573. It is singular that the effects of the respiration of pure Oxygen should not be dissimilar. At first, the rapidity of the pulse and the number of the respirations are increased, and the animal appears to suffer little or no inconvenience for an hour; but symptoms of coma then gradually develop themselves, and death ensues in six, ten, or twelve hours. If the animals are removed into the air before the insensibility is complete, they then quickly recover. When the body is examined, the heart is seen beating strongly, while the diaphragm is motionless; the whole blood in the veins, as well as in the arteries, is of a bright scarlet color; and several of the membranous surfaces have the same tint. The blood is observed to coagulate with remarkable rapidity; and it is to the alteration in its properties, occasioned by hyper-arterialization, and indicated by this condition, that we are probably to attribute the fatal result. There can be no doubt that in this instance, an undue amount of oxygen is absorbed; and it does not seem unlikely that one cause of the fatal result, is a stagnation of the blood in the systemic capillaries, consequent upon the want of sufficient change in its passage through them. When Nitrogen or Hydrogen is breathed for any length of time, death results from the deprivation of Oxygen, rather than from any deleterious influence which these gases themselves exert. Death is also caused by the inhalation of several gases of an irritant character, such as Sulphurous, Nitrous, and Muriatic acids; but it is doubtful how far they are absorbed, or how far their injurious effects are due to the abnormal action which they excite in the lining membrane of the air-cells and tubes. It cannot be doubted, that Miasmata and other morbid agents diffused through the atmosphere, are more readily introduced into the system through the pulmonary surface than by any other; and our aim should, therefore, be directed to the discovery of some counteracting agents, which can be introduced in the same manner. The Pulmonary surface affords a most advantageous channel for the introduction of certain medicines that can be raised in vapor, when it is desired to affect the system with them speedily and powerfully; such is pre-eminently the case with those Anæsthetic agents, ether and chloroform, whose introduction into the various departments of Medical and Surgical practice constitutes a most important era in the history of the healing art; also with Mercury,¹ Iodine, Tobacco, Stramonium, &c.

3.—*Effects of Suspension or Deficiency of Respiration.*

574. We have now to consider the results of the cessation of the Respiratory function, and the consequent retention of Carbonic Acid in the blood. If this be sufficiently prolonged, a condition ensues, to which the name of *Asphyxia* has been given; the essential character of which is the cessation of muscular movement, and shortly afterwards of the circulation; with an accumulation of blood in the venous system. The time which is necessary for life to be destroyed by Asphyxia varies much, not only in different animals, but in different states of the same. Thus, warm-blooded animals are much sooner asphyxiated than Reptiles or Invertebrata; on the other hand, a hibernating Mammal sup-

free in the combustion of charcoal, besides carbonic acid. Mr. Coathupe (loc. cit.) states these to be Carbonate, Muriate, and Sulphate of Ammonia, Carbonic Oxide, Oxygen, Nitrogen, Watery vapor, and Empyreumatic Oil: to these Sulphurous acid may appear to be properly added.

¹ The beneficial results of the introduction of Mercury by inhalation are strikingly set forth in Mr. Langston Parker's Essay on "The Treatment of Secondary, Constitutional, and Confirmed Syphilis."

ports life for many months, with a respiration sufficiently low to produce speedy asphyxia if it were in a state of activity. And among Mammalia and Birds, there are many species which are adapted, by peculiarities of conformation, to sustain a deprivation of air for much more than the average period.¹ Excluding these, it may be stated as a general fact, that, if a warm-blooded animal in a state of activity be deprived of respiratory power, its muscular movements (with the exception of the contraction of the heart) will cease within five minutes, often within three; and that the circulation generally fails within ten minutes. Many persons, however, are capable of sustaining a deprivation of air for two, three, or even four minutes,² without insensibility or any other injury; but this power, which seems possessed to the greatest degree by the divers of Ceylon, can only be acquired by habit. The period during which remedial means may be successful in restoring the activity of the vital and animal functions, is not, however, restricted to this. There is one well-authenticated case, in which recovery took place after a continuous submersion of fifteen minutes;³ and many others are on record, of the revival of drowned persons after an interval of half an hour, or even more; but, there is not the same certainty in regard to these, that the individuals may not have occasionally risen to the surface and taken breath there. It is not improbable, however, that in some of these cases a state of Syncope had come on at the moment of immersion, through the influence of fear or other mental emotion, concussion of the brain, &c.; so that, when the circulation was thus enfeebled, the deprivation of air would not have the same injurious effect, as when this function was in full activity. The case would then closely resemble that of a hybernating animal; for, in both instances, the being might be said to live very slowly, and would therefore not require the usual amount of respiration. The condition of the stillborn infant is in some respects the same; and reanimation has been successfully attempted, when nearly half an hour had intervened between birth and the employment of resuscitating means, and when probably a much longer time had elapsed from the period of the suspension of the circulation.

575. It has now been sufficiently proved, both by experiment and by patho-

¹ Thus, the Cetacea contain far more blood in their vessels, than do any other Mammalia; and these vessels are so arranged, that both arteries and veins are in connection with large reservoirs or diverticula. The reservoirs belonging to the former are usually full; but when the Whale remains long under water, the blood which they contain is gradually introduced into the circulation, and, after becoming venous, accumulates in the reservoirs connected with the venous system. By means of this provision, the Whale can remain under water for more than an hour.

² Dr. Hutchinson states, that any man of ordinary "vital capacity," can pass two minutes without breathing, if he first makes five or six forcible inspirations and expirations, so as to cleanse the lungs of the old air, and then fills his chest as completely as he can. "For the first 15 seconds a giddiness will be experienced; but when this leaves us, we do not feel the slightest inconvenience for want of air." (See "Cyclop. of Anat. and Phys.," vol. iv. p. 1066.)

³ The following are the facts of this case, as narrated by Marc (Manuel d'Autopsie Cadavérique Médico-Légale," p. 165) on the authority of Prater.—A woman convicted of infanticide was condemned to die by drowning. This punishment was formerly inflicted in Germany, according to the now obsolete Caroline law, the culprit being inclosed in a sack with a cock and a cat, and sunk to the bottom of the water. In this instance, the woman, after having been submerged for a quarter of an hour, was drawn up, and *spontaneously* recovered her senses. She stated that she had become insensible at the moment of her submersion; a circumstance which adds considerable weight to the supposition, based upon the *post-mortem* appearances in many cases of drowning, that death often takes place as much by Syncope (or primary failure of the heart's action, consequent upon sudden and violent emotion, or upon physical shock) as by Asphyxia. If the reality of this state of Syncopal Asphyxia be admitted, there does not seem any adequate reason for limiting the possible persistence of vitality in a submerged body, even to half an hour; especially if the temperature of the water be such as not to cause any rapid abstraction of its heat.

logical observation, that the first effect of the non-arterialization of the blood in the lungs, is the retardation of the fluid in their capillaries; of which the accumulation in the venous system, and the deficient supply to the arterial, are the necessary consequences. It is some time, however, before a complete stagnation takes place from this cause; since, as long as the proportion of oxygen which remains in the air in the lungs is considerable, and that of the carbonic acid is small, so long will some imperfectly arterialized blood find its way back to the heart, and be transmitted to the system. This blood exerts a depressing influence upon the nervous centres, which is aided by the diminution that gradually takes place in the quantity of blood propelled to them; and thus the powers of the Sensorial centres are suspended, so that the individual becomes unconscious of external impressions; whilst the activity of the Medulla Oblongata also becomes diminished, so that the respiratory movements are enfeebled. The progressive exhaustion of the oxygen of the air in the lungs and the accumulation of carbonic acid in the blood, increase the obstruction in the pulmonary capillaries; less and less blood is delivered to the systemic arteries, and what is thus transmitted becomes more and more venous; the nervous centres are now completely paralyzed, and the respiratory movements cease; and the deficient supply of blood, with the depravation of its quality, act injuriously upon the muscular system also, and especially weaken the contractility of the heart (§ 324). In this enfeebled state, the final cessation of its movements seems attributable to two distinct causes, acting on the two sides respectively; for on the right side is the result of the over-distension of the walls of the ventricle, owing to the accumulation of venous blood; and on the left to deficiency of the stimulus necessary to excite the movement, which is no longer sustained by its spontaneous motility (§ 499). The heart's contractility is not finally lost, nearly as soon as its movements cease; for the action of the right ventricle may be renewed, for some time after it has ceased, by withdrawing a portion of its contents—either through the pulmonary artery, their natural channel—or, more directly, by an opening made in its own parietes, in the auricle, or in the jugular vein (§ 504). On the other hand, the left ventricle may be again set in action, by renewing its appropriate stimulus of arterial blood. Hence, if the stoppage of the circulation have not been of too long continuance, it may be renewed by artificial respiration; for the replacement of the carbonic acid by oxygen in the air-cells of the lungs, restores the circulation through the pulmonary capillaries; and thus at the same time relieves the distension of the right ventricle, and conveys to the left the due stimulus to its actions.—Of the mode in which the Pulmonary circulation is thus stagnated by the want of oxygen, and renewed by its ingress into the lungs, no other consistent explanation can be given, than that which is based on the doctrine already laid down in regard to the capillary circulation in general (§ 527); namely, that the performance of the normal reaction between the blood and the surrounding medium (whether this be air, water, or solid organized tissue) is a condition necessary to the regular movement of the blood through the extreme vessels. That no mechanical impediment to its passage is created (as some have maintained) by the want of distension of the lungs, has been fully proved by the experiments of Dr. J. Reid on the induction of Asphyxia by the respiration of azote. And that a contraction of the small arteries and capillaries, under the stimulus of venous blood, cannot be legitimately assigned as the cause of the obstruction, is evident from the consideration brought to bear upon it by the same excellent experimenter (§ 526); namely, the *suddenness* with which the flow is renewed on the admission of oxygen, as contrasted with the *slowness* with which arteries dilate after the removal of the cause of their contraction.¹

¹ For a fuller discussion of the Pathology of Asphyxia, see the "Cyclop. of Anat. and Phys.," art. "Asphyxia," by Prof. Alison; the "Library of Practical Medicine," vol. iii.

576. It cannot be necessary here to dwell upon the fact, that by the repeated passage of the same air through the lungs, it may, though originally pure and wholesome, be so strongly impregnated with carbonic acid, and may lose so much of its oxygen, as to become utterly unfit for the continued maintenance of the aerating process; so that the individual who continues to respire it, shortly becomes asphyxiated. There are several well-known cases, in which the speedy death of a number of persons confined together has resulted from neglect of the most ordinary precautions for supplying them with air. That of the "Black Hole of Calcutta," which occurred in 1756, has acquired an unenviable pre-eminence, owing to the very large proportion of the prisoners, 123 out of 146, who died during *one night's* confinement in a room 18 feet square, only provided with two small windows; and it is a remarkable confirmation of the views formerly stated (§ 210), and presently to be again adverted to, that of the 23 who were found alive in the morning, many were subsequently cut off by "putrid fever." Such catastrophes have occurred even in this country, from time to time, though usually upon a smaller scale; there has happened one at no distant date, however, which rivalled it in magnitude. On the night of the 1st of December, 1848, the deck-passengers on board the Irish steamer *London-derry* were ordered below by the Captain, on account of the stormy character of the weather; and although they were crowded into a cabin far too small for their accommodation, the hatches were closed down upon them. The consequence of this was, that out of 150 individuals, no fewer than 70 were suffocated before the morning.

577. It cannot be too strongly impressed upon the Medical practitioner, however, and through him upon the Public in general, that the continued respiration of an atmosphere charged in a far inferior degree with the exhalations from the Lungs and Skin, is among the most potent of all the "predisposing causes" of disease, and especially of those *zymotic* diseases whose propagation seems to depend upon the presence of fermentable matter in the blood. That such is really the fact, will appear from evidence to be presently referred to; and it is not difficult to find a complete and satisfactory explanation of it. For, as the presence of even a small percentage of carbonic acid in the respired air, is sufficient to cause a serious diminution in the amount of carbonic acid thrown off and of oxygen absorbed (§ 561), it follows that those oxidating processes which minister to the elimination of effete matter from the system must be imperfectly performed, and that an accumulation of substances tending to putrescence must take place in the blood. Hence there will probably be a considerable increase in the amount of such matters in the pulmonary and cutaneous exhalation; and the unrenewed air will become charged, not only with carbonic acid, but also with organic matter in a state of decomposition, and will thus favor the accumulation of both these morbid substances in the blood, instead of effecting that constant and complete removal of them, which it is one of the chief ends of the respiratory process to accomplish.—It has been customary to consider the consequences of imperfect respiration, as exerted merely in promoting an accumulation of carbonic acid in the system, and in thus depressing the vital powers, and rendering it prone to the attacks of disease. But the deficiency of oxygenation, and the consequent increase of putrescent matter in the body, must be admitted as at least a concurrent agency; and when it is borne in mind that the atmosphere in which a number of persons have been confined for some time, becomes actually offensive to the smell in consequence of the

art. "Asphyxia," by the Author; the Experimental Essay by Dr. J. Reid, "On the Order of Succession in which the Vital Actions are arrested in Asphyxia," in the "Edinb. Med. and Surg. Journ.," 1841, and in his "Anat., Physiol., and Pathol. Researches;" and the Experimental Inquiry by Mr. Erichsen, in the "Edinb. Med. and Surg. Journ.," 1845.

accumulation of such exhalations, and that this accumulation exerts precisely the same influence upon the spread of zymotic disease (as will presently appear) that is afforded by the diffusion of a sewer-atmosphere through the respired air, it scarcely admits of reasonable doubt that the pernicious effect of over-crowding is exerted yet more through its tendency to promote putrescence in the system, than through the obstruction it creates to the due elimination of carbonic acid from the blood. For it is to be remembered, that whilst the *complete* oxidation of the effete matters will carry them off by the lungs in the form of carbonic acid and water, leaving urea and other highly-azotized products to pass off by the kidneys, an *imperfect* oxidation will only convert them into those peculiarly offensive products which characterize the fecal excretion (§ 458).¹

578. Of the remarkable tendency of the Respiration of an atmosphere charged with the emanations of the Human body, to favor the spread of Zymotic diseases, a few characteristic examples will now be given.—All those who have had the widest opportunities of studying the conditions which predispose to the invasion of Cholera, are agreed that *overcrowding* is among the most potent of these; and the “Report of the General Board of Health,” on the late epidemic, contains numerous cases in which this was most evident, of which the two following may be selected.—In the autumn of 1849, a sudden and violent outbreak of Cholera occurred in the Workhouse of the town of Taunton; no case of cholera having previously existed, and none subsequently presenting itself, among the inhabitants of the town in general, though diarrhœa was prevalent to a considerable extent. The building was altogether badly constructed, and the ventilation deficient; but this was especially the case with the school-rooms, there being only about 68 cubic feet of air for each girl, and even less for the boys. On Nov. 3, one of the inmates was attacked with the disease; in ten minutes from the time of the seizure, the sufferer passed into a state of hopeless collapse; within the space of forty-eight hours from the first attack, 42 cases and 19 deaths took place; and in the course of one week, 60 of the inmates, or nearly 22 per cent. of the entire number, were carried off, whilst almost every one of the survivors suffered more or less severely from cholera or diarrhœa. Among the fatal cases were those of 25 girls and 9 boys; and the comparative immunity of the latter, notwithstanding the yet more limited dimensions of their school-room, affords a remarkable confirmation of the general doctrine here advanced; for we learn that, although “good and obedient in other respects, they could not be kept from breaking the windows,” so that many of them probably owed their lives to the better ventilation thus established. Now in the jail of the same town, in which every prisoner is allowed from 819 to 935 cubic feet of air, and this is continually being renewed by an efficient system of ventilation, there was not the slightest indication of the epidemic influence (Op. cit., pp. 37 and 71).—The other case to be here cited, is that of Millbank Prison, in which the good effects of the diminution of previous overcrowding were extremely marked. In the month of July, 1849, when the epidemic was becoming general and severe in the Metropolis (especially in the low ill-drained parts on both sides of the river, in the midst of which this prison is situated), the number of *male* prisoners was reduced, by the transfer of a large proportion of them to Shorncliff barracks, from 1039 to 402; the number of *female* prisoners, on the other hand, not only underwent no reduction, but was augmented

¹ It is a remarkable confirmation of Prof. Liebig's analogy between the imperfect oxidation of effete matters within the body, and that combination in a lamp or furnace insufficiently supplied with air, which causes a deposit of soot and various empyreumatic products, that a set of acids have been found by Städeler in the urine of the cow, bearing a remarkable analogy to well-known products of destructive distillation, and one of them actually identical with the *carbolic acid* previously known as one of the ingredients of smoke.—See Prof. Gregory's “Handbook of Organic Chemistry,” p. 450.

from 120 to 131. Now the general mortality of London, which was 0.9 in 1000 in June and July, *increased* to 4.5 in 1000 in August and September; and the mortality among the *female* prisoners underwent a similar *increase*, from 8.3 to 53.4 per 1000; but the mortality among the *male* prisoners exhibited the extraordinary *diminution*, from 23.1 per 1000, which was its rate during June and July, when the prison was crowded, to 9.2 per 1000, which was its rate during August and September, after the reduction had taken place (Op. cit., App. B., p. 67). It is scarcely possible to imagine a more *probative* case than this; since it shows, in the first place, the marked influence of the crowded state of the prison upon the fatality of the disease—the diminution of mortality consequent upon the relief of the overcrowding, notwithstanding the augmented potency of the epidemic influence, as indicated by the quintupling of the general mortality of the Metropolis—and the yet greater increase of mortality among the female prisoners, which proved that the diminution among the males could not be attributed to any recession of the epidemic influence from the locality.

579. The cholera-experience of the Indian army is fertile in examples of the same kind, whose peculiar character makes them even more remarkable. It is to be remembered that the normal amount of Respiration is much lower in a hot than in a temperate climate (§ 564, *a*); consequently, any deficiency of oxygenation will tend in a yet higher degree to promote the accumulation of putrescent matter in the system, and this especially when there has been any unusual source of "waste," such as that induced by excessive muscular exertion.—The circumstances attendant upon the outbreak of Cholera, in 1846, at Kurrachee in Scinde, in which *ten per cent.* of an army of 6380 men were carried off, place the influence of these conditions in a very striking point of view. In order that the comparison may be fairly made, the data will be taken only from European regiments, similar to each other in diet, clothing, regimen, habits, and every other conceivable particular, save such as will be mentioned. Out of 200 Officers, there were only 3 deaths from Cholera (only 1 of these being in an uncomplicated case), or at the rate of 15 per 1000. The 2d Troop of Horse Brigade, 135 strong, lost 5 men, or at the rate of 37 per 1000. The 60th Rifles, 980 strong, lost 75 men, or at the rate of 76.5 per 1000. Four Batteries of Artillery, 375 strong, lost 37 men, or 96.6 per 1000. The Bombay Fusiliers, 764 strong, lost 83 men, or 108.6 per 1000. And the 86th Regiment, 1091 strong, lost 238 men, or 218 per 1000. Among 42 ladies (wives and families of Officers), there was not a single case of cholera. But among 159 soldiers' wives, there were 23 deaths, or 144.6 per 1000. Now most of the Officers, and all the ladies, were quartered in well-ventilated apartments; and the only predisposing cause from which the former could be considered as liable to suffer, was the exposure, in common with the soldiers, to the burning heat during the hours of drill. Of the 9 officers attacked with cholera, 4 belonged to the Bombay Fusiliers, and had been living (like their men) in tents. The Horse Brigade were lodged in good barracks, but had recently come off a march of 1000 miles; being mounted, however, they must have suffered comparatively little fatigue from this. The 60th Rifles were quartered in barracks; but the ventilation of these was very imperfect, and the men were much crowded. The battalions of Artillery were quartered in good barracks; but three out of the four had recently made the march of 1000 miles on foot. The Bombay Fusiliers were quartered in tents, whose accommodation was so limited that 10 or 12 men were cooped up in a space 14 feet square, with the thermometer ranging from 96° to 100°, without any adequate provision for ventilation. The 86th Regiment was quartered in precisely the same manner; and had recently made the march of 1000 miles under very unfavorable circumstances, besides having previously suffered from the debilitating influence of severe service. The condition of the

soldiers' wives as regards their accommodation would be the same as that of their husbands, but they would not be subjected to the fatigue and exposure of drill; on the other hand, their fatigue and exposure during a march would be scarcely inferior to that of the men; and it was among the women, as among the soldiers, of the 86th Regiment, that the chief mortality occurred, their loss having been 1 in 6, or 166.6 per 1000. Now if we arrange these several divisions in a tabular form, we shall see how very closely their respective rates of mortality correspond with the separate or concurrent influence of the different factors here enumerated.

Designation.	Strength.	Deaths.	Deaths per 1000.	Exposure at Drill, &c.	Provision for Respiration.	Previous exertion.
Officers' Ladies . .	42	0	0	Nil.	Good	Nil.
Officers	200	3	15	Ordinary	Mostly Good	Nil. or slight.
Horse Brigade . .	135	5	37	Ordinary	Good	Moderate.
60th Rifle	980	75	76.5	Ordinary	Bad	Nil.
Artillery	375	37	96.6	Ordinary	Good	Severe.
Bombay Fusiliers	764	83	108.6	Ordinary	Very bad	Nil.
Soldiers' Wives . .	159	23	144.6	Nil.	Mostly very bad	Partly severe.
Do. of 86th Regt.	—	—	166.6	Nil.	Very bad	Very severe.
86th Regiment. . .	1091	238	218	Ordinary	Very bad	Very severe.
	3746	464	124			

Thus we see that the *highest* rate of mortality presents itself where the three causes were in concurrent action; the *absence* of mortality, where neither of them was in operation. The difference between the mortality of the Bombay Fusiliers (108.6 per 1000) and that of the 86th Regiment (218 per 1000), which were under precisely the same conditions as regards exposure and ventilation, showed the extraordinary influence of previous exertion; but that this would not of itself account for the high rate of mortality in the 86th, is shown by the smaller proportion of deaths in the Artillery; the influence of the same march upon three out of its four battalions, having been in a great degree kept down by the adequate provision for their respiration, so that their mortality was less than that of the 60th Rifles, who had not suffered from previous exertion, but were overcrowded in ill-ventilated barracks.—It is scarcely possible to imagine any more satisfactory proof of the *preventibility* of a large part of this terrible mortality, than is afforded by the analysis of this case;¹ but if any confirmation be required, it is afforded by the case of Bellary, a fortress about 250 miles north-west of Madras. Although by no means unhealthily situated, this station was not free from Cholera for a single year between 1818 and 1844; and violent outbreaks took place occasionally, such as that of 1839, in which the 39th Regiment was reduced in five months from 735 men to 645, the number of deaths being 90, or 122½ per 1000. The barrack-accommodation in this fort was extremely insufficient; and small as it was, it was occasionally encroached upon still further by the introduction of troops upon their march, in addition to the regular garrison. Every such occasion of overcrowding was shortly followed by a large increase in mortality.² But since the barrack-accommodation has been improved, the troops quartered at Bellary have ceased to suffer from cholera in any exceptional degree, and the ordinary rate of mortality has been considerably diminished.

580. The only condition of atmosphere which can be compared with that

¹ For a fuller statement of it, see the "Brit. and For. Med.-Chir. Rev.," vol. ii. pp. 81–89.

² See Mr. Rogers's "Report on Asiatic Cholera in the Regiments of the Madras Army, from 1822 to 1844."

arising from overcrowding, in its effect upon the spread of Cholera, is that produced by the diffusion of the effluvia of drains, sewers, slaughter-houses, manure-manufactories, &c., which correspond closely in their nature and effects with the putrescent emanations from the living human body. So remarkably was the localization of the disease connected with this condition, that the knowledge of the existence of the latter rendered it quite safe to predict the former, such predictions being scarcely ever falsified by the result.—As a characteristic illustration of the operation of this cause, the outbreak of Cholera at Albion Terrace, Wandsworth-road, may be specially referred to. This place consisted of 17 houses, having the appearance of commodious comfortable dwellings; the population does not seem to have averaged more than 7 individuals per house, so that there was no overcrowding; yet out of the total 119 or 120, no fewer than 42 persons were attacked with cholera, of whom 30 (or 25 per cent.) died. It was not difficult to account for this fearful result, when the circumstances of the case were inquired into. About 200 yards in the rear of the terrace was an open sewer, whose effluvia were most offensive at the backs of these houses, whenever the wind wafted them in that direction; and the drainage of the houses themselves was so bad, that a stench was continually perceived to arise from different parts of the kitchen floor, and more especially from the back-kitchen. Moreover, in the house in which the first case of cholera occurred, there was an enormous accumulation of most offensive rubbish, exhaling a putrid effluvia. —And there was also reason to believe that the water supplied to some of the houses accidentally became contaminated with the contents of a sewer and cess-pool.¹—The accumulation of night-soil and other rubbish in a triangular space of about three acres in Witham, a suburb of Hull, had been represented to the local authorities as almost certain to induce a severe outbreak of cholera in the neighborhood; the prediction was disregarded; but it was most fearfully verified by the occurrence of no fewer than 91 deaths in its immediate neighborhood.² —Numerous examples of the same kind might be cited; but the following shows the efficacy of preventive measures. The Coldbath-fields House of Correction, situated in the neighborhood of some of the most overcrowded and ill-drained parts of the metropolis, had suffered severely from Cholera in the epidemic of 1832–3; for out of 1148 prisoners, 207 were attacked with Cholera, of whom 45 died, and 319 more suffered from diarrhoea. At that time, however, it was discovered that the whole drainage of the prison was in a most defective state, and steps were taken to have it completely and effectually renewed; at the same time the diet was somewhat improved, and more attention paid to temperature and ventilation. In the epidemic of 1848–9, with 1100 prisoners, there was not a single case of cholera in this prison, although the disease was raging in its vicinity; and the cases of diarrhoea were few in number, and were mild in their character.³

581. Now although the Cholera-epidemics have been here referred to, as affording the most remarkable examples of the influence of a contaminated atmosphere in predisposing the individuals habitually living in it to the invasion of Zymotic disease, yet the evidence is not less strong in regard to the uniform prevalence of ordinary Fevers, &c., in the same localities; the places in which Cholera was the most severe having been almost invariably known as “fever-nests,” at other periods, and being distinguished by a very high rate of mortality. Thus the average age of all persons who die in Witham is only 18 years; whilst the average age at death in the town of Hull (itself distinguished by an unusual brevity of life) is 23 years.—In the “Potteries,” at Kensington, a locality in which filth and overcrowding prevail to an almost unequalled degree, the mor-

¹ “Report of the General Board of Health on the Epidemic Cholera of 1848–9,” p. 43.

² Op. cit., p. 45.

³ Op. cit., App. B, p. 68.

tality for three years previously to the invasion of cholera had been such, that the average age at death was only 11 yrs. 7 mos.; and in the first 10 months of 1849, out of a population of about 1000, there were 50 deaths, of which 21 were from cholera and diarrhoea, and 29 from typhus fever and other diseases. It is illustrative of the common points between cholera and other zymotic diseases, that the former appeared there not only in the same streets and in the same houses, but even in the same rooms, which had been again and again visited by typhus; and there were several tenants of such rooms who recovered from fever in the spring, to fall victims to cholera in the summer. Subsequently to this epidemic, the average age at death has been further reduced, by an increase of infantile mortality, to as low as 10 years.—By way of contrast it may be stated that in one of the “Model Lodging-Houses,” containing about 550 inmates, among whom was an unusually large proportion of children, the rate of mortality during the three years ending May, 1851 (including the whole period of the cholera-epidemic), was scarcely more than 20 in 1000; the proportion of deaths under ten years of age was only half that of the metropolis in general; there was not a single attack of cholera, and there were only a few cases of choleraic diarrhoea, although the disease was raging in the immediate vicinity; and from the time that the sewerage had been put into complete order, typhus fever had entirely disappeared, a few cases having occurred soon after the opening of the buildings, which were distinctly traceable to a defect in the drainage.²—The following case may be added, in proof of the potency of an atmosphere charged with putrescent emanations, in rendering the system liable to the attacks of Zymotic diseases of various kinds. A manufactory of artificial manure formerly existed immediately opposite Christchurch workhouse, Spitalfields⁴ which building was occupied by about 400 children, with a few adult paupers. Whenever the works were actively carried on, particularly when the wind blew in the direction of the house, there were produced numerous cases of fever, of an intractable and typhoid form; a typhoid tendency was also observed in measles, smallpox, and other infantile diseases, and for some time there prevailed a most unmanageable and fatal form of aphthæ of the mouth, ending in gangrene. From this last cause alone, 12 deaths took place among the infants in one quarter. In the month of December, 1848, when cholera had already occurred in the neighborhood, 60 of the children in the workhouse were suddenly seized with violent diarrhoea in the early morning. The proprietor was compelled to close his establishment, and the children returned to their ordinary health. Five months afterwards, the works were recommenced; in a day or two subsequently, the wind blowing from the manufactory, a most powerful stench pervaded the building. In the night following, 45 of the boys, whose dormitories directly faced the manufactory, were again suddenly seized with severe diarrhoea; whilst the girls, whose dormitories were in a more distant part, and faced in another direction, escaped. The manufactory having been again suppressed, there was no subsequent return of diarrhoea.²

582. It may not be amiss to add a few examples drawn from the experience which our Indian possessions have afforded, of the influence of an insufficient supply of pure air upon the ordinary mortality in our army and among the people under our control.—There are various military stations which have lain under a most ill-deserved repute for unhealthiness, in consequence of the very imperfect barrack-accommodation afforded to the troops quartered in them. Thus at Secunderabad, in the Madras command, the average annual mortality for the fifteen years previous to 1846–7 was 75 per 1000; this being *nearly*

¹ “Report on Cholera,” App. B, pp. 48 and 77; and Mr. Grainger’s subsequent “Report on the present state of certain parts of the Metropolis, and on the Model Lodging-Houses of London,” pp. 29, 36.

