a rivulet of the same name, three leagues to the south of Lugo.

AQUÆ SEX'TIÆ, a colony to the north of Marseilles, so called both from the founder Sextus Calvinus, and from its quantity of water, and number of cold and hot springs; built after the defeat of the Salyes, or Salvii, whose territory in the south of Provence reached from the Rhone to the borders of Italy. By an inscription the colony appears to have been either increased or renewed by Augustus. In the Notitia it is called *Civitas Aquensis*; now *Aix*. Here the Teutones and Cimbri were defeated with great slaughter by Marius. Lat. 48. 4. lon. 6. 4. E.

AQUÆ SATIEL'LE, or SATIELLO'RUM, a town in Liguria, on the river Bormia; now *Aqui*, a town of Montserrat. Lat. 44. 45. lon. 8. 40. E.

AQUÆ TAURI, hot waters or baths in Tuscany, three miles from the sea, said to be discovered by a bull, whence the appellation; now *Aquapendente*, in Orvieto. Lat. 42. 40. lon. 12. 40. E.

AQUAM'BOË, one of the principal monarchies on the coast of Guinea in Africa, stretching twenty miles in breadth, and ten times that space in length from east to west. According to Bosman, the coast is divided into a great number of petty royalties, but all of them subject to the king of Aquamboe, who indiscriminately uses an unlimited authority over them. His despotism gave rise to a proverbial saying, that "there are only two ranks of men at Aquamboe; the royal family, and slaves." The natives of this country are haughty, turbulent, and warlike; and their power is formidable to all the neighbouring nations.

AQUA-NE'GRA, a town of Italy, on the river Chiesia, twelve miles west of Mantua. Lat. 45. 12. N. lon. 10. 25. E.

AQUAPENDENTE. See FABRICIUS.

AQUA'PIM, a Danish settlement on the western coast of Africa, founded by D. Ifert, conformable to an edict of his Danish majesty, dated the 7th of November, 1792, which provides for the abolition of the slave-trade in his dominions, opens the Danish African ports to all nations, and ordains the establishment of a colony, in which the introduction of hired labour should be attempted, and every labourer be free. This edict is said to have been suggested by the humane count Bernstorff, as an experiment to try whether the African negroes might not be induced to civilization, and voluntary labour, and to embrace the Christian religion, by putting them on the same footing with husbandmen and hired servants in free countries. Social improvement, indeed, is but progressive; and, though its advancement may not be perceptible to vulgar eyes, yet the philosopher will trace it by comparing the present with the past; and the Christian will rest satisfied, that every real improvement which, in the course of Providence, has once been begun, will in due time, arrive at perfection.

AQUA'RIANS, Christians in the primitive church who consecrated water in the eucharist instead of wine. This they did under pretence of abstinence and temperance; or, because they thought it universally unlawful to eat flesh or drink wine. Epiphanius calls them *Encratites*, from their abstinence; St. Austin, *Aquarians*, from their use of water; and Theodoret, who says they sprung from Tatian, *Hydropostata*, because they offered water instead of wine.

AQUA'RIOUS, in astronomy, one of the celestial constellations, being the eleventh sign in the zodiac, reckoning from Aries, and is marked by the character ♒, representing part of a stream of water, issuing from the vessel of Aquarius, or the water-pourer. This sign also gives name to the eleventh part of the ecliptic, through which the sun moves in part of the months of January and February. The poets feign that Aquarius was Ganymede, whom

whom Jupiter ravished under the shape of an eagle, and carried away into heaven to serve as a cup-bearer, instead of Hebe and Vulcan; whence the name. Others hold, that the sign was thus called, because that, when it appears in the horizon, the weather commonly proves rainy. The stars in the constellation Aquarius, are, in Ptolemy's catalogue, forty-five; in Tycho's, forty-one; in Hevelius's, forty-seven; and, in Flamsteed's, 108.

AQUAR'TIA, f. [so named by Jacquin, in honour of his friend *Aquart*, merchant of Martinico, who assisted him in his botanical researches.] In botany, a genus of the tetrandria monogynia class, ranking in the natural order of solanæ. The generic characters are—Calyx: perianthium monophyllous, permanent; tube bell-shaped; limb subquadrid, expanding; two opposite divisions obsolete. Corolla: monopetalous, rotate; tube very short; limb quadrid; divisions linear, widely spreading. Stamina: filaments short; antheræ erect, very large, linear. Pistillum: germ ovate; style filiform, declined, the length of corolla; stigma simple. Pericarpium: berry globular, one-celled. Seeds: very many, compressed—*Essential Character.* Calyx, bell-shaped; corolla, wheel-shaped with linear divisions; berry, many-seeded.

There is but one species, known by the name of *aquartia aculeata*. It is a perennial aculeate plant, unarmed at top. Leaves alternate, ovate, obtuse, petioled. The stature of *solanum*. A native of South America. Swartz is of opinion, that it is rather a species of *solanum*, with four stamens to the flower; differing from it in number, in the segments of the corolla being linear, and the calyx bell-shaped; the habit however is quite the same.

AQUATIC, adj. [*aquaticus*, Lat. from *aqua*, water.] That which inhabits the water.—The vast variety of worms found in animals, as well terrestrial as aquatic, are taken into their bodies by meats and drinks. Ray.—Applied to plants, that which grows in the water.—Flags, and such-like *aquatics*, are best destroyed by draining. *Mortimer*.

A'QUATILE, adj. [*aquatilis*, Lat.] That which inhabits the water.—We behold many millions of the *aquatile* or water frog in ditches and standing plashe. *Brown*.

AQUATINTA, f. a method of etching on copper, lately invented, and by which a soft and beautiful effect is produced, resembling a fine drawing in water-colours or Indian ink. Previous to the operation upon the plate, the following powder must be prepared. Take equal parts of asphaltum and fine transparent rosin, and powder them separately in a mortar. Through a muslin sieve sift upon a sheet of paper a thin stratum of the asphaltum, above which sift a similar layer of the rosin, and upon this another layer of asphaltum, continuing these alternate layers till both of the powders are exhausted. Then pass the mixture both together through the same sieve so as to mix them sufficiently for use. Some, instead of the above mixture, used powdered gum sandarach only.

The process is as follows: A copper plate being polished in the usual way, lay the etching-ground upon it, and etch the outlines of your design in the manner directed under the article **ETCHING**. The ground is then to be softened with a little greafe, and wiped off with a piece of rag; leaving, however, as much greafe upon the plate as just to dim the copper. Next sift the powder upon the surface of the plate; after which, strike the other side of it pretty smartly against the edge of a table to discharge it of the loose powder. This done, with a hand-vice hold the back of the plate over a chaffing-dish of burning charcoal, till it becomes so hot as to give pain upon being touched with the back of the hand; and the powder which adhered to the greafe will now be fixed to the plate. The plate being then suffered to cool, take turpentine-varnish mixed with ivory black; and with a hair-pencil dipped in it cover all the lights or places where there is no work or shade. A rim or border of bees-wax is now to be raised round the plate; and, having reduced a quantity of aquafortis to a proper strength with water, pour it on, and let it stand five minutes for the first or lightest shade; after which,

pour it off; and, having washed the plate with water, let it edgewise to dry. Then with varnish stop out all the light shades, pour on the aqua fortis for the second tint, and let it stand five minutes more; proceeding in the same manner for every tint till you produce the darkest shades. If a bold open ground is wanted in any part, this requires an after-operation. The ground must be laid as in the other case, by sifting on the powder; only this powder must be much coarser, and the plate more heated in order that the particles of the powder may spread, and form small circles: even good clean rosin will do by itself. In etching landscapes, the sky and distant objects are also performed by a second operation, and the powder is sifted upon the plate with a finer sieve. If the trees or any part of the fore-ground require to be finished higher, the plate must be entirely cleaned from greafe with bread, and a ground laid in the common way of etching; when you may finish as highly and neatly as you please with the needle or point, by stippling with dots, and biting in those parts, or by a rolling-wheel, which is more expeditious.

