NORTH ATLANTIC OCEAN STATION ECHO
TERMINAL REPORT
1966 - 1973

by

ADRIAN W. LONGACRE¹

INTRODUCTION

Ocean Station ECHO, (figure 1), one of five stations in the North Atlantic Ocean formerly occupied by U.S. Coast Guard Cutters on which meteorological and oceanographic data was collected, was centered at 35° 00'N latitude, 48° 00'W longitude. Oceanographic stations at ECHO were first taken by the USCGC CASCO in January 1963. The final occupation was by the USCGC INGHAM in June 1973, after which Ocean Station ECHO was disestablished. Between those dates, a total of eighty-six oceanographic occupations occurred. Data from the first occupation, January - February 1963, was published in U.S. Coast Guard Oceanographic Report No. CG 373-2 (Morse and McGary, 1964). Data collected between September 1966 and October 1967 was published in U.S. Coast Guard Oceanographic Report No. CG 373-21 (Shuhy, 1969) and that from November 1967 to December 1968 were covered in U.S. Coast Guard Oceanographic Report No. CG 373-49 (Rosebrook, 1971).

DATA COLLECTION AND PROCESSING

A total of 2048 oceanographic stations were taken by U.S. Coast Guard Cutters during the 86 patrols between January 1963 and June 1973. A summary of these oceanographic operations since

January 1963 is presented in Table 1. Nine hundred eleven stations were occupied using an STD system, with the remaining 1137 consisting of shallow and deep Nansen casts. Data was collected using established procedures outlined in the U.S. Coast Guard Manual for Oceanographic Operations (CG-410).

Temperature data from Nansen casts were transmitted to the U.S. Coast Guard Oceanographic Unit immediately after each cast for real-time data processing and quality control. Corrected temperature values were forwarded to the Navy Fleet Numerical Weather Central, Monterey, California, for use in forecasting synoptic oceanographic conditions.

Upon completion of a cruise, collected data were processed and quality controlled and submitted to the National Oceanographic Data Center (NODC). Observed values of temperature, salinity, and dissolved oxygen and computed values of sigma-t and sound velocity for occupations 21 through 87 are presented in Appendix A.

TEMPERATURE

August was the warmest month as indicated by the surface water temperature, figure 2, with the average surface temperature between 26.8°C and 24.5°C, averaging 26°C over all years. The coldest average surface temperature was between February and April, usually in March. Below 100

OCEAN STATION ECHO DISESTABLISHED

meters reactions to seasonal changes were much less extreme and were almost non-existent. The rapid surface temperature decrease in the fall and winter showed its effect down to depths of 200 meters. Possible effects were seen to 300 meters.

Averaged temperatures for the 300 meter to 1000 meter levels were similar in their monthly variations. Between some months there were differences in the monthly variations of temperature at the 300 meter and 400 meter levels as compared to those below 500 meters, but such occurrences were the exception rather than the rule. The steeper vertical temperature gradient of the shallower levels would have caused larger temperature differences for equal changes in the depth of the isotherms.

Response to seasonal cycles over the year was most pronounced in the surface layer, as already mentioned. In the 300 meter to 1000 meter layers, temperatures dropped from June 1967 to July 1967, after which there was a sharp increase through September. Temperatures dropped sharply until November, and then fell more gradually until February 1968. By March, temperatures had risen, followed by a slight decrease above 400 meters and a continued rise below. By June, all temperatures had fallen from their earlier spring high. From June to October, all temperatures showed a gradual rise, except for a slight decrease between August and September at certain deeper levels. Temperatures decreased through December. Temperatures in these levels

increased through March 1969, except at 300 meters where the increase lasted only until February and March was slightly cooler. Temperatures decreased between March and April, then rose for the next two months. Between June and July temperatures decreased. They increased in August. Little change occurred through September. Subsequently temperatures dropped through January 1970, except for a slight brief increase in November between 300 meters and 500 meters. Temperatures then generally increased through March, decreased in April, increased in May, sharply decreased in June, followed by increasing temperatures through September 1970. October showed a sharp drop, followed by an increase through November. By January 1971, temperatures had dropped by from 1.7°C at 300 meters to 2.7°C at 700 meters. By April, temperatures had increased, and then fell through July, to increase again, reaching a peak in August. Temperatures then fell until November, increased until January 1972, and then fell until March. By June, temperatures were much higher, and started falling. This continued until November (October at 700m) and fell in December. Until March 1973, temperatures remained within 0.6°C of the December 1972 temperature. They fell in April.