² “Report on Cholera,” p. 42.

double the average of the whole presidency, and more than double that of the remainder of the stations. Now the complaints made year after year, by the medical officers of the troops which have been successively quartered at this station, leave no room for doubt as to the chief cause of this excess; for the regiments of the line quartered at Secunderabad have been always crowded in barracks quite insufficient for their accommodation, one-third of the men having been obliged to sleep in the verandahs, and the remainder getting by no means a due allowance of fresh air; whilst, on the other hand, the officers of these very regiments, who are better accommodated, and the detachment of artillery quartered in more roomy barracks, at no great distance, have never participated in this unusual mortality, thereby clearly showing the absence of any special causes of disease at this station, which might not be easily removed.¹—The Barrackpore station, in the Bengal command, is even worse than the foregoing, for every regiment quartered there seems to suffer an almost complete *decimation* annually. Yet there is ample evidence that here also the chief fault lies in the barrack accommodation.—But one of the most terrible instances of the continuance of a high rate of mortality, which is almost entirely attributable to an insufficient supply of air, is that which is furnished by the jails under British control in India. In these are usually confined no fewer than 40,000 prisoners, chiefly natives; and the average annual mortality of the whole was recently 10 per cent., rising in some cases to 26 per cent., or more than *one in four*. This is easily accounted for, when it is known that in no case is there an allowance of more than 300 cubic feet of air-space for each individual, whilst in some instances 70 cubic feet is the miserable average!²

583. One more set of cases will be cited, as showing the marked effect of the habitual respiration of a contaminated atmosphere, not merely in engendering a liability to zymotic disease, but in directly producing a special form of infantile disease, of the most fearful nature.—The dwellings of the great bulk of the population of Iceland seem as if constructed for the express purpose of poisoning the air which they contain. They are small and low, without any direct provision for ventilation, the door serving alike as window and chimney; the walls and roof let in the rain, which the floor, chiefly composed of hardened sheep-dung, sucks up; the same room generally serves for all the uses of the whole family, and not only for the human part of it, but frequently also for the sheep, which are thus housed during the severer part of the winter. The fuel employed in the country districts chiefly consists of cow-dung and sheep-dung, caked and dried; and near the sea-coast, of the bones and refuse of fish and sea-fowl; producing a stench, which, to those unaccustomed to it, is completely insupportable. In addition to this, it may be mentioned that the people are noted for their extreme want of personal cleanliness; the same garments (chiefly of black flannel) being worn for months without being even taken off at night. Such an assemblage of unfavorable conditions, combined with the cold damp nature of the climate, might have been expected to induce tubercular diseases of various kinds; but from these the Icelanders appear to enjoy a special exemption (§ 404,

¹ It is a remarkable confirmation of the view formerly stated (§ 411), as to the tendency of the habitual use of Alcoholic liquors to induce a "fermentible" condition of the blood, by obstructing the elimination of effete matters by the respiratory process (§ 564, *i*), that when the 84th Regt., which is distinguished for its sobriety, was quartered at Secunderabad in 1847–8, it lost only 39 men out of 1139, or 34.2 per 1000, the average mortality of the other stations in the Presidency being about the same as usual. On the other hand, the 63d Regt., which was far from deserving a reputation for temperance, had lost 73 men during the first nine months of the preceding year, or at the rate of 78.8 per 1000 during the entire year.—All the facts here stated in regard to Secunderabad, have been obtained by the Author direct from the Army Medical Returns.

² Dr. Mackinnon's "Treatise on the Public Health, &c., of Bengal," Cawnpore, 1848, Chap. 1.

III.). Syphilis, also, is wanting, or nearly so; and yet, notwithstanding that the number of births is fully equal to the usual average, the population is stationary, and in some parts actually diminishing. This is partly due to the extent and fatality of the epidemic diseases, of which some one or other spreads through the island nearly every year; but it is chiefly owing to the extraordinary mortality of infants from *Trismus nascentium*, which carries off a large proportion of them between the fifth and the twelfth days after their birth. It is in the little island of Westmannoe and the opposite parts of the coast of Iceland, where the bird-fuel is used all the year round, instead of (as elsewhere) during a few months only, that this disease is most fatal; the average mortality, for the last twenty years, during the first twelve days of infantile life, being no less than 64 per cent., or nearly *two out of three*.¹—Now it is not a little remarkable that the very same disease should have prevailed, under conditions almost identically the same, in the island of St. Kilda, one of the Western Hebrides; the state of which was made known by Mr. Maclean, who visited it in 1838. The population of this island, too, was diminishing rather than increasing, in consequence of the enormous infantile mortality; *four out of every five* dying, from *Trismus nascentium*, between the eighth and twelfth days of their existence. The great if not the only cause of this mortality, was the contamination of the atmosphere by the filth amidst which the people lived. Their huts, like those of the Icelanders, were small, low-roofed, and without windows; and were used during the winter as stores for the collection of manure, which was carefully laid out upon the floor, and trodden under foot to the depth of several feet. On the other hand, the clergyman, who lived exactly as did those around him, except as to the condition of his house, and brought up a family of four children in perfect health; whereas, according to the average mortality around him, at least three out of the four would have been dead within the first fortnight.—Of the degree in which this fearful disease is dependent upon impurity of the atmosphere, and is preventible by adequate ventilation, abundant proof is afforded by the experience of Hospitals and Workhouses in our own country. Thus in the Dublin Lying-in Hospital, up to the year 1782, the mortality within the first fortnight, almost entirely from *Trismus nascentium*, was 1 in every 6 children born. The adoption, under the direction of Dr. Joseph Clarke, of an improved system of ventilation, reduced the proportion of deaths from this cause to 1 in 19½. And further improvements in ventilation, with increased attention to cleanliness, during the seven years in which Dr. Collins was Master of this Institution, reduced the number of deaths from this disease to no more than three or four yearly.²—A similar amelioration took place about a century ago, in the condition of the London Workhouses, in which 23 out of 24 infants had previously died within the first year, and a large proportion of these within the first month; for owing to a parliamentary inquiry which was called forth by this fearful state of things, the proportion of deaths was speedily reduced (chiefly by improvement in ventilation) from 2600 to 450 annually.

584. Thus it appears that in all climates, and under all conditions of life, the purity of the atmosphere habitually respired is essential to the maintenance of that power of resisting disease, which, even more than the habitual state of health, is a measure of the real vigor of the system. For, owing to the extraordinary capability which the human body possesses of accommodating itself to circumstances, it not unfrequently happens that individuals continue for years to breathe a most unwholesome atmosphere, without apparently suffering from it; and thus, when they at last succumb to some Epidemic disease, their death is

¹ See "Island undersøgt fra lægevidenskabeligt Synspunct." Af P. A. Schleisner, M. D.—Copenhagen, 1849.

² See Dr. Collins's "Practical Treatise on Midwifery," p. 513.

attributed solely to the latter; the previous preparation of their bodies for the reception and development of the zymotic poison, being altogether overlooked. It is impossible, however, for any one who carefully examines the evidence, to hesitate for a moment in the conclusion, that the fatality of epidemics is almost invariably in precise proportion to the degree in which an impure atmosphere has been habitually respired; that an atmosphere loaded with putrescent miasmata may afford a *nidus* wherein a zymotic poison undergoes a marked increase in quantity and intensity, the putrescent exhalations from the lungs and skin of the living subject being at least as effectual in furnishing such a "nidus," as are the emanations from fecal discharges or from other decomposing matters; that the habitual respiration of such an atmosphere tends to induce a condition of the blood, which renders it peculiarly susceptible of perversion by the introduction of zymotic poisons, and which favors their multiplication within the system;¹ and lastly, that by due attention to the various means of promoting atmospheric purity, and especially to efficient ventilation and sewerage, the rate of mortality may be enormously decreased, the amount and severity of sickness lowered in at least an equal proportion, and the fatality of epidemics almost completely annihilated. And it cannot be too strongly borne in mind, that the efficacy of such *preventive* measures has been most fully substantiated, in regard to many of the very diseases in which the *curative* power of Medical treatment has seemed most doubtful; as, for example, in Cholera and Malignant Fevers.

CHAPTER XI.

OF NUTRITION.

1.—General Considerations.—Formative Power of Individual Parts.

585. THE function of Nutrition, considered in the widest acceptance of the term, includes the whole series of operations, by which the alimentary materials—prepared by the Digestive process, introduced into the system by Absorption, and carried into its penetralia by the Circulation—are converted into Organized tissue; but in a more limited sense it may be understood as referring to the last of these operations only, that of *Histogenesis* or tissue-formation, to which all the other organic functions, in so far as they are concerned in maintaining the life of the individual, are subservient, by preparing and keeping in the requisite state of purity the materials at the expense of which it takes place. It has been shown in the earlier portion of this volume, that every integral part of the living body possesses a certain capacity for growth and development, in virtue of which it passes through a series of successive phases, under the influence of the steady heat, which in the warm-blooded animal is constantly acting upon it (CHAP. III., SECT. 1, 2); this capacity being an endowment which it derives by direct descent

¹ A careful consideration of the very satisfactory evidence which has been of late years collected on this point, must (in the Author's opinion) satisfy any *competent* and *unprejudiced* inquirer, that Endemic Fevers, originating in local causes (marsh miasmata and the like), and affecting those only who are exposed to such causes, may find, by the crowding together of infected subjects, a *nidus* for development within the Human system; so that these diseases *then* become communicable by human intercourse, although not so originally.—For a discussion of this subject, see the Articles on "Yellow fever" in the "Brit. and For. Med.-Chir. Rev.," vols. i. and iv.

from the original germ, but undergoing a gradual diminution with the advance of life, until the power of *maintenance* is no longer adequate to antagonize the forces that tend to the *disintegration* of the system (CHAP. III., SECT. 3). It has been also shown that, notwithstanding the diversities in the structure and composition of the several tissues, the Blood supplies the materials which each requires; every tissue possessing (so to speak) an *elective affinity* for some particular constituents of that fluid, in virtue of which it abstracts them from it and appropriates them to its own uses.—But it has been shown, on the other hand, that the “formative capacity” does not exist in the tissues alone, but is shared by the Blood, which must itself be regarded as deriving it from the original germ; for there are certain simple kinds of tissue, which seem to take their origin directly in its plastic components (§§ 26–29). Of others which cannot be said thus to originate in the blood, the development is entirely determined by the quantity of their special *pabula* which it may contain (§ 120). And even of those tissues which must be considered as most independent and self-sustaining, the development is not only checked by the want of a due supply of their appropriate materials, but it is modified in a very remarkable degree by the presence of abnormal substances in the blood, which single out particular parts, and effect determinate alterations in their nutrition, in such a constant manner as to show the existence of a peculiar “elective affinity” between them (§ 201).—In so far, then, as the process of Nutrition is dependent upon the due supply and normal state of the Blood, its conditions have been already sufficiently discussed; and we have now only to consider it in its relations to the Tissues.

586. The demand for Nutrition primarily arises from the tendency of the organism to simple *increase* or *growth*. Of this we have the most characteristic illustration in the multiplication of the first embryonic cell, by the simple process of “duplicative subdivision,” (§ 104;) whereby a multitude of cells is produced, every one of which is similar in all essential particulars to the original. But after the different parts of this homogeneous embryonic mass have taken upon themselves their respective modes of development, so as to generate a diversity of tissues and organs, each one of these continues to increase after its own plan; and thus the child becomes the adult, with comparatively little change but that of growth. An excess of growth, taking place conformably to the normal plan of the tissue or organ, constitutes *Hypertrophy*; whilst a diminution, without degeneration or alteration of structure, is that which is properly distinguished as *Atrophy*.—But Growth is not confined to the period of increase of the body generally; for it may manifest itself in particular organs or tissues, as a normal operation, at any subsequent part of life. Thus when there is an extraordinary demand for the functional activity of a particular set of Muscles, it is supplied by an increase in the amount of their contractile tissue (§ 312); or if one of the Kidneys be disabled from performing its office, the other may be rendered capable of fulfilling it, by an augmented production of its own secretory tissue; or if there be an excess of fatty matters in the blood, they may be eliminated by an augmentation of the Adipose tissue throughout the body.—And further, even where there is no such manifestation of increase, there is really a continual growth in all the tissues actively concerned in the vital operations, and this even to the very end of life; although it may be so far counterbalanced, or even surpassed, by changes of an opposite kind, that, instead of augmentation in bulk, there is absolute diminution.

587. The evolution of the complete organism from its germ, however, does not consist in mere growth; for by such a process nothing would be produced but an enormous aggregation of simple cells, possessing little or no mutual dependence, like those which constitute the shapeless masses of the lowest Algae. In addition to increase, there must be *development*, that is, a passage to a higher

condition, both of form and structure, so that the part in which this change takes place becomes fitted for some special function, and is advanced towards the state in which it exists in the highest or most completed form of its specific type. Thus the development of *tissue* consists in the change from a simple mass of cells or fibres into any other form; as in the production of dentine from the cellular substance of the tooth-pulp (§ 279), or in the formation of bone in the sub-periosteal membrane (§ 267). So, again, the developmental change is seen in the passage of an entire *organ* from a lower to a higher condition, by the evolution of new parts, or by a change in the relations of those already existing, even though the change in its texture should consist of little else than of simple increase; thus, in the development of the heart, we have the original single cavity subdivided, first into two and at last into four chambers; and in the development of the brain we find the sensory ganglia to be the parts first formed, the anterior lobes of the cerebrum to be evolved (as it were) from these, the middle lobes sprouting forth from the back of the anterior, and the posterior from the back of the middle; yet, with all this, there is no production of any new kind of tissue, the new parts being generated at the expense of histological components identical with those of the pre-existing. Now it is in the early period of embryonic life, that the *developmental* process is most remarkably displayed; for it is then that we see that transformation of the primordial cells into tissues of various kinds, which originates a special *nisus* in each part, whereby the production of the same tissue in continuity with that first formed, comes to be a simple act of growth; and it is then also that we observe that marking out of all the principal organs, by the development of tissue in particular directions, which makes all subsequent evolution but a completion or filling up of the plan thus sketched out. Thus during the first few days of incubation in the Chick, the foundation is laid of the vertebral column, the nervous centres, the organs of sense, the heart and circulating system, the alimentary canal, the respiratory apparatus, the liver, the kidneys, and of many other parts; and at the termination of that period the chick emerges in such a state of completeness of development, that little else than increase is wanting, save in the plumage and sexual organs, to raise it to its perfect type. The same may be said of the Human organism; save that the period of its development is relatively longer, in accordance with the higher grade which it is ultimately to attain; its earliest stages being passed through, however, with extraordinary rapidity. The completer evolution of the generative organs, of the osseous skeleton, and of the teeth, constitute the principal developmental changes which the Human organism undergoes in its progress from the infantile to the adult condition; almost every other alteration consisting in simple increase of its several component tissues and organs, without any essential change in their form or structure. And when the adult type has been once completely attained, every subsequent change is one rather of degeneration than of development, of retrogression rather than of advance.

588. The difference between the two processes of Growth and Development is most characteristically shown in those cases in which there is a partial or complete arrest of one of them without any corresponding impairment of the other. Thus a dwarf, however small in stature, may present a perfect development of every part that is characteristic of the complete human organism; the deficiency being solely in the capacity for *growth*. On the other hand, the usual size at birth may be attained, and every organ may present its ordinary dimensions, and yet some important part may be found in a condition of *arrested development*; thus the heart may consist of but a single cavity, or the inter-ventricular or interauricular septa may be incomplete, so that it has not passed beyond the grade of development which it had attained at an early period of embryonic life, although its growth may have continued; or the brain may in

like manner exhibit a deficiency of the posterior lobes, or of the corpus callosum, or of some other part whose formation normally takes place in the latter months of intra-uterine life, although the parts already produced may have continued to grow at their usual rate.—Numerous instances of the same kind might be cited, but these must suffice.

589. The demand for Nutrition arises, however, not merely from the exercise of the formative powers which are concerned in the building up of the organism, but also from the degeneration and decay which are continually taking place in almost every part of it, and the effects of which, if not antagonized, would speedily show themselves in its complete disintegration. We have seen (§ 114) that as each component cell of the organism has to a certain degree an independent life of its own, so has it also a limited duration; and that its duration usually bears an inverse ratio to its functional activity. This is particularly striking, when we compare the ratio of change in the organism of cold-blooded animals at low and at high temperatures; for they live slowly, need little nutriment, give off but a small amount of excretory products, and require a long time for the performance of the reparative processes, under the former condition; but live fast, require a comparatively large supply of nutriment, give off a far greater amount of carbonic acid and other compounds resulting from the "waste" of tissue, and exhibit a far more rapid reparation of injuries, in the latter state. The constantly high temperature of Man, as of other warm-blooded animals, prevents this difference from being displayed in him in a similar manner; but it is well seen when we contrast his different tissues with each other, and study their respective histories. For whilst there are some which appear to pass through all their stages of growth, maturation, and decline, within a limited period, there are others whose existence seems capable of almost indefinite prolongation, and others, again, which are liable to have a period put to it at any time, by the direction of their vital force into other channels.—Of those belonging to the first category, a characteristic example is presented by the ovule; which if not fertilized within a limited period after its maturation, speedily declines and decays; and the same law of limited duration doubtless extends to a large proportion of such tissues as are actively concerned in the maintenance of the organic functions; as, for example, the corpuscles of the blood (§ 148), the epithelial cells of mucous membranes, which minister to absorption in one situation (§ 461) and to secretion in another (§ 235), the cells forming the parenchyma of the ductless glands (§ 482, *rv.*), and many others.—The contrary extreme to this may be found in those tissues whose functions are rather physical than vital; and especially in such as undergo consolidation by the deposit of solidifying matter, either in combination with the animal membrane or fibre, or in its interstices. Such tissues are withdrawn from the general current of vital action, and there seems to be no definite limit to their duration, except such as is imposed by the chemical and mechanical degradation to which they are subjected. This appears to be the case with the simple fibrous tissues, especially the yellow, even in their soft or unconsolidated state; but it is far more obvious in the osseous substance, which is chiefly formed by the combination of calcareous salts with the fibrous animal basis. So, again, in the dentine and enamel of teeth, we have examples of tissues that have once undergone a similar consolidation, retaining their condition unchanged through the whole remainder of life, under circumstances which show that, if any nutritive change take place in them, its amount must be extremely small. Yet it is curious to observe that, both in the osseous and dentinal structures of the young, there is obviously a determinate limit of existence; as is shown in the rapid disappearance of a considerable part of the lamellæ first formed in the cartilaginous matrix (§ 265), as also in the death and removal which continue to take place in the inner and older portions of the shaft of a round bone during the whole period of its increase (§ 267); and in

the exuviation, at a certain definite epoch, of the first set of teeth, which exuviation is usually preceded by the death and disintegration of their own texture (§ 289). In hair, nails, and other epidermic appendages, which, when once their component cells have undergone consolidation by the deposit of horny matter in their interior, may remain unchanged for centuries, we must recognize the same principle of indefinite duration, in connection with the annihilation of vital activity; the chemical constitution of these substances, moreover, being such as renders them but little prone to be acted upon by ordinary decomposing agencies.—In the case of the Muscular and Nervous tissues, however, we trace the operation of causes that differ from any of those already specified. These tissues are doubtless subject, like all others that are distinguished by their vital activity, to the law of limited duration; for we find that, when not called into use, they undergo a gradual disintegration or wasting, which is not adequately repaired by the nutritive processes (§§ 313, 347). But their existence as living structures appears to be terminable at any time, by the exercise of their functional powers; for the development of muscular contractility or of nervous force seems to involve, as its necessary condition, the metamorphosis (so to speak) of the vital power which was previously exercising itself in the nutritive operations; and the materials of these tissues, now reduced to the condition of dead matter, undergo those regressive changes which speedily convert them into excrementitious products. But the very manifestation of their peculiar vital endowments determines an afflux of blood towards the parts thus called into special activity; and from this it comes to pass that the nutrition of these textures is promoted, instead of being impaired, by the losses to which they are thus subjected; so that their constant exercise occasions an augmentation, rather than a diminution, of their substance—a due supply of the requisite materials being always presupposed.

590. Thus it comes to pass that, during the whole period of active life, a demand for Nutrition is created by every exertion of the vital powers, but more especially by the evolution of the Nervous and Muscular forces. The production and application of these, indeed, may be considered as the great end and aim of the Human organism, so far at least as the individual is concerned; the whole apparatus of Organic life being subservient to the building up and maintenance of the Nervo-muscular apparatus, and of those parts of the fabric (*e.g.* the bones, cartilages, fibrous textures, &c.) which it uses as its mechanical instruments. Thus the activity of all the organic operations, when once the full measure of growth has been attained, is mainly determined by that of the animal functions; and as the “rate of life” of all the parts which minister to the former will be in proportion to the energy with which they are called upon to perform their functions, their duration will diminish in the same proportion, and hence occasion will arise for their continual renewal.¹ But since, in the attainment of the

¹ Such an excellent illustration is afforded by the phenomena of Vegetation, of the doctrines here propounded, that it would be scarcely desirable to pass it by in this place, although it has been elsewhere more fully referred to (“Princ. of Phys., Gen. and Comp.,” §§ 494, 554).—The leaves of Plants serve, like the absorbing and assimilating cells of Animals, for the introduction and elaboration of the nutritive materials which are to be applied to the extension of the fabric, the more permanent and inactive parts of which are thus generated at the expense of materials prepared by the vital operations of the more transitory and energetic. Now there is an obvious limit to the duration of the leaf-cells; but this limit is not precisely one of time, being rather dependent upon the completion of their series of vital actions. Thus, although we are accustomed to look upon the “fall of the leaves” (which is nothing else than an exuviation consequent upon death) as a phenomenon of regular seasonal recurrence, and to regard their replacement by a new growth as occurring at a not less constant interval, yet experience shows that these intervals are entirely regulated by temperature; for if one of the ordinary deciduous trees of temperate climates be transferred to a tropical climate, it will live much faster,

adult condition, the germinal capacity has undergone a gradual diminution, whilst the exercise of the animal powers has become vastly increased, the formative processes are only capable of *maintaining* the organism in its state of completeness and vigor, by making good the losses consequent upon the continual disintegration to which it is subjected by its nervo-muscular activity (§ 132). And with the advance of years, the further diminution of the reproductive capacity involves, on the one hand, a progressive decrease in the substance of the tissues and organs most important to life (their bulk, however, frequently remaining unchanged, or even increasing, in consequence of the accumulation of fat), and on the other, a gradual weakening of its powers of action (§ 133).

591. The performance of the function of Nutrition, the demand for which arises out of the causes that have been now discussed, is dependent, not merely upon a due supply of pure and well-elaborated blood, but also upon the normal condition of the part to be nourished, and especially upon its possession of a right measure of "formative capacity;" in virtue of which, the newly produced tissues are generated in the likeness, as well as in the place, of those which have become effete. The exactness of this replacement is most remarkably shown in the retention of the characteristic form and structure of each separate organ or part of the body, and thus of the entire organism, through a long series of years; no changes being apparent (so long as the state of health is preserved), but such as are conformable to the general type of that alteration which the organism undergoes with the advance of life. And not only is this to be noticed in the conservation of all those distinguishing points of structure which mark the species, and are essential to its well-being; but it is still more remarkably displayed in the continuous renewal of those minor peculiarities, which constitute the characteristic features of the individual, and which serve to distinguish him from his fellows. And how much this depends upon the formative capacity originally derived from the germ, is evident from this, that a similar moulding (so to speak) of the nutritive material takes place, in the first instance, into the form characteristic of the species, and afterwards into that which marks the individual, and that the peculiarities of the individual are frequently such as have been distinctive of one or other of the parents, or present a combination of both. But it is curious that the formative power should often be exercised, not only in maintaining the original type, but also in keeping up some acquired peculiarity; as, for example, in the perpetuation of a cicatrix left after the healing of a wound. For, as Mr. Paget has remarked, the tissue of a cicatrix grows and assimilates nutrient material, exactly as do its healthy neighboring tissues; so that a scar which a child might have said to be as long as his own forefinger, will still be as long as his forefinger when he becomes a man. And when the mode of nutrition in any part has been altered by disease, there is frequently an obstinate tendency to the perpetuation of the same alteration; or, if the healthy action be for a time restored, there is a peculiar tendency to the renewal of the morbid process in the part; and this is stronger the more frequently it recurs, until at last it becomes inveterately established. There is, however, in the tissues generally, as in the blood (§ 207), a general tendency to a return to the normal type, after it has undergone a temporary perversion; and thus it is that we find the normal structure of parts gradually restored, when the morbid tendency has been overcome; and that even cicatrices and indurations, notwithstanding their usual obstinate persistence, occasionally disappear. The normal type is, perhaps, less likely to be thus recovered, when the departure from it is very slight, and

its leaves being shed far more frequently, and being replaced much more speedily; so that two, or even three, successive exuviations and reproductions of its foliage may take place within a year.

consists rather in the wrong plan (so to speak) on which the new matter is laid down, than in a perversion of the nutritive process itself.

592. Of the mode in which the substitution of new tissue for that which has become effete, is effected in the process of Nutrition, our knowledge is at present limited; but there can be little doubt that it nearly always takes place in a manner closely conformable to the first development of each tissue. In some instances there is an obvious *replacement* of the old and dead by the young and active elements: this is the case, for example, in the constantly-repeated production of the Epidermic and Epithelial layers; for whether they are developed from germs imbedded in the subjacent basement-membrane, or from nuclei formed *de novo* in the blastema on its free surface, or by the duplicative subdivision of pre-existing cells, there is a continual succession of new cells, which take the place of those that are cast off as defunct and useless. So in the growth of Hair, the increase of which takes place only at its base, we can trace at any period the same development of newly formed spheroidal cells into horny fusiform fibres, as that which took place when first the hair began to sprout from the aggregation of epidermic cells at the bottom of its follicle. So, again, in the vesicular tissue which constitutes the essential part of the Nervous centres, there are appearances which indicate that its peculiar cells are in a state of continual development, newly formed ganglionic vesicles taking the place of those which have undergone disintegration. But there are other textures whose nutrition is more completely *interstitial*; their elements being more closely coherent, and their newly-formed portions being developed throughout the substance of the old, instead of (as in the case of the epidermis and its appendages) *superficially* or in mere continuity with it. Such is the case, for example, with Muscle, the mode of whose nutrition has not yet been elucidated. We can only infer from analogy, that here too each fibre or fibril will pass, in the course of its development, through the same stages which those of the embryo did when its muscles were first formed. And this analogy seems to derive confirmation, from the presence, in all well-nourished muscles, of bodies which bear the appearance of nuclei; for these, as Mr. Paget remarks, "are not the loitering impotent remains of embryonic tissue, but germs or organs of power for new formation." And it is further confirmatory of this view, that losses of substance of muscle, which involve the destruction of these centres of nutrition, are not replaced, like losses of cuticle, by new tissue of the same kind; the power to form it not being inherent in the blood or in the neighboring parts. Nevertheless, it must be admitted that no intermediate stages of development can be traced in the fibres, even of those muscles of the adult which are in most constant use, and of which the nutrition is the most active, that are at all comparable to those which are met with in the muscular tissues of the embryo.—With regard, again, to the interstitial nutrition of Bones and Teeth, we know nothing whatever. That some nutritive change is continually taking place in them, is certain from the fact that if the supply of blood be withdrawn, the parts thus affected die and are cast out of the body; and it is also made apparent by the effects of madder in gradually tinging even the bones and teeth of the adult, though for such a change a much longer period is required in the adult than in the young animal.—The nutrition of the simple Fibrous tissues would also appear to take place interstitially; but there is no proof that the pre-existing tissues are here in any way concerned in their replacement, which probably takes place in virtue of the self-developing powers of the blood itself.

593. Of the modes in which the effete particles of tissues whose term of life has expired, or whose vital energy has been exhausted, are removed and disposed of, our present knowledge is no less imperfect. In the case of those tissues which are *superficially* nourished, a continual loss of substance is obviously taking place by the exuviation of dead particles *en masse*; this is the case with

the whole series of Epithelial and Epidermic cells, which are thrown off with little previous change, like the leaves of trees, their decay not taking place, for the most part, until after they have become detached from the organism. But the fact is altogether different with regard to those whose nutrition is *interstitial*, especially the nervous and muscular tissues; for the decomposition of these would seem to occur in their very substance, its products being taken up by the blood, and subsequently eliminated from it by organs appropriated to that purpose. The evidence of this is seen, as regards Muscle, in the presence of creatine, creatinine, inosine, and other undoubted products of regressive metamorphosis, in the "juice of flesh;" as regards the Nervous substance, however, no such definite proof can be at present afforded, since its normal constitution has not yet been sufficiently studied to enable the products of its decomposition to be distinguished.—There is one remarkable form of degeneration, however, which is common to nearly all the tissues, and which seems to occur as a normal alteration in many of them at an advanced period of life; this consists in the conversion of their albuminous or gelatinous materials into fat, thus constituting what is known as "fatty degeneration." That this change is not due to the removal of the normal components of the tissues, and the substitution of newly deposited fatty matter in their place, but is (in most cases at least) the result of a real conversion of the one class of substances into the other, has been already pointed out (§ 40). And there are certain facts which indicate that this kind of degeneration is a part of the regular series of processes, by which tissues that have served their purpose in the economy are prepared for being removed by absorption; one of the most remarkable being the observations of Virchow¹ and Kilian² with regard to the fatty degeneration of the muscular tissue of the uterus after parturition. So, as Mr. Paget has pointed out, the fibrinous and corpuscular products of inflammation are often brought into a state fit for absorption, by passing through this intermediate stage; the fibrinous substance being observed to be dotted by granules, which are known to be oil particles by their peculiar shining black-edged appearance, and at the same time losing its toughness and elasticity, and being no longer rendered transparent by acetic acid; whilst the lymph-cells present a similar increase of shining black-edged particles like minute oil-drops, which accumulate until they nearly fill the cell-cavity, their nuclei at the same time gradually fading and disappearing.³ Thus, then, if the fat, which is one of the products of this regressive metamorphosis, be absorbed as fast as it is formed, and the effete tissue be replaced by a new production, which seems to be the case with Muscles in a state of healthy activity, there is no appearance of degeneration, and the nutrition is kept up to its normal standard. But if, from the advance of age or from the insufficient exercise of the muscles, their nutrition take place less rapidly than their waste, whilst the products of their degeneration are still removed, simple atrophy is the result. If, on the other hand, the general conditions being similar, the fat produced in degeneration be not absorbed, but remain in the tissue (as is, perhaps, most likely to happen when a copious supply of respiratory material is afforded by other substances), an obvious "fatty degeneration" is the result.—It may be stated as a general rule that no absorption of the materials of tissue can take place without a previous degeneration such as this, or a more complete decomposition. There is no evidence that any healthy tissue is ever thus absorbed, or that any preternatural activity of the absorbent vessels can ever (as formerly supposed) be the occasion of a loss of substance; in fact, so long as the vital force is in active operation in a part, and its processes of growth and develop-

¹ "Verhandlungen der Gesellschaft für Geburtshülfe," Berlin, vol. iii. p. xvii.