If different colours are to be expressed in aquatinta, there will be required so many different plates, each having only that part etched upon it which is designed to be charged with its proper colour. It may happen however in particular subjects that some of the colours are so distant from each other as to allow the printer room to rub them in without blending; in which case, two or three different colours may be printed from the same plate at once. Where different plates are necessary, a separate one, having a pin in each corner, must be provided as a sole or bottom to the aquatinta plates; and these again must be exactly fitted, having each a small hole in their corners for passing over the pins of the sole: the said pins serving the double purpose of retaining the plates successively in their due position, and of directing the printer in placing the paper exactly on each plate so as not to shift; by which means each tint or colour will be exactly received on its proper place. This is the method practised with so much beauty and effect in France. A landscape or any similar subject may be printed off at once in its different proper colours, by laying these upon the plate. In this case, the colours must be pretty thick in their consistence; and the plate must be carefully wiped in the usual way, after the laying on of each tint, as well as receive a general wipe when charged with all the tints.

The art of engraving in aquatinta is kept a secret by those artists who practise it. In order to succeed in it, great care and judgment are requisite; and much depends upon a certain nicety of management, which is only attainable by practice.

AQUAVIVA, a town of the kingdom of Naples, and province of Barri.

A'QUEDUCT, f. [*aquæductus*, Lat.] A conduit, or construction of stone or timber, built on an uneven ground, to preserve the level of water, and convey it, by a canal, from one place to another. Aqueducts are either visible, or subterraneous: visible, when constructed above-ground, and supported by arches or arcades; subterraneous, when formed by piercing through rocks or mountains, or any elevated ground; which, in the construction of navigable canals, is called **TUNNELLING**.

Aqueducts were long ago the wonders of Rome; the quantity of them which they had; the prodigious expence employed in conducting waters over arcades from one place to another, at the distance of even 100 miles, by cutting through mountains, and piercing rocks; were performances which justly excite our admiration. Appias the censor advised and constructed the first aqueduct. His example gave the public luxury a hint to cultivate these objects; and the force of prodigious and indefatigable labour diverted the courses of rivers and floods to Rome. Agrippa, in that year when he was ædile, put the last hand to the magnificence of these works. It is chiefly in this respect that the modern so much resembles the ancient city of Rome. For this advantage, she is peculiarly indebted to

to Sextus V. and Paul V. who for grandeur and magnificence, in repairing and beautifying the aqueducts, emulated the masters of the universe.

It has been a matter of surprise, that these aqueducts, which might have been directed in a straight line to the city, approach towards it by frequent and winding mazes. Some have said that this oblique track was pursued to avoid the expence which must attend the building of arcades to an extraordinary height: others, that it was their intention to diminish the impetuosity of the current, which, rolling in a straight line through an immense space, must always have increased its velocity, must have worn the canals by perpetual and forcible attrition, and of consequence afforded an impure and unwholesome draught to the inhabitants. But since there was so great a descent between the cascade of Tivoli and Rome, it is demanded why they drew water from the same river at the distance of more than twenty miles higher; nay, of more than thirty miles, if we reckon the curvatures of its direction through that mountainous country? It is replied, the motive of obtaining the water more salubrious, and more limpid, was sufficient to make the Romans think their labour necessary, and their expence properly bestowed; and to those who reflect that the waters of this river were impregnated with mineral particles, and by no means wholesome, the answer will appear satisfactory.

If any one will cast his eyes upon plate 128th of the Antiquities of Father Montfaucon, he will see with how much care these immense works were constructed. From distance to distance spiramenta were left, that, if the water should happen to be stopped by any accident, it might gradually disembogue, till they could clear its ordinary passage. There were likewise, even in the very canals which conveyed the water, cavities considerably deeper than its internal surface, into which the stream was precipitated, and where it remained stagnant till it was refined from mud and feculence; and ponds, where it might expand itself till it was purified.

The aqueduct of the *aqua Marcia* had an arch of sixteen feet in diameter. Above, there appeared two canals; of which the highest was fed by the waters of the Tivertine, and the lower by the *Clodian* river. The entire edifice is seventy Roman feet high. The arch of the aqueduct of the *aqua Claudia* is of hewn stone, very beautiful; that of the aqueduct of the *aqua Neronia* is of brick: they are each of them seventy-two Roman feet in height. The canal of the aqueduct which was called the *aqua Appia*, deserves to be mentioned for the singularity of its being much narrower at the lower than at the higher end. Nor must we forget to mention the aqueduct of Drusus, and that of Rimini, so celebrated in ancient Rome. We are told by Frontinus, a man of consular dignity, who had the superintendence of the aqueducts under the emperor Nerva, that nine of them emptied their waters into the city through 13,594 pipes, of an inch diameter each; and Vignere relates, that every twenty-four hours, Rome received no less than 300,000 hogsheads of water by means of her aqueducts!

The munificence of the Roman emperors, in providing their subjects with this necessary article of domestic comfort and cleanliness, was not merely confined to the capital, nor limited to their natural dominions. The luxury of excellent water was provided in a liberal manner to many cities that submitted to the Roman arms. Athens, the seat of Grecian glory and magnificence, was indebted to Rome for its most valuable supply of water. That city, even in the most flourishing state of its republic, had recourse only to wells, which were held so sacred, that, by a law of Solon, those only who lived contiguous to a well could claim the benefit of its waters. This defect was at length removed by the munificence of the emperor Adrian, who erected an aqueduct to supply all Athens with water, and which still bears his name; and is adorned with a frontispiece of the Ionic order, said to be a more correct specimen

of that style of ancient architecture than any Rome can furnish.

Another very surprising instance of human art and industry, is the aqueduct of Metz, of which a great number of arcades still remain. These arcades crossed the Moselle, a river which is very broad at that place. The copious sources of this aqueduct furnished water for the representation of a sea-fight. This water was collected in a reservoir: from thence it was conducted by subterraneous canals formed of hewn stone, and so spacious that a man could walk erect in them: it traversed the Moselle upon its superb and lofty arcades, which may be still seen at the distance of two leagues from Metz: so nicely wrought and so firmly cemented, that, except those parts in the middle which have been carried away by the ice, they have resisted, and will still resist, the severest shocks of the most violent seasons. From these arcades, other aqueducts conveyed the waters to the baths, and to the place where the naval engagement was represented. It is also said, that the aqueduct of Segovia, in Spain, may be recorded among the most admired labours of the Romans. It was built by the emperor Trajan, and is said to be the best preserved of all the Roman works. There still remain 159 arcades, wholly consisting of stones enormously large, and joined without mortar. These arcades, with the edifice, are 102 feet high; there are two ranges of arcades, one above another. The aqueduct flows through the city, and runs beneath the greatest number of houses which are at the lower end. The aqueduct which Louis XIV. caused to be built near Maintenon, in France, for carrying the river Eure to Versailles, is perhaps the greatest which now exists in the universe: it is 7000 fathoms in length, above 2560 in height, and contains 242 arcades.