SALINITY

Monthly averaged sea surface salinity values showed a seasonal variation much like that of sea surface temperature, but to a less noticeable degree, figure 3. The highest average sea surface salinity usually occurred during the summer months, though not always, followed by a rapid

decrease during the early fall months. A rapid increase in the surface salinity occurred during the early winter, after which there was a more gradual net increase toward the summer maximum. However, between the rapid rise in early winter, and the more gradual spring rise, there was, on several occasions, a decrease. The variation of salinity with time showed a greater variation at the surface as compared to the deeper levels, showing the effects at the air-sea interface.

The monthly average salinity at 100 meters seemed to vary more along the lines of the deeper layers than the surface layers.

From 200 meters to 1000 meters the variation in salinity showed a high degree of similarity, with salinity decreasing as one moved deeper.

Between 1000 meters and 1500 meters, the variations in salinity were similar to one another, but with much less uniformity.

The similarity in variation of both salinity and temperature between 700 and 2000 meters indicates this layer was a single water mass, the North Atlantic Central Water mass, as previously reported by Rosebrook (1971).

The similarity in variation of temperature and salinity down to 1500 meters again supports Rosebrook's (1971) observation of this being the Upper North Atlantic Deep Water (Wust, 1936).

DISSOLVED OXYGEN

Dissolved oxygen samples were collected and analyzed during two occupations of Ocean Station ECHO. These were occupation No. 49 by USCGC DUANE (14

November 1970 to 7 December 1970), figure 4a, and occupation No. 52 by USCGC INGHAM (25 January 1971 to 11 February 1971), figure 4b. During the first occupation 10 stations were analyzed for dissolved oxygen; during the second occupation there were 19 stations.

Surface values of dissolved oxygen averaged around 5.15 ml/l for occupation 49. The oxygen minimum occurred between 600 meters and 800 meters, with O_2 values around 4.0 ml/l. After the minimum, O_2 values increased with depth and reached a maximum of about 6 ml/l around 1500 meters.

Occupation No. 52 showed higher surface values (average around 5.5 ml/l) followed by a more rapid decrease with depth to the O_2 minimum layer between about 500 meters and 650 meters. The minimum value was about 3.60 ml/l. Again, values increased with depth to 1500 meters after which values were nearly constant with increasing depth at about 6 ml/l.

Both sets of data showed a great similarity below the oxygen minimum layer. The greater surface values during occupation 52, and the more shallow and lower minimum values indicated greater biological activity, both production and consumption, during the later occupation.

Temperatures were cooler during occupation 52 than during occupation 49. There was, however, a warming trend between January and February 1971, while temperatures decreased between November and December 1970. Salinity showed a similar pattern. The cooling during the first occupation may have resulted in a sinking of the surface waters, causing a removal of producers and nutrients, while the warming trend during

the second occupation could have caused an increase in productivity.

ISOTHERMS

The coolest surface temperatures present at Ocean Station ECHO was about 17° C, figure 5. This isotherm varied in depth between 460 meters (September 1967) and the surface (April 1970). During the period where ECHO was continually manned (starting in April 1968), the minimum depth of the 17° C level was reached in April, and on two occasions in June.

The greatest depth of this level usually occurred in late summer, and or in late winter. The former occurring due to the isotherms being depressed due to summer heating and the latter due to winter cooling and mixing. There was generally a slight rise in depth of the isotherm between the fall and winter deep values.

This pattern was generally followed by all isotherms from 17° C to 5° C. There were some minor exceptions to this, but these exceptions generally occurred during months where the isotherms made only small migrations. For example, between April and May 1968 the 17° C through 10° C isotherms became shallower, while the 9° C through 5° C isotherms moved to deeper levels. The most radical departure from this general uniformity was between February and March 1970, where the 16° C through 5° C isotherms moved 50 meters deeper, while the 17° C isotherm rose from 275 meters to 80 meters. This may have been a result of atmospheric (temperature) effects, although such effects usually did not appear below 200 meters.