³ See Mr. Paget's "Lectures on Inflammation," in "Medical Gazette," 1850, vol. xlv. p. 7.

ment are being normally carried on, such absorption may be considered to be impossible. On the other hand, if a part die *en masse*, it is not removed by absorption, but becomes isolated by the separation and recedence of the living parts, and is then cast out altogether, even from the interior of the body as we see in the case of a necrosed bone; its condition being then essentially the same as that of the outer layers of the tegumentary organs, which are cut off, by their distance from a vascular surface, from all further nutrient change. The difference between these two modes of removal is well seen (as Mr. Paget has remarked) in the case of the Teeth; for the fangs of the deciduous teeth undergo degeneration, when the current of nutrition is diverted towards those which are to succeed them, their materials being slowly decomposed so as to become soluble, and being gradually removed by absorption, so that nothing is left at last but the crowns of the teeth; on the other hand, the permanent teeth which are not to be succeeded by others, when no longer receiving their due nutrition, die, and are cast out entire.

594. Among the conditions of healthy Nutrition, a due supply of Nervous power is commonly enumerated; and it cannot be questioned that the want of such a supply is frequently the source of a perversion of the normal operations. This, however, by no means proves that the formative power is derived from the nervous system; and such an idea is at once negatived by a number of incontestable facts. Yet it may be freely admitted that the right direction and application of this power in Nutrition may sometimes depend upon guidance and direction afforded by the Nervous centres, in the same manner as the Secreting process is capable of being thus influenced; in fact, we can scarcely explain in any other mode that influence of mental states upon the nutrient operations, which frequently leads to very important modifications of them. The whole of this subject, however, will be more appropriately considered hereafter (CHAP. XVII.).¹

2.—*Varying Activity of the Nutritive Processes.—Reparative Operations.*

595. Without any change in the *character* of the Nutritive processes, there may be considerable variations in their *degree of activity*; and this, either as regards the entire organism, or individual parts, though most commonly the latter. These variations may be so considerable as to constitute Disease; though there are some which take place as part of the regular series of Physiological phenomena. Thus, as we have seen, it is to the excess of formative activity, that the increase of the organism in the earlier period of life is due, its "waste" being at the same time extremely rapid; whilst it is to a corresponding reduction in the regenerative power, and not to positive excess of "waste" or decay (this, indeed, taking place very slowly), that the gradual decline of the organism in advancing years is to be attributed. So also we find that local as well as general variations may take place, as a part of the regular series of vital phenomena; and this during the period of adult life, as well as in the earlier and later epochs. Thus all those differences in the proportional development of the several parts of the organism, which mark the distinction between the adult and the child, even where (as in the case of a dwarf), there is no difference in stature, result from a decline in the formative capacity of those which are peculiarly adapted to the wants of the earlier stage (the Thymus gland, for example), and from an increased activity of nutrition in those which are destined to the use of the adult, the Generative organs more particularly. And the

¹ In the treatment of this subject, the Author has made free use of the valuable materials contained in Mr. Paget's "Lectures on Nutrition, Hypertrophy, and Atrophy" ("Med. Gaz.," 1847), which have enabled him, whilst still expressing the same general doctrines as in previous editions, to make great improvements in the exposition and illustration of them.

intermittent activity of the sexual apparatus of the female affords a remarkable example of the same principle; this being marked not merely in the enormous development of the uterus and mammary glands, as a consequence of conception, but in the periodical change which takes place in the ovaries, whereby the ova are matured and thrown off at certain regular intervals. The decline in the formative power of these same organs, moreover, when as yet the organism in general shows but little indication of deterioration, is another characteristic example of the variation in Nutritive activity resulting from the inherent endowments of the part, and essentially irrespective of the condition of the blood, of the circulation, and of the organism as a whole; but, as formerly shown (§ 203), the production and maintenance of other and apparently unconnected organs are *complementally* dependent upon the formative activity of the generative apparatus.

596. The abnormal excess of Nutritive change which properly constitutes *Hypertrophy*, appears to depend upon a departure from one or other of the conditions, under which, as already specified, the change normally takes place; namely, the right composition of the blood, a due supply of such blood, and a proper formative capacity in the part itself.—Of the excess of nutrition resulting from the presence of an excess of the peculiar materials of certain tissues in the circulating fluid, examples have already been given (§ 120); it is important to remark, however, that, although hypertrophy may be thus induced in any of the tissues which constitute the instruments of *organic* life, yet there is no evidence that either the nervous or the muscular apparatus can be forced (so to speak) to an augmentation in bulk by the abundance of their nutritive materials.—With regard, in the next place, to the supply of blood, there can be no doubt that in general an increased flow of blood towards a part is consequent upon, rather than a cause of, an excess in its nutritive activity; but still, there are cases in which its causative agency may be traced. Various examples of this have been supplied by the experiments and observations of John Hunter, the records of which are left in his Museum. Thus, if the spur of a cock be transplanted from the leg to the comb, which is a part far more vascular than that with which it was originally connected, it undergoes an extraordinary augmentation in size; having in one instance grown in a spiral form, until it was six inches long; and in another curved forwards and downwards like a horn, so that its end needed to be often cut, to enable the bird to bring his beak to the ground in feeding. So, again, it was remarked by Hunter, and has been frequently observed since, that an increased growth of hair often takes place on surfaces to which there is an increased determination of blood as a consequence of inflammation in some neighboring part, though not from the surface of the inflamed part itself. So it sometimes happens that when an ulcer of the integuments of the leg has long existed in a young person, the subjacent bone may share in the increased afflux of blood, and may enlarge and elongate. And it seems not improbable that we are to attribute the increased thickness of the cuticle on parts which are exposed to continual pressure or friction, to the augmented afflux of blood which is determined to the irritated surface (§ 241).¹—The greater number of cases of Hypertrophy, however, must undoubtedly be referred to the preternatural formative capacity of the part itself; and this may either be congenital or acquired. Of this congenital excess, we have a remarkable example in the abnormal growth of an entire limb, or of fingers or toes,²

¹ It is commonly said that local hypertrophy may be induced by long-continued Congestion; but this is not true hypertrophy; for the bulk of the organ is not augmented by the increased production of its normal tissue, but by the addition of tissue of an inferior type of organization, as in Inflammation (§ 609).

² A case of hypertrophy of an entire limb was described by Dr. John Reid in the "Edinb. Monthly Journ.," 1843, p. 198; and several cases of hypertrophy of the fingers were described by Mr. Curling in the "Med.-Chir. Trans.," vol. xxviii.

which cannot with any probability be referred to an original excess in the supply of blood, the enlargement of the arteries leading towards such parts being almost certainly consequent upon their unusually rapid growth, just as in the case of the uterine and mammary arteries of the pregnant female. The most remarkable instances of the acquirement of increased formative activity, are presented to us in that augmented growth of the nervous and muscular tissues, which is consequent upon the exercise of their functional powers. This may be considered as to a certain extent a normal adjustment of the supply to the demand; but there are some instances in which it takes place to such an extent as to become a positive disease. Thus it not unfrequently happens, that if young persons who naturally show precocity of intellect, are encouraged rather than checked in the use of the brain, the increased nutrition of the organ (which grows faster than its bony case) occasions pressure upon its vessels, it becomes indurated and inactive, and fatuity and coma may supervene. Now although in such cases there must probably have been some congenital tendency to preternatural activity of the brain, which manifests itself in precocity of intellect, yet there is no doubt that this may be augmented by the "forcing system" of education; whilst, on the other hand, it may be controlled by a system of management adapted to the peculiar circumstances of the case. Excess of muscular development is peculiarly prone to show itself in the involuntary muscles; but this production is in almost every instance the result of the demand for increased muscular exertion, which is consequent upon some obstruction to the usual function of the part. Thus an extraordinary hypertrophy of the muscular coat of the urinary bladder is often seen as a consequence of obstruction to the exit of the urine, through the presence of a stone in the bladder or of a stricture in the urethra; so, again, hypertrophy of the muscular coat of the gall-bladder may take place as a consequence of obstruction of its duct by a gall-stone; hypertrophy of the muscular coat of any part of the alimentary canal may take place in consequence of stricture lower down; and even hypertrophy of the heart is generally, if not always, attributable to obstruction to the exit of the blood which it propels, resulting either from stagnation of the pulmonary circulation by the deficient aëration consequent upon disease of the lungs (in which case the hypertrophy is limited to the right side of the heart), or from thickening or induration of the semilunar valves or narrowing of the orifices of the aorta and pulmonary artery. It is curious, moreover, to observe that hypertrophy of muscles frequently becomes a source of increased nutrition of the bones to which they are attached; this being manifested, not merely in the augmented bulk of the bones of limbs that are specially exercised, but also in the increased prominence of the ridges and processes to which the muscles are attached. This adaptiveness on the part of the formative activity of the osseous tissue, is curiously manifested also in the relation of the skull to the brain; for if the bulk of the brain be not too rapidly augmented, the skull will enlarge accordingly, and this (in some instances) not merely by the extension of its normal bones, but by the intercalation of new osseous elements, the "*ossa wormiana*;" whilst, on the other hand, if there be a diminution in the bulk of the brain, the cranium may adapt itself to this also, by a thickening on its internal surface, or concentric hypertrophy—this change, rather than a diminution in the whole substance of the skull, being more liable to take place in cases in which the cranial sutures have already closed, and the nutrition of the bone has become inactive, so that the modelling process, which consists in the absorption of old and the deposition of new osseous tissue (§ 130), cannot take place.

597. The production of *Tumors* must be considered as a manifestation of an excess of formative activity in individual parts, and as constituting, therefore, a species of Hypertrophy. For a tumor may be composed of the tissues which

are normal to the part; as we see especially in the case of those tumors of the uterus, which are made up of an excess of its ordinary muscular and fibrous elements. But, as Mr. Paget has justly remarked, "an essential difference lies in this; the uterus (often itself hypertrophied) in its growth around the tumor maintains a normal type, though excited to its growth, if we may so speak, by an abnormal stimulus; it exactly imitates, in vascularity and muscular development, the pregnant uterus, and may even acquire the like power; and at length, by contractions like those of parturition, may expel the tumor spontaneously separated. But the tumor imitates in its growth no natural shape or construction; the longer it continues, the greater is its deformity. Neither may we overlook the contrast in respect of purpose, or adaptation to the general welfare of the body, which is as manifest in the increase of the uterus as it is improbable in that of the tumor."¹ A gradation is established, however, between true Hypertrophies and Tumors, by those productions of glandular tissue, which are made up of the proper substance of the gland with which they are connected, as the mammary, the prostate, or the thyroid, and which (though frequently encysted) are sometimes met with as outlying portions of the gland itself.—There is another class of objects to which Tumors come into close relation, and which must be referred, like them, to a local excess of formative activity; these are the "supernumerary parts" which are not unfrequently developed during foetal life, as, for example, additional fingers and toes. It seems absurd to refer these, formed as they are by simple outgrowth from the limbs to which they are attached, to the "fusion of germs," which has been hypothetically invoked to explain more important excesses, as those of additional limbs, double bodies, or double heads; and yet from the lower to the higher form of excess, the transition is so gradual that what is true of the former can scarcely but be true of the latter; so that even complete "double monsters" must be regarded, not as having proceeded from two separate germs which have become partially united in the course of their development, but from a single germ, which, being possessed of an unusual formative capacity, has evolved itself into a structure containing more than the usual number of parts, and comparable to that which may be artificially produced by partial fission of the bodies of many of the lower animals.²—We can scarcely fail to recognize, in this whole series of abnormal productions, the operation of a similar power. In the formation of a supernumerary part, this has been sufficient, not merely to produce the tissues, and to develop them according to a regular morphological type, but to impart to the fabric thus generated a separate and even an independent existence; thus producing an additional finger or thumb on each hand, a double pair of arms or legs, a double head or trunk, or even a complete double body. In the hypertrophy of a regular or normal part, the new tissues are still developed according to a regular morphological type; but they have not the power of individualizing themselves (so to speak), and are so incorporated with the normal elements as to augment the size of the existing organ. In the formation of a tumor, on the other hand, whilst its component tissues are themselves perfectly formed, and have a marked power of independent growth, the mass composed of them is altogether amorphous, its configuration being usually determined rather by the physical conditions under which it is produced, than by any peculiar tendencies of its own; so that we recognize the action of the formative power, undirected by that morphological *nîsus*, which normally models (so to speak) the growing tissues into the likeness of the organ to which they belong.

¹ "Lectures on Tumors," in "Medical Gazette," 1851, vol. xlvii. p. 925.

² See "Princ. of Phys., Gen. and Comp.," §§ 646, 709, *Am. Ed.*; Prof. Vrolik in "Cyclop. of Anat. and Phys.," art. "Teratology," vol. iv. p. 976; and Prof. Allen Thomson on "Double Monstrosity," in "Edinb. Monthly Journal," June and July, 1844.

But further, in many of the large class of tumors distinguished as "malignant" (§ 616), the development of tissue has not gone to the extent of producing any of those species of which the body is normally constituted; and in this respect as well as in their tendency to rapid degeneration, the vital endowments of their elements must be reckoned as below those of the normal tissues.—It is not always easy to draw the line between certain tumors and supernumerary parts, especially when the production of the former is symmetrical; but the first appearance of the latter never takes place save during embryonic life, and their structure is more complex, and is more conformed to the plan and construction of the body at large, than is that of tumors, whose production may take place at any period of life. And between those tumors which are known as "pili-ferous" and "dentigerous cysts," and those encysted embryos (usually incomplete in their formation) which are sometimes found in the bodies even of males, it is impossible to establish any line of demarcation sufficiently precise to prevent our recognizing them as all having the same origin and being expressions of the same power—the simple cyst being a kind of rude attempt at the production of a distinct individual—and the encysted embryo being but the result of an unusually high development of a proliferous cyst.

598. The state of *Atrophy* is in all respects the very opposite of *Hypertrophy*; consisting in such a reduction in the rate of formative activity as compared with that of their "waste," that their nutrition is no longer maintained at its previous standard; so that they are gradually reduced in bulk, or degenerate into some inferior histological type, or (which is the more common occurrence) undergo both diminution and deterioration at the same time. It is important to bear in mind, that *Atrophy* may take place, either locally or generally, from an unusually rapid disintegration of the tissues, uncompensated by a corresponding increase in the rate of their nutrition; of the former we have a characteristic example in the rapid reduction of the bulk of the uterus after parturition, and of that of the mammary glands after the sudden cessation of lactation; of the latter we see an illustration in the rapid wasting of the system, which takes place in the irritable state that results from excessive and prolonged exertion of body or anxiety of mind, especially when accompanied with want of sleep, the increased disintegration being marked by the presence of an unusual amount of urea and of the alkaline phosphates in the urine. But in the ordinary forms of *Atrophy*, there is not merely a *relative* but an *absolute* reduction in the rate of the formative process, or a lowering of its standard of perfection; and here also we have to look for its causes, on the one hand, in the condition and supply of the blood, and, on the other, in the formative capacity of the tissues themselves.—The *Atrophy* dependent upon an insufficient supply of nutritive materials, may be either general or partial. General atrophy, or emaciation, is a necessary result of deficiency of food; but it may also proceed from an imperfect performance of the assimilating processes, whereby the nutritive materials do not receive their requisite elaboration, as in cases of disease of the mesenteric glands; or from an unusual energy of the metamorphic processes, whereby the azotized constituents of the food are decomposed into excrementitious products, without undergoing assimilation at all, as seems to be the case in diabetes. Of the atrophy of a particular tissue consequent upon the deficiency of its proper materials in the blood, we have an example in the reduction of the adipose, when there is no surplus of fatty matter to serve for its nutrition, but on the other hand a withdrawal of the contents of the fat-cells into the circulating current, whilst the nutrition of the muscular and other azotized tissues may proceed with its usual vigor.—Instances of complete local atrophy, or gangrene, resulting from deficiency in the supply of blood to a part, are by no means unfrequent; but it is less common to meet with a prolonged diminution in the rate of nutrition from such a cause, since a partial obstruction to the circulation is usually

removed after a short time by the enlargement of the collateral vessels. Yet there are peculiar circumstances under which this does not take place; thus Mr. Curling has shown that atrophy may occur in fractured bones, in that portion which is cut off from the direct supply of blood through the great medullary artery; the circulation being restored by anastomosis to such an extent as to prevent the death of the bone, but not so completely as to support vigorous nutrition.¹—The most frequent cause of Atrophy lies, however, in the deficiency of formative power in the tissues themselves, arising from the decline of that capacity which they inherit from the germ. This decline, as already shown, takes place in the body at large, as a part of the regular order of things, with the advance of years, and also normally occurs in particular organs at earlier periods of life; but it sometimes takes place prematurely, either in the body at large, or in particular organs, so that they undergo a wasting or degeneration without any ostensible cause. A remarkable example of this has been already referred to, in the account of Cartilage (§ 253); and many similar cases might be cited. There is reason to believe that “fatty degeneration,” the form under which degeneration most commonly presents itself (§ 593), is in reality far more frequent than simple wasting of the tissues; but it attracts less notice, because their bulk is little or not at all diminished; and it is only when their function becomes impaired, that attention is seriously drawn to the change. This form of Atrophy can seldom be attributed to antecedent diminution in functional activity; for it is most common in organs upon which there is the most constant demand for the energetic performance of their respective duties, as, for instance, in the heart, the kidneys, and the liver. But the formative activity of Muscles and Nerves is so closely dependent, as already several times pointed out, upon the active exercise of their functional powers, that atrophy is certain to supervene if this be interrupted; and this atrophy may or may not present itself under the form of fatty degeneration; a shrinkage of the parts, concurrently with the production of an increased amount of fat in them, being perhaps the mode in which it most frequently takes place. Atrophy of one part, moreover, may be dependent upon atrophy or imperfect functional activity of another, if the two be so related in their normal functions that a decline of one involves a corresponding decline in the other. Thus if a motor nerve be paralyzed, the muscles which it habitually calls into action will be atrophied; and this will equally happen, whether the want of motor power depend upon a deficient production of it in the nervous centres, or upon an interruption to its conduction through the trunks.² On the other hand, if the muscles of a part undergo degeneration from want of use (as in disease of the hip-joint), the nerves which supply them also suffer. The same is the case in regard to the nerves and organs of sense; for atrophy of the

¹ “Medico-Chirurgical Transactions,” vol. xx.

² The Author has for some time had under his observation a case in which three males of a family have progressively become affected, between the ages of 3 and 5 years, with fatty degeneration of the muscles, which has proceeded in the most advanced case to the almost complete obliteration of their normal structure. This change had been considered by many eminent practitioners to be idiopathic, that is, to have its primary origin in the muscular tissue; and the measures which had been employed to arrest it had been of no avail whatever. It was a strong argument, however, against such a view of the case, that, in the heart of the eldest son, who died of fever at the age of 16, no fatty degeneration could be discovered; and on making inquiry into the history of the parents and their families, ample evidence was discovered for the belief that the disease was dependent upon want of functional power in the nervous centres. Acting on this view, it was recommended that the muscular system should be kept as much as possible in a state of active exercise, and that a weak galvanic current should be frequently transmitted through the limbs from the spine. This treatment has proved so far successful, that the progress of the disease appears to have been arrested in the most advanced case, whilst a decided improvement has taken place in the condition of a younger child, who was previously passing rapidly into a state resembling that of his elder brothers.

eye will occasion atrophy of the optic nerve, and destruction of the optic ganglia will induce atrophy of the eyes and optic nerves. Even the bones of a limb will suffer, in cases of atrophy of the muscles consequent upon disuse; for in the case already cited (§ 313) from Dr. J. Reid, the bones of the quiescent limb only weighed 81 grains, whilst those of the exercised limb weighed 89 grains.—It is an important fact, which was first pointed out by Mr. Paget,¹ that when fatty degeneration is commencing in any tissue which is characterized by the persistence of its nuclei, it is in the nuclei that the first alterations are seen; for they become pale and indistinct, and gradually disappear altogether, almost before any other change is discernible in the contents of the cells or tubes to which they appertain; but in atrophy from mere decrease, this disappearance of the nuclei does not occur.

599. *Reparative Process*.—The nutritive operations take place, with extraordinary energy and rapidity, in the process of *Reparation*; by which losses of substance, occasioned by injury or disease, are made good. In its most perfect form, this process is exactly analogous to that of the *first development* of the corresponding parts; and its results are as complete in the one case as in the other. In fact, among the lowest tribes of Animals, we find these two conditions blended, as it were, together; for the process of reparation may be carried in them to such an extent as to regenerate the whole organism from a very small portion of it. In the Hydra or Fresh-water Polype, there would seem to be scarcely any limit to this power; for even if the body of the animal be minced into small fragments, every one of these can produce a new and perfect being. In this manner, no less than forty have been artificially generated from a single individual.—In ascending the Animal scale, we find this reparative power less conspicuous, because limited in its exercise to particular tissues and to comparatively insignificant parts of the body; and in Man, as in other warm-blooded Vertebrata, the regenerative power is for the most part restricted in its exercise, as Mr. Paget has pointed out,² to three classes of parts;—namely, (1.) “Those which are formed entirely by nutritive repetition, like the blood and epithelia, their germs being continually generated *de novo* in the ordinary condition of the body; (2.) Those which are of lowest organization, and (what seems of more importance) of lowest chemical character, as the gelatinous tissues, the areolar and tendinous, and the bones; (3.) Those which are inserted in other tissues not as essential to their structure, but as accessories, as connecting or incorporating them with the other structures of vegetative or animal life, such as nerve-fibres or bloodvessels. With these exceptions, injuries or losses are capable of no more than repair in its limited sense; i. e., in the place of what is lost, some lowly organized tissue is formed, which fills up the breach, and suffices for the maintenance of a less perfect life.”—Yet, even thus restricted, the operations of this power are frequently most remarkable; and are in no instance, perhaps, more strikingly displayed, than in the re-formation and remodelling of an entire bone when the original one has been destroyed by disease. That this power is intimately related to that by which the organism is normally built up and maintained, is evident, not merely from the peculiar mode in which it is exercised—its tendency being always to reproduce each part in the form and structure characteristic of it at the particular period of life, and not according to its embryonic type—but also from the fact that it is more effectual in the state of growth than in the adult condition, and that it can do far more in the embryonic state, when development as well as growth is taking place, than after the developmental process

¹ “Lectures on Nutrition,” &c., in “Medical Gazette,” 1847, vol. xl. pp. 145, 146.

² “Lectures on Reproduction and Repair,” in “Medical Gazette,” 1849, vol. xliii, p. 1022.

has ceased. In fact, as Mr. Paget has pointed out (*loc. cit.*), its amount at different periods of existence, as in different classes of animals, seems to bear an inverse ratio to the degree of development which has already taken place. Thus it is well known to every Practitioner how much more readily and perfectly the lesions resulting from accident or disease are repaired in childhood and youth, than they are after the attainment of the adult state. And there is evidence that during embryonic life, the regeneration of lost parts may take place in a degree to which we have scarcely any parallel after birth; for Prof. Simpson has brought together numerous cases, in which, after "spontaneous amputation" of the limbs of a foetus, occurring at an early period of gestation, there has obviously been an imperfect attempt at the re-formation of the amputated part from the stump;¹ and it seems probable, from the history of normal development, that in the cases in which perfect hands and feet have been present without the corresponding limbs, these hands and feet have been secondary productions from the stumps of amputated limbs, since any original defect of development would have affected the hands and feet rather than the arms and legs. There are occasional instances, however, in which this regenerative power has been prolonged to an unusually late period; thus an instance is recorded, on authority that can scarcely be doubted, of the twice repeated reproduction of a supernumerary thumb, after it had been twice completely removed;² and the Author has been assured by a very intelligent Surgeon, that he was cognizant of a case in which the whole of one ramus of the lower jaw had been lost by disease in a young girl, yet the jaw had been completely regenerated, and teeth were developed and occupied their normal situations in it.³

600. It has been a general opinion among British surgeons (founded upon what they believe, but erroneously, to have been the doctrine of Hunter), that Inflammation is essential to the process of Reparation. There is no doubt that, as usually conducted, the healing of wounds is attended by a greater or less degree of Inflammation; but it does not thence follow that this morbid condition is essential to the renewal of the healthy state; and in fact it can be shown that, in the majority of cases, the occurrence of Inflammation is injurious rather than beneficial. It was by Dr. Macartney that the first clear enunciation of this important truth was made; and his conclusions, founded upon a philosophical comparative survey of the operations of Reparation and Inflammation, as performed in the different classes of animals—namely, "that the powers of reparation and reproduction are in proportion to the indisposition or incapacity for inflammation;—that inflammation is so far from being necessary to the reparation of parts, that, in proportion as it exists, the latter is impeded, retarded, or prevented;—that, when inflammation does not exist, the reparative power is equal to the original tendency to produce and maintain organic form and structure;—and that it then becomes a natural function, like the growth of the individual, or the reproduction of the species"⁴—may be regarded as substantially correct, although requiring some modification in particular cases.

601. The simplest of all the methods of healing of an open wound is that which is termed by Dr. Macartney "immediate union." It is often seen in the case of small incised wounds, such as cuts of the fingers, or the incision

¹ These cases were brought by Prof. Simpson before the Physiological Section of the British Association at its meeting in Edinburgh, Aug. 1850. The Author, having had the opportunity of examining two living examples, as well as Prof. Simpson's preparations, is perfectly satisfied as to the fact.

² See Mr. White's Treatise on the "Regeneration of Animal and Vegetable Substances" (1785), p. 16.

³ For a sketch of the Regenerative Process as performed in different tribes of Animals, see "Princ. of Phys., Gen. and Comp.," §§ 645 and 646, *Am. Ed.*, and the account of each class in CHAP. VII.

⁴ Dr. Macartney's "Treatise on Inflammation," p. 7.

made in venesection, in which the two edges can be brought into close approximation, so that they grow together without any connecting medium of blood or lymph; but it sometimes occurs in larger ones,¹ and as it is the best imaginable process, the surgeon ought to favor it as much as possible, by procuring the most exact coaptation of the wounded parts, and by repressing any tendency to inflammation, which will interfere with it. This is the mode of union which was spoken of by John Hunter as "healing by the first intention." He supposed that the union takes place through the medium of the blood intervening between the lips of the wound, which undergoes organization into a connecting tissue; but it is now certain that although blood *may* become organized, especially when effused into a wound secluded from the air, yet that its intervention rather opposes than favors healing by immediate union.

602. That which is commonly known amongst British Surgeons as "healing by the first intention," is that which was designated by Hunter as "union by adhesion" or by "adhesive inflammation." This process takes place in the case of incised wounds, of which the edges are not brought into perfect coaptation, or in which some inflammatory action is present, which gives rise to the effusion of plastic lymph. In either case, the connection is finally re-established by the organization of the lymph, into which vessels pass from both surfaces; but the intervention of this bond is manifested in the persistence of the cicatrix, which is quite distinguishable by its peculiar appearance from the surrounding tissue. A very good example of this process, as it takes place under favorable circumstances, is presented after operations for harelip; the wound left by which, however, may partly heal by "immediate union." Even the moderate effusion of lymph, to a degree that is altogether salutary, cannot be regarded as alone sufficing, under such circumstances, to constitute Inflammation. It is well known that if a slight wound, which is thus healing, be provoked to an increased degree of inflammation, its progress is interrupted; and all the means which the Surgeon employs to promote union, are such as tend to prevent the accession of this state.—The only case in which the concurrence of Inflammation can be regarded as salutary, is that in which there is a deficiency of Fibrin in the blood, causing a deficient *organizability* of the lymph. It has been seen that the amount of fibrin is rapidly increased by inflammation: and the Surgeon well knows that a wound with pale flabby edges, in a depressed state of the system, will not heal, until some degree of Inflammation has commenced. But when the inflammatory state has developed itself, in however trifling a degree, there is always a risk of its proceeding further, and occasioning a degeneration of the plastic material, so that the formation of pus-cells and the effusion of purulent fluid take place, instead of the development of uniting tissue.

603. The reparation of wounds, in which there has been so great a loss of substance that neither immediate union nor adhesion by a thin layer of coagulable lymph can take place, is accomplished by the gradual development of new tissue from the "nucleated blastema" with which the cavity is first filled. But this may take place in different modes, according to the degree in which it is disturbed by the Inflammatory process; and it should be the great object of the Surgeon to procure the most favorable method of its performance. It has been shown by Mr. Paget, that the mode in which the process of filling up is accomplished differs essentially according as the wound is subcutaneous, or is exposed to air. In the former case, the nucleated blastema is gradually developed into fibrous tissues (§ 224) without any loss, and usually with freedom from local

¹ Mr. Paget mentions a case of extirpation of a mammary tumor, in which the greater part of the wound was found to have healed after this fashion; the skin and fascia having so firmly adhered, that no indication existed of their previous detachment; and no effusion of coagulable lymph, or production of a connecting tissue, being detectable by microscopic examination.

inflammation (beyond what may have been requisite for the production of the plastic fluid), as well as from constitutional irritation. In the latter case, the nucleated blastema is developed into cells; and those on its exposed surface are unable, either from degeneration or from imperfect development, to pass on to any higher form of organization, but take on the characters of pus-cells, and are only fit to be cast off. Hence there is a continual loss of plastic material, the amount of which, in the case of an extensive suppurating sore, forms a most serious drain upon the system; whilst, at the same time, the local inflammation gives rise to more or less of constitutional disturbance, and the formation of new tissue is by no means so perfect as in the preceding case. In cold-blooded animals, however, the contact of air does not produce this disturbance; and we see wounds with extensive loss of substance gradually filled up in them by the development of new tissue, without any suppuration or other waste of material, very much as in the subcutaneous wounds of warm-blooded animals. This method of healing, which has been termed by Dr. Macartney the "modelling process," is nothing else than healing by granulations under the most favorable circumstances; and to procure this should be the endeavor of the Surgeon, who too frequently considers suppurative granulation as the only means by which an open wound can be filled up. The difference between the two modes of reparation is often one of life and death, especially in the case of large burns on the trunk in children; for it frequently happens that the patient sinks under the great constitutional disturbance occasioned by a large suppurating surface, although he has survived the immediate shock of the injury.—Now the means adopted by Nature to bring this about, in warm-blooded animals, is the formation of a scab; which reduces the wound more nearly to the condition of a subcutaneous one, so that the reparative growth and formation of new tissue take place (under favorable circumstances) without any suppuration, and with scarcely any irritation; the subsequent cicatrix, too, being much more like the natural parts, than are any scars formed in wounds that remain exposed to the air. In the Human subject, however, the process is far less certain than it is among the lower animals, owing to the liability to inflammation in the wounded part, and the consequent effusion of fluid, which produces pain, compresses the wounded surface, or forces off the scab, with great discomfort to the patient, and retardation of the healing. Small wounds, however, in persons of good habit of body, and in parts which can be completely kept at rest, readily heal in this manner; and large wounds have been known to close, in the same desirable mode, beneath a clot of inspissated blood. In fact, among "uncivilized" nations, whose habits of life are favorable to health—their bodies being continually exposed to fresh air, their food wholesome and taken in moderation, and their drink water or other unstimulating liquids—there seems to be as great a tendency to this method of reparation as among the lower animals; and the difficulty of procuring it among the members of "civilized" communities is owing, without doubt, to the *unnatural* conditions under which they too frequently live. Seeing, as we continually do, the effects of foul air, of habitual excess in diet, and of the constant abuse of stimulants, in impairing that form of the reparative process which must be regarded as the least favorable, namely, the closure of a wound by suppurating granulations, it is very easy to comprehend that, to induce the most favorable method, the most perfect freedom from all pernicious agencies should be required.