A'QUEOUS, *adv.* [from *aqua*, Lat. water.] Watery. —The vehement fire requisite to its fusion, forced away all the *aqueous* and fugitive moisture. *Ray*.

AQUEOUS HUMOUR. See **ANATOMY**, p. 597.

A'QUEOUSNESS, *f.* [*aqueositas*, Lat.] Wateriness.

AQUIFOLIUM, *f.* in botany. See **LEX**.

A'QUILA, *f.* in ornithology, a synonyme of the eagle. See **FALCO**.

AQUILA, *f.* in astronomy, the *Eagle*, or the *Vulture*, as it is sometimes called, is a constellation of the northern hemisphere, usually joined with Antinous. It is one of the forty-eight old constellations, according to the division of which Hipparchus made his Catalogue of the Fixed Stars, and which are described by Ptolemy. The number of stars in Aquila, and those near it, now in the later-formed constellation Antinous, amount to fifteen in Ptolemy's Catalogue, to nineteen in Tycho's, to forty-two in that of Hevelius, and to seventy-one in Flamsteed's. But in Aquila alone, Tycho counts only twelve stars, and Hevelius twenty-three; the principal star being *Lucida Aquila*, and is between the first and second magnitude. The Greeks, as usual, relate various fables of this constellation, to make the science appear as of their own invention.

AQUILA, a city of Italy, and the capital of Abruzzo, seated on the banks of the river Pescara, near its source. It has an ancient castle, and is a bishop's see immediately under the pope. The land about it produces great plenty of saffron. It was very near being destroyed by an earthquake, in February, 1703. The first shock was so terrible, that the inhabitants abandoned the city; but returning to vespers, it being Candlemas-day, the shocks followed one another with such violence, that 24,000 people perished; 800 were killed in one single church; many other churches, monasteries, and noble buildings, were either swallowed up or overturned, together with the greater part of the city and its walls. Aquila stands thirty miles from the sea, and fifty-two N. E. of Rome. Lat. 42. 20. N. lon. 13. 39. E.

AQUILA-DEL-CAMPO, a small town of Old Castile.

AQUILARIA, *f.* [*aquila*, Lat. an eagle; in French, *bois d'aigle*, eagle-wood, from its lofty situation.] In botany,

tany, a genus of the dicandria monogynia class. The generic characters are—Calyx: perianthium one-leaved, permanent; tube bell-shaped; border five-cleft; clefts ovate, acute, flat, spreading; nectary one-leaved, pitcher-shaped, length of the tube of the calyx, half five-cleft; clefts bifid, obtuse. Stamina: filaments ten, alternate to the clefts of the nectary, and shorter than them; antheræ oblong, versatile. Pistillum: germ ovate, on a very short pedicel, superior; style none; stigma simple. Pericarpium: capsule on a very short pedicel, obovate, woody, two-celled, two-valved; with the partition contrary and bipartite. Seeds: solitary, oblong.—*Essential Character.* Calyx, five-cleft; nectary pitcher-shaped, half five-cleft, with bifid clefts; capsule superior, woody, two-celled, two-valved; seeds solitary.

There is only one species, called *agularia ovata*: it is a large tree, with the trunk and branches erect, and covered with a brown or grey bark, smooth except towards the ends of the twigs, which are villose; leaves alternate, about eight inches in length, quite entire, very smooth, somewhat coriaceous, having one branched nerve, and very fine veins; the petioles are short and hairy; there are no stipules: flowers terminating, on many-flowered peduncles. The wood of the tree is white and inodorous. Native of the mountains of Malacca and Cochinchina. The *aroma* of aloes-wood is a disease, caused by oleaginous particles stagnating and concreting in the inner parts of the trunk and branches into a resin, by which means the natural appearance of the wood is altered as to colour, smell, &c. till at length the tree dies, and when split the valuable resin is taken out of it. No part of the tree is lactescent or poisonous. All the true *lignum aloes*, so called, proceed from this tree, even the most valuable, which is commonly called *calumbac*, and is found in the mountains of Champava, belonging to Cochinchina. The inferior species, or rather varieties, are less rare, and are found in various places. Perfumes from this wood are highly esteemed by the oriental nations, and from the bark of the tree is made the common paper which the Cochinchinese use for writing, in the same manner as in Japan from the bark of the mulberry (*morus papyrifera*). This perfume is said to be good in vertigo and palsy: the powder restrains vomiting and fluxes, and particularly henteries; this it brings about, not by astringing, properly speaking, but by its corroborating power. It has the name of *lignum aloes*, or *wood aloe*, from its bitter taste.

AQUILEGIA, *f.* [from *aquila*, Lat. an eagle; because the nectaries are fancied to resemble an eagle's claws. Our English name, *columbine*, is derived from the resemblance which the same parts bear, both in form and colour, in the wild state, to the head and neck of a pigeon, *columba*.] In botany, a genus of the polyandria pentagynia class, in the natural order of multifloræ or corniculatæ. The generic characters are—Corolla: petals five, lanceolate-ovate, flat, spreading, equal; nectaries five, equal, alternate with the petals; each horned, gradually broader upwards, with an oblique mouth, ascending outwardly, annexed inwardly to the receptacle; produced below into a long attenuated tube, with an obtuse top. Stamina: filaments thirty to forty, subulate, the outer one shorter; antheræ oblong, erect, the height of the nectaries. Pistillum: germs five, ovate-oblong, ending in subulate styles, longer than the stamens; stigmas erect, simple; chaffs ten, wrinkled, short, separate, and involving the germs. Pericarpium: capsules five, distinct, cylindric, parallel, straight, acuminate, one-valved, gaping from the tops inward. Seeds: very many, ovate, keeled, annexed to the gaping future.—*Essential Character.* Petals five; nectaries five, horned, between the petals; capsules five, distinct.

Species. 1. *Aquilegia viscosa*, or clammy columbine: stem almost naked, with viscid hairs, and one or two flowers; leaves subtrilobate. Root perennial; stem a foot high at most, hispid with glutinous hairs, quite simple, or with only a single branch or two. Petioles from an inch to three inches in length, with viscid hairs like the stem,

proceeding from wide, coloured, stem-clasping, sheaths. The first root-leaf palmate-three-lobed, the divisions two-lobed or three-lobed; the other root-leaves, which are four or five in number, ternate, the leaflets equally petioled, blunt, digitate-three-parted; the lateral segments three-lobed or four-lobed; the middle ones always three-lobed. Stem-leaf one only, or seldom two, ternate; the leaflets quite entire, lanceolate, the middle one longest. Peduncles usually two, one axillary, the other terminating, one-flowered. Nectary curved inwards. Capsules five, viscid, with netted veins. It varies with a short, one-flowered, leafless, stem. Native of the south of France, and the mountains of Piedmont.