Since deep stations were not made with

enough frequency, annual fluctuations of the 3° C and 4° C isotherms were not sufficiently well defined. However, that data which were collected seems to agree with the fluctuations of the warmer levels.

ISOHALINES

The isohalines showed a similar seasonal variation of depth, figure 6. The salinity appeared to generally decrease with depth. The lowest surface salinity present was about 36.3 ‰. The salinity down to about 100 meters (about 35.1 ‰) generally followed the fluctuations of the 36.3 ‰ isohaline. The 35.0 ‰ isohaline also followed the general trend of the shallower isohalines, but less closely than the others.

Monthly variations of the 36.3 ‰ to 35.1 ‰ isohalines were similar except for several occasions where there appeared to be a lag between the shallower and deeper isohalines.

Between June 1967 and July 1967 the isohalines became shallower and then descended 280 meters or more by September. The levels rose to within about 40 meters of the July level by February 1968. These lower winter values were followed by the depth of isohalines increasing for the next one to three months (depending on the isohaline), followed by isohalines moving to their shallowest level in June, for the higher values of salinity, and July for less saline water. By August, all layers had descended, but September showed the isohalines to be rather irregular, with some moving shallower, and others deeper. From October to November, the isohalines had become shallower, followed by a general sinking through February 1969.

Various layers moved differently until April when all layers were shallower than February. During the next two to three months, the layers moved deeper, followed by a general overall rise until January 1970. Levels moved deeper until March, after which they rose to a June peak. Levels descended until September. A sharp rise was apparent for October, then November showed layers had moved deeper.

The following year was similar to 1970 with layers shallow in January, descending through April, a yearly high in July, descending to September, a short rise to November, followed by descending levels which continued to January 1972, after which levels rose through March.

From June 1972 until March 1973 levels did not generally appear to vary by more than 50 meters between any two months.

STANDARD DEVIATION

Since all data for a month was averaged, the standard deviation for both temperature and a salinity for each month was computed at 100 meter intervals.

Normally, one would expect the greatest deviation to occur at the surface or in the near surface layer where the atmospheric effects would be greatest. Furthermore, an open ocean area, such as Ocean Station ECHO, should have a greater deviation in this surface region for temperature, than for salinity, since runoff would not have an effect.

As expected, temperature did show a much greater deviation than salinity for virtually all months and depths. However, the greatest deviation did not only occur at the surface, but in deeper layers, figure 7.

To be sure, large values of standard deviation did occur in the upper 100 meters, particularly from May to October of most years studied. These surface layer values were generally more noticeable in the temperature parameter than in the salinity parameter. However, the greatest values of standard deviation generally occurred at depths between about 400 and 800 meters, with a few occasions where it was slightly above or below this level. Additionally, this maximum deviation for both salinity and temperature usually occurred at or nearly the same depth. Where they differed, the maximum salinity deviation usually occurred 100 meters shallower than temperature. However, where a salinity peak did occur, a high standard deviation value for temperature was always present. The maximum deviation invariably occurred in the region of the largest gradient of the thermocline/halocline. Therefore, small variations in the depth of the isopleths resulted in relatively large variations in temperature and salinity values.

The vertical migration of the isotherms and isohalines from about 200 meters to below 1000 meters (and almost noticeable to about 3000 meters, although the data were almost too sparse to extrapolate conclusions to that depth) were fairly independent of the seasonal surface temperature and salinity variations. In particular, the variations of temperature and salinity depicted in figures 6 and 7 for the months of July, September and November 1971 and January 1972 show excursions of the isopleths of up to 250 meters. At first glance it might appear that these variations were due to transiting water masses through Ocean Station ECHO. However, the T-S diagrams for these four months, figures 8a through 8d, are nearly identical except for the expected variations in the surface levels. This would tend to discount intruding water masses and eddies. It

would appear that these variations might be a barotropic response.

SUMMARY

The seasonal effects at Ocean Station ECHO were clearly visible only in the upper 100 meters. On some rare occasions, however, the turnover may have resulted in nearly isothermal conditions as deep as 300 meters.

The permanent thermocline-halocline may have had an annual cycle but one which was masked by a shorter period, possibly a barotropic response.