604. The most effectual means of promoting this kind of Reparative process, and of preventing the interference of Inflammation, vary according to the nature of the injury. The exclusion of air from the surface, and the regulation of the temperature, appear the two points of chief importance. By Dr. Macartney, the constant application of moisture is also insisted on.¹ He states that the

¹ "Treatise on Inflammation," p. 178.

immediate effects of injuries, especially of such as act severely upon the sentient extremities of the nerves, are best abated by the action of "*steam* at a high but comfortable temperature, the influence of which is gently stimulant, and at the same time extremely soothing." After the pain and sense of injury have passed away, the steam, at a lower temperature, may be continued; and, according to Dr. M., no local application can compete with this, when the Inflammation is of an active character. For subsequently restraining this, however, so as to promote the simple reparative process, Water-dressing will, he considers, answer sufficiently well; its principal object being the constant production of a moderate degree of Cold, which diminishes, whilst it does not extinguish, sensibility and vascular action, and allows the Reparative process to be carried on as in the inferior tribes of animals. The reduction of the heat in an extreme degree, as by the application of ice or iced water, is not here called for, and would be positively injurious; since it not only renders the existence of Inflammation in the part impossible, but, being a direct sedative to all vital actions, suspends also the process of restoration. The efficacy of Water-dressing in injuries of the severest character, and in those which are most likely to be attended with violent Inflammation (especially wounds of the large joints) has now been established beyond all question; and its employment is continually becoming more general.¹—Other plans have been proposed, however, which seem in particular cases to be equally effectual. To Dr. Greenhow, of Newcastle, for instance, it was accidentally suggested, a few years since,² to cover the surface of recent burns with a liquefied resinous ointment, so as to form an artificial scab; and he states that in this manner suppuration may be prevented, even where large sloughs are formed; the hollow being gradually filled up by new tissue, which is so like that which has been destroyed, that no change in the surface manifests itself, and none of that contraction, which ordinarily occurs even under the best management, subsequently takes place. A plan has, moreover, been proposed for preventing suppuration, and promoting reparation by the "*modelling*" process, which consists in the application of *warm dry air* to the wounded surface. Although the experiments yet published have not been entirely satisfactory, they seem to show that, whilst the process of healing may be slower under treatment of this kind, it is attended with less constitutional disturbance than is often unavoidable in the ordinary method; and that it may therefore be advantageously put in practice in those cases in which the condition of the patient requires every precaution against such an additional burden—as after amputation in a strumous subject.³

605. When the process of healing of an open wound by Suppurative Granulation is attentively watched, it is seen that the first stage is the formation of a "*glazing*" on the exposed surface, which closely resembles the buffy coat of the blood, being composed of coagulated fibrin and colorless corpuscles; in this manner a sort of imperfect epithelium may be formed within half an hour after the surface has been laid bare. The increase of this glazing is the prelude to the formation of granulations; but whilst it is going on, there is, in and about the wound, an appearance of complete inaction, a sort of calm, in which scarcely anything appears except a slight oozing of serous fluids from the wound, and which continues from one day to eight, ten, or more, according to the nature and extent of the wounded part, and the general condition of the body. "*This calm,*" says Mr. Paget, "*may be the brooding-time for either good or evil; whilst it lasts, the mode of union of the wound will, in many cases, be deter-*

¹ See an account of the result of this treatment by Dr. Gilchrist, in "*Brit. and For. Med. Rev.*," July, 1846, p. 242.

² "*Medical Gazette*," Oct. 13, 1838.

³ See M. Jules Guyot "*De l'emploi de la Chaleur dans le Traitement des Ulcères, &c.*"

mined; the healing may be perfected, or a slow uncertain process of repair may be but just begun; and the mutual influence which the injury and the patient's constitution are to exercise on one another appears to be manifested more often at or near the end of this period, than at any other time." The cessation of this period of calm, and the active commencement of the reparative operations, are marked by the restoration of the flow of blood in the vessels of the wounded part; but the current is not altogether normal, being slower but fuller than natural, so that on the whole more blood than usual passes through the capillary plexus. This increased afflux of blood is followed by effusion of plastic material in increased proportion; and it is from this effusion that the granulating process properly commences.—The plastic material effused upon the surface of an open wound is first developed into cells; and these cells, in the deeper portions of the effusions, are metamorphosed into fibrous tissue, of which the substance of the granulations is composed. Those which are formed upon the surface, however, are converted into pus-cells (§ 614); in some instances (as Mr. Paget has pointed out) by degeneration from a higher development; in other cases by an originally imperfect development: and thus the granulation surface is constantly in a state of morbid action, and a large proportion of the plastic material is completely wasted. The layer of pus, however, serves as a sort of epithelium for the subjacent granulation tissue, in which we find not only a complete formation of cells, but a commencement of the metamorphosis of these cells into fibres, before bloodvessels make their appearance in the tissue. These bloodvessels are formed by "out-growth" from the subjacent capillaries, in the mode formerly described (§ 295). From the investigations of Mr. Liston, it appears that the vessels of the subjacent tissue are much enlarged, and assume a varicose character. The bright red color of the granulations, however, does not depend on their vascularity alone; for the cells themselves, especially those most recently evolved, are of nearly as deep a color as the blood-corpuscles; and the sanguineous exudation which follows even the slightest touch of the granulating surface, does not proceed from blood effused from the newly-formed vessels only; for the red fluid shed in this manner contains, besides blood-disks, newly developed red cells, ruddy cytoblasts, pale granules, and reddish serum. It is a common property of animal cytoblasts, that they present a reddish color on their first formation, when in contact with oxygen; but this hue they lose again, whether they advance to perfect development and become integral parts of a living tissue, or die and degenerate.

606. The process of Suppurative Granulation, then, appears to differ from the process of granulation as it takes place in closed wounds, or in a warm moist atmosphere (the "modelling process" of Dr. Macartney), essentially in this—that a large part of the exudation-corpuscles deposited on the wounded surface degenerate into pus in the former case, whilst none are thus wasted in the latter:—but that the existence of inflammation occasions a more copious supply of fibrin in the former case, and increases its tendency to become organized; the filling up of a wound with granulations being thus a much more rapid process than that renewal of the completely formed tissues which may take place in the absence of inflammation. The imperfect character of the granulation structure is shown, by the almost complete disappearance of it after the wound has closed over. The portion of it in immediate contact with the subjacent tissue, however, appears to undergo a higher organization; for it becomes the medium by which the cicatrix is made to adhere to the bottom of the wound. It is very liable to undergo changes which end in its disintegration; as is evident from the known tendency to re-opening, in wounds that have been closed in this manner.

607. When two opposite surfaces of granulations, well developed, but not yet covered with cuticle, are brought into apposition, they have a tendency to unite, like the two original surfaces of an incised wound. This method of union,

which was noticed by John Hunter, has been appropriately termed "secondary adhesion" by Mr. Paget. The surgeon may frequently have recourse to it with great advantage, when primary adhesion is impossible, and when the filling up of the wound with granulations would be a tedious process, and very exhausting to the patient. In applying it to practice, it is essential to success, first, that the granulations should be healthy, not inflamed or profusely secreting, nor degenerated as those in sinuses commonly are; and secondly, that the contact between them should be gentle but maintained; it seems desirable, also, that the granulation surfaces should be as much as possible of equal development, and alike in character.¹

3.—*Abnormal Forms of the Nutritive Process.*

608. Under the preceding head, we have considered the chief variations in the degree of activity that are witnessed in the ordinary or normal conditions of the Nutritive process—those conditions, namely, in which the products are adapted, by their similarity of character, to replace those which have been removed by disintegration. But we have now to consider those forms of this process—in which the products are *abnormal*—being different from the tissues they ought to replace. We shall confine ourselves to a brief examination of a few of some of the most important of these states; and that which first claims our consideration, on account of the frequency of its occurrence and the importance of its results, is *Inflammation*.—Although Pathologists have been accustomed to look for the "proximate cause" of the phenomena which essentially constitute the Inflammatory state, or, in other words, for the first departure from the normal course of vital action, in the enlarged or contracted dimensions of the bloodvessels of the inflamed part, or in the altered rate of movement of the blood through it, yet it may now be safely affirmed that these are only secondary alterations, depending upon an original and essential perversion of that normal reaction between the blood and the tissues which constitutes the proper Nutritive process. This perversion manifests itself (1) in a diminution in the formative activity of the tissues, leading to their degeneration and death; (2) in a tendency to augmented production of the plastic components of the blood; and (3) in the effusion of these components, either in a state in which they may pass into a low form of organized tissue, or in such a degraded condition that they are altogether unorganizable, and are fit only to be cast out of the body. Each of these phenomena requires a separate examination, both as to its causes and its consequences.

609. Although it has been customary to speak of Inflammation as a state of "increased action" in the part affected—of which increased action the augmentation in the bulk and weight of an inflamed part, and in the quantity of blood which passes through it, together with its higher temperature and more acute sensibility, would seem to furnish sufficient evidence—yet all these signs are found to be deceptive when they are more closely examined; and the conclusion is forced upon us, that the vital power of the part is really *depressed* rather than exalted. For the increase in bulk and weight is not due to such an augmentation of its proper tissue as would truly constitute Hypertrophy; on the contrary, even in the slightest forms of Inflammation there is such a diminution in the rate of its nutrition as really constitutes Atrophy; and such augmentation of the solid mass as may take place, is produced by the passage of the effused fluid into an organized tissue of the lowest kind, and this in

¹ On the whole subject of the Reparative Processes, see the admirable Lectures of Mr. Paget, in the "Medical Gazette," 1849; from which many of the foregoing statements and doctrines are adopted.

virtue rather of its own plasticity, than of the vital force which it derives from the tissues which it infiltrates. That there has been an atrophy rather than a hypertrophy of the proper fabric of the part, becomes evident enough when the inflammation has passed away, and this newly-formed tissue undergoes degeneration and absorption. The only tissues in which there is any appearance of increased formation during the inflammatory state, are those which correspond in their low type of organization with the new tissue thus generated; namely, the areolar and other simple fibrous tissues, and also the osseous, of which the organized basis is of the same kind. When the Inflammation is more severe, the tendency to degeneration in the proper tissues of the part becomes very obvious; for it is by their *interstitial* decay and removal, that the cavity of an *abscess* is formed; it is by their *superficial* death and absorption or solution that *ulceration* takes place; and it is in the death of a whole mass at once, that *gangrene* consists.—That a diminution in the formative activity of the tissues is an essential characteristic of the Inflammatory state, further appears from the study of its etiology; for whether the causes to which the inflammatory attack may be traced are *local* or *general*, acting primarily upon the tissues of the part, or first affecting the blood, their operation is essentially the same. For the *local* causes are all obviously such as tend either directly to depress the vital powers, or to elevate them at first, and then to depress them by exhaustion. Of the former kind are cold and mechanical injury; also many chemical agents, whose operation tends to bring back the living tissues to the condition of inorganic compounds. Under the latter category are to be ranked all those agencies which produce over-exertion of the functional power of the part, amongst which may be named heat, when not too excessive to produce a directly destructive effect. Now cold, heat, chemical agents, and mechanical injury, when operating in sufficient intensity, at once *kill* the part, by entirely destroying, instead of merely depressing, its vital powers; and it is on the borders of the dead part, where the cause has acted with less potency, that we find the inflammatory state subsequently presenting itself. On the other hand, there can be no doubt that many inflammations have their origin in morbid conditions of the blood, which, without any other cause whatever, may determine all the other phenomena. This is most obvious with regard to those of a “specific” kind; but it is also probably true of the majority of the so-called spontaneous or constitutional, as distinguished from traumatic inflammations. We seem, indeed, to be able to trace a regular gradation between inflammatory attacks which are entirely traceable to the introduction of a poison into the blood, and those which result from causes purely local. Under the first head we may unquestionably rank such inflammatory diseases as are producible by inoculation, the eruptive fevers for example; and scarcely less thoroughly demonstrated are the cases of rheumatism and gout, and many inflammations of the cutaneous textures, which, when occurring in the chronic form, tend to exhibit a regular symmetry (§ 201). In all such cases, the local affections are the external signs of the general affection of the blood, just as are the inflammations produced by the introduction of arsenic or of other irritant poisons into the circulation; and they may in fact be reasonably attributed to the impairment of the formative activity of the parts upon which these poisons fix themselves, in virtue of their “elective affinity” (§ 207), just as the peculiar functional activity of the nervous centres is affected by narcotic poisons. And this view of the really local action of what are primarily regarded as general or constitutional causes of inflammation, is confirmed by the fact that the localization of the perverted nutritive condition is often determined (as Dr. W. Budd and Mr. Paget have remarked) by a previous or concurrent weakening or depression of the vital activity of the part. Thus, a part which has been the seat of former disease or injury, and which has never recovered its vigor of

nutrition, is always more liable than another to be the seat of local manifestation of blood disease; it is, in common language, the "weak part."¹ And it frequently needs the concurrent operation of a local depressing cause, to fix and develop the action of the constitutional cause, or blood disorder; thus, a rheumatic or gouty diathesis may exist for some time (as when, to use a common expression, the disease is "flying about" the patient), and yet the poison may not have sufficient potency to produce an attack of acute inflammation, until the vitality of some particular organ becomes depressed by cold, over-exertion, or some similar influence, which would not have itself engendered the diseased action, had it not been for the concurrence of the morbid condition of the blood.—Thus we seem justified in concluding, that, whether the causes of Inflammation act directly upon the tissues of a part, or whether they act upon it through the intermediation of the blood, their effect is to produce a depression in its vital powers, which manifests itself in a *deficient formative activity*, and in an *increased tendency to degeneration*; and that this is one of the primary and essential conditions of Inflammation.

610. This view is by no means inconsistent with other manifestations of Inflammation which have been supposed to indicate "increased action;" and, in fact, it is in such striking accordance with the phenomena presented by the movement of the blood, when these are interpreted by the principles already laid down, as to afford a powerful confirmation to both doctrines. The usual condition of the vessels of an inflamed part is one of dilatation; and this may be fairly attributed to the lowered vitality of their walls, whereby they yield too readily to the distending force of the current of blood. But this current moves too slowly; and its retardation may gradually increase, in the part most intensely inflamed, to the point of complete stagnation. Now this altered rate of movement cannot be attributed to any general cause: nor can it be accounted for by the change in the diameter of the vessels; for, on the one hand, it may occur with a constricted state of the vessels, whilst, on the other, in the vessels surrounding the inflamed part, which partake of the dilated condition, the flow of blood is so far from being retarded, that it usually takes place more rapidly than usual. But it may be fairly considered as the result of the lowered or suspended nutritive activity of the part, which will tend to retard or entirely check the motion of blood in the systemic capillaries, just as the want of aeration retards or checks the pulmonary circulation (§ 527). It is quite true that a larger amount of blood passes through a limb, of which *some part* is in a state of active inflammation, than passes through the corresponding sound limb; but this is far from indicating "increased action" in the inflamed part, being dependent upon the augmented flow of blood through the tissues which surround it; and if *the whole* of a limb be in a state of inflammation passing on to gangrene (as occurs when a "frost-bitten" limb has been incautiously warmed) the amount of blood which passes through it is diminished. It would be just as erroneous to assume the elevated temperature of an inflamed part as a sign of "increased action" in it; for this elevation is no doubt attributable in part

¹ A patient under Dr. W. Budd's care had Smallpox soon after a fall on the nates; the pustules were thinly scattered everywhere, except in the seat of former injury, and on this they were crowded as thickly as possible. So a man who was under Mr. Paget's care with chronic inflammation of the synovial membrane of the knee-joint, and general swelling about it, having been attacked with Measles, the eruption over the diseased knee was a diffused bright scarlet rash. So Impetigo appears about blows and scratches in unhealthy children, and Erysipelas first attacks the seat of local injury in men with unhealthy blood. Perhaps as good an example as any is afforded by the uniform limitation of the inflammation consequent upon the introduction of Vaccine matter into the blood, to the spots in which the puncture was made; notwithstanding that the whole mass of blood is affected by it, as is shown by its incapacity for subsequently developing the poison of smallpox.

to the augmented flow of blood through the surrounding vessels; and, so far as it depends upon local changes, it obviously indicates a more rapid disintegration of tissue, rather than a more energetic production of it; since it is in the former state rather than in the latter, that the conditions of the development of heat (on the chemical theory) are supplied, as we see that the heat of a muscle is the greatest when it is being disintegrated by active exercise (§ 330), not when it is being repaired by the formation of new tissue in the intervals of repose. But, as Mr. Paget justly remarks, "this phenomenon is involved in the same difficulty as are all those that concern the local variations of temperature in the body; difficulties which the doctrines of Liebig, however good for the general production of heat, are quite unable to explain." (See CHAP. XIII.)—And lastly, with regard to the unusual tenderness of inflamed parts, this is obviously due to such a combination of causes, none of which can be legitimately held to indicate an increase of its proper vital activity, that nothing can be rested on this alone; especially as we see an augmentation in the susceptibility of the sentient nerves, under many circumstances (as in hysterical disorders), in which, far from an *augmented* there is obviously a *diminished* activity in the parts from which they spring.—That neither an alteration in the circulation of a part, nor a departure from the normal condition of its nervous supply, can be regarded as one of the essential phenomena of inflammation, is obvious from this, that the most important phenomena of inflammation may present themselves, as results of injury or disease, in parts that have neither bloodvessels nor nerves: this is seen in the deposition of lymph in the cornea, in the ulceration of the cornea and of articular cartilages, and in other morbid actions in these parts, which, if ever they are vascular, become so only after the effusion of lymph in them, the new vessels being formed in this lymph, and not in the tissues themselves. Here it is obvious that the whole change consists in a perversion of the nutritive actions which the tissues ought to carry on, at the expense of the materials which they draw from the blood of the surrounding vessels (§§ 253, 254).

611. Of the alterations in the condition of the *Blood* in Inflammation, an account has already been given (§§ 171–177); and it is here only necessary to recapitulate them. The most characteristic is the augmentation either of the organizable or plastic fibrin, or of the organized colorless corpuscles; the increased production of these two components seeming to bear in some degree a relation of reciprocity, the one to the other. The increase of Fibrin may be considered as the alteration most characteristic of a previously healthy and vigorous state of the system; and it is in the inflammations which occur in such subjects, that the effusions are most strongly disposed to become organized, and show the least tendency to undergo degenerative changes. On the other hand, the increase of the Corpuscular element seems to occur in cachectic or otherwise unhealthy individuals; and the inflammatory effusions, which partake of the same character, are far less plastic originally, and are extremely prone to undergo degeneration, either at the time of their effusion or subsequently. With this increase in the proportion of fibrin and colorless corpuscles, separately or in combination, there is a diminution in the proportion of the red corpuscles, albumen, and salts of the blood. None of these changes, however, can be legitimately regarded as originally or essentially characteristic of the inflammatory condition; they are, in fact, to be looked-on rather as the results of its establishment, constituting that series of alterations in the circulating fluid, which is of parallel order to that which occurs in the solid tissues wherein the inflammatory action has been set up.

612. The Inflammatory state is further characterized by the *effusion* of certain of the components of the Blood, upon the surface, or into the substance, of the inflamed tissues.—The effusion of pure *serum* cannot be regarded as characteristic of inflammation; since it may take place as a mere result of congestion,

especially when this congestion is due to an obstruction to the return of the blood; whilst, again, it may be due to an altered condition of the albuminous constituent of the blood, which favors its transudation (§ 167). The so-called serous effusions which are poured forth in inflammation do in reality contain fibrin in solution; but this fibrin may not manifest its presence by spontaneous coagulation, until its passage into the solid state is favored by some extraneous influence (§ 26). The presence of fibrin in such an effusion, however, is not in itself a sufficient proof of the existence of inflammation; for it has been shown by the experiments of Mr. Robinson,¹ that when the obstruction to the return of blood by the veins is so great as to occasion an excessive pressure within the capillaries, the fluid which transudes may contain enough fibrin to render it spontaneously coagulable.—The form of exudation which is most characteristic of Inflammation is that which is known as *coagulable lymph*; it is much to be desired, however, that some other designation should be applied to it, since the term “lymph” can only be appropriately employed for the fluid contents of the lymphatic vessels. The peculiar characteristic of this inflammatory exudation is its capability of spontaneously passing into the condition of an organized tissue, either fibrous or cellular, or a mixture of both; and of thus forming “false membranes” on inflamed surfaces, or solidifying the inflamed part by the interstitial production of similar lowly-organized textures. Although it has been too much the habit of Pathologists to speak of “coagulable” or “plastic lymph” as if it were always one and the same thing, yet it really presents various gradations of character, which are manifested in its different degrees of organizability, and in the diverse nature of the tissues developed from it; and, as Mr. Paget has pointed out,² there are two typical forms, the *fibrinous*, and the *corpuscular*, between which the others are intermediate. The former coagulates into a fibrous clot, resembling that of healthy blood, but usually showing a more distinct fibrillation. The latter (the “croupous” exudation of Rokitsansky) is characterized by the want of any proper coagulation, the fibrous clot being replaced by an aggregation of cells, which in their first appearance resemble very nearly the primordial condition of the corpuscles of the fluids of the absorbent vessels, and the colorless corpuscles of the blood. It is seldom, however, that either of these typical forms of lymph presents itself in a state of complete isolation from the other; they are much more commonly blended in various proportions, so that one or the other predominates; and it is mainly upon the preponderance of fibrin, that the “plasticity” of the exudation (or its capacity for organization) depends; whilst according to the preponderance of corpuscles will be its tendency to degeneration. Thus the exudation of fibrinous lymph is the symbol of the “adhesive” inflammation; whilst that of the “corpuscular” is similarly characteristic of the “suppurative” inflammation. It is obviously of great consequence to ascertain the conditions which determine the production of one or other of these states; and these, as Mr. Paget has pointed out (*loc. cit.*), may be considered under three heads—(1) the previous state of the blood, (2) the seat of the inflammation, and (3) the degree and character of the inflammation.

613. The *condition of the blood*, as determining that of the lymph, has been carefully studied by Rokitsansky; who has shown that the characters of inflammatory deposits in different diatheses correspond very generally and closely with those of the coagula found in the heart and pulmonary vessels after death. The results of Mr. Paget’s experiments on the same subject have been already cited (§ 196). And clinical observation fully confirms this doctrine by evidence of another kind; that, namely, which is afforded by the different course of the same

¹ “Medico-Chirurgical Transactions,” vol. xxvi. p. 51.

² “Lectures on Inflammation,” in “Medical Gazette,” 1850, vol. xlv. p. 1012.

specific diseases, in different individuals, according to the previously healthy or abnormal condition of their blood. There can be no doubt that a very large proportion of what are called "unhealthy inflammations," especially those of the erysipelatous type, are to be regarded as owing their peculiarity to a deficiency in the due elaboration of the fibrin, and to the low vitality of the cellular components of the blood, both of which conditions seem to be favored by the presence of those decomposing matters whose accumulation in the blood acts in many ways so prejudicially on the system at large (§ 210).—That the quality of the exudation is in some degree determined by the *seat* or *tissue* in which the Inflammation occurs, appears from the different character of the product of the disordered action occurring simultaneously in different organs of the same individual, and apparently under the operation of the same cause; thus it may happen that in pleuro-pneumonia, the two surfaces of the pleura become connected by an organized exudation of a fibrous character; whilst the effusion in the substance of the lung is rather of the corpuscular nature, and speedily passes into suppurative degeneration. Mr. Paget ingeniously proposes to account for the determining influence in question, on the idea that the inflammatory product is influenced at the time of its formation by the assimilative force of each part, so that it is to be regarded as a mixture of true lymph with its special product of assimilation; thus we observe that in inflammations of bone the lymph usually ossifies, in those of ligaments it is converted into a tough ligamentous tissue, and in those of secreting organs it contains a mixture of the ordinary secreted product.—The mode in which the *intensity* of the Inflammation affects the character of the effused lymph is twofold. For, in the first place, the nature of the original effusion is likely to vary according to the degree in which the ordinary nutritive process is interrupted; since, the more intense the inflammation, the less will be the assimilating force of the part, and the more will the matters effused from the vessels deviate from the natural plasma which would be drawn from them in healthy nutrition; whilst, on the other hand, when the inflammation is less severe, its product will not differ so widely from the natural one, and will from the first tend to manifest in its development some characters corresponding to those of the natural formations of the part. But, secondly, the influence of the inflammation, or rather of the depressed vitality of the inflamed tissues, is shown in the tendency to degeneration which it impresses on the exuded product; so that, even though this may be disposed to pass on under favorable circumstances to the complete formation of an organized tissue, its development is early checked, and it undergoes retrograde metamorphosis, or else from the very commencement its development takes place according to a lower or degraded type. The normal product of the organization of either fibrinous or corpuscular lymph is undoubtedly a tissue closely allied to the ordinary areolar or connective; it is of this that false membranes and adhesions are formed, and that the material of most thickenings and indurations of parts is composed; and it is by the production of this tissue, also, that losses of substance are in the first instance repaired, and that divided surfaces are made to adhere. The mode in which this development takes place has been already described (§§ 223, 224). Various kinds of degeneration may take place, according to the stage at which the developmental process is checked; and among these, in tissues which have once attained an advanced stage of development, the most common is the fatty (§ 593).

614. But the most frequent of all the degenerations of lymph, being almost invariable when the lymph is placed *from the first* in conditions unfavorable to its development, is into the entirely unorganizable or *aplastic* product which is known as Pus. This, as already mentioned, is specially liable to occur in lymph which is originally rather corpuscular than fibrinous; and every gradation may be seen from the most characteristic form of the lymph-cell to that of the pus-cell.

But it would seem as if even the most perfectly fibrinous lymph may pass almost immediately into the condition of pus, when it is effused among tissues which are passing rapidly into a state of decomposition; and thus it appears to be, that in a phlegmonous inflammation, the lymph effused into the parts where the inflammatory process has been most intense (the stagnation of the blood being the most complete, and the normal tissues most disposed to disintegration), does not present the slightest tendency to a higher type of organization, but is developed from the first in the condition of pus, which fills the vacant space previously occupied by living tissue; whilst, in the surrounding parts, the fibrinous effusion produces a consolidation of the tissue, and thus forms the walls of the abscess, by which the purulent effusion is limited. Whether the disintegrating tissues are entirely removed by absorption (having previously undergone that degenerative softening which is requisite for the occurrence of this process), or whether they are broken up and dissolved in the purulent fluid, is a point not yet determined.—The *conservative* nature of the fibrinous exudation, and the consequent importance of fibrin as an element of it, are well shown by the results of its deficiency. Thus, if there be no “sac” formed around a collection of pus, this fluid infiltrates through the tissues, and by its mere presence so impairs their nutrition, that a corresponding degradation takes place in the characters of the plastic material furnished for their assimilation; and thus the purulent effusion spreads without limit, and the tissues through which it percolates undergo rapid degeneration. So, again, when gangrene is spreading by contiguity (the proximity of the dead tissue tending to lower the vitality, and even to occasion the death, of that with which it is continuous), it is only when an inflammatory “reaction” takes place, or, in other words, when an exudation of fibrinous lymph is poured into the substance of the tissues bordering on those which have lost their vitality, that a line of demarcation between the dead and the living parts is formed. And generally, it may be said that, as the ultimate tendency of inflammation is to produce the disintegration of the part, the ultimate tendency of the fibrinous exudation is to keep its elements together, and to repair the losses which have taken place, although with a very inferior material.—It is only, however, with the subsidence of the inflammation, and the return to the ordinary type of nutrition, that the highest development of the lymph can take place; and it is in proportion as this occurs more speedily, that the recovery of the organization proper to the part is more completely effected.¹

615. In persons of that peculiar constitution which is termed *Scrofulous* or *Strumous*, we find an imperfectly organizable or “caco-plastic” deposit, or even an altogether *aplastic* product, known by the designation of *tubercular* matter, frequently taking the place of the normal elements of tissue; both in the ordinary process of Nutrition, and still more when Inflammation is set up. From an examination of the Blood of tuberculous subjects it appears, that although the bulk of the coagulum obtained by stirring or beating it is usually greater than that of healthy blood, yet this coagulum does not consist of well elaborated fibrin; for it is soft and loose, and contains an unusually large number of Colorless corpuscles, whilst the Red corpuscles bear an unusually small proportion to it. We can understand, therefore, that such a constant deficiency in plasticity must affect the ordinary nutritive process; and that there will be a liability to the deposit of caco-plastic products, without inflammation, instead of the normal elements of tissue. Such appears to be the history of the formation

¹ The Author has pleasure in referring to Mr. Paget's “Lectures on Inflammation” (Medical Gazette, 1850) as containing, in his opinion, the best exposition of the subject yet made public; and in acknowledging his obligations to them for much assistance in the short view of it given above. The fundamental doctrines on which the Author would now lay the greatest stress, however, are the same in all essential particulars with those which he has taught in previous Editions of this Treatise.

of Tubercles in the lungs and other organs, when it occurs as a kind of metamorphosis of the ordinary Nutritive process; and in this manner it may proceed insidiously for a long period, so that a large part of the tissue of the lungs shall be replaced by tubercular deposit, without any other ostensible sign than an increasing difficulty of respiration. In the different forms of tubercular deposit, we see the gradation most strikingly displayed, between the plastic and the aplastic formations. In the semi-transparent, miliary, gray, and tough yellow forms of Tubercle, we find traces of organization in the form of cells and fibres, more or less obvious; these being sometimes almost as perfectly formed as those of plastic lymph, at least on the superficial part of the deposit, which is in immediate relation with the living structures around; and sometimes so degenerated, as scarcely to be distinguishable. In no instances do such deposits ever undergo further organization; and therefore they must be regarded as *caco-plastic*. But in the opaque, crude, or yellow Tubercle, we do not find even these traces of definite structure; for the matter of which it consists is altogether granular, more resembling that which we find in an albuminous coagulum. The larger the proportion of this kind of matter in a tubercular deposit, the more is it prone to soften, whilst the semi-organized tubercle has more tendency to contraction. This is entirely *aplastic*.—It may be questioned, however, whether Tubercular matter is not always, even in its most amorphous state, a product of cell-formation; and whether the difference between the amount of organization which its several forms present, is not due rather to a variation in the degree of its subsequent degeneration than to an original diversity in histological condition. On this view, Tubercle is to be considered as a formation *sui generis*, whose production is dependent upon a special taint in the blood; and just as the normal lymph-products vary greatly in their degree of vitality, so that some undergo a progressive and others a retrograde metamorphosis, so may tubercular deposits either retain their original characters more or less completely (though never advancing towards a higher character), or may undergo a very early and complete degeneration.¹ Now although Tubercular matter may be slowly and insidiously deposited, by a kind of degradation of the ordinary Nutritive process, yet it cannot be doubted that Inflammation has a great tendency to favor it; so that a larger quantity may be produced in the lungs, after a Pneumonia has existed for a day or two, than it would have required years to generate in the previous mode. But the character of the deposit still remains the same; and its relation to the plastic element of the blood is shown by the interesting fact, of no unfrequent occurrence—that, in a Pneumonia affecting a tuberculous subject, plastic lymph is often thrown out in one part, whilst tubercular matter is deposited in another. Now Inflammation, producing a rapid deposition of tubercular matter, is peculiarly liable to arise in organs, which have been previously affected with chronic tubercular deposits, by an impairment of the process of textural Nutrition; for these deposits, acting like foreign bodies, may of themselves become sources of irritation; and the perversion of the structure and functions of the part renders it peculiarly susceptible of the influence of external morbid causes.