2. *Aquilegia vulgaris*, or common columbine: nectaries incurved. Stem three feet high, erect, branching, leafy, somewhat angular; leaves smooth, glaucous underneath; the lower ones petiolate, biternate; the leaflets roundish, trilobate, gashed, and notched; the upper ones digitate, the lobes oval and quite entire; the radical petioles very long. The flowers are produced from the tops of the naked branches, and hang down; they have generally six pistils and eight nectaries. There are many varieties of this species. The usual colour of the flowers in their wild state is blue, but Haller says the red is common about Berne; white ones are also seen about Berne. Mr. Woodward has found both red and white flowers in Norfolk. Haller mentions double flowers occurring in the Pays de Vaud. The columbine is found native in most parts of Europe, in woods, hedges, and among bushes. It is perennial; and flowers with us in June. The flowers vary much by culture; and become double either by multiplying the petals, or the nectaries. Of all these varieties, there are subordinate variations, both in the degree of doubleness, as with two or more rows of petals, two or three rows of nectaries, curiously inserted one into the other; and in the colours, as blue, white, red, purple, flesh-coloured, ash-coloured, chestnut-coloured, and striped or variegated blue and purple, blue and white, red and white. From the different shape of these flowers, persons not well skilled in the culture of plants might suppose they were distinct species. The root, the herb, the flowers, the seeds, have been recommended to be used medicinally, on good authority; but this plant is of a suspicious tribe, and Linneus affirms, as of his own knowledge, that children have lost their lives by an over-dose of it. The sensible qualities of the seeds, says Lewis, afford little foundation for their supposed virtues in the jaundice, measles, and small-pox; as they do not seem to differ materially from those of the cold seeds, being only somewhat more mucilaginous, with a disagreeable relish. The virtues ascribed to a tincture of the flowers, as an antiphlogistic, and for strengthening the gums, and detaching scorbutic ulcers in the mouth, appear to be better founded; the tincture being made with an addition of the vitriolic acid, and differing little from our official tincture of roses. The flowers themselves, as well as the conserve and distilled water of them, directed in some foreign pharmacopœias, are insignificant.

3. *Aquilegia alpina*, or Alpine columbine: nectaries straight, shorter than the lanceolate petal. Root biennial; leaves biternate, tender, and smaller than in the common sort; the leaflets multifid; the lobes sublinear and blunt, with the appearance and tenderness of Canadian columbine. The leaflets in the common sort are trifid, but in this they are ternate; or they have one pair of sessile lobes, with the odd lobe petioled and trifid; the middle segment again trifid, and the side ones bifid; the middle segment, and the uppermost of the side ones, three-toothed; the side-lobes are of the same form, but only bifid; all the teeth are roundish. In common columbine the petioles are twice trifid, and all the lobes petioled; in this the side-leaves are sessile, and the lobes more deeply cut. The corollas are blue, with the tips of the petals yellowish green; the anterior part of the nectaries paler blue; the claws of the petals whitish within. According to Haller and Al-lioni, the nectaries are bent in at the end. The former of these

these adds, that the stem is only a foot or at most eighteen inches high, that the divisions of the leaves are linear, not rounded, and that there are only one or two flowers on a stem. They both are of opinion, that the Alpine columbine is distinct from the common sort. Native of the Alps of Switzerland and Savoy: said also to be found in Westmoreland. It flowers in May and June.

4. *Aquilegia canadensis*, or Canadian columbine: nectaries straight, stamens longer than the corolla. Root perennial; stems very slender, reddish; leaves of the same form and size with those of thalictrum, or meadow rue; the lower ones biternate, irregularly divided, the extreme lobes blunt; the upper ones simply ternate, toothed, or quite entire; the uppermost simple, lanceolate, acuminate. Corollas yellow within, and red on the outside. Native of Virginia, Canada, and most of the northern parts of America. It flowers in April, and the seeds ripen in August. Introduced before the year 1640, by Mr. John Tradescant, sen.

5. *Aquilegia viridiflora*, or green-flowered columbine: nectaries straight, thickened, and a little bent in at the tip; stamens nearly equal to the corolla. Root perennial; stems a foot high or more, upright, slightly angular and villose; leaves biternate, petioled; leaflets frequently two-lobed, gashed, blunt, pale green underneath: flowering peduncles nodding, short, fruiting ones erect. Petals pale green, wrinkled, shorter than the borders of the nectaries, which are greenish yellow within, and brownish on the outside, the border cordate-wedge-shaped, the horn subulate and straight, blunt, and a little bent in at the end. Stamens shorter by half than the corolla. Styles longer than the corolla. Germs five, with brownish styles, surrounded with ten subulate, acuminate, white, wrinkled, pellucid, chaffs. The whole plant is smooth; it flowers in May, and the seeds ripen in July. Native of Siberia; where it was found by Pallas.

Propagation and Culture. These plants are all raised by sowing the seeds, or parting the old roots, but the former method is chiefly practised; for the old roots are very apt to degenerate after they have blown two or three years, so as to become quite plain. The seeds should be sown in a nursery-bed in August or September, for the seeds which are kept till spring seldom grow well, or at least remain in the ground a whole year. The spring following the plants will appear above ground, therefore should be kept clear from weeds, and, if the season should be dry, they must be refreshed with water, that they may gather strength. In the middle or latter end of May, these plants will be strong enough to transplant; therefore some beds of good fresh undunged earth should be prepared, planting them therein at eight or nine inches distance every way, keeping them clear from weeds, and refreshing them with a little water, as they may require it. In the following autumn, by which time the plants will have acquired strength enough to flower the summer following, the roots should be carefully taken up, and planted in the borders of the flower-garden; but, where their roots are designed to be preserved in perfection, all their flower-stems should be cut off, as soon as the flowers are past, to prevent their degenerating by the mixture of the farina from other flowers. But, in order to be sure of having no single or bad flowers in the borders, you may suffer the plants to remain in the nursery-beds until they have blown; at which time you may put a stick by each root you fancy to preserve, or pull out all the single or bad-coloured ones, and throw them away, cutting off all the flowers from your best roots as soon as they have shewn themselves, which will greatly add to the preserving them fair in their colours. In order to keep up a succession of good flowers, fresh seeds should be sown every year; and, if you can meet with a friend at some distance, who is furnished with good flowers of this kind, it will be very advantageous to both parties, to exchange seeds once in two years, by which means they will not be so apt to degenerate into plain colours. In sowing the seeds of the variegated columbines, great care should be taken

not to suffer any plain flowers to remain for seed, there being generally some plain flowers intermixed with the striped ones on the same plant, and often in the same branches: these should be cut off, for, if they are permitted to seed, or if their farina impregnate the striped flowers, they will degenerate into plain colours; so that there cannot be too much care taken in sowing the seeds, where the beauty of their flowers are regarded. The Canada columbine flowers almost a month before the other sorts; for which reason it is preserved in the gardens of the curious, though there is no great beauty in the flowers. There is another variety of this with taller flower-stems, which flowers a little after the other, but does not differ either in the shape of its flowers or leaves from this; therefore I conclude that they are but one species. The Canada columbines flower in April, and their seeds ripen the beginning of August. The other sorts flower towards the end of May, and in cool seasons will continue to produce flowers till the middle of July, and the seeds ripen towards the middle or end of September, according as the season proves more or less favourable.