OCEAN STATION ECHO DISESTABLISHED

Codes Utilized

A complete description of the codes utilized in the tabulation of oceanographic station data can be found in National Oceanographic Data Center publication M-2, Processing Physical and Chemical Data from Oceanographic Stations. (Rev. August 1964, supplement issued May 1966.)

To facilitate use of the oceanographic station data listing, entry headings which are not self-explanatory are described below.

REFID	NODC reference identity number.
CONSEC	Consecutive station number.
BOTDP (B)	Uncorrected sounding depth in meters.
SHIP (B)	NODC assigned platform identity code.
DATA USE	Entry 1 identifies DNP data.
AREA	NODC ocean area code.
CLOUD T/A (B)	Cloud type according to WMO code 0500 and cloud amount according to WMO code 2700.
Wave observations	
DIR	Direction from which dominant waves are coming in tens of degrees according to WMO code 0885.
HGT	Height of dominant waves according to WMO code 1555.
PER	Period of dominant waves according to WMO code 3155.
SEA (B)	Sea state according to WMO code 3700.
CL/TB (B)	Water color according to fore-Ule code. Transparency in meters as determined by Secchi disc.
WIND DIR (B)	Direction from which wind is blowing in tens of degrees according to WMO code 0877.
WIND SPD (B)	Wind speed in knots.
WIND FOR (B)	Wind force in beaufort code.
WEATHER (B)	Weather code—If preceded by letter X is according to WMO code 4501. A numeric two digit entry indicates weather according to WMO code 4677.
INST	Instrument used for observation—"Nansen Cast" indicates station consists of Nansen cast data—"STD Recorder" indicates station consists of STD data or a mixture of STD and Nansen cast data.
TRACE DIR (B)	"Trace" indicator U (UP), D (DOWN), and A (AVERAGED)—used with STD casts, and specify that data were taken while hoisting or lowering respectively or that the two traces were averaged.
DURATION (B)	Time elapsed during raising or lowering of the STD recorder to tenths of hours.
ORIG (B)	Originator's reference number in two parts—cruise number or 3 characters (if year of cruise forms part of cruise number years digits may sometimes only be found in "Year" field), and station number.
TEN SQ	Ten-degree square—modified Canadian square number.
5 SQUARE	Five-degree squares—modified Canadian system.
2 SQUARE	Two-degree squares—modified Canadian system.
1 SQUARE	One-degree squares—modified Canadian system.
CASTNUM (B)	Number of cast on multicast stations (blank when messenger time is given).
TIME (B)	Time of release of messenger in hour and tenths for applicable observed levels. If multicast series extends past midnight, 24 hours are added to cast time of next day. Beginning time for STD is given at first obs depth.
LVL TYP	Type of record at depth indicated. "OBS"—observed values. For STD recorder = level of data read-out. "STD"—NODC standard interpolated values. "ORG"—Standard or other depths carrying non-NODC interpolated values. "LIT"—Interpolated standard depth values used as obs for computational purposes. Note—When an observed level coincides with a STD depth level, both "STD" and "OBS" lines will appear.
DEPTH	Depth of sample (or standard level) in whole meters. Prefix "T" indicates thermometrically determined depth (depth of unprotected thermometers). Subscript "Q" indicates that the value is marked doubtful by the originator. A value designated as implausible by NODC is marked with a "P". Postscript "Z" indicates uncorrected and inaccurate 'Wire-out' depths (high wire angle present).
TEMP (R)	Temperature in degrees celsius. For 'Q' and 'P' notation see depth field.
SAL (B)	Salinity in parts per thousand. For 'Q' and 'P' notation see depth field.
SIGMA-T (B)	Seawater density anomaly to 2 decimal places. When depth, temp, or salinity is doubtful, a 'Q' is suffixed. An asterisk indicates a decrease of 0.02 or more from the previous level.
DYNDPTH	Dynamic depth anomaly in dynamic meters to millimeters.
SND VEL (B)	Sound velocity in meters per second to decimeters according to Wilson's formula. (A standard depth-pressure term is used for stations not beginning at the surface).
OXYG (B)	Oxygen in ML/L to hundredths.

TABLE I. Observed and interpolated oceanographic data for stations taken by USCGC HUMBOLDT at Ocean Station ECHO, 22 December 1968 - 11 January 1969, prepared from NODC listing No. 31 - 1395.