616. We frequently meet with abnormal growths of a Fatty, Cartilaginous, Fibrous, or even Bony structure; which result from the development of these tissues in unusual situations, and appear to originate in some perverted action of the parts themselves (§ 597).—But there is another remarkable form of disordered Nutrition, which is concerned in producing what have been termed *heterologous* growths; that is, masses of tissue that differ in character from any which is normally present in the body. Most of these are included under the general designation of *Cancerous* or *Fungous* structures; and it has been shown

¹ See Mr. Paget in the "Pathological Catalogue of the Hunterian Museum," vol. i. p. 134; also Dr. Madden's "Thoughts on Pulmonary Consumption."

by Müller and succeeding inquirers, that the new growth consists of a mass of cells; which, like the Vegetable Fungi, develop themselves with great rapidity; and which destroy the surrounding tissues by their pressure, as well as by abstracting from the Blood the nourishment which was destined for them. These parasitic masses have a completely independent power of growth and reproduction; and they can be propagated by inoculation, which may convey into the tissues of the animal operated on, the germs of the peculiar cells that constitute the morbid growth, these soon developing themselves into a new mass. So it may be by the diffusion of the germs produced in one part, through the whole fabric, by means of the circulating current, that the tendency to re-appearance (which is one great feature in the *malignant* character of these diseases) is occasioned. But it would seem more probable that this character rather depends upon the presence of a morbid matter in the blood, of which the formation of the cancerous tissue is only the manifestation (§ 120); the local disease thus being the consequence of a constitutional cachexia, rather than the constitutional affection the result of the local disease.¹

CHAPTER XII.

OF SECRETION AND EXCRETION.

1.—Of Secretion in General.

617. THE literal meaning of the term Secretion is *separation*; and this is nearly its true acceptance in Physiology. But the ordinary processes of Nutrition involve a separation of certain of the components of the Blood, which are withdrawn from it by the appropriating power of the solid textures; and every such removal may be considered in the light of an act of *excretion*, so far as the blood and the rest of the organism are concerned (§ 202). Moreover, the separation of certain matters from the blood in a fluid state, either for the purpose of being cast forth from the body, or of being employed for some special purpose within it, which constitutes what is ordinarily known as Secretion, is effected by an agency of the same nature with that whose operation constitutes the essential part of the nutritive process; namely, the production and growth of cells. Hence there is no other fundamental difference between the two processes, than such as arises out of the diverse *destinations* of the separated matters, and the anatomical

Fig. 147.

arrangements which respectively minister to these. For the products of the secreting action are all poured forth either upon the external surface of the body, or upon the lining of some of the cavities which communicate with it; and the cells by which they are separated from the blood, usually stand in the relation of epithelium-cells to those prolongations of

¹ See Dr. Walshe on "The Nature and Treatment of Cancer;" and Mr. Simon's "General Pathology," Lect. VIII., *Am. Ed.*

the skin or mucous membranes that form either the projecting fringes (Fig. 147), or the follicles, or extended tubuli (Fig. 148), of which the Glandular organs are for the most part composed (§ 235), and are thus readily thrown off from their free surfaces. Thus, the act of Secretion essentially consists in the successive production and exuviation of the cells which minister to it; these cells giving up, by rupture or deliquescence, the substances which they have eliminated from the blood. Each group of cells is adapted to separate a product of some particular kind, which constitutes its special *pabulum*; and the rate of its production seems to depend *cæteris paribus* upon the amount of that pabulum supplied by the circulating fluid (§ 120). The substances at the expense of which the secreting cells grow, however, may not be precisely those which are subsequently cast forth at their death; for it is very probable that some of them, at least, undergo a certain degree of chemical transformation by the agency of these cells; the characteristic materials of the several secretions not always pre-existing *as such* in the blood.

618. A distinction may be drawn, as regards this point, between those *Excretions*, the retention of whose materials in the Blood would be positively injurious, and those *Secretions* which are destined for particular purposes within the system, and the cessation of which has no immediate influence on any other function than those for which they are respectively destined. The solid matter dissolved in the fluids of the latter class is little else than a portion of the nutritive constituents of the blood; either so little altered as still to retain its nutritive character, as is the case with the casein of Milk, and with the albuminous constituent of the Serous fluid of areolar tissue and of serous and synovial membranes; or in a state of incipient retrograde metamorphosis, as seems to be the case with the peculiar "ferments" of the salivary, gastric, pancreatic, and intestinal secretions. On the other hand, the characteristic ingredients of the *Excretions* are very different in character from the normal elements of the blood. They are all of them completely unorganizable; and they possess, for the most part, a simple atomic constitution.

Fig. 148.

Plan of extension of secreting membrane, by inversion or recession in form of cavities.—A, simple glands; a, b, c, as in the last figure; g, follicle; h, follicle dilated into a sacculus; i, follicle lengthened into a tubule, which is coiled up.—B, multilocular crypts; k, of tubular form; l, saccular.—C, Racemose or vesicular compound glands; m, entire gland, showing branched duct and lobular structure; n, a lobule detached, with o, branch of duct proceeding from it.—D, Compound Tubular gland.

Some of them, also, have a tendency to assume a crystalline form; which is considered by Dr. Prout to indicate their unfitness to enter into the composition of organized tissues. With regard to some of the chief of these, there is sufficient evidence of their existence, in small quantity, in the circulating Blood; but it is also clear, that they exist there as products of decomposition, and that they are destined to be separated from it as speedily as possible. If their separation be prevented, they accumulate, and communicate to the circulating fluid a positively deleterious character. Of this we have already seen a striking example in the case of Asphyxia (§ 574); and the history of the other two principal excretions, the Bile and Urine, will furnish evidence to the same effect.—As a general fact, then, it may be stated that the materials of the Secretions pre-exist in the Blood, in a state nearly resembling that in which they are thrown off by the secreting organs; but that the materials of those secretions which are destined to perform some particular function within the economy, are derived from the substances which are appropriated to its general purposes; whilst those of the excretions are the result of the destructive changes that have taken place in the system, and cannot be retained in it without injury.

619. The composition and uses of the principal Secretions which are elaborated for special purposes within the economy, have already been partly described in connection with the functions to which they respectively minister; and the remainder will hereafter come under notice in the same manner. It is here intended, however, to consider that important system of Excretory operations which serves to maintain the purity of the circulating fluid; by removing from it those products of the disintegration of the tissues which are not capable of serving any purpose in the nutrition of the system, and which even act upon it as poisons; and also by withdrawing the products (apparently of a similar character) of the decomposition of those surplus alimentary materials which, not being required for the nutrition of the tissues undergo retrograde metamorphosis without having ever undergone the process of organization. The process of Respiration, as already pointed out (§ 535), is in part to be regarded as one of an excretory character, though the peculiar manner in which it ministers to the removal of carbon and hydrogen from the system, and its subserviency to other purposes, necessitate its separate consideration. The true Secreting processes which are to be regarded as more or less completely *excretory*, are the separation of bile by the Liver, that of urine by the Kidneys, that of perspiration by the Skin, and that of fecal matter by the glandulæ of the Intestinal surface. The sum total of these, with the addition of the carbonic acid and watery vapor poured from the Lungs, and of the indigestible matter rejected in the form of feces, must be equal to the total amount of the solid and fluid ingesta, and of the oxygen which disappears from the inspired air; the weight of the body remaining the same. The experiments of Dr. Dalton on his own person gave the following as the proportional quantities discharged through the principal channels of excretion.¹ The mean quantity of solid and liquid Aliment taken into the system daily (during 14 days in spring) being 91 oz., or about 5½ lbs., the average amount of Feces (including part of the solid matter of the bile) was 5 oz.; the average amount of Urine was 48½ oz. daily; and, as the total weight of the body remained the same, the quantity of fluid and solid matter excreted by the Skin and the Lungs must have been 37½ oz. At other periods of the year, a variation was observed; especially in the relative amount of fluid passing off by the Urine, and by Cutaneous exhalation.—A more elaborate series of researches, however, has been recently made by M. Barral; a part of whose results has been given in the preceding chapter. The following are the average daily amounts of the several components of the food consumed, and of the

¹ "Edinburgh New Philosophical Journal," 1832, 1833.

various excretions, in the five cases already referred to (§ 566); water being excluded in each case :—

Ingested as Food.		Excreted.		
		In Urine.	In Feces.	By Lungs and Skin.
Carbon	21770.4 grs.	1060.7 grs.	798.3 grs.	19911.4 grs.
Nitrogen	1649.0 “	756.6 “	142.0 “	750.4 “
Hydrogen	3370.6 “	213.1 “	122.0 “	3035.5 “
Oxygen	16446.7 “	563.6 “	467.8 “	15415.3 “
Total	43236.7 “	2594.0 “	1539.1 “	39112.6 “

The water ingested amounted on an average to about three times the solid matters; that egested in various ways was commonly between one-fifth and one-sixth more, showing that there is an absolute production of water in the system (§ 569). The following table gives the general results of the comparison of the matters assimilated and excreted, so calculated that the sum in each case amounts to 100 :—

	ASSIMILATED		EXCRETED			
	Food.	Oxygen.	As water; by exhalation.	As carbonic acid.	In the evacuations.	In other ways.
A.	72.2	27.8	33.8	32.3	33.2	0.7
B.	75.4	24.6	36.1	28.8	34.7	0.4
C.	76.7	23.3	38.2	28.3	33.2	0.3
D.	75.3	24.7	14.5	30.2	54.6	0.7
E.	72.5	27.5	31.0	31.5	36.9	0.8

620. It is obvious that the demand for the performance of the Excretory processes generally will, in the first place, arise, as in the case of Respiration, from the continual disintegration and decay to which the organized fabric is liable in the maintenance of a merely *vegetative* existence; and this will be constant during the whole life of Man, as of any other warm-blooded animal, its amount varying with the degree of general vital activity.—But, secondly, the exercise of the *animal* functions, involving (as this does) the disintegration of the nervous and muscular tissues as the very condition of the evolution of their respective forces, becomes a special source of the production of excrementitious matter, the amount of which will vary with that of the forces thus developed.—The removal of excrementitious matter may become necessary, thirdly, from the decomposition of superfluous aliment, which has never been assimilated. This would not be the case, if the amount of food prepared by the digestive process, and taken up by absorption into the current of the circulation, were always strictly proportional to the demand for nutriment created by the wants of the system; but such a limitation seldom exists practically, in those individuals at least who do not feel themselves obliged to put a restraint upon the indulgence of their ordinary appetite; and all that is not appropriated to the reparation of the waste, or to the increase of the bulk of the body, must be thrown off by the excretory organs. It has been already shown that an abundance of nutritive material in the blood does not augment the production of the ordinary tissues to any considerable extent (§ 596); and it would appear that all such materials as are not speedily assimilated pass rapidly into a state of retrograde metamorphosis. How large a proportion of the solid matters of the urine ordinarily has this source, will appear from facts hereafter to be stated (§ 640). Moreover, in the last place, it cannot be deemed improbable that the changes which the crude aliment undergoes, from the time of its first reception into the absorbents and bloodvessels, to that of its conversion into organized tissues and special

secretions, involve the liberation of many products of which the elements are superfluous, and therefore injurious to the system if retained in it. Thus it has been shown to be quite possible, that, in the production of Gluten (gelatin) from Albumen, an equivalent of Choleic (tauro-cholic) acid may be generated (§ 91, VI.). The condition of Organic Chemistry, however, is not yet such as to allow of anything being advanced with certainty under this head.—From these various sources, then, a large amount of effete matter is being continually received back from the tissues into the current of the circulation, or is generated in the blood by the changes to which it is itself subject; and it is the great object of the Excretory apparatus to free that fluid from the products which would rapidly accumulate in it, but for the provision which is thus made for their removal.

621. Notwithstanding that, under ordinary circumstances, the several parts of the Excretory apparatus are limited, each to its own special function, yet we see that there are certain *complementary* relations between them, which make the action of one to a certain extent vicarious with that of another. Such a relation exists, for instance, between the lungs on one side, and the liver and intestinal glandulæ on the other; for, the more active the respiration, the less bile is secreted; whilst, if the respiration be lowered in amount by inactivity of body and a high external temperature, a larger proportion of unoxidized or imperfectly oxidized excrementitious matters accumulate in the blood, giving rise to that augmented production both of the biliary and of the fecal excretions which constitutes diarrhœa.¹ And thus, on the other hand, when the liver is not adequately effecting the depuration of the blood from the constituents of bile, an augmentation of the respiration by active exercise in a low temperature gives most effectual relief.—Still more obviously vicarious, however, are the kidneys and the skin; for here we find that not only do the kidneys allow the transudation of whatever superfluous water may remain in the circulating current, after a sufficient amount has been exhaled from the skin to keep down the temperature of the body to its normal standard, but the skin actually assists in the elimination of one of those products of the metamorphosis of the azotized tissues, the removal of which has been until recently considered as the special function of the kidney. Consequently, whenever the due action of the skin as an excreting organ is interfered with, it is the kidney especially that will be called on to take its place; whilst, on the other hand, if it be thought necessary to relieve the kidney, this may be most effectually done by stimulating the skin to increased excretory activity.

622. This vicariousness of function among the Excretory organs presents itself far more remarkably, however, in certain states of disease; in which a complete “metastasis of secretion” exhibits itself. The capability of one organ thus to take upon itself the special actions of another, seems to have reference to the community of function which exists in the secreting surface among the lower animals, in which there is none of that “specialization” or setting apart for particular offices, which we see in the higher; for it seems to be a general law in Physiology, that, even where the different functions are most highly specialized, the general structure retains, more or less, the primitive community of action which characterized it in the lowest grade of development.² It is in regard to the *Urinary* excretion, that the evidence on this point is most complete; for it seems to be established by a great mass of observations, that urine, or a fluid presenting its essential characters, may pass off by the mucous membrane of the intestinal canal, by the salivary, lachrymal, and mammary glands,

¹ Such is probably the occasion of the “bilious attacks” and “autumnal cholera” so prevalent at the close of the summer; the subjects of these being most commonly persons who have not reduced their consumption of food during the warm season, in accordance with the diminished demand for the production of heat within the body.

² See “Princ. of Phys., Gen. and Comp.,” §§ 351, 605, *Am. Ed.*

by the testes, by the ears, nose, and navel, by parts of the ordinary cutaneous surface, and even by serous membranes, such as the arachnoid lining the ventricles of the brain, the pleura, and the peritoneum. A considerable number of such cases was collected by Haller:¹ many more were brought together by Nysten;² more recently Burdach has furnished a full summary of the most important phenomena of the kind;³ and Dr. Laycock has compiled a valuable collection of cases of urinary metastasis occurring as complications of hysteria.⁴ The following table of cases referred to by the last of these authors will give some idea of the relative frequency of the different forms of this curious affection:—

Vomit.	Stool.	Ears.	Eyes.	Saliva.	Nose.	Mammæ.	Navel.	Skin.	Total.
33	20	4	4	5	3	4	34	17	124

It is to be borne in mind, however, that cases of hysterical ischuria are frequently complicated with that strange moral perversion which leads to the most persevering and ingenious attempts at deceit; and there can be little doubt that a good many of the instances on record, especially of urinous vomiting, are by no means veritable examples of metastasis. The proofs of the fact we are seeking to establish are, therefore, much more satisfactory when drawn from experiments upon animals, or from pathological observations, about which, from their very nature, there can be no mistake. Thus Mayer⁵ found that when the two kidneys were extirpated in the guinea-pig, the cavities of the peritoneum and the pleura, the ventricles of the brain, the stomach, and the intestinal canal, contained a brownish liquid having the odor of urine; that the tears exhaled the same odor; that the gall-bladder contained a brownish liquid not resembling bile; and that the testicles, the epididymis, the vasa deferentia, and the vesiculæ seminales, were gorged with a liquid perfectly similar to urine. Chirac and Helvetius are quoted by Haller as having tied the renal arteries in dogs, and having then remarked that a urinous fluid was passed off from the stomach by vomiting. A remarkable case is quoted by Nysten from Zeviani, in which a young woman having received an incised wound on the external genitals, which would not heal, the urine gradually became more scanty, and at last none could be passed even with the assistance of the catheter; at last dropsy supervened, with sweats of a urinous odor, and vomiting of a urinous fluid, which continued daily for thirty-three years. On post-mortem examination, the kidneys were found disorganized, the right ureter entirely obliterated and the left nearly so, and the bladder contracted to the size of a pigeon's egg. In some other instances, the urine appears to have been secreted, and then reabsorbed in consequence of some obstruction to its exit through the urinary passages. Thus Nysten quotes from Wrisberg a case in which, the urethra having been partially obstructed for ten years by an enlarged prostate, the bladder was so distended as to contain ten pounds of urine; and the serosity of the pericardium and of the ventricles of the brain exhaled a urinous odor. He cites other instances in which the presence of calculi in the bladder prevented the due discharge of the secretion; and in which a urinous liquid was ejected from the stomach by vomiting, or was discharged by stool. A still more remarkable case is recorded of a girl born without either anus or external geni-

⁵ "Zeitschrift für Physiologie," tom. ii. p. 270.

tals, who nevertheless remained in good health to the age of fifteen years, passing her urine from the nipples, and getting rid of fecal matters by vomiting. There are cases, moreover, in which it would seem that the mucous lining of the urinary bladder must have had a special power of secreting urine; the usual discharge having taken place to the end of life, when, as appeared by post-mortem examination, the kidneys were so completely disorganized that they could not have furnished it, or had been prevented by original malformation, or by ligature of the urethra, from discharging it into the bladder. A considerable number of these have been collected by Burdach.⁴ In all the older statements of this kind, there is a deficiency of evidence that the fluids were really urinous, urea not having been obtained from them by chemical analysis, and the smell having been chiefly relied upon. The urinous odor, however, when distinct, is probably nearly as good an indication of the presence of the most characteristic constituent of human urine as is the sight of the urea in its separated form. The passage of a urinous fluid from the skin has been frequently observed in cases in which the renal secretion was scanty; and the critical sweats, by which attacks of gout sometimes terminate, contain urates and phosphates in such abundance as to form a powdery deposit on the surface. —The metastasis of the *Biliary* secretion is familiar to every practitioner, as being the change on which *jaundice* is dependent. It is not, however, in every case of yellowish-brown discoloration of the tissues that we are to impute such discoloration to the presence of biliary matter; and we can only safely do so, when we have at the same time evidence of concurrent disturbance of the biliary apparatus. The urinary apparatus then becomes the principal channel through which the biliary matter is eliminated; the urine becomes tinged with the coloring principle of bile, being sometimes of a yellowish or orange hue, and sometimes of a brown color with a considerable sediment; and the presence of the most characteristic constituents of the bile has been determined in the urine. The same result presents itself, when the biliary duct has been artificially obstructed by ligature. Other secretions have been found tinged with the coloring matter of bile: thus the pancreatic fluid has been seen of a yellow color in jaundice; and the milk has presented not merely the hue, but the characteristic bitterness, of the biliary secretion. The cutaneous transpiration is not unfrequently so much impregnated with biliary matter, as to communicate the tinge to the linen covering the skin; and even the sputa of patients affected with bilious fevers have been observed to be similarly colored, and have been found to contain biliary matter. The secretions of serous membranes, also, have been frequently seen to present the characteristic hue of bile; and biliary matter has been detected, by analysis, in the fluid of the pleural and peritoneal cavities. Biliary matter, however, when unduly present in the circulating current, is not removed from it by the secreting organs alone; for it seems to be withdrawn also in the ordinary operations of nutrition, entering into combination with the solid tissues. Thus, in persons affected with jaundice, we find the skin, the mucous and serous membranes, the lymphatic glands, the brain, the fibrous tissues, the cartilages, the bones and teeth, and even the hair, penetrated with the coloring matter of the bile, which they must have withdrawn from the blood, and which seems to have a particular affinity for the gelatinous tissues. It is impossible at present to say, however, to what extent the more characteristic ingredients of the bile are thus withdrawn from the blood; for the presence of its coloring matter cannot by any means be taken as an indication that its peculiar resinoid acids are also incorporated with the normal components of the tissues.

2.—*The Liver.—Secretion of Bile.*

623. The *Liver* is probably more constantly present, under some form or other, throughout the entire animal series, than any other gland. Its form and condition vary so greatly, however, in different tribes, that, without a knowledge of its essential structure, we should be disposed to question whether any identity of character exists among the several organs which are regarded as Hepatic. It is, in fact, the presence of bile-secreting cells, that must be held to constitute a Liver; and these may be scattered over the general lining membrane of the alimentary canal, or may be restricted within follicles which are formed by depressions of it; these follicles, again, may be multiplied in some particular spot, so as to be aggregated into a mass, or may be extended into long tubes. In all the Invertebrata, however, the Liver is obviously conformable to the general type of glandular structures; the hepatic cells being in immediate relation with a basement-membrane, and being discharged upon a free surface. This will be readily

Fig. 149.

Lobule of Liver of *Squilla Mantis*: A, exterior; B, the same cut open.

understood from an examination of any one of the higher forms of it, such as that presented in the liver of the Crab (Fig. 149), which, like the liver of the Mollusca generally, is a lobulated glandular mass, formed by the aggregation of a multitude of follicles with distinct caecal terminations; these follicles discharging their secreted products into cavities which occupy the centre of the lobules, whence they are collected by the ducts which discharge them into the alimentary canal. On a careful examination of these follicles (Fig. 150), and a comparison of the size and contents of the cells at the bottom and towards the outlet, it becomes evident that the cells originate in the former situation, and gradually increase in size as they advance towards the latter. It is also to be observed that the cells which lie deepest in the caecum (*a, b*) contain for the most part the yellow granular matter, which may be regarded as the proper biliary secretion; but as they increase in size, there is also an increase in the quantity of oil-globules which they contain (*c*), until past the middle of the follicle, where they are found full of oil, so as to have the appearance of ordinary fat-cells (*d, e*). From this it happens, that when an entire caecum is examined microscopically, its lower half appears filled with a finely granular matter, intermingled with nucleated particles; and the upper half with a mass of fat-cells, whose nuclei are obscured by the oily particles.¹—In Vertebrated animals, however, the Liver seems

¹ See Dr. Leidy's "Researches into the Comparative Structure of the Liver," in "Amer. Journ. of Med. Sci.," Jan. 1848.

Fig. 150.

One of the hepatic caeca of *Astacus affinis* (Cray fish), highly magnified, showing the progress of development of the secreting cells from the blind extremity to the mouth of the follicles; specimens of these, in their successive stages, are shown separately at a, b, c, d, e.

to be constructed upon a different plan; and the relation between the secreting cells of which its mass is composed, and the ducts by which their product is conveyed away, is very difficult to determine satisfactorily except in certain Fishes, in whose liver the ducts may be shown to terminate in caeca filled with cells, as in the lower animals.¹ In ascending through the Vertebrated series, this organ presents a more and more solid parenchymatous texture, which strikingly contrasts with its loosely lobulated racemose aspect in even the highest Invertebrata. This character is very obvious in the liver of Man, which is peculiarly firm and compact, and has less of connective tissue between its different parts than is found in that of many other Mammalia. It is observable, moreover, in the Human liver, that certain parts are rudimentary which are elsewhere fully developed. Thus in the Carnivora and Rodentia, which present the most complex form of liver that we meet with among Mammalia, there are five, distinct parts; namely, a "central" or principal lobe, and a right and left "lateral" lobe, each with its "lobular appendage." The whole mass of the liver of Man (Fig. 151), which we are accustomed to describe as consisting of a "right" and "left" lobe, does in reality form but one (there being no real division between its two portions), which must be regarded as the "central" lobe; the "lobulus Spigelii" is the rudiment of a right "lateral" lobe, and the "lobulus

Fig. 151.

¹ See Dr. T. Williams, in "Guy's Hospital Reports," 1846, p. 323.

caudatus" is its "lobular appendage;" but the left "lateral" lobe, with its "lobular appendage," is altogether undeveloped.

624. In examining into the minute structure of the Liver, we shall first consider the peculiarities in the arrangement of its Bloodvessels and Ducts; for our present knowledge of which we are almost entirely indebted to Mr. Kiernan,¹ whose account of them will be here followed; his researches having been confirmed in all essential particulars by other Anatomists.—When the Liver is closely examined with the naked eye, it is seen to be made up of a great number of small granular bodies, about the size of a millet-seed, of an irregular form, and presenting a number of rounded projecting processes upon their surfaces. These are commonly termed *lobules*, although by some Anatomists they are spoken of as *acini*. When divided longitudinally, they have a somewhat foliated appearance (Fig. 152), arising from the distribution of the Hepatic Vein; which, passing into the centre of each division, is termed the *intralobular vein*. The exterior of each lobule is covered by a process of the "capsule of Glisson;" which is very dense in the Pig and other animals, but is so thin as to be almost undistinguishable in the Human liver. Its substance is composed of the minute ramifications of the before-mentioned vessels, arranged in the manner presently to be described; the spaces between which are filled with a parenchyma, composed of nucleated cells, like those shown in Fig. 157, B. The structure of each lobule, then, gives us the essential characters of the whole gland.—The lobules, when transversely divided, are usually found

to present somewhat of a pentagonal or a hexagonal shape, the angles being somewhat rounded, so as to form a series of passages or *interlobular spaces* (Fig. 159); in these lie the branches of the Vena Portæ, and of the Hepatic Artery and Duct, from which are derived the plexuses that compose the lobules. Each lobule, when examined with the microscope, is found to be apparently composed of numerous minute bodies of yellowish color, and of various forms, connected together by vessels; to these the name of *acini* was given by Malpighi; and to these, if they deserve a name, it ought to be restricted. They will be presently shown, however, to be nothing else than the irregular islets, left between the meshes of the plexus formed by the ultimate ramifications of the portal vein. The *Vena Portæ*, which is formed by the convergence of the veins that return the blood from the chylopoietic viscera, probably also receives the blood which is conveyed to the liver for the purpose of nutrition by the Hepatic Artery. Like an artery, it gradually subdivides into smaller and yet smaller branches; and at last it forms a plexus of vessels, which lie in the interlobular spaces, and spread with the freest inosculation throughout the entire Liver. To these vessels, the name of *interlobular Veins* was given by Mr. Kiernan. They ramify in the capsules of the lobules, covering with their ramifications the whole external surface of these; and then enter their substance. When they enter the lobules, they are termed *lobular veins*; and the plexus formed by their convergence from the circumference of each lobule towards its centre (where their ultimate ramifications terminate in those of the intralobular or hepatic vein), is designated as the *lobular venous plexus* (Fig. 153). In the islets of this plexus (the acini of Malpighi), the ramifications of the hepatic

¹ "Philosophical Transactions," 1833.

duct are distributed, in the manner to be presently described.—The *Hepatic Artery* sends branches to every part of the Liver, supplying the walls of the portal and hepatic veins, and of the hepatic ducts, as well as Glisson's capsule. The principal distribution of its branches, however, is to the Lobules, which they reach, in the same manner with the portal vessels and biliary ducts, by

Fig. 153.

tion of bile, only by passing into the portal plexus; whilst, if the latter be the correct statement, either the arterial blood is not at all subservient to the formation of bile, or the secretion can be elaborated from the arterial capillaries. The experiments of Mr. Kiernan have satisfactorily proved that the intralobular or hepatic veins cannot be filled by injection from the hepatic artery, though they may be readily filled from the portal plexus; whilst, on the other hand, there is reason to believe that a very fine injection into the hepatic arteries will find its way into the portal plexus.¹ It is certain that all the branches of the hepatic artery, of which the termination *can* be ascertained, end in the vena portæ; a free capillary communication existing between their two systems of branches, on the walls of the larger bloodvessels and ducts. According to Müller, there is an ultimate plexus of capillary vessels, with which all the three systems freely communicate; but for this idea there is no adequate foundation; and it is inconsistent with the fact just stated, that injection into the hepatic artery does not return by the hepatic vein. The views of Mr. Kiernan upon this point have received important confirmation from the researches of Mr. Bowman on the circulation in the Kidney (§ 635).—It now only remains to describe the *Hepatic Veins*, the branches of which occupy the interior of the lobules, and are termed *intralobular veins* (1, 1, Figs. 153, 154). On making a transverse section of a lobule, it is seen that the central vessel is formed by the convergence of from four to six or eight minute venules, which arise from the processes upon the surface of the lobule. In the superficial lobules (by which term are designated those lobules which lie upon the exterior of the glandular substance, not only upon the surface of the liver, but also against the walls of the

¹ This is stated to have been the case in the injections of Lieberkühn, although Mr. Kiernan has not succeeded in effecting it.

larger vessels, ducts, &c.) the intralobular veins commence directly from their surface; and the minute venules of which each is composed may be seen in an ordinary injection, converging from the circumference towards the centre, as in the transverse section of other lobules. The intralobular veins terminate in the larger trunks, which pass along the bases of the lobules, collecting from them their venous blood; these are called by Mr. Kiernan *sublobular* veins. The main trunk of the Hepatic Vein terminates in the ascending Vena Cava.