AQUILEIA, a large city of the Carni, or Veneti, and a noble Roman colony, which was led thither between the first and second Macedonian wars. It was washed by two rivers, the Natiso and Turrus. The reason of leading this colony was, in order to be a bulwark against the neighbouring barbarians. The colony was afterwards increased with 1500 families by a decree of the senate; from which it became a very famous port-town. The emperor Julian ascribes the appellation to the augury of an eagle at the time of building it; but Isaac Vossius on Mela, to the great plenty of water, as if the town were called *Aquilegia*. The harbour, at the mouth of the Natiso, is distant sixty stadia from the city, so that ships of burden are towed up the river. In 452, it was besieged by Attila, with an innumerable host of barbarians. The walls were assaulted by a formidable train of battering-rams, moveable turrets, and engines, that threw stones, darts, and fire; and the monarch of the Huns employed the forcible impulse of hope, fear, emulation, and interest, to subvert the only barrier which delayed the conquest of Italy. Aquileia was at that period one of the richest, the most populous, and the strongest, of the maritime cities of the Adriatic coast. Three months were consumed without effect in the siege; till the want of provisions, and the clamours of his army, compelled Attila to relinquish the enterprize, and reluctantly to issue his orders that the troops should strike their tents the next morning and begin their retreat. But, as he rode round the walls, pensive, angry, and disappointed, he observed a stork preparing to leave her nest in one of the towers, and to fly with her infant family towards the country. He seized, with the ready penetration of a statesman, this trifling incident which chance had offered to superstition; and exclaimed, in a loud and cheerful tone, that such a domestic bird, so constantly attached to human society, would never have abandoned her ancient seats, unless those towers had been devoted to impending ruin and solitude. The favourable omen inspired an assurance of victory; the siege was renewed, and prosecuted with fresh vigour; a large breach was made in that part of the wall from whence the stork had taken her flight; the Huns mounted to the assault with irresistible fury; and the succeeding generation could scarcely discover the ruins of Aquileia. The place, however, is still called *Aquileia*, and there are several inscriptions and antiquities to be seen in it, which are worthy of a traveller's notice; and, though dwindled into a poor village, it gives a title to the patriarch of Aquileia. The patriarch is named by the Venetians, and resides at Udino, because the town of Aquileia belongs to the house of Austria. It is situated fifty-seven miles N. E. of Venice. Lat. 46. 0. N. lon. 13. 8. E.

AQUILICIA, *f.* in botany. See *LEE*.

AQUILICIUM, or *AQUILICIANA*, *f.* in Roman antiquity, sacrifices performed in times of excessive drought, to invoke rain from the gods.

AQUILIFER,

AQUILIFER, *f.* A standard-bearer of the Roman army, the picture of an eagle being in his colours; a cornet or ensign.

A'QUILINE, *adj.* [*aquilinus*, Lat. from *aquila*, an eagle.] Resembling an eagle; when applied to the nose, hooked: His nose was *aquiline*, his eyes were blue, Ruddy his lips, and fresh and fair his hue. *Dryden.*

Gryps signifies some kind of eagle or vulture; from whence the epithet *grypus* for an hooked or *aquiline* nose.

A'QUILLO, *f.* is used by Vitruvius for the north-east wind; or that which blows at 45° from the north towards the east point of the horizon. The poets gave the name *aquilo* to all stormy winds dreaded by the mariner.

A'QUILUS, *f.* among the ancients, a dark or dusky colour approaching to black. Hence some of the heathen gods were called *dei aquili*, q. d. *nigri*.

AQUIMINARIUM, *f.* in antiquity, a kind of lustral vessel, wherein the Romans carried their holy water for expiation and other religious offices.

AQUINAS (St. Thomas), styled the *Angelical Doctor*, was of the ancient and noble family of the counts of Aquino, descended from the kings of Sicily and Arragon, and was born in the castle of Aquino, in the Terra di Lavorna, in Italy, in the year 1224 or 1225. He entered into the order of Dominicans; and, after having taught school-divinity in most of the universities of Italy, at last settled at Naples, where he spent the rest of his life in study and acts of piety; and was so averse to ambition or profit, that he refused the archbishopric of that city, offered him by pope Clement IV. He died in 1274, leaving an amazing number of manuscripts, which were printed at Venice, in seventeen volumes folio, in the year 1490. He was canonized by pope John XXII. in the year 1323; and Pius V. who was of the same order with him, gave him, in 1567, the title of the *fifth doctor of the church*, and appointed his festival to be kept with the same solemnity as those of the other four doctors. His authority has always been of great importance in the schools of the Roman catholics. Lord Herbert, in his *Life of Henry VIII.* tells us, that one of the principal reasons which induced that king to write against Luther was, that the latter had spoken contemptuously of Aquinas. This extraordinary person, like many men of great talents, shewed in his early youth none of that liveliness and vivacity of disposition which is but too often mistaken for quick parts. He was called by his companions *le bœuf muet*, "the silent ox;" but his master, Albert the Great, more capable of distinguishing, used to say of him to those who gave him that appellation: *Les doctes mugissemens de ce bœuf retentiroient un jour dans l'univers*: "The learned bellowings of this ox will one day be heard through the world." St. Thomas, possessing an ardent mind, devoted it to the studies then in vogue, scholastic philosophy and theology: in the latter, indeed, he was so eminently successful, that Bucer said of him: *Tolle Thomam, ecclesiam Romanam subvertetrem*: "Take away Thomas, and I will effect the downfall of the Romish church." It is to be observed that this speech has a double meaning, as the word *Thomam* may be taken to mean the holy volume, or the Bible, as well as *Thomas*.

St. Thomas was one day with pope Innocent IV. in his

closet, when an officer of his chancery came in with a bag of gold, procured by absolutions and indulgences. The pope profanely said, "See, young man, the church is not what it was in the times when it used to say, Silver and gold have I none."—"Holy father, that is very true, indeed," replied St. Thomas, "but then it cannot say to the poor afflicted with the palsy, Rise, take up thy bed and walk."

A'QUINO (Philip d'), in Latin *Aquinas*, or *Aquinus*, having turned from Judaism, had a pension from the clergy of France, and acquired much reputation by his knowledge of the Hebrew language, which he taught at Paris, in the reign of Louis XIII. and by the books he published, among which is his *Dictionarium Hebraeo-Chaldaeo-Thaludico-Rabbinicum*. His grandson, Anthony d'Anquin, was first physician to Louis XIV.

AQUINO, a town in Italy, in the kingdom of Naples, and Terra di Lavorna; a bishop's see, but ruined by the emperor Conrade. It was the birth-place of the poet Juvenal, and of Thomas Aquinas. It was anciently called *Aquinum*, and was a Roman colony. Lat. 41. 32. N. lon. 14. 30. E.

AQUITA'NIA, was anciently one of the three principal divisions of Gallia Comata, bounded by the Garonne, the Pyrenees, and the Ocean; this is the *Aquitania Casariiana*, or *Vetus*. Augustus set the different boundaries, viz. the Loire, the Cevennes, the Pyrenees, and the Ocean. It was called *Gallia Aquitanica*; and in the old Notitiae, *Provincia Aquitanica*. Now comprising Guienne (which seems to be a corruption of Aquitania) and Gascony.

AQUO'SE, *adj.* [from *aqua*, Lat.] Watery; having the quality of water.

AQUO'SITY, *f.* [from *aquose*.] Wateriness.

A. R. anno regni; that is, the year of the reign; as, A. R. G. R. 20. *Anno regni Georgii regis vigesimo*, in the twentieth year of the reign of king George.

AR, the metropolis of Moab, in Arabia Petrea; and the royal residence situate on the east side of the river Arnon. It was called also *Rabba*; and, to distinguish it from Rabba of the Ammonites, *Rabbat Moab*, and on coins *Rabbath Moma*. Eusebius says it was called *Arcopolis* in his time, from *Ar* and *Polis*. The inhabitants are called *Arcopolitae*. St. Jerome says, that this city was entirely destroyed by an earthquake when he was a young man.

A'RA, *f.* in astronomy, the *Altar*, one of the forty-eight old constellations, mentioned by the ancient astronomers, and is situated in the southern hemisphere; containing only seven stars in Ptolemy's Catalogue, and nine in that of Flamsteed; none of which exceed the fourth magnitude.