625. The *Hepatic Duct* forms, by its subdivision and ramification, an interlobular plexus very like that of the portal vein; but the anastomosis between the branches going to the different lobules is less intimate than that of the interlobular veins, and cannot be directly demonstrated; although Mr. Kiernan thinks that his experiments leave but little doubt of its existence—a communication (which cannot be seen to be established by any nearer channel) being proved to exist between the right and left primary subdivisions of the duct. The interlobular ducts ramify upon the capsular surface of the lobules, with

Fig. 154.

Horizontal section of two superficial Lobules, showing the interlobular plexus of *Biliary Ducts*: 1, 1, intralobular veins; 2, 2, trunks of biliary ducts, proceeding from the plexus which traverses the lobules; 3, interlobular tissue; 4, parenchyma of the lobules.

the branches of the portal vein and hepatic artery; they then enter its substance, and subdivide into minute branches, which are believed to anastomose with each other, and to form a reticulated plexus, termed by Mr. K. the *lobular biliary plexus* (Fig. 154). This plexus constitutes the principal part of the substance of the lobule; and when seen through the meshes of the portal plexus, gives rise to the appearance of caecal terminations of ducts. No such terminations of these ducts have been traced, however, in the adult liver of any of the higher animals, although they are sufficiently evident in the embryonic condition. From the analogy of other organs, there would seem good reason to believe that the ultimate ramifications of the hepatic ducts anastomose freely together, and that they form a network, in which their terminations are lost, as it were, without forming true caeca. This view of the matter finds confirmation in the curious fact pointed out by Mr. Kiernan, that, in the *left lateral ligament*, the essential parts of a lobule are found in the simplest form and arrangement. From the edge of the liver next to the ligament, numerous ducts emerge, which ramify between the two layers of peritoneum of which the ligament is composed. They are accompanied by branches of the portal and hepatic veins, and of the hepatic artery; which also ramify in this ligament, especially around the parietes of the ducts. These ducts, of which some are occasionally of considerable size, divide, subdivide and anastomose with each other; and the meshes formed by the network of larger or excreting ducts are occupied by minute plexuses of their ultimate ramifications or secreting ducts.—The more recent observations of Dr. Leidy (loc. cit.) harmonize precisely with the view promulgated by Mr. Kiernan, and seem to confirm the idea, that here, as elsewhere, the hepatic cells are inclosed in a limiting membrane. “The lobules are composed of an intertexture of biliary tubes (Fig. 155); and in the interspaces of the network the bloodvessels ramify and form among themselves an intricate anastomosis, the whole being intimately connected together by a combination of the white fibrous and the yellow elastic tissue. In structure, the biliary tubes (Figs. 155, 156) correspond with those of Invertebrata, consisting of cylinders of basement-membrane,

containing numerous secreting cells, and the only difference exists in the arrangement, the free tubes of the lower animals becoming anastomosed on forming

an intertexture in the Vertebrata. The tubuli vary in size in an unimportant degree in different animals, and also in the same animal, being generally from

two to two and a half times the diameter of the secreting cells. The tubes of one lobule are distinct from those of the neighboring lobuli, or only communicate indirectly by means of the trunks of hepatic ducts, originating from the tubes, and lying in the interspaces of the lobuli. The secreting cells (Fig. 157, B) are irregularly angular or polygonal in form, from mutual pressure, and line the interior surface of the tubes. They vary in size in a moderate degree in different animals, and also in the same animal, appearing to depend upon certain conditions of the animal and liver."¹ The subsequent observations of Dr. Natalis Guillot² are mainly to the same effect. He has not been able, how-

¹ See "American Journal of the Medical Sciences," Jan. 1848.—Dr. Leidy does not specify the mode in which his preparations have been made; but we understand that his plan is to *dry* a small portion of injected liver, then to make as thin a slice of this as possible, and to examine this slice when restored to its original condition by moisture.

² "Annales des Sciences Naturelles," Mars, 1848.

ever, to distinguish membranous parietes around these canals; and he considers that they are simply channelled-out in the parenchyma of the liver, the particles of which form its sole borders. Professor Retzius, however, by a particular method of preparation, has been able to demonstrate the existence of a basement-membrane surrounding the biliary cells, and forming a plexus of hepatic ducts, as described by Dr. Leidy.¹

626. The *biliary cells* of the Human Liver (Fig. 157, B) are usually of a flattened spheroidal form, and from 1-1500th to 1-2000th of an inch in diameter. Each of them presents a distinct nucleus; and the cavity of the cell is occupied by yellow amorphous biliary matter, usually having one or two large adipose globules, or five or six small ones, intermingled with it (*a, b*). The size and number of these, however, vary considerably, according to the nature of the food, the amount of exercise recently taken, and other circumstances. If an animal be very fat or well fed, especially with farinaceous or oleaginous substances, the proportion of adipose particles is much greater than in an animal moderately fed and taking much exercise (*c*). The size of the globules varies from that of mere points, scarcely distinguishable from the granular contents of the cells except by their intense blackness, up to one-fourth of the diameter of the cell. The finely-granular matter is the portion from which the color of the cell is derived; it seems to fill the space not occupied by the oil-globules; and it often obscures the nucleus, so that the latter cannot be distinguished until acetic acid is added, which makes the granular matter more transparent without affecting the nucleus.—A still greater accumulation of adipose particles in the biliary cells gives rise, as was first pointed out by Mr. Bowman,² to the peculiar condition termed “fatty liver” (§ 628).³

627. The knowledge of the distribution of the Biliary ducts, and of the two chief systems of Bloodvessels, in the lobules of the Liver, has enabled Mr. Kiernan to give a most satisfactory explanation of appearances, by which Pathological anatomists had been previously much perplexed. When the liver is in a state of *Anæmia* (which rarely happens as a natural condition, although it may be induced by bleeding an animal to death), the whole substance of the lobules is pale, as represented in Fig. 158. In general, however, the liver is more or less congested at the moment of death; and this congestion may manifest itself in several ways. The whole substance may be congested; in which case the lobules present a nearly uniform dark color throughout their substance, their centres being usually more deeply-colored than the margins. An appearance more frequently offered after death, however, is that represented at Fig. 159, and termed by Mr. Kiernan the *first stage of Hepatic Venous congestion*. In this, the isolated centres of the lobules alone present the color of sanguine-

¹ See the account of his researches in “Müller's Archiv,” 1850. His method consists in first macerating a piece of liver in ether, then drying it, cutting thin sections from it in this condition, and soaking these in water until they become transparent.—For a very different view of the structure of the Liver, see Dr. Handfield Jones's papers in the “Philosophical Transactions” for 1846 and 1849.

² “Medical Gazette,” Jan. 1842.

³ It has been recently maintained by Dr. Handfield Jones (“Medical Times,” Jan. 31, 1852, p. 122), that “the cells of the liver are not the constant and necessary agents in the secretion of bile, and that the occurrence of this secretion in them is rather to be viewed as an accidental if not a pathological phenomenon; the real function of the cell being to produce the sugar out of the blood supplied to them, which is absorbed and carried off by the hepatic vein.” The arguments adduced in support of this opinion are, that in perfectly healthy livers of animals, bile is not ordinarily to be seen in the contents of the cells, while it is very common in those of persons who have died of various diseases; and that in extracts made of the parenchymata of various livers, Pettenkofer's test gave very little or no evidence of the presence of biliary matter.—A far larger amount of research is necessary, however, to establish such a novel and (at first sight) very improbable view.

ous congestion; and the surrounding substance varies from a yellowish-white, yellow, or greenish color, according to the quantity and quality of the bile which

Fig. 158.

1, angular lobules in a state of *Anæmia*, as they appear on the external surface of the liver; 2, interlobular spaces; 3, interlobular fissures; 4, interlobular veins, occupying the centres of the lobules; 5, smaller veins, terminating in the central veins.

Fig. 159.

it contains. This accumulation of the blood in the hepatic veins, and the emptiness of the portal plexus, seem due to the continuance of capillary action after the general circulation has ceased, a circumstance to which we find an exact parallel in the emptiness of the systemic arteries, and the fulness of the veins, after most kinds of death.—In the *second* stage of Hepatic Venous congestion, the accumulation of blood is found not only in the intralobular veins, but even in parts of the portal or lobular venous plexus. The parts which are freest from it are those surrounding the interlobular spaces; so that the non-congested substance here appears in the form of circular or irregular patches, in the midst of which the spaces and fissures are seen (Fig. 160).¹ Although the portal as well as the hepatic venous system is thus involved in this form of congestion, yet, as the obstruction evidently originates in the latter, the term given by Mr. Kiernan is still applicable; and it is important to distinguish this appearance from that next to be described. The second stage of Hepatic Venous congestion very commonly attends disease of the heart, and other disorders in which there is an impediment to the venous circulation; and in combination with accumulation in the biliary ducts, it gives rise to those various appearances, which are known under the name of dram-drinkers' or nutmeg liver.—The other form of partial congestion arises from an accumulation of blood in the portal veins, with a reverse condition of the hepatic or intralobular veins; in this condition, which Mr. K. designates as *Portal Venous congestion*, the marginal portions of the lobules are of deeper color than usual, and form a continuous network, the isolated spaces between which are occupied by the non-congested portions (Fig. 161). This is a very rare occurrence; having been seen by Mr. K. in children only.—These differences fully explain the diversity of the statements of different anatomists, as to the relative position of the so-called *red* and *yellow* substances; for it now appears that the *red* substance is the *congested* portion of the lobules, which may be either interior or exterior, or irregularly

¹ This very common aspect of the Liver, which presents numerous modifications, has been a source of great perplexity to those who have studied the minute anatomy of this organ, and has even led Anatomists of the highest eminence into serious errors. See Mr. Erasmus Wilson, in "Cyclop. of Anat. and Physiol.," vol. iii. pp. 185, 186.

disposed; whilst the *yellow* is the *non-congested* part, in which the biliary plexus shows itself more or less distinctly.—Another very interesting form of Patho-

logical change in the aspect of the Liver, which the knowledge of the structure of the lobules enables us to comprehend, is that to which the name of *Cirrhosis* has been given. This has been erroneously attributed to the presence of a new deposit, analogous to that of tubercular matter; but it is really due to atrophy and partial congestion in the liver itself. It is described by Laennec as usually presenting itself in small masses, varying in size from a cherry-stone to a millet-seed, and scattered through the substance of the liver. When these are minute and closely set, they impart what appears at first to be a uniform brownish-yellow tint to the divided surface of the liver; but when the tissue is more attentively examined, their separation becomes evident. These small masses are not distinct lobules in a variable state of hypertrophy (as supposed by Cruveilhier), but small uncongested patches, composed of parts of several adjoining lobules; and having one or more interlobular spaces for a centre; and the biliary plexuses of these, being filled with bile, give them their yellow color. On the other hand, there is an atrophy, more or less complete, of the portions of the substance of the liver intervening between them; so that the bulk of the whole organ is much diminished very commonly to one-half and sometimes to one-third of its original size.

628. Among the most frequent of the pathological changes which the assistance of the Microscope enables us to discern in the biliary cells, is that engorgement with adipose particles, which is observable in the condition of the organ known as "*fatty liver*" (Fig. 162). This state having been frequently observed in individuals who have died of phthisis or other diseases of the lungs involving deficient respiration, has been imputed to a vicarious action of the liver, which (as was supposed) made an effort thus to discharge the hydrocarbonaceous matters that should normally be eliminated by the lungs. But such a view is inconsistent with various facts,

Fig. 162.

Hepatic Cells gorged with Fat
a, atrophied nucleus: b, adipose globules.

which show (as Mr. Paget has justly remarked¹) that the fatty liver is an inactive organ, one which is discharging *less* than its ordinary function, and that the accumulation of fat in its cells is rather to be considered as a mark of "fatty degeneration." For the nuclei disappear, the proper coloring matter of the bile can no longer be distinguished, the liver increases in size owing to the tardy or obstructed removal of its cells, and its paleness indicates a slow and defective supply of blood; moreover, the fatty liver presents itself in many cases in which there has been no deficiency of respiration, and is frequently absent in phthisical subjects; and there is no evidence whatever that the organ when in this state discharges any unusual amount of fat into the alimentary canal. Still there can be little doubt that the accumulation of adipose matter in the biliary cells is favored by deficiency of respiration, since this will tend to increase the quantity which the circulating fluid contains. Throughout the Animal series, moreover, a marked relation of reciprocity is discernible between the amount of fat contained in the Hepatic apparatus, and the activity of the respiratory function; thus in Birds, the biliary cells scarcely contain any fatty particles, whilst in Reptiles and Fishes they are loaded with them; and nearly the same difference may be seen between the biliary cells of Insects and those of Crustacea and Mollusca.—Various other alterations, however, have been noticed. Dr. T. Williams mentions² that, in a case of obstruction of the ductus choledochus by malignant disease, which occasioned complete interruption to the passage of bile, and consequent jaundice, scarcely an entire nucleated cell could be discovered by attentive examination of a large part of the organ. Nothing more than minute free particles of fat, and free floating amorphous glandular matter, could be detected. He further states that, in a case of fever, the hepatic cells were found to be almost entirely destitute of fatty particles; and that in what is known as "granular liver," the granules (which have much the appearance of tubercles) consist of cells, which strongly resemble the ordinary cells of the parenchyma of the liver in every respect, except that they are almost or completely destitute of yellow contents. Similar observations have been also recorded by Dr. G. Budd.³—In two cases of jaundice examined by Mr. Gulliver, the hepatic cells were gorged with biliary matter; some of them to such an extent that they had become nearly opaque. Perhaps, if this condition had continued, these cells would have been all ruptured, and the state of the organ would have resembled that described by Dr. Williams.

629. Previously to birth, the Liver is the only decarbonizing organ in the system, the lungs being at that time inert; and nearly the whole of the blood returning from the placenta passes through this organ before proceeding to the heart, to be distributed by it to the body generally. The liver of the fœtus, moreover, is considerably larger in proportion than that of the adult; and its functional importance is obviously great. There can be no question that the secretion of bile is actively taking place during the latter part (at least) of fetal life; for a large accumulation of it presents itself in the intestinal canal of the new-born infant—the *meconium* having been found by the analyses of Simon⁴ and of Frerichs⁵ to be chiefly made up of the characteristic components of the biliary secretion.—As soon, however, as the placental circulation is cut off, and the Lungs of the infant come into play, the supply of blood transmitted to the liver is almost immediately lessened; this diminution being usually made very evident within a short time after birth, by the comparative paleness of the substance of the gland. It has been proposed to give this fact a practical bearing,

in those judicial inquiries which are directed to the determination of the question, whether or not an Infant has respired after birth; it having been conceived, that the diversion of the current of blood from the Liver to the Lungs, consequent upon the first inspiration, would be sufficient to make a certain difference in their relative weights, if that inspiration had taken place. More careful and extended observations, however, have satisfactorily proved that, although an increase in the weight of the Lungs, and a diminution of that of the Liver, are generally found to exist after respiration has been fully established, they are not by any means constantly produced when the inspirations have been feeble, as they frequently are for some hours or days after birth; whilst, on the other hand, it is not uncommon to meet, in infants that have not breathed, with Lungs as heavy, and Livers as light, as in the average of those which have respired.¹

630. We have now to consider the conditions under which the secretion of Bile takes place; and one of the most important of these is the character of the Blood with which the organ is supplied. We have seen that there is anatomical reason for the belief that the blood supplied by the hepatic artery is not directly concerned in the secretion; but that it first serves for the nutrition of the organ, and then, passing into the portal system (in the same manner as does the blood of the mesenteric and other arteries), forms part of the mass of venous blood, from which the secreting cells elaborate their product. This view is borne out by the results of experiment and of pathological observation. For, if the Vena Portæ be tied, the secretion of bile still continues, though in diminished quantity; and several cases are on record, in which, through a malformation, the vena portæ terminated in the vena cava without ramifying through the liver, and in which secretion of bile took place—evidently from the blood of the hepatic artery, which had become venous by circulating through the substance of the liver; and this blood appears² to have passed into the ramifications of the umbilical vein, which formed a plexus in the lobules, exactly resembling the ordinary portal plexus. It must be remembered, however, that in all these instances, the *arterial* Blood will become abnormally charged with the elements of bile; since the blood of the chylipoietic viscera, from which it ought to have been separated, returns to the heart without undergoing any such purification; and the secretion of bile from the blood supplied by the hepatic artery, under such circumstances, cannot, therefore, be considered as proving that the arterial blood is ordinarily concerned in the secretion to the same degree.—The fact that this secretion is normally formed from *venous* blood is a strong indication that one purpose of its separation is the removal of a portion of the products of the disintegration of the tissues: and that a large amount of hydrocarbonaceous matter will remain to be excreted, after the constituents of urea have been subtracted from those of albumen or gelatin, has been already pointed out (§ 91, VI.). But, again, the position of the Liver in regard to the mesenteric vessels is such, that all the new alimentary materials which are received by them must pass through it and be submitted to its action, before they enter the general current of the circulation; and there are several circumstances which render it probable that it exercises a depurative as well as an assimilating power over these, and that whilst it assists in preparing for nutrition those azotized substances which are capable of being applied to that purpose, and also transforms non-azotized matters into compounds which are more ready to undergo combustion and are thus better fitted for sustaining the heat of the body by respiration, it also eliminates certain substances whose passage into the general circulation would be

¹ See Dr. Guy, in "Edinb. Med. and Surg. Journ.," vols. lvi. and lvii.

² This, at least, was found to be the case in the only instance in which the Liver was examined with sufficient care. See Kiernan, loc. cit.

injuriously.—This is assuredly the case with regard to copper and certain other mineral poisons (§ 89); and it seems also to be true with respect to pus, which, when taken up from ulcers in the intestinal walls, is stopped in the liver, and not unfrequently gives rise to abscesses in its substance.¹

631. When from any cause the secretion of Bile is *suspended*, the substances at the expense of which it is formed accumulate in the Blood; and their excrementitious character is strikingly demonstrated by the disturbance of other functions, especially those of the Nervous system, which then ensues. When the suppression is complete, the patient suddenly becomes jaundiced, the powers of that system are speedily lowered (almost as by a narcotic poison), and death rapidly supervenes.² When the secretion is diminished, but not suspended, the same symptoms present themselves in a less aggravated form. It is probable that much of the disorder in the functions of the brain, which so constantly accompanies deranged action of the digestive system, is due to the less severe operation of the same cause; namely, the partial retention within the blood of certain constituents of the bile, which should have been eliminated from the circulating fluid. Such an abnormal accumulation, which may depend either on a deficiency in the functional activity of the liver, or on an excess of the excrementitious matters brought to it for elimination, is habitual in some persons; and it produces a degree of indisposition to bodily or mental exertion which it is difficult to counteract. More, probably, is to be gained in such cases by the regulation of the diet, especially the reduction of its hydrocarbonaceous components, and by active exercise (which, by augmenting the respiration, will promote the elimination of any superfluity of this kind through the lungs), than by continually inciting the liver to increased functional activity, by medicines which have a special power of temporarily augmenting its energy.—The *reabsorption* of Bile into the blood, as seen in ordinary cases of jaundice dependent upon the obstruction of the biliary ducts, does not act on the general system in a manner nearly so injurious as the *retention* of the matters at the expense of which it is formed has been shown to do;³ in fact, much of the disturbance which then ensues may be attributed to the disorder of the digestive function, which is consequent upon the stoppage of the flow of bile into the intestinal canal (§§ 453, 454). And when it is further remembered that the greater part of the bile which passes into the intestinal canal is ordinarily destined for re-absorption (§ 457), it seems fair to conclude that the matters which accumulate in the blood

¹ See Dr. G. Budd's "Treatise on Diseases of the Liver," 2d edit. Chap. ii. sect. 1.

² See Dr. Alison in "Ed. Med. & Surg. Journ.," vol. xlv.; and Dr. Budd, Op. Cit., Chap. iii.—From the evidence collected by Dr. Budd, he is led to think it probable that the cerebral symptoms are not due to the simple retention of the materials of Bile; but depend upon some metamorphosis which these undergo whilst circulating with the blood, whereby a more noxious poison is generated. For the general symptoms of suppressed secretion may have shown themselves for some time, before any serious disturbance occurs in the cerebral functions; and this may supervene very suddenly, and be fatal in a few hours (p. 263). The analogy of Uræmia (§ 637) seems to afford some confirmation to this view; but it must be borne in mind, as a possible explanation of the phenomena, and one which has evidence in its favor, that the kidneys, by a vicarious action, remove the most poisonous of the retained biliary matters; and that it is only when *they* can no longer effect this, that the results of the accumulation of these matters begin to show themselves in the perversion of the functions of the nervous centres.

³ Dr. Budd mentions several cases (Op. cit., pp. 209–227) in which the passage of bile into the intestines was entirely prevented by the complete closure of the ductus communis, and in which, nevertheless, life was prolonged for many months; in one of these cases, the jaundice first occurred in a woman four months pregnant, who nevertheless bore a living child at the full period, and suckled it up to the time of her death, which happened when the child was three months old.—In all these cases, death seemed to result from gradual exhaustion, consequent upon the imperfect assimilation of food, rather than from any toxic agency; and this even when the liver was in such a state of disorganization, that its functional activity must have been suspended for some time before death.

when the secreting action of the liver is suspended, are not in the same condition with those which are received back into it after being submitted to that action; and that the liver, therefore, not merely separates them, but exercises a certain *transforming* agency upon them, as it is known to effect upon other constituents of the blood which pass through it (§ 472).

632. Bile is a viscid, somewhat oily-looking liquid, of a greenish-yellow color, and very bitter taste, followed by a sweetish after-taste. It is readily miscible with water, and its solution froths like one of soap. The proportion of solid matter which it contains is usually from 9 to 12 per cent.; and nearly the whole of this consists of substances peculiar to Bile.—The following are the general results of the analyses made by Berzelius, of Human Bile, and of that of the Ox:—

	MAN.	OX.
Water	90.44	92.84
Biliary matter	8.00	5.00
Mucus of the gall-bladder	.30	.23
Soda	.41	
Chloride of sodium, and extractive	.74	1.50
Phosphates and sulphates of soda and lime	.11	.43
	<hr/> 100.00	<hr/> 100.00

In the Biliary matter, according to the researches of Strecker (which are undoubtedly the most accurate and satisfactory that have been hitherto made), the following substances may be distinguished: *Glycocholic acid* (the *cholic* of Strecker and of many former authors), which is its principal organic constituent, united for the most part with soda, but with small and variable quantities of potash and ammonia (§ 68);—*Taurocholic acid* (the *choleic* acid of Strecker, also known as *bilin*), which also is united with alkaline bases (§ 69);—*Cholesterin* (§ 43), the proportion of which in healthy bile is usually very small;—and *Bile-pigments* (§ 70), of which also the proportion is usually small. It is remarkable that, notwithstanding the comparatively minute proportion in which these two last substances exist in ordinary bile, Cholesterin should usually be the principal ingredient of the biliary concretions which are frequently found in the gall-bladder and bile-ducts; and that the bile-pigment should also occasionally accumulate, so as to form solid masses which consist of little else.¹ It would appear from this that the peculiar resinous acids of the bile are far more readily re-absorbed than are its other ingredients; and this corresponds with the results of experiments upon the contents of the alimentary canal, which show that, whilst the color of the feces is chiefly due to the presence of bile-pigment, the conjugated acids are scarcely to be recognized.—The quantity of Bile ordinarily secreted by the liver, the circumstances which favor or retard its production, the mode in which it is discharged into the intestine, and the purposes which it answers in the digestive process, have all been considered in a previous chapter (§§ 453, 454); and it now only remains to point out, that the fact of the performance of this operation during foetal life, as shown by the accumulation of biliary matter in the intestinal canal at birth (§ 629), is a clear indication of the truly excrementitious matter of this product. Its separation from the blood during intra-uterine life can have no reference to the process of digestion, which is not then taking place; nor can it be subservient to that of respiration, which has not commenced; but it must be regarded, like the elimi-

¹ The cholesterin and bile-pigment (which forms a definite compound with lime) are held in solution in healthy bile by the tauro-cholic acid. Hence it seems likely that the production of the biliary concretions which are composed of these substances, is due either to a relative deficiency of tauro-cholic acid, or to a decomposition of that substance in the gall-bladder.

nation of urea, as a necessary means of removing from the blood those products of the disintegration of the tissues, which are taken back into the circulation even when the life of the being is most purely vegetative; and this necessity arises from that limitation to the existence of each individual part, which is most remarkable when the processes of growth and development are taking place with the greatest rapidity.

633. If, now, we bring together all the facts at present known, with regard to the actions performed by the Liver, they appear to justify the following conclusions with respect to its offices.—1. That the Liver is essentially an organ of excretion, designed to remove from the Blood those hydrocarbonaceous products of the disintegration of the tissues, which cannot be converted into sugar or fat so as to be prepared for direct elimination by the respiratory organs. 2. That in doing this, it converts these excrementitious matters into the glycocholic and taurocholic acids; substances which have a certain utility in the digestive process, and which, after ministering to that function, are capable of being reabsorbed, and of undergoing oxidation; whereby the greater part of their components are carried off in the form of carbonic acid and water by the lungs, the remainder (chiefly the alkaline bases, with the sulphur of the taurine, which is converted into sulphuric acid) being eliminated by the kidneys.—3. That not only by the separation of biliary matter from the blood and by the operation of this upon the alimentary substances, but also by the change in the constituents of the blood itself, the Liver aids in preparing materials for the combustive process. For it converts all forms of saccharine matter derived from the food into “liver-sugar,” the form which is most favorable to oxidation; and it would seem capable also of generating this sugar from protein-compounds, or from certain products of their decomposition (§ 46). And it exercises a similar transforming power upon fatty matter; generating the peculiar “liver-fat,” either from other oleaginous or from saccharine substances supplied by the food, or, as it would also appear, from protein-compounds, or from the products of the early stages of their retrograde metamorphosis (§ 40).—In all the foregoing actions, the Liver is subservient to the Respiratory function; but in a mode very different from that formerly propounded by Prof. Liebig,¹ who represented the Liver as destined to prepare by secretion the materials adapted for the sustenance of the combustive operation. For it is quite certain that if the whole of the solid biliary matter poured into the intestine were reabsorbed, it could furnish but a small proportion (probably not more than one-twelfth) of the total amount of hydrocarbon which is eliminated by the lungs; and the preparation of the liver-sugar and liver-fat in the blood itself is evidently the far more important part of the office of the Liver as regards the Respiratory function.—4. But the Liver also aids, if the statements of M. Bernard on this point be correct, in the assimilation of the histogenetic materials, which have been newly absorbed from the digestive cavity; the raw albumen being converted by its means into a form more suitable for transmission through the system in the current of the circulation, and even fibrin being generated at its expense (§§ 167, 169). It must be admitted, however, that there are many points in the function as well as in the structure of the Liver which still remain to be cleared up.

3.—*The Kidneys.—Secretion of Urine.*

634. The *Kidneys* cannot be regarded as inferior in importance to the Liver, when considered merely as excreting organs; but their function only consists in separating from the blood certain effete substances which are to be thrown off from it, and has no direct connection with any of the nutritive operations con-

¹ “Chemistry applied to Animal Physiology,” 1842.

cerned in the introduction of aliment into the system. The following are the points in the minute structure of these organs which are of most importance in their Physiological relations.¹ The distinction between the *cortical* and *medullary* parts of the Kidney essentially consists in this—that the former is by far the most vascular, and the plexus formed by the tubuli uriniferi seems to come into the closest relation with that of the sanguiferous capillaries, so that it is probably the seat of the greater part of the process of secretion; whilst the latter is principally composed of tubes, passing in a straight line from the former towards their point of entrance into the ureter. The adjoining figure (Fig. 163) represents the appearance presented by a portion of an injected Kidney, as seen by the naked eye, and under a low magnifying power. The tubuli uriniferi, in passing outwards from the calices, increase in number by divarication to a considerable extent, as shown in Fig. 165, but their diameter remains the same. When they arrive in the cortical substance, their previously straight direction is departed from, and they become much convoluted. The closeness of the texture formed by their interlacement with the bloodvessels renders it

difficult to obtain a clear view of their mode of termination; but they seem to inosculate with each other, so as to form a plexus, with free extremities here and there (Fig. 165); the number of these free extremities, however, does not appear to be nearly equal to that of the uriniferous tubes themselves.² The tubuli are lined with an epithelium, the cells of which are irregularly roundish or polyhedral in form (Fig. 164); each cell contains a nucleus; and in its inte-

¹ See especially Mr. Bowman's Memoir in the "Philosophical Transactions," 1842; also Goodsir in "Edinb. Monthly Journal," 1842; Gerlach, Bidder, and Kölliker, in "Müller's Archiv.," 1845; Toynbee in "Med.-Chir. Trans.," 1846; Johnson in "Cyclop. of Anat. and Phys.," art. "Ren.;" Gairdner in "Edinb. Monthly Journal," 1848; and Frerichs, "Die Bright'sche Nierenkrankheit und deren Behandlung," 1851.

² In Mr. Bowman's opinion, *all* the free extremities of the tubuli uriniferi include Corpora Malpighiana; and the appearance of caecal terminations, such as those represented at 1 and 3, Fig. 165, he regards as an optical illusion, caused by a change in the direction of the tubuli, which occasions them to dip away suddenly from the observer.

rior there is ordinarily to be seen a little finely granular matter, with a few minute fat-globules clustered round the nucleus. The cell-wall is remarkable for its delicacy, and is one of the first structures to undergo decomposition; and

Fig. 165.