ARABELLA, [of *ara* and *bella*, Lat. i. e. a fair altar.] A proper name of women.

ARABES'QUE, or **ARABES'K**, *f.* something done after the manner of the Arabians. *Arabesque*, *Grotesque*, and *Moreque*, are terms applied to such paintings, ornaments of friezes, &c. wherein there are no human or animal figures, but which consist wholly of imaginary foliages, plants, stalks, &c. The words take their rise from hence, that the Moors, Arabs, and other Mahometans, use these kinds of ornaments; their religion forbidding them to make any images or figures of men or other animals.

G E N E R A L I N D E X.

A C O U S T I C S.

AIR, a vehicle for sound, but not the only one, 85.
 Difference of tone in sounding bodies, 86.
 Echoes how produced, 90.
 Elastic and non-elastic bodies distinguished, 88.
 Eolian lyre, its construction and action, 86.
 Organ and harpsichord, to make them play of themselves, 91.

Reverberation of sounds, 89.
 Sounds, how conveyed, 85; objections to Newton's system of sounds, *ibid.* theory to which these objections give rise, 86; strength and softness of sound, 87; objections to the foregoing theory, 88.
 Speaking figures, how to make, 90.
 Speaking-trumpet, its action and use, 89.

Velocity of sounds, 89.
 Vibration of musical strings, 87; four sounds produced from one string, *ibid.*
 Whispering gallery, construction of, 89.

A L G E B R A.

ADDITION of algebraical quantities, 283.
 Annuities, calculation of, 308; for lives, 317.
 Approximation, mode of, for discovering roots of numeral equations, 302.
 Authors who have written on algebra, 281, 282.
 Axioms, or self-evident truths, 283.
 Binomial theorem, 293.
 Cardan's rule for solving a cubic equation, 299.
 Chances, doctrine of, 315; throwing dice or balls, 315; chances of life, 316.
 Curve-lines, their general properties, 322.
 Definition and etymology of algebra, 281; definitions explanatory of the art, 282.
 Differential method, 313.
 Diophantus, the first writer on algebra, 281.
 Division of algebraical quantities, 284; of fractions, 286.
 Divisors, method of, 301.
 Equations simple, 288; quadratic, 289; their nature, 295; transformation of,

296; limits of their roots, 297; depression and solution of, 298; solution of recurring equations, 299; to solve a cubic equation by Cardan's rule, *ibid.* to solve a biquadratic by Des Cartes's method, 300; by Dr. Waring's, 301; construction of equations, by geometry, 321.
 Evolution, or extracting of roots, 286.
 Fractions, transformation of to others of equal value, 284; multiplication and division of, 285; continued fractions, 306.
 Geometry, application of algebra to, 318.
 Increments, method of, 314.
 Interest and annuities, 308.
 Involution, or raising of powers, 286; Sir Isaac Newton's rule for raising a binomial, 293.
 Italians, the first cultivators of algebra in Europe, 281.
 Logarithms, 308.
 Multiplication of algebraical quantities, 283; of fractions, 285.
 Permutations and combinations, 293.

Problems which produce simple equations, 289; which produce quadratic equations, 290; unlimited problems, 305.
 Progression, arithmetical, 292; geometrical, 293.
 Proportion, 291.
 Ratios, their nature and use, 290.
 Reversion of series, 302; recurring series, 312.
 Roots of equations, their limits, 297; the impossible roots of an equation, 303.
 Signs used in algebra explained, 282.
 Solution of equations, 298: of recurring equations, 299; of a cubic equation, *ibid.* of a biquadratic, by Des Cartes, 300; by Dr. Waring, 301.
 Subtraction of algebraical quantities, 283.
 Summation of series, 309.
 Surds, or imperfect roots, 294; binomial surds, 307.
 Transformation of fractions, 294; of equations, 296.
 Variable quantities, 292.

A M E R I C A.

ABORIGINAL America described, 420.
 Algonquin woman, anecdote of, 424.
 America, continent of, its boundaries and extent, 412; supposed to be imperfectly known to the ancients, *ibid.* pretensions of the Welch to the first discovery of it, *ibid.* of the Norwegians, 413; really discovered by Columbus, *ibid.* general description of, 416; divided into the North and South continent, *ibid.* climate, why so different from the old continent, *ibid.* population uncertain, 417; how first peopled, 417, &c. character and manners of the inhabitants, as described by various authors, 418, &c. monuments of art in the interior parts, 425.
 America, North, when first discovered, 428; progressive settlement, 429-433; its boundaries, extent, &c. 433; divisions, 434; history of the revolution, 435-465; establishment of the United States, 465.
 America, South, its divisions and provinces, 434, 435.
 America, United States of, history of the revolution which gave rise to the establishment of them, 435-465; sketch of events which preceded the revolution, 435; stamp-act, 437; duty on tea, &c. *ibid.* tea destroyed at Boston, 439; Boston port-bill, *ibid.* meeting of congress, 440; actions at Concord and Lexington, 441; battle of Bunker's hill, *ibid.* declaration of congress, 442; Washington appointed commander in chief of the American army, 444; expedition into Canada, *ibid.* defeat of General Carleton, *ibid.* unsuccessful attack on Quebec, and death of General Montgomery, 445; occurrences in Virginia, *ibid.* British governors expelled from several provinces, 446; Boston evacuated by the British, *ibid.* Americans declare themselves independent, *ibid.* the British foiled in their attempt on Charlestown, 448; arrival of commissioners from England, *ibid.* Americans defeated at Staten Island, 449; battle of the White Plains, 450; Philadelphia taken by the British, 452; capture of Burgoyne and his army at Saratoga, 454; treaty of alliance between France and America, 455; Philadelphia evacuated by the British, *ibid.*

French fleet arrives on the coast of Virginia, 456; Charlestown taken by the British, 459; Arnold defects the Americans, 461; execution of Major André, *ibid.* Americans defeated at Guildford, 463; action between the British and French fleets, 464; surrender of Lord Cornwallis's army at York-town, 465; treaty of peace between England and the United States, *ibid.* establishment and boundaries of the United States, *ibid.* their constitution and government, 466; manufactories, &c. 467.
 Americus Vesputius publishes the first written account of the new world, and thence gives name to America, 416, 470.
 Boundaries and extent, 412.
 Cabot, John, sent on a voyage of discovery by Henry VII. 428.
 Cabot, Sebastian, explores the coast of Brazil, 428.
 Clavigero, abbé, his opinion relating to the first peopling of America, 418; his remarks on the character and manners of the Americans, 421.
 Climate of America, 416.
 Columbus, Christopher, his birth and education,

education, 413; his early voyages, *ibid.* remarkable escape, *ibid.* marries and settles at Lisbon, *ibid.* conceives the idea of making discoveries to the westward, *ibid.* offers his services to the Genoese states, who reject them, 414; cause of his overtures being rejected in Portugal, *ibid.* applies to the courts of Castile and England, *ibid.* is invited by Isabella queen of Castile, and engaged in the Spanish service, *ibid.* fails from Spain, *ibid.* an island discovered, 415; his first interview with the natives, *ibid.* prosecutes his discoveries southward, *ibid.* returns to Spain, *ibid.* his second,

third, and fourth, voyages to America, 415; his death, *ibid.*
Columbus, Bartholomew, is sent by his brother Christopher to negotiate with Henry VII. of England, 414.
Commerce of the United States, 468.
Constitution of the United States, 466.
Convention between France and America, 455.
Hell-gate, straits so called, 450.
Lakes in America, the largest in the world, 417.
Lexington, battle of, 441.
Logan, an Indian chief, his eloquent speech to Lord Dummore, 424.