A small portion of the *Kidney*, magnified about 60 times: 1, supposed caecal extremity of a tubulus uriferus; 2, 2, recurrent loops of tubuli; 3, 3, bifurcations of tubuli; 4, 5, 6, tubuli converging towards the papilla; 7, 7, 7, Corpora Malpighiana, seen to consist of convoluted knots of bloodvessels, connected with a capillary network; 8, arterial trunk.

after its destruction, free nuclei, interspersed among amorphous granules, alone remain in the interior of the tubules. The epithelial cells are arranged more or less regularly on the interior of the basement-membrane, in such a manner that a free channel is left in the centre of each tubule.—Scattered through the plexus formed by the bloodvessels and uriniferous tubes, a number of little dark points may be seen with the naked eye, to which the designation of *Corpora Malpighiana* has been given, after the name of their discoverer. Each one of these, when examined with a high magnifying power, is found to consist of a convoluted mass of minute blood-vessels (Fig. 165, 7); and this is included in a flask-like dilatation of one of the tubuli uriniferi (Fig. 166). According to Mr. Bowman, this dilatation proceeds only from the termination of the tubulus; and this seems to be usually the case, although it seems not improbable that it may sometimes be a lateral diverticulum, as described by Gerlach (*loc. cit.*). The epithelium, which elsewhere lines the tube, is altered in appearance where the tube is continuous with this capsular dilatation (Fig. 166, *b'*); being there more transparent and furnished with cilia (as shown at *b''*), which in the Frog may be seen for many hours after death, in very active motion, directing a current down the tube. Further within the capsule, this epithelium becomes excessively delicate, and sometimes disappears altogether. The surface of the Malpighian tuft is often seen to be studded with nuclear particles, which suggest the idea that it is covered by an epithelial layer; and hence Gerlach, followed by other anatomists, has maintained that the flask-shaped dilatation of the tubulus uriniferus is not perforated by the bloodvessels which form the Malpighian tuft, but is reflected over it. It appears probable, however, that these nuclear particles really belong to the walls of the vessels; and the most careful examination has failed to detect any such reflexion. On this as on all other points of importance, therefore, Mr. Bowman's original description proves to be unsailable.¹

Fig. 166.

635. The Circulation of Blood through the Kidney presents a very remarkable peculiarity. The supply is derived in Man (as in other Mammalia) direct from the *arterial* system; though in Fishes and Reptiles, the urinary apparatus is connected, as well as the biliary, with the *portal venous* system, and even in Birds a portion of its blood is derived from the latter. But although this organ is supplied from the renal artery, yet it is not to its proper secretory apparatus that the blood of that artery is distributed in the first instance; for, on entering the kidney, this vessel speedily and entirely divides itself into minute twigs, which are the *afferent* vessels of the Malpighian tufts (Fig. 167, *af*). After it has pierced the capsule, each twig dilates; and suddenly divides and subdi-

¹ The *a priori* improbability that the basement-membrane of a glandular tubule or follicle should be thus penetrated by bloodvessels, has been entirely removed by the discovery that such penetration does take place in other cases, as the Peyerian glandulæ (§ 456) and the *Corpora Malpighiana* of the Spleen (§ 482).

vides itself into several minute branches, terminating in convoluted capillaries, which are collected in the form of a ball (*m, m*); and from the interior of the ball, the solitary *effluent* vessel, *e f*, arises, which passes out of the capsule by the side of the single *afferent* vessel. This ball seems to lie loose and bare in the capsule, being attached to it only by its *afferent* and *effluent* vessels (Fig. 166, *m*). The *effluent* vessels, on leaving the Malpighian bodies, separately enter the plexus of capillaries, *p*, surrounding the tubuli uriniferi, *st*, and supply that plexus with blood; from this plexus the renal vein arises.—Thus there is a striking analogy between the mode in which the tubuli uriniferi are supplied with blood, for the purpose of elaborating their secretion, and the plan on which the hepatic circulation is carried on. For as the secretion of the Liver is formed from blood conveyed to it by one large vessel, the vena portæ, which has collected it from the venous capillaries of the chylopoietic viscera, and which subdivides again to distribute it through the liver, so the secretion of the Kidney is elaborated from blood which has already passed through one set of capillary

Fig. 167.

Distribution of the Renal vessels; from *Kidney of Horse*:—*a*, branch of Renal artery; *af*, *afferent* vessel; *m, m*, Malpighian tufts; *ef, ef*, *effluent* vessels; *p*, vascular plexus surrounding the tubes; *st*, straight tube; *ct*, convoluted tube.

vessels, those of the Malpighian tufts; this blood is collected and conveyed to the proper *secreting* surface, however, not by one large trunk (which would have been a very inconvenient arrangement), but by a multitude of small ones, the *effluent* vessels of the Malpighian bodies, which may be regarded as collectively representing the vena portæ, since they convey the blood from the systemic to the secreting capillaries. Hence the Kidney may be said to have a *portal* system within itself.—This ingenious view of Mr. Bowman's finds support from the fact that in Reptiles the *effluent* vessels of the Malpighian bodies (which receive their blood, as elsewhere, from the renal artery) unite with the branches of the vena portæ, to form the secreting plexus around the tubuli uriniferi. Here, therefore, the blood of the secreting plexus has a double source, the vessels which supply it receiving their blood in part from the capillaries of the organ itself, and in part from those of viscera external to it; just as, in the Liver, the secreting plexus is supplied in part by the nutritive capillaries of the organ itself, which receive their blood from the hepatic artery, and in part by the blood conveyed from the chylopoietic viscera through the vena portæ.

636. These admirable researches of Mr. Bowman on the structure of the Malpighian bodies, and on the vascular apparatus of the Kidney, have thrown great light upon the mode in which the Urinary secretion is elaborated. One of the most remarkable circumstances attending this excretion, in the Mammalia particularly, is the large but variable quantity of *water* which is thus got rid of—the amount of which bears no constant proportion to that of the solid matter dissolved in it. The Kidneys, in fact, seem to form a kind of regulating valve, by which the quantity of water in the system is kept to its proper amount. The amount of exhalation from the Skin, which, with that from the Lungs, is the other principal means of removing superfluous liquid from the blood, is liable to be greatly affected by the temperature and degree of humidity of the air around (§ 647): hence, if there were not some other means of adjusting the quantity of fluid in the bloodvessels, it would be subject to continual and very injurious variation. This important function is performed by the Kidneys; which allow such a quantity of water to pass into the urinary tubes, as may keep the *pressure* within the vessels at a nearly uniform standard. The quantity of

water which is passed off by the Kidneys, therefore, will depend in part upon that exhaled by the Skin; being greatest when this is least, and *vice versa*: but the quantity of solid matter to be conveyed away in the secretion has little to do with this; being dependent upon the amount of *waste* in the system, and upon the quantity of surplus azotized aliment which has to be discharged through this channel.—The Kidney contains two very distinct provisions for these purposes. The *cells* lining the tubuli uriniferi are probably here, as elsewhere, the instruments by which the *solid* matter of the secretion is elaborated; whilst it can scarcely be doubted that the office of the Corpora Malpighiana is to allow the transudation of the superfluous fluid through the thin-walled and naked capillaries of which they are composed. “It would indeed,” Mr. Bowman remarks (*Op. cit.*, p. 75), “be difficult to conceive a disposition of parts more calculated to favor the escape of water from the blood than that of the Malpighian body. A large artery breaks up in a very direct manner into a number of minute branches; each of which suddenly opens into an assemblage of vessels of far greater aggregate capacity than itself, and from which there is but one narrow exit. Hence must arise a very abrupt retardation in the velocity of the current of blood. The vessels in which this delay occurs are uncovered by any structure. They lie bare in a cell, from which there is but one outlet, the orifice of the tube. This orifice is encircled by cilia, in active motion, directing a current towards the tube. These exquisite organs must not only serve to carry forward the fluid which is already in the cell, and in which the vascular tuft is bathed; but must tend to remove pressure from the free surface of the vessels, and so to encourage the escape of their more fluid contents.”—Here we see the essential difference which exists between the *vital* agency concerned in the true Secreting process, and the *physical* power which occasions fluid exhalation or transudation. This difference is precisely the same as that which exists between the *vital* act of selective absorption, and the *physical* operation of endosmose or imbibition. By Imbibition and Transudation, certain fluids may pass through organic membranes, in the dead as well as in the living body; and this passage depends merely upon the physical condition of the part, in regard to the amount and the nature of the fluid it contains, and the permeability of its tissues. Not only does water thus transude, but various substances that are held in complete solution in it, especially albuminous and saline matter: it is in this manner that the Blood absorbs fluids from the digestive cavity (§ 464), and pours out the serous fluid which occupies the interspaces of the areolar tissue and the serous cavities. The transudation of the watery portion of the blood is much increased by any impediment to its flow through the vessels, and also by any causes that produce a diminished resistance in their walls.

637. The nature and purposes of the Urinary secretion, and the alterations which it is liable to undergo in various conditions of the system, are much better understood than are those of the Bile; this is owing, in great part, to the two circumstances, that it may be readily collected in a state of purity, and that its ingredients are of such a nature as to be easily and definitely separated from each other by simple chemical means. There can be no doubt that the chief purpose of this excretion is to remove from the system the effete azotized matters, which the blood takes up in the course of the circulation, or which may have been produced by changes occurring in itself. This is evident from the large proportion of Nitrogen contained in the solid matter dissolved in it; and from the crystalline form presented by much of this solid matter when separated—a form which indicates that its state of combination is such, as to prevent it from conducting to the nutrition of the system. The injurious effects of the retention of the components of the Urinary secretion in the Blood are fully demonstrated by the results of its cessation; whether this be made to take place experimentally (as by tying the renal artery), or be the consequence of a disordered condi-

tion of the kidney. The symptoms of *Uræmia* (as this condition has been appropriately termed) are altogether such as indicate the action of a specific poison upon the Nervous system; affecting either the Brain or the Spinal Cord separately, or both together. In the first form, a state of stupor comes on rather suddenly, out of which the patient is with difficulty aroused; and this gradually deepens into complete coma, with fixed pupils and stertorous breathing, just as in ordinary kinds of narcotic poisoning. In the second form, convulsions of an epileptic character, frequently affecting the whole muscular system, suddenly occur; but there is no loss of consciousness. In the third form, coma and convulsions are combined. It has been generally supposed that these results are attributable to the accumulation of *urea* in the blood; but clinical observation affords sufficient evidence, that there is no constant relation between the severity of these symptoms and the amount of urea in the circulating system;¹ and experiment has determined that the other constituents of the urine do not exert any more potent influence.² It seems probable, then, that some substance formed at the expense of the normal constituents of urine, rather than either of these substances themselves, is the real poisonous agent in cases of *Uræmia*; and very cogent evidence has been adduced by Prof. Frerichs, in proof of his idea that the symptoms of this disorder arise from the conversion of the Urea in the circulating current into Carbonate of Ammonia, by the agency of a suitable ferment; so that, however great may be the accumulation, it does not give rise to any serious consequences, unless this ferment be also present. Two series of experiments are described by him as supporting this doctrine; the first showing that in cases of uræmic intoxication, a resolution of urea into carbonate of ammonia is actually taking place, ammonia being found in the expired air when the first symptoms make their appearance, and in the blood and in the contents of the stomach after death; and the second proving that the injection of carbonate of ammonia into the circulating current induces a train of symptoms essentially corresponding with those of uræmia, stupor and convulsions occurring either separately or conjointly.³—It seems not improbable that, as in the case of the retention of Bile in the Blood (§ 631), many of the minor as well as of the severer forms of sympathetic disturbance, connected with disordered secretion from the kidney, are due to this directly poisonous operation of the decomposing constituents of the urine, upon the several organs whose function is disturbed; and that many complaints, in which no such agency has been until recently suspected—especially Convulsive affections arising from a disordered action of the nervous centres—are thus due to the insufficient elimination of Urea from the Blood.⁴

638. In order to form a correct opinion of the state of the Urinary secretion in morbid conditions of the system, it is desirable to be acquainted with every leading particular regarding its normal character.—Fresh healthy Urine is a perfectly transparent, amber-yellow-colored liquid, exhaling a peculiar but not disagreeable odor, and having a bitterish saline taste. In all natural conditions of the Human system (even when a vegetable diet is used), the urine possesses

¹ It has been remarked by Bright, Christison, G. O. Rees, and Frerichs, that urea may often be obtained in considerable quantity from the blood of patients suffering under "Bright's disease," who were at the same time free from all nervous symptoms.

² Thus Frerichs (as Bichat, Courten, and Gaspard had before done) repeatedly injected from 20 to 40 grammes of filtered human urine, sometimes even with the addition of urea, into the veins of animals, without any ill effects resulting.

³ On this subject, the chapter on "*Uræmia*" in the admirable treatise of Frerichs "*Die Bright'sche Nierenkrankheit und deren Behandlung*," should be especially consulted.

⁴ Of the truth of this view, which was propounded by the Author in the first edition of this work, many illustrations have been since afforded; among the most interesting of which, is the very frequent coincidence of "*Bright's disease*" with Puerperal Convulsions, first pointed out by Dr. Lever.

a well-marked acid reaction. When it is left to itself for some time, slight *nebulæ*, consisting of mucus, are formed in it; and these gradually descend to the bottom. Soon afterwards, an unpleasant odor is developed; instead of an acid, an alkaline reaction is presented, in consequence of the decomposition of the urea into carbonate of ammonia; and a precipitation of earthy phosphates then takes place. A turbidity may occur, however, on the simple cooling of the urine, without any such departure from its normal composition as would properly constitute disease; this being due to the precipitation of urates of soda and ammonia, under the conditions formerly specified (§ 56). If the urine be turbid, however, when it is passed from the body, having a temperature of 98° or 100° , it must be considered as abnormal. The average *Quantity* of urine passed during the 24 hours, has been variously estimated: it differs, of course, with the amount of fluid ingested, and it is influenced also by the external temperature; a much smaller amount of the superfluous fluid of the body being set free from the skin in winter than in summer, and a larger proportion being carried off by the kidneys. Probably we shall be pretty near the truth, in estimating the amount (with Dr. Prout) at from about 30 oz. in summer, to 40 oz. in winter, for a person who does not drink more than the simple wants of nature require.—The *Specific Gravity* comes to be a very important character, in various morbid conditions of the urine: and it is therefore desirable to estimate it correctly. This also is liable, of course, to the same causes of variation; since, when the same amount of solid matter is dissolved in a larger or smaller quantity of water, the specific gravity will be proportionably lower or higher. The average, according to Dr. Prout, in a healthy person, taking the whole year round, is about 1020; the standard rising in summer (on account of the greater discharge of fluid by perspiration) to 1025; and being lowered in winter to 1015. Simon, however, states the average specific gravity at no more than 1012. It will depend, in each individual case, upon the amount of fluid habitually ingested, as compared with that dissipated by cutaneous exhalation; and it will also vary with the period that has elapsed since the last introduction of liquid into the stomach. From these and other causes, the proportion of solid matter in 1000 parts of Urine may vary from 20 to 70; and hence the various recorded analyses of this liquid present very wide diversities in the proportions of its solid constituents. These discrepancies, however, being chiefly due to the fluctuating amount of water, become very much less (as Simon¹ pointed out) when we calculate the proportion which each principal component bears to 100 of solid residue; as is shown in the following Table:—

	Berzelius.	Lehmann.	Simon.	Marchand.
Urea	45.10	49.68	33.80	48.91
Uric Acid	1.50	1.61	1.40	1.59
Extractive matter, Ammonia-salts, and Chloride of Sodium	36.30	28.95	42.60	32.49
Alkaline Sulphates	10.30	11.58	8.14	10.18
Alkaline Phosphates	6.88	5.96	6.50	4.57
Phosphates of Lime and Magnesia	1.50	1.97	1.59	1.81

We shall presently find the causes of some of the variations even here shown, to lie in the nature of the ingesta, and in the amount of exercise taken by the individual.

639. The most important of those organic constituents of the Urine, whose presence may be directly traced to the metamorphosis of the azotized components of the tissues and of the blood, is evidently that which, from its being the principal cause of the characteristic properties of the secretion, is termed *Urea*. This substance, as already shown (§ 52), exists preformed in the Blood; being

¹ "Animal Chemistry," translated by Dr. Day, p. 405, *Am. Ed.*

generated by the retrograde metamorphosis of Muscular tissue (probably through the intermediation of creatine or of uric acid), and also by similar changes in the unassimilated portions of the Blood itself.¹—The amount of Urea excreted in the 24 hours has been made the subject of examination by M. Lecanu:² and the following are his results as deduced from a series of 120 analyses:—

	Minimum.	Mean.	Maximum.
By Men ³	357.51 grs.	433.13 grs.	510.36 grs.
By Women	153.25 “	295.15 “	437.06 “
By Old Men (84 to 86 years) . .	61.08 “	125.22 “	295.15 “
By Children of eight years . .	161.78 “	207.99 “	254.20 “
By Children of four years . .	57.28 “	69.55 “	81.83 “

It is very interesting to perceive, in this table, how large an amount of Urea is excreted by children; and how small a quantity in proportion to their bulk, by old men. This corresponds precisely with the rapidity of interstitial change at different periods of life. (See CHAP. III. SECT. 3.) The quantity of Urea secreted at any given period of life seems to depend mainly on two conditions; namely, the degree of muscular exertion previously put forth, and the amount of azotized matter ingested as food. Thus, Prof. Lehmann ascertained that, by the substitution of *violent* for *moderate* exercise, the quantity of Urea was raised from 32½ to 45½ parts; and Simon found that, by two hours' violent exercise, the proportion of the urea in the urine passed half an hour subsequently, was double that contained in the morning urine. Again, Prof. Lehmann has shown that the amount of Urea excreted daily, when no azotized matter was taken in as food, and when the excretion was simply a measure of the “waste” of the tissues, was not above *half* that excreted when an ordinary mixed diet was employed, and only about *two-sevenths* of that which was passed when the diet was purely animal. The recent experiments of Prof. Bischof are to the same effect; for he found that a large dog secreted, with mixed food, from 230 to 300 grains of urea daily; with flesh diet, 802 grains; and when fed on intestines and gelatine, no less than 1110 grains daily. This last statement confirms the inference to which the injection of a solution of Gelatin directly into the blood appears to lead (§ 399); namely, that urea may be formed directly from the metamorphosis

¹ A new and easy method of determining the amount of Urea in Urine has lately been introduced by Prof. Liebig. It is founded on the fact that urea forms with pernitrate of mercury two compounds, one with 2, the other with 4 equivs. of peroxide of mercury. The latter is almost insoluble; and therefore, by adding to urine pernitrate of mercury, from a solution of known strength, the urea may be precipitated and its quantity determined in a few minutes. All the phosphoric acid in the urine, however, must first have been precipitated by barytes; which will also, of course, throw down its sulphuric acid. The presence of a chloride prevents the action of the pernitrate on the urea, converting it into a perchloride; hence the chloride of sodium always contained in the Urine must be allowed for, before the quantity of Urea can be determined. The appearance of the precipitate shows when all the chlorine present has been taken into combination with the mercury; so that the quantity of the pernitrate added to produce it gives that of the common Salt, while the quantity *afterwards* required to throw down the whole Urea gives the amount of that substance. (See Prof. Gregory's “Handbook of Organic Chemistry,” p. 509; and Dr. Martin Barry's communication in the “Lancet,” April 17, 1852.)

² “Journal de Pharmacie,” tom. xxv.

³ According to Prof. Bischof, of Giessen, who has employed Prof. Liebig's method of estimating the amount of urea in Urine (described in the preceding note), the quantity ordinarily excreted daily by a healthy man is not less than 830 grains, or nearly 2 ounces avoirdupois. If this be correct, the estimates of Lecanu are far below the truth, his *mean* for men being only 433 grains, or little more than half the estimate of Bischof. Still the above table will have a certain value; since all the amounts stated in it were obtained by the same method, and may therefore be fairly compared with each other. The speedy publication of Prof. Liebig's process “in a form adapted for easy and accurate use by medical men” has been promised; and it is to be hoped that a large body of valuable facts will then be collected.

of this substance, and probably, therefore, from the disintegration of the gelatinous as well as of the albuminous tissues. Next in importance to urea, among the organic products of the metamorphosis of the azotized constituents of the tissues or of the blood, but ordinarily bearing a very small proportion to it in quantity, is *Uric acid*. It has been shown (§ 57) that the formation of this substance is probably anterior to that of urea; and we shall see that its proportion in the urine is augmented under the same conditions as regards food (§ 640). On the other hand, there is reason to think that exercise, by augmenting the respiration, tends to diminish the proportion of uric acid in the urine, by converting it into urea. The circumstances that most favor the *genesis* of uric acid in the system, therefore, and its increased proportion in the urine if there be no obstacle to its elimination, are a highly azotized diet and inactive habits; whilst the reduction of the azotized portion of the diet to what is really wanted for the nutrition of the system, and the promotion of the respiration by active exercise, tend to the reduction of the proportion of this component. The *precipitation* of uric acid (usually in combination with alkaline bases), which frequently takes place on the cooling of the urine, must not be regarded as indicative of the presence of an unusual amount of this substance; since it may depend upon a variety of other conditions (§ 56). There are many diseases, however, especially those of a febrile nature, in which the presence of an excess of uric acid is a very marked symptom; there is usually, at the same time, a reduction in the proportion of urea; and thus it would seem that, with perhaps an augmented tendency to disintegration of the tissues, there is an incapacity for the performance of that higher process of oxidation which is requisite for the genesis of urea; so that a larger proportion of the products of the "waste" passes off in the state of uric acid, as in animals whose respiration is feeble. This view derives support from the fact that *Hippuric acid*, which is only to be found in extremely minute proportion in healthy Human urine, and the composition of which indicates that it is to be regarded as a result of very imperfect oxidation (§§ 58, 59), undergoes a marked increase under the same circumstances, and especially when obstructed action exists in either of the other great excretories, the lungs, liver, or skin, so that a larger amount of carbonaceous matter is thrown upon the kidneys for elimination; for in this case, also, there is a deficiency in the normal amount of urea. Although the presence of *Creatine* and *Creatinine* in the Urine, the former in very small proportion, but the latter in considerably larger amount, is now a well-established fact, the actual quantities ordinarily excreted, and the circumstances which favor their increase and diminution, have not yet been determined. From the considerations formerly adduced (§§ 60, 61), it seems likely that Creatine is one of the first products of the disintegration of muscular tissue, and that a portion of the urea eliminated in the urine, as well as of the greater part (if not the whole) of the Creatinine, is generated at its expense. The presence of *Lactic acid* in the Urine, although by no means infrequent, must be regarded as exceptional. We have seen that a constant genesis of this substance is taking place in the body, not merely as a product of the metamorphosis of the saccharine matters employed as food, but also as one of the results of the disintegration of the azotized tissues (§§ 48–50); but that the respiratory process affords the ordinary channel for its removal; so that it is only when its production is excessive, or when there is some obstruction to its elimination by the lungs, that it makes its appearance in the urine. These conditions are so often present in disease, that Lactic acid is far more commonly present in abnormal than in normal states of the secretion. The *Extractive Matters* of the Urine, as already pointed out (§ 64), are made up of a variety of different compounds, our knowledge of which is gradually being extended. Among the substances which rank under this head in the ordinary analyses of Urine, are creatine, creatinine, and hippuric acid;

and others are being successively determined. Thus Städeler has shown that the "extractive" of the Urine of the Cow contains a peculiar azotized compound, and several volatile non-azotized acids, analogous to, and in one instance absolutely identical with, the products of the imperfect oxidation of wood or coal.¹ And Prof. Ronalds has shown that the "extractive" of Human urine ordinarily contains a sulphurized and a phosphorized compound, which serve for the excretion of sulphur and phosphorus in an unoxidized state.² The *Urine-Pigment*, again, has been to a certain extent separated as a definite compound from the "extractive," especially by the researches of Heller (§ 64). On the whole, we may say that with the exception of Creatine and Creatinine, all the known constituents of the "Urinary extractive" are substances which are rich in carbon and comparatively poor in nitrogen; so that their increase will be favored by an excess of carbonaceous food, an imperfect action of the liver, and a low degree of respiration;³ whilst, on the other hand, a highly azotized diet, especially if combined with active exercise, will tend to their reduction. This view is confirmed by the results of Prof. Lehmann's experiments, which were performed with a view to determine the influence of diet upon the constitution of the Urine.

640. In the *first* series of these experiments, Prof. Lehmann adopted an ordinary *mixed* diet; but he took no more solid or liquid aliment than was needed to appease hunger or thirst, and abstained from fermented drinks. Every two hours he took exercise in the open air, but he avoided immoderate exertion of every kind. The average result of the examination of the Urine passed under these circumstances, for fifteen days, is given in the first line of the subsequent table.—In a *second* series of experiments, Prof. L. lived for twelve days on an exclusively *animal* diet; and for the last six of these, it consisted solely of eggs. He took 32 eggs daily; which contained 2929 grains of dry albumen, and 2431 grs. of fatty matters; or about 3532 grs. of carbon, and 465½ grs. of azote. The amount of Urea is shown, in the second line of the table, to have undergone a very large increase; and it contained more than five-sixths of the whole azote ingested.—In a *third* series of experiments, Dr. L. lived for twelve days on a *vegetable* diet; and its effect upon the solid matter of the Urine is shown in the third line of the table.—In a *fourth*, he lived for two days upon an *unazotized* diet, consisting entirely of pure farinaceous and oleaginous substances, so that the azotized matter of the Urine must have been solely the result of the disintegration of the tissues. It is seen to undergo a very marked diminution, under this regimen; as is shown in the fourth line of the table. His health was so seriously affected, however, by this diet, that he was unable to continue it longer.

	Solid Matters.	Urea.	Uric Acid.	Extractive Matters and Salts.
I. Mixed diet . . .	1047.14 grs.	501.76 grs.	18.26 grs.	196.65 grs.
II. Animal diet . . .	1350.07 "	821.37 "	22.82 "	112.89 "
III. Vegetable diet . .	914.66 "	347.10 "	15.77 "	295.95 "
IV. Non-Azotized diet .	643.53 "	237.90 "	11.34 "	264.48 "

² See "Philosophical Transactions," 1846, pp. 461-464.

³ This is particularly obvious in cases in which the functions of the Liver are imperfectly performed. For there is first to be observed an increase in the ordinary Urine-pigment (which contains 58½ per cent. of carbon), giving a high color to the secretion, and causing the addition of a few drops of hydrochloric acid to the warmed fluid to develop a fine crimson or purple hue. If the inactivity of the liver increase, a deposit of *purpurine* (a substance which contains 62½ per cent. of carbon) is thrown down (§ 64). And the complete arrest of the elimination of bile is marked by the appearance of the proper Bile-pigment in the urine. (See Dr. Golding Bird's "Lectures on Therapeutics," in "Med. Gaz.," 1848, vol. xlii. p. 229.)

The following inferences are drawn by Prof. Lehmann from these experiments:—1. Animal articles of diet augment the *Solid matters* of the Urine. Vegetable substances, and still more such as are deprived of azote, on the contrary, diminish it.—2. Although Urea is a product of decomposition of the organism, yet its proportions in the urine depend also on the food, for we find that a richly-azotized diet considerably augments its quantity. In the above experiments, the proportion of the Urea to the other solid matters was as 100 to 116 on a mixed diet; as 100 to 63 on an animal diet; as 100 to 156 on a vegetable diet; and as 100 to 170 on a non-azotized diet.—3. The quantity of *Uric acid* depends less on the nature of the diet than on other circumstances; the differences observed in it being too slight to warrant us in ascribing them to the former cause.—4. The Protein-compounds, and consequently the azote of the food, are absorbed in the intestinal canal; and what is not employed in the formation of the tissues, is thrown off by the Kidneys in the form of Urea or Uric acid; these organs being the chief, if not the sole channel through which the system frees itself of its excess of azote.—5. The urine contains quantities of *Sulphates* and *Phosphates* proportional to the azotized matters which have been absorbed; and the proportion of these salts is sensibly increased under the use of a large amount of those substances.—6. In the same circumstances, the *Extractive matters* diminish, while their quantity is increased by the use of vegetable diet; a fact which proves the influence of vegetable aliment over the production of these matters in the urine.—7. The urine, after the use of animal food, has a strong acid reaction, but contains little or no lactic acid and no hippuric acid. Under a vegetable diet there is more lactic acid, but it is united to bases. The largest production of lactic acid is under a non-azotized diet; and most of it is then combined with ammonia. Therefore the lactic acid eliminated with the urine is in great part the product of non-azotized substances not entirely assimilated; but it results also in part from the decomposition of the azotized substances entering into the composition of the body and the food.—8. The Kidneys not only separate certain constituent parts of the organs which have become inadequate for the maintenance of life, but they also expel the superfluous nutritive matters that may have been absorbed.¹

641. Besides its organic materials, the Urine contains a considerable amount of *Saline* matter; the excretion of which, in a state of solution, appears to be one of the principal offices of the Kidney. Various saline compounds are continually being introduced with the food; and others are formed within the system, by the oxidation of the Sulphur and Phosphorus of the tissues or of the food, and by the combination of the sulphuric and phosphoric acids thus formed, with alkaline and earthy bases which the food may contain, usually in a state of combination with weaker acids which are otherwise disposed of. Thus the Saline compounds found in the urine are to be regarded as partly proceeding from the retrograde metamorphosis of the materials of the tissues, after these have served their purpose in the economy, and partly from that of such components of the food, as, being superfluous, do not undergo organization. But the Kidney also serves as the channel for the elimination of saline compounds introduced into the system *per se*; these being sometimes normally present in the body, but ingested in too large an amount, as is often the case with common Salt; whilst, on the other hand, they may be altogether foreign to the composition alike of its solids and its fluids.—The *Alkaline Sulphates* usually constitute, as we have seen (§ 638), about 10 per cent. of the whole solid matter of the Urine. Being always in solution, however, they never make their presence known by the formation of sediments, and are only

¹ "Journ. für praktische Chemie," 1842-3; see also "Simon's Animal Chemistry," translated by Dr. Day, pp. 414-420, *Am. Ed.*; and Prof. Lehmann's "Lehrbuch der Physiologischen Chemie," band ii. p. 447.

to be detected by chemical tests. The causes which influence their amount have been carefully studied by Dr. Bence Jones; who has shown that they vary (like urea) with the amount of food ingested, and with the degree of nervo-muscular activity put forth; as might be anticipated from the fact that, under ordinary circumstances, the sulphuric acid is entirely formed within the system, by the oxidation of the sulphur of the protein-compounds, the bases being furnished by the alkaline carbonates or phosphates of the blood, whose source has been already considered (§ 83). When sulphuric acid or soluble sulphates are taken into the system *per se*, they partly find their way out of it by the Kidneys (§ 88); the proportion of sulphuric acid in the urine being for a time augmented, although the increase is not considerable until some hours have elapsed after the introduction of these substances into the stomach.¹—The amount of *Alkaline Phosphates* (§ 84) in the Urine is usually about half that of the alkaline sulphates. The acid of these also is ordinarily generated within the system by the oxidation of the phosphorus originally introduced in the protein-compounds; and thus, as in the case of the sulphates, the quantity of them which is excreted by the urine bears a certain relation to the amount of these compounds ingested as food, and also to the amount of muscular tissue which has undergone disintegration by exercise. But it further appears that there is a special relation between the *quantity* of the alkaline phosphates in the urine, and the amount of disintegration of the *nervous* tissue (§ 361); as might have been suspected from the fact that this tissue is distinguished by the very large proportion of phosphorus, united with fatty acids, which it contains (§ 345). And a marked increase of these salts is observed in those inflammatory diseases of the brain, in which there is reason to believe that an unusually rapid disintegration of its texture is taking place.²—The *Earthy Phosphates* usually bear but a small proportion to the Alkaline; but their presence in the urine comes to be of great importance, with reference to the precipitates which they form in particular conditions of that secretion. From the researches of Dr. Bence Jones (*loc. cit.*) it appears that the quantity of these phosphates in the urine chiefly varies with the amount of them contained in the food, into many articles of which they enter largely (§§ 76, 78); but he has also ascertained that their formation within the system is determined by the presence of their bases; for, if any earthy salt, a little chloride of calcium or sulphate of magnesia for instance, be taken into the system, the quantity of earthy phosphates in the urine undergoes an increase. The small quantity of carbonate of lime taken into the system with the food (§ 77), or set free by the slow disintegration of the osseous tissue, is probably excreted in Man almost entirely in the form of phosphate; although of the much larger amount ingested by herbivorous animals, a considerable proportion is excreted in the urine in its original state. The Earthy Phosphates, although insoluble in water, are soluble in all acid liquids; and they are held in solution in Urine, like the urates, by the acid phosphate of soda. Their precipitation in an alkaline state of the urine is owing to the want of this solvent, not to an excess in their production; for, as Dr. Bence Jones has pointed out, that excess of alkaline and earthy phosphates in the urine which constitutes the true “phosphatic diathesis,” is generally coincident with a highly acid state of the urine.—The only other inorganic saline constituent of the Urine whose

¹ Dr. Bence Jones in “Philosophical Transactions,” 1849.