Mariners compass, 413.
San Salvador, the island first discovered in America by Columbus, 415.
Staten Island, defeat of the Americans there, 449.
Treaty of peace concluded between France and America, 455; between Great Britain and the United States, 465.
Washington, George, appointed commander in chief of the American army, 441; his various operations throughout the war, 446, &c. &c. elected president of the United States, *ibid.*

A N A T O M Y.

ABDOMEN, its division into regions, contents, arteries, veins, and nerves, 528; muscles of, 570, 572.
Absorbent system, 629-633; absorbent vessels, 630.
Amphibious and aqueous animals, their conformation and parts, 667.
Anus, muscles of the, 571.
Arm, 528, 552; fore-arm, 553.
Arteries, 624-627; aorta and arteria pulmonalis, 624; arteries of the arteries, 625.
Blood, 607; its parts, and quantity in the human body, 608; circulation of, 609.
Bones, 523, 532; their substance, and degree of susceptibility, 528, 529; their formation, 532; technical terms to express their connection, 533; bones of the head, 534-544; of the trunk, 544, &c.
Brain, 531, 591; veins thereof, 594; nerves, 595.
Breasts, 604.
Bursa mucosæ described, 638.
Carnivorous bird, anatomy of one, 666.
Carpus, its figure, substance, articulation, motion, &c. 554.
Cartilages, 526; their substance, 529; cartilages and ligaments of the joints, 582; cartilages of the sternum and ribs, 583; of the pelvis and inferior extremities, 584. See **LIGAMENTS**.
Cellular substance, its several uses, 529.
Cerebellum, 593.
Cerebrum, 592.
Chyle, its preparation, &c. 632.
Classification of the various parts of the human body, 525, 527.
Cock, anatomy of, 661; its oesophagus, and how digestion is performed 661; duodenum and small guts, 662; lymphatic system and course of the lacteals, *ibid.* kidneys and organs of generation, 663; nutrition of the fœtus, *ibid.* description of the parts about the neck and head, 666; the eye and ear, *ibid.*
Comparative anatomy, 652-671.
Corpus adiposum 588.
Cow, anatomy of, 638; considered as a ruminating animal, 659; progress of the food, and changes produced on it in the different stomachs, 660; parts of generation, and heart, *ibid.*
Cranium, or skull, 527.
Cuticle, or scarf-skin, 586.
Cutis vera, its texture, papilla, appearance, inflammation, &c. 587.
Digestion, 613.
Dog, anatomy of, 652; does not sweat, but perspires insensibly, *ibid.* stomach and intestines, 653; pancreas, spleen, and liver, 654; kidneys and glandulæ atrabilarie, *ibid.* spermatic vessels, scrotum, &c. 655; their manner of gene-

ration accounted for, 655; diaphragm, mammae, and heart, *ibid.* thymus and lungs, 656; neck and jaws, *ibid.* tongue nose, ear, and eye, 657; brain, &c. 658.
Dura mater, 591.
Ear, its various parts, 601; how acted upon by the air, 602.
Egg, its gradual changes by incubation, 603.
Extremities, the upper, of the human body, 527, 551; the lower, 528, 556.
Eye, 597; its different coats, *ibid.* vitreous humour and white, *ibid.* eye-brows, palpebræ, lachrymal gland, &c. 598; phenomena of the eye, with the different modes in which objects are discerned, 599.
Face, comprehends the forehead, eye-brows, cheeks, ears, upper and lower jaw, &c. 527.
Fat, how formed; difference between marrow and fat, *ibid.*
Feeling, 589.
Female skeleton, distinguishing marks of it, 540.
Fibres, 526; muscular and nervous, 530.
Fibula, its articulation and use, 557.
Fingers, their bones, phalanges, &c. 555.
Filices, their peculiar conformation, 667; abdomen, spleen, and organs of generation, 668; swimming-bladder, heart, and absorbent system, 669; brain, organs of smelling, seeing, and hearing, 670.
Foot, composed of tarsus, metatarsus, and toes, 558.
Fowls, anatomy of, 660-666. See **COCK**.
Glands, 527.
Gravid uterus, anatomy of, 641-652.
Growth and decay, 639.
Hairs, their texture and use, 589.
Hand, consists of carpus, metacarpus, and fingers, 554.
Hawk, anatomy of, 666.
Head, 527, 591. See **BRAIN**.
Hearing, phenomena of, 602.
Heart, with its ventricles and auricles, 605; motion of the blood to and from the heart, 606.
Hermaphrodites, 623.
Insects, their general structure, 670; difference of sex, 671; are not produced by putrefaction; their various changes, &c. *ibid.*
Integuments, their situation, size, and divisions, 586.
Intestines, 613.
Kidneys, their three different substances 616.
Larynx, its uses, 603.
Leg, composed of tibia, fibula, &c. 556.
Ligaments, 526; of the lower jaw and temporal bones, 582; of the occipital bone and vertebrae of the neck, *ibid.* of

the vertebrae, 583; of the sternum, vertebrae, and ribs, *ibid.* of the clavicle and scapula, *ibid.* between the scapula and os humeri, 584; of the joint of the elbow, *ibid.* joining the head of the radius to the ulna, *ibid.* between the bodies of the radius and ulna, *ibid.* of the inferior extremity of the bones of the fore-arm, *ibid.* of the carpus and bones of the fingers, *ibid.* of the hand and fingers in situ, *ibid.* of the pelvis, 585; between the pelvis and head of the os femoris, *ibid.* at the joint of the knee, *ibid.* of the fibula and inferior extremity of the leg, *ibid.* the basis of the metatarsal bones, *ibid.*
Liver, 615.
Lungs, their parts and office, 610.
Lymphatics of the lower extremities, 629; of the head and neck, 631; of the upper extremities, *ibid.*
Marrow, its sensibility, 526; different from fat, 527.
Medulla oblongata, 593; medulla spinalis, 594.
Membranes, 526.
Menstruation, 621.
Metacarpus, 555.
Metatarsus, 559.
Mouth, its parts, 602.
Muscles, 527, 530, 561-579; of the cranium, 567; of the ear, *ibid.* of the eyeball, 568; of the nose, mouth, and lips, *ibid.* of the neck, 569, 573; between the lower jaw and the os hyoides, 569; between the os hyoides and trunk, *ibid.* at the entry to the fauces, 570; on the posterior part of the pharynx, *ibid.* about the glottis, *ibid.* on the anterior parts of the abdomen, *ibid.* of the organs of generation, and anus, 571; within the pelvis and abdomen, 572; between the ribs and within the thorax, 573; on the posterior part of the trunk, *ibid.* of the superior extremities, 574; on the os humeri and fore-arm, 575; on the hand, 576; of the inferior extremities, 577; on the thigh, *ibid.* of the leg, 578; of the foot, 579. Explanation of three Plates of muscles, *ibid.*
Nails, how formed; their texture and use, 588.
Neck, divided into the anterior and posterior parts, 527.
Nerves, 527, 531, 595, 633; nervous fluid, 637.
Nose, its different parts, 600; phenomena of smelling, 601.
Omentum, or caul, 616.
Os sacrum, 557; os coccygis, or rump-bone, 548; os ilium, or haunch-bone, 549;

548; ossa innominata, *ibid.* os ischium, or hip-bone, 549; os pubis, or share-bone, *ibid.* os humeri, 552; os scapoides, 554; os lunare, *ibid.* os cuneiforme, *ibid.* os pisiforme, *ibid.* os trapezium, *ibid.* os trapezoides, *ibid.* os magnum, *ibid.* os unciforme, *ibid.* os calcis, or heel, 558; ossa sesamoidea, 559.
 Palate of the mouth, 602.
 Pancreas and pancreatic juice, 616.
 Pelvis, 548; its contents described, 617.
 Periosteum, external and internal, 526.
 Peritoneum, 612.
 Perspiration, or sweat, its quality and uses, 590.
 Pharynx and salivary glands, 604.
 Pia mater, 591.
 Pleura and other parts of the thorax, 604, 605.
 Pores, two different kinds of, 587.
 Pulses different sorts of, 626, 627.
 Pylorus, 613.

Radius, 553; its use in certain motions, 554.
 Renal glands, 617.
 Rete mucosum, 586.
 Ribs, 549; true and false, 550.
 Rotula, its substance and articulation, 557.
 Shoulder, 551; shoulder-blade, *ibid.*
 Skeleton, description of the, 532; distinctive marks between the male and female, 540; description of the plate of the human skeleton, 540.
 Skin, properly so called, 587.
 Spleen, 616.
 Sternum, or breast-bone, its substance and cartilages, 551.
 Stomach, 612; curious experiments on the digestive powers of the stomach, 614.
 Stone-eater, 614.
 Tarfus, a description of its seven bones 558; its articulation, 559.
 Tastes, diversity of accounted for, 603.
 Teeth, their number, structure, &c. 543.
 Thigh, 556; its articulation and motions, *ibid.*

Thorax, 527, consists of vertebræ, ribs, and sternum, 549; description of its contents, 604.
 Thumb, 555; its uncommon articulation, *ibid.*
 Thyroides, 549.
 Tibia, its cartilages and articulation, 557.
 Toes, difference between the bones of them and of the fingers, 559.
 Tongue, its texture and offices, 603.
 Tympanum, or drum of the ear, 601.
 Ulna, its extremities, body, and articulation, 553.
 Veins, the different kinds, 627, 628.
 Vertebræ, or back-bones, 544; conical vertebræ, 546; dorsal *ibid.* lumbar, 547; false, *ibid.* os sacrum, *ibid.*
 Vessels, 526; blood-vessels, *ibid.* arteries, *ibid.*
 Viscera, 527.
 Womb, its parts and action described, 642; contents of the pregnant uterus, 650.

A P P R E N T I C E.

ASSIGNING apprentices, 826, 829.
 Bankruptcy of the master, 828.
 Binding of apprentices must be by indenture, 821.
 Binding of poor apprentices, 822.
 Binding in incorporated districts, 825.
 Charities for binding out poor apprentices, how to be ordered, 825.
 Children compellable to be bound apprentices, 820.

Death of the master, 825, 829; of the apprentice bound out by charity, 825.
 Differences between masters and apprentices, 820, 826.
 Discharging apprentices from their masters, and of masters from their apprentices, 828.
 Inticing away an apprentice, 820.
 Leaving his master's service, 829.

Sea-service, of binding poor boys apprentice thereto, 825.
 Setting up in trade, 820, 830.
 Stamp-duty on indentures, 821.
 Stealing the master's goods, 829.

DIRECTIONS for placing the COPPER-PLATES to VOL. I.

1. FRONTISPIECE—MINERVA and her PUPILS, to face the Title		33. ANAS, Plate II. the CHINESE TEAL	523
2. HIS MAJESTY'S ARMS and PATRONAGE, to follow the Title		34. ANATOMY, Plate I. Front and Back View of the Human BONES or SKELETON	560
3. ABORTION, Plate I. Six Dissections of the Womb	p. 24	35. ANATOMY, Plate II. Front and Back View of the First Layer of the MUSCLES	579
4. ABORTION, Plate II. Child strangled by the Navel-string	26	36. ANATOMY, Plate III. Front and Back View of the Second Layer of the MUSCLES	580
5. ACCIPENSER, the STURGEON	56	37. ANATOMY, Plate IV. Front and Back View of the Third Layer of the MUSCLES	581
6. PORTRAIT of ADDISON	109	38. ANATOMY, Plate V. View of the BRAIN and different VISCERA	617
7. PORTRAIT of ADRIAN	125	39. ANATOMY, Plate VI. Male and Female ORGANS of GENERATION, with four Views of HERMAPHRODITES	624
8. AEROSTATION—a View of four AIR BALLOONS	169	40. ANATOMY, Plate VII. A Front and Back View of the BLOOD VESSELS	628
9. MAP of AFRICA	185	41. ANATOMY, Plate VIII. View of the ABSORBENT VESSELS	630
10. ABORIGINES of AFRICA	187	42. ANATOMY, Plate IX. A Front and Back View of the NERVES	636
11. AGAVE, the AMERICAN ALOE	194	43. ANATOMY—GRAVID UTERUS, Plate I. View of the Pelvis, dissected open	643
12. AIR-GUNS	221	44. ANATOMY—GRAVID UTERUS, Plate II. a Front View of the PREGNANT WOMB	646
13. AIR-PUMPS	225	45. ANATOMY—GRAVID UTERUS, Plate III. a Side View of the PREGNANT WOMB	648
14. ALAUDA, the LARK of North America	234	46. ANATOMY—GRAVID UTERUS, Plate IV. a Front View of the PELVIS and VESSELS of the WOMB	650
15. ALBINOS, of WHITE NEGROES	241	47. ANATOMY—GRAVID UTERUS, Plate V. the PREGNANT WOMB dissected open, to shew the true position of the FOETUS	652
16. ALCA, the PUFFIN and RAZOR-BILL	244	48. ANIMAL FLOWERS	715
17. ALCEDO, the KINGFISHER	248	49. ANIMALCULE, the various Kinds	718
18. PORTRAIT of ALEXANDER the GREAT	267	50. PORTRAIT of QUEEN ANNE	732
19. PORTRAIT of ALFRED the GREAT	280	51. ANNONA, the Trifid-fruited CUSTARD-APPLE	735
20. The BARBADOES ALOE	362	52. PORTRAIT of ANTONINUS PIUS	780
21. AMARANTHUS, the various-leaved nodding AMARANTH	388	53. APIS—the Structure and Economy of the BEE	796
22. ABORIGINES of NORTH AMERICA	423	54. AP TENODYTES, the PENGUINS	836
23. MAP of NORTH AMERICA	429		
24. MAP of the BRITISH PROVINCES in NORTH AMERICA	433		
25. MAP of SOUTH AMERICA	435		
26. MAP of the UNITED STATES of AMERICA	465		
27. AMPELIS, or CRESTED CHATTERER of AMERICA	484		
28. AMPHISBÆNA SERPENTS	487		
29. AMYGDALUS, the PEACH and NECTARINE	494		
30. ANACARDIUM, the CASHEW-NUT TREE	505		
31. ANARRHICAS, the SEA WOLF	514		
32. ANAS, Plate I. the SWAN	516		

The Subscribers are particularly recommended to have each Volume done up in Boards, as soon as completed, with the Copper-Plates placed at the end. The numbers will by this means be preserved, and the Plates kept clean, until the Work is finished; when a set of TITLE PAGES, with new and elegant FRONTISPIECES to each, will be delivered, in order that the whole may be bound in an uniform manner. The Copper-Plates may then either be placed opposite their respective Pages, or be bound all together in a separate Volume, as the purchaser may deem most proper and convenient.