² See Dr. Bence Jones’s valuable series of papers in the “Philosophical Transactions” for 1845, 1847, and 1850, and in the “Medico-Chirurgical Transactions” for 1847 and 1850. It is curious to observe that, whilst the increase in the alkaline phosphates in Inflammatory affections of the nervous centres is very marked, there appears to be a positive diminution of them in Delirium Tremens. A certain allowance must be made, however, for the abstinence from food, which will of itself occasion a reduction in the quantity excreted.

quantity gives it importance is *Chloride of Sodium*. By far the larger proportion of this is doubtless derived directly from the food; but little being furnished by the disintegration of Muscle, which will set free potash rather than soda (§ 307). The amount eliminated by the urine is consequently subject to great variation, it being the function of the Kidneys to remove whatever is superfluous, so as to prevent the blood from becoming overcharged with this substance (§ 82). Of the chloride of sodium introduced as food, a part appears to undergo decomposition in the system, whereby hydrochloric acid is furnished to the gastric fluid, and soda to the bile; part of this acid, however, must reunite with its base in the alimentary canal, so that the chloride of sodium thus regenerated will be absorbed with the products of the digestive operation.—Although *Nitric Acid* cannot be regarded as a normal constituent of the Urine, yet the recent investigations of Dr. Bence Jones¹ show that it is formed by a combusive process within the body, whenever ammoniacal salts are introduced into the system; its amount, however, being very small. He has also found that it is generated after the ingestion of small quantities of urea; a fact which affords some confirmation to the doctrine of Frerichs (§ 637), that urea may undergo decomposition into carbonate of ammonia, whilst still circulating in the current of blood.—The presence of *Oxalic Acid* in the urine (in combination with Lime) has been usually regarded as a pathological phenomenon, consequent upon an irregular performance of the retrograde metamorphosis of the tissues; but there can be no doubt that it may also result from the presence of soluble salts of oxalic acid in certain articles of vegetable food.²

642. The ordinary *acid* reaction of the Urine appears to be due, not to the presence of any free acid, but to the conversion of the *basic* phosphate of soda into the *acid* phosphate, by the subtraction of a part of the base, which occurs when uric, hippuric, lactic or other free acids come into contact with the former substance. There is no adequate reason to believe that, in the healthy state, there is ever any other cause than this; although in morbid urine, free organic acids are almost certainly present.³ It has been shown by the researches of Dr. Bence Jones, however, that the acid reaction is far from being constant in its degree, even when an ordinary mixed diet is steadily employed; for that it varies at different periods of the day, increasing and decreasing *inversely with the acidity of the stomach* (§ 443). Thus the acidity of the Urine decreases soon after taking food, whilst that of the Stomach is increasing; and attains its lowest limit from three to five hours after a meal, frequently giving place to an alkaline reaction. The acidity then gradually increases, whilst that of the stomach is decreasing; and attains its highest limit after a fast of some hours, when the stomach is quite empty, and its secretion neutral. If no food be taken, the acidity does not decrease, but remains at nearly the same point for ten or twelve hours. When *animal* food was alone employed, the diminution of the acidity after a meal was more marked, and continued longer, than when a mixed diet was eaten (apparently on account of the greater demand for acid in the stomach); and the acidity did not rise quite so high after fasting, as with a mixed diet. On the other hand, when the diet was purely *vegetable*, the diminution of its acidity was never such as to render the urine absolutely alkaline, although its acidity was reduced to the point of neutrality; and the increase of its acidity after fasting was sometimes very considerable, though by no means so marked as the decrease of alkalescence.—These diurnal variations in the acidity of the urine make it highly probable that corresponding variations occur in the alkalescence of the blood; such diurnal variations being produced by the

¹ "Philosophical Transactions," 1851.

² See Dr. Golding Bird on "Urinary Deposits," 2d *Am. Ed.*, p. 188.

³ See Prof. Lehmann's "Lehrbuch der Physiologischen Chemie," band ii. pp. 398-400.

quantity of acid separated from it, and poured into the stomach for the purpose of dissolving the food. The introduction of dilute sulphuric acid into the stomach, even in large doses, was not found to produce any decided change in the acidity of the urine; the only perceptible effect being a slight diminution of the decrease which takes place after taking food, and a slight augmentation of the increase after fasting. On the other hand, the use of liquor potassæ in large doses lessens the acidity of the urine, preventing it from rising after fasting to the height it would otherwise attain, and increasing its alkalescence after a meal; but it does not render the urine by any means constantly alkaline, nor does it hinder the variations produced by the state of the stomach from being very evident. Tartaric acid, in large doses, increases the acidity of the urine, causing it to rise considerably higher than usual after a fast, but not preventing that which is passed a few hours after food from becoming alkaline. Tartrate of potash in large doses, on the other hand, has a marked effect in rendering the urine alkaline; still, it does not prevent the usual recurrence of the acidity some hours after a meal.¹

643. It seems to have been clearly proved by Dr. Bence Jones (loc. cit.), that there is no relation whatever between the *acidity* of the urine and the *absolute amount* of Uric acid which it may contain; for in the urine which is most acid, and which deposits the largest uric-acid sediment, very little uric acid may really exist; whilst that which contains most uric acid may hold it in perfect solution, and may have but a feeble acid reaction.²—The main cause of the deposit of Uric-acid sediments is doubtless the presence of some other acid; for the addition of any acid to healthy urine passed soon after food is always sufficient to produce it. But the deposit takes place less readily if the temperature of the fluid be high, since the solvent power of the acid phosphate of soda is then more strongly exerted; so, on the other hand, a deposit often takes place in urine which would not otherwise exhibit it, through an unusual reduction in its temperature, as by exposure to the cold air of a sleeping-room in the winter. Again, the deposit of uric-acid sediment is favored by concentration of the liquid, which thus augments the proportion of the urate to the water, and at the same time increases the acid reaction; and thus urine whose constituents are otherwise normal may throw down a copious deposit of this kind, merely from deficiency of water; whilst an unusual amount of uric acid may be really present without being deposited—the urine, too, possessing its ordinary acidity—if the proportion of water be large. Thus the uric sediment may be regarded as dependent upon three concurrent conditions: (1) Decrease of temperature; (2) Increased proportion of uric acid compound to the water, positively or relatively; (3) Increased acidity of the urine. Sometimes one condition is most influential, sometimes another; but they are all usually concerned in some degree.

644. The Urine of Herbivorous animals is almost invariably *alkaline*; partly because their food contains a large quantity of alkaline and earthy bases, in combination with citric, tartaric, oxalic, and other acids, which are decomposed within the system (§ 83); and partly because the amount of sulphuric and phosphoric acids, generated as products of the oxidation of the elements of the tissues or of the surplus food, is not sufficient to neutralize them. Such is the condition which occasions the alkalinity of Human Urine, when a portion of

¹ See Dr. Bence Jones's "Contributions to the Chemistry of the Urine," in "Philosophical Transactions," 1849.

² It will be remembered that these sediments nearly always consist of Uric acid in union with a base (§ 56); this base is regarded by Prof. Lehmann as chiefly soda; whilst Dr. Bence Jones, in common with Dr. Golding Bird, maintains it to be ammonia. The term "uric-acid sediment" is used above to designate this compound, whatever may be the substance with which the uric acid is united.

the acid which would otherwise show a predominance, is directed into another channel; and it is exaggerated in those states in which, either from the irritating nature of the food, or from the irritable condition of the stomach, an undue quantity of acid is poured out into that viscus; so that, its reaction being habitually acid, that of the urine becomes habitually alkaline. Such a state of the urine must be carefully distinguished, as Dr. Bence Jones has pointed out,¹ from that in which the alkalescence is due to the presence of *volatile*, and not to that of *fixed* alkali; the difference being easily recognizable by the influence of the liquid upon reddened litmus-paper, for the restoration of its blue color is permanent in the latter case, but only transitory in the former. The alkalescence due to the presence of volatile alkali is due to the decomposition of urea, whilst the urine is yet within the bladder, through the agency of morbid secretions of that viscus; and it disappears when this organ returns to its healthy state. On the other hand, the alkalescence from fixed alkali proceeds from disordered action of the stomach, which is usually connected with disorder of the general system; and it persists until this can be remedied. In both forms of alkalescence, there is a precipitation of earthy phosphates; but in the alkalescence from fixed alkali, the precipitate usually consists almost entirely of phosphate of lime; whilst in that from volatile alkali, the amorphous sediment of phosphate of lime is mingled with prismatic crystals of the phosphate of ammonia and magnesia. These precipitates may be obtained from healthy urine, by adding to it a solution of potash or of ammonia; and the decomposition of such urine, which begins to take place very soon after it leaves the body, gives rise to the same precipitation, by the production of carbonate of ammonia at the expense of its urea (§ 52).

645. Thus, then, we have seen that the Kidneys serve as the special instruments for depurating the Blood of those highly-azotized compounds, which are formed in the system by the decomposition of the materials of the albuminous and gelatinous tissues, and also by that of the non-assimilated components of the food. We have seen, also, that they serve for the removal of certain compounds of which carbon is a principal ingredient; and these, although normally present in but small amount, may undergo a marked increase in disease, especially when the liver is insufficiently performing its functions, or the respiratory process is obstructed. Further, we have been led to regard the Kidneys as the emunctory, not only for the superfluous water of the blood, but also for those saline compounds, which, having been introduced into the system, or generated within it, in larger amount than is compatible with the normal constitution of the blood, or than is required for the reparation of the solids of the body, or for the production of its fluid secretions, are only fitted for elimination. And this statement is to be extended from saline compounds to such other soluble matters as are not removed by other channels. On this point a very elaborate series of researches was made by Wöhler,² who showed that of the soluble salts taken into the circulation, those are most readily excreted which produce a determination of blood towards the kidneys, whereby an increased quantity of liquid is filtered off through the outlet which they afford. And it is in this manner that the system makes an effort to free itself (so to speak) from various foreign substances which have been introduced into it by absorption, and which would be injurious if retained; the rate at which it does so being in a great degree dependent upon the functional activity of the Kidneys (§§ 89, 207, 208).—It does not appear, however, that the excretion of the organic compounds which are formed within the system is augmented by those “diuretic” medicines which, by determining an increased flow of blood to the Kidneys, cause a larger amount of liquid

¹ “Medical Times,” Dec. 13, 1851.

² “Müller's Elements of Physiology,” translated by Baly, p. 589.

to be passed off through them. On the contrary, it would seem as if, by producing congestion and irritation, they sometimes interfered with the normal process of secretion; so that the quantity of solid constituents is actually decreased, notwithstanding the large augmentation in the watery part of the urine. This very important fact has been demonstrated by Prof. Krahmer,¹ who gives the following as the result of his observations upon the amounts excreted in 24 hours, after the administration of diuretics to persons in health:—

Medicine given.	Total Solids in Urine.	Organic Compounds.	Inorganic Compounds.
None	2.40 oz.	1.28 oz.	1.13 oz.
Juniper	2.12 “	0.94 “	1.18 “
Venice Turpentine	1.94 “	1.11 “	0.83 “
Squill	2.25 “	1.04 “	1.21 “
Digitalis	2.45 “	1.28 “	1.17 “
Guaiacum	2.43 “	1.38 “	1.05 “
Colchicum	2.32 “	1.36 “	0.96 “

Similar results have been obtained by Dr. Golding Bird,² who has shown that, on the other hand, there is a class of remedies, which is capable of producing the most marked increase in the amount of organic as well as of saline matters eliminated by the Kidneys. These are the Alkalies and their carbonates, with such of their salts as are formed by acids which are decomposed in the blood into the carbonic, such as the acetates, tartrates, and citrates. It has been shown (CHAP. II. SECT. 1) that the alkalies and their carbonates have a powerful solvent action on the albuminous compounds generally; and that they tend to break up these compounds into simpler forms of combination. Hence it seems likely that their presence in the Blood in increased amount will tend to hasten the retrograde metamorphosis of the tissues; their chemical force being exerted, not merely upon those which are already in a state of disintegration, but also upon those, which, being disposed to degenerate, cannot exercise that resisting power which they possess when in a state of complete vital activity (§ 116). The increase which their administration occasions in the solids of the Urine is strikingly displayed in the following comparative table, given by Dr. G. Bird, of the entire constituents of the secretion passed during 24 hours, before and after the administration of three drachms of acetate of potash:—

	Before Medicine.	After Medicine.
Quantity of Urine	℥ ³ xvi	℥ ³ xlv
Specific Gravity	1.025	1.017
Total Solids	416 grs.	782 grs.
Uric Acid	2.6 grs.	3.5
Urea	130.5 “	202.4
Other Organic Compounds	189.3 “	295.5
Soluble Salts	72.0 “	248.4
Insoluble Salts	21.6 “	32.2

The increase (176.4 grains) in the quantity of “soluble salts” is to be chiefly set down to the account of the medicine taken in; but the whole remainder of the augmentation seems fairly attributable to the increased metamorphosis. A certain degree of such increase is producible by the simple ingestion of a large amount of water; so that this is by no means so inoperative as it might at first sight appear, in cleansing and purifying (so to speak) the penetralia of the system.—It seems highly probable that the “critical evacuations” of urine, as of sweat, or fecal matter, on which the older physicians were accustomed to lay great stress, are really charged with noxious substances, of which the blood is thus depurated; and that great benefit would frequently arise in practice from

¹ “Heller's Archiv,” Dec., 1847.

² See his “Lectures on the Influence of Researches in Organic Chemistry on Therapeutics,” in “Medical Gazette,” 1848, vol. xlii. p. 230.

the use of the “alterative diuretics,” as suggested by Dr. G. Bird, where (as in chronic rheumatism, gout, &c.) there is reason to believe that a quantity of mal-assimilated matter exists in the system, of which it is important to get rid. In many such cases, indeed, clinical observation had already established the benefit derivable from such medicines, without affording the rationale of it.

4.—Of the Skin;—Cutaneous Transpiration.

646. The Skin is the seat of various secretions, for each of which it is provided with special organs (§§ 237, 238); but these have reference chiefly to its own protection, or to some other *local* purpose; and the only one which can be regarded as truly *excrementitious*, is the Transpiration of aqueous fluid, holding certain matters in solution. The elimination of this fluid from the blood is effected by the *Sudoriparous glandulæ* (Fig. 168), which are seated rather *beneath* than *in* the Cutis, and are diffused in varying proportions over the entire surface of the body (§ 238). According to Mr. Erasmus Wilson,¹ as many as 3528 of these glandulæ exist in a square inch of surface on the palm of the hand; and as every tube, when straightened out, is about a quarter of an inch in length, it follows that, in a square inch of skin from the palm of the hand, there exists a length of tube equal to 882 inches, or 73½ feet. The number of glandulæ in other parts of the skin is sometimes greater, but generally less than this; and according to Mr. Wilson, about 2800 may be taken as the average number of pores in each square inch throughout the body. Now the number of square inches of surface, in a man of ordinary stature, is about 2500; the total number of pores, therefore, may be about *seven millions*; and the length of the perspiratory tubing would thus be 1,750,000 inches, or 145,833 feet, or 48,611 yards, or nearly 28 miles.—Although a separation of fluid by this extensive glandular apparatus is continually taking place, yet this fluid, being usually carried off in the form of vapor as fast as it is separated, does not accumulate so as to become sensible. If, however, from the increased amount of the secretion, or from the condition of the surrounding air, the whole fluid thus poured out should not evaporate, it accumulates in minute drops upon the surface of the skin. Thus the Sudoriparous excretion may take the form either of *sensible* or of *insensible* transpiration; the latter being constant, the former occasional. It is difficult to obtain enough of this secretion for analysis, free from the sebaceous and other matters which accumulate on the surface of the skin; and its character can only, therefore, be

Fig. 168.

Sudoriparous Gland from the palm of the hand, magnified 40 diam.: 1, 1, contorted tubes, composing the gland, and uniting into two excretory ducts, 2, 2, which unite into one spiral canal that perforates the epidermis at 3, and opens on its surface at 4; the gland is imbedded in fat-vesicles, which are seen at 5, 5.

¹ “On the Management of the Skin,” 3d edit. p. 37.

stated approximately. It has usually an acid reaction, which seems due to the presence of acetic acid; and to this, or to lactic acid, we are probably to attribute the sour smell which it has, especially in some disordered states of the system. The proportion of solid matter, according to Anselmino, varies between 5 and 12.5 parts in 1000. The greater part of it consists of organic matter, the larger proportion of which appears to be a protein-compound in a state of incipient decomposition; urea, however, has been detected in this product by Dr. Landerer.¹ The remainder consists of saline compounds; of which the chlorides of potassium and sodium appear to be pretty constantly present; whilst muriate of ammonia, alkaline phosphates, free acetic and butyric acids, and acetate of soda, have also been said to occur in it.—The proportion of solid ingredients would probably be found larger in the true secretion of the Sudoriparous glands, if we had the means of collecting it separately; for of the whole fluid which passes off from the surface of the skin, only a portion can be properly said to be *secreted* by these glands, a large part, as in the case of the Kidneys, being the product of simple *transudation* (§ 636). It will be this part which will undergo augmentation, when a special determination of blood to the skin is produced by external heat; and there is no more reason to think that an increase in the amount of *solid* matter thus excreted is induced by such agency, than that an increase in the solids of the urine can be determined by ordinary diuretics (§ 645). Hence the debilitating effects commonly assigned to profuse perspirations must be attributed to some other causes; and these it does not seem very difficult to find. Thus, the great fatigue which is experienced as a consequence of muscular exertion in a heated atmosphere, may fairly be set down to the diminished activity of the respiratory process at high temperatures (§ 564, *a*); and the “colliquative sweating” of hectic fever is obviously not a cause, but a consequence, of the debilitated state of the general system.

647. The entire amount of fluid which is “insensibly” lost from the Cutaneous and Pulmonary surfaces is estimated by Seguin at 18 grains per minute; of which 11 grains pass off by the skin, and 7 by the lungs. The maximum loss by Exhalation, cutaneous and pulmonary, during twenty-four hours (except under very peculiar circumstances) is 5 lbs.; the minimum $1\frac{3}{4}$ lb. It varies greatly, according to the condition of the atmosphere, and that of the body itself; and these variations, as we shall hereafter see (§ 665), have a most important share in the regulation of the temperature of the body. The whole amount of Cutaneous transpiration, “sensible” and “insensible,” is greatly increased by heat and dryness of the surrounding air; for the heat occasions the determination of an augmented amount of blood to the cutaneous vessels; and of the fluid which thus transudes, a large portion is carried off in the state of vapor. The more the heated atmosphere is already charged with watery vapor, the smaller will be the proportion of the transuded fluid that will thus “insensibly” pass away; and the more will accumulate as “sensible” perspiration. Exact observations on this point, however, are much wanting, in which not merely the temperature, but the hygrometrical state of the air should be precisely determined; the best hitherto recorded being those made by Dr. Southwood Smith² at the Phoenix Gas-Works, in which the former element only was carefully noted. These observations were made upon eight of the workmen employed in drawing and charging the retorts and in making up the fires, during which they are exposed to intense heat; the men were accurately weighed in their clothes, immediately before they began, and after they had finished their work; and in the interval between the first and second weighings, they were

¹ “Heller’s Archiv.,” band iv. p. 196.

² “Philosophy of Health,” vol. ii. pp. 391–396.

not allowed to partake of any solid or liquid *ingesta*, nor to part with urine or feces.

Experiment I. Nov. 18, 1836. Day bright and clear. Temperature of the air in which the men worked, 60° Fahr. Barometer 29.25 in. to 29.4 in. Duration of labor, 45 minutes.—Average loss of weight, 3 lbs. 6 oz.; maximum, 4 lbs. 3 oz.; minimum 2 lbs. 8 oz.

Experiment II. Nov. 25, 1836. Day foggy, with scarcely any wind. Temperature of the air, 39° Fahr. Barometer 29.8. Duration of labor, 75 minutes.—Average loss of weight, 2 lbs. 2 oz.; maximum, 2 lbs. 15 oz.; minimum, 14 oz.

Experiment III. June 3, 1837. Day exceedingly bright and clear, with little wind. Temperature of the air, 60°. Duration of labor, 60 minutes.—Average loss of weight, 2 lbs. 8 oz.; maximum, 3 lbs.; minimum, 2 lbs.

Experiment IV. On the same day, two other men worked in an unusually hot place for 70 minutes; the loss of weight of one of these was 4 lbs. 14 oz.; and of the other, 5 lbs. 2 oz.

Although the individuals subjected to these experiments were not in all instances the same, yet there was enough of identity among them to admit of the certain inference, that the amount of fluid lost must be influenced by the state of the individual system, as well as by that of the surrounding medium. Thus in the second experiment, Michael Griffiths lost 2 lbs. 6 oz., and Charles Cahell 2 lbs. 15 oz.; whilst in the third, Michael Griffiths lost 3 lbs., and Charles Cahell only 2 lbs. It is probable that the amount of liquid ingested not long previously might have a considerable influence on the quantity lost by transpiration under such circumstances.

648. The Cutaneous excretion, as already pointed out, is in great degree vicarious with the Urinary, in regard to the amount of fluid eliminated; the urine being more watery in proportion as the cutaneous exhalation is diminished in amount, and *vice versa* (§ 636). But we are also to look at these two excretions as vicarious, in regard to the elimination of the products of the "waste" of the system. The share which the Skin has in this office has probably been generally underrated. There is reason to believe that at least 100 grains of azotized matter are excreted from it daily; and any cause which checks this excretion must throw additional labor on the kidneys, and will be likely to produce disorder of their function.—The secreting action of the Skin is influenced by general conditions of the vascular and nervous systems; which are as yet ill understood. It is quite certain, however, that through the influence of the latter the secretion may be excited or suspended; this is seen on the one hand in the state of syncope, and in the effects of depressing emotions, especially fear, and its more aggravated condition, terror; and on the other, in the dry condition of the skin during states of high nervous excitement. It is very probable that, in many forms of fever, the suppression of the perspiration is a cause, rather than an effect, of disordered vascular action; for there are several morbid conditions of large parts of the surface, in which the suppression of the transpiration appears to be one of the chief sources of danger, having a tendency to produce congestion and inflammation of internal organs. From the experiments of Dr. Fourcault, it appears that complete suppression of the perspiration in animals, by means of a varnish applied over the skin, gives rise to a state termed by him "cutaneous asphyxia;" which is marked by imperfect arterialization of the blood, and considerable fall of temperature (§ 660); and which, as it produces death in the lower animals, would probably do the same in Man. A partial suppression by the same means gives rise to febrile symptoms, and to albuminuria.—There can be no doubt whatever that imperfect action of the Cutaneous glandulæ, consequent upon inactive habits of life and want of ablution, is a very frequent source of disorder of the general system; occasioning

the accumulation of that decomposing organic matter in the blood which it is the special office of these glandulæ to eliminate. Hence the due maintenance of health requires that this excretion should be promoted by the use of the natural and appropriate means just referred to; and this is the more necessary, when from any cause the function of the kidneys is imperfectly performed. There are many diseased states, moreover, in which there appears to be a special determination of the *materies morbi* to the skin; and in which, therefore, the use of means that promote the cutaneous excretion constitutes the most efficient method of eliminating them from the blood.¹

CHAPTER XIII.

EVOLUTION OF HEAT, LIGHT, AND ELECTRICITY.

1.—General Considerations.

649. THE series of Nutritive operations which has now been passed in review has been shown to consist in the continual appropriation, by the Animal organism, of certain "organic compounds" or "alimentary materials," which have been generated for its use by Plants; and in the constant restoration of their elements to the Inorganic world, either in the very same forms of combination in which they originally existed there, or as products of incipient decay, by whose further decomposition those simple binary compounds will be reproduced. And thus, so far as the material components of the Organic Creation are concerned, the agency of Vegetable life is concerned in withdrawing them from the Mineral world, and that of Animal life in returning them to it, after they have served their purpose in the living structure. But if we examine into the source of those active powers or "forces," on whose operation every change, no less in the organized body than in what is commonly designated as "inert" matter, is dependent, we shall find that they are all traceable to the solar radiations. It is by the action of the Light and Heat of the Sun upon the Vegetable germ, that it is enabled to exercise its wonderful transforming capacity, whereby it extracts carbon, hydrogen, nitrogen, and oxygen from the carbonic acid, water, and ammonia furnished by the atmosphere or the soil; and that it converts these into the albuminous, saccharine, and oleaginous compounds, which are the destined food of Animals. And it is under the influence of Heat chiefly derived from the same source, that the greater number of tribes of Animals are enabled to apply these compounds to the purposes of organization; and that, through the peculiar instruments thus constructed, those various kinds of *Vital force* are evolved, whose operations are so different from any which we witness in the Inorganic world. Accordingly, we observe that the "rate of life" in this larger proportion of the Animal kingdom is regulated, as in Plants, by the amount of Heat supplied to the organism from external sources; and that, when the ex-

¹ The practical value of active diaphoresis in many febrile diseases is well understood by the native practitioners among the Negroes of the Guinea Coast; who, according to Dr. Daniell (*Medical Topography, and Native Diseases of the Gulf of Guinea*, pp. 119-20) make use of it most successfully in the treatment of adynamic remittent fevers. Dr. Daniell states that having himself had abundant experience of its efficacy, he has no doubt of its superiority in these cases to the ordinary practice of venesection, saline purgatives, large doses of calomel, &c. And he has repeatedly stated that one great secret of preserving health in tropical climates lies in due attention to the cutaneous functions.

ternal temperature is reduced below a certain point, there is an entire cessation of all vital activity.¹ But there are certain tribes, especially Birds and Mammals, which possess the power of generating *Heat* within themselves, to such a degree as to render the rate of their vital processes almost entirely independent of external influences; and there is probably no one species that can exercise this power more effectually, and through a greater range of external conditions, than Man is able to do. Of this we shall presently have evidence. The evolution of *Light*, again, is by no means an unusual phenomenon among the lower tribes of Animals; but where it does occur, it usually appears to have some special purpose, as is obvious enough in the case of the glowworm and other luminous Insects. But the luminosity which is occasionally exhibited in Man must be regarded as an altogether abnormal phenomenon, whose physiological interest arises out of the peculiarity of the circumstances under which it presents itself. Of the degree in which *Electricity* is generated in the living body, we know comparatively little. There is strong evidence that a disturbance of Electric polarity must take place in every action of Organic as well as of Inorganic Chemistry; and thus that every molecular change in the Animal as well as in the Vegetable organism must involve an alteration in its electric condition. But it would seem that in the Animal body generally, these alterations are made to balance each other so exactly, that no considerable disturbance of the electric equilibrium ordinarily takes place in the organism as a whole; and it is only in certain peculiar cases (as in the Electric Fishes) that a provision exists for the generation of Electricity in considerable amount and intensity, with a view to some special purpose. In the Human subject, however, an extraordinary production of free Electricity, as of Light, occasionally presents itself; and this, taken in connection with other evidence, would seem rather to indicate a departure from the usual balance between the opposite electrical changes continually taking place, than to be due to the introduction of any extraordinary sources of electric disturbance.²

2.—*Evolution of Heat.*

650. All the vital actions of the body of Man, as of that of "warm-blooded" animals generally, require an elevated temperature as a condition of their performance; and the high degree of constancy and regularity which is observable in these actions appears to depend in great degree upon the provision which the organism contains within itself for the maintenance of that temperature at a fixed standard. This constancy and regularity are most remarkably exhibited in the various *periodical* changes to which the body is subject both in health and disease; the uniformity of whose recurrence is due to a corresponding uniformity in the rate of vital action taking place in the interval. Thus, as will be shown hereafter, the period of parturition is in great degree determined by the maturation of the foetal structures; and the uniformity of the time which this requires (like the corresponding uniformity in the period of development in the embryo bird) may be fairly attributed to the regularity of the supply of Heat, which is the power that especially determines the formative operations. For the periods of all similar phenomena in "cold-blooded" animals, which have no power of maintaining an independent temperature, exhibit no such uniformity;

¹ See "Princ. of Phys., Gen. and Comp.," CHAP. III. Sect. 3, *Am. Ed.*

² Having recently had an opportunity of witnessing some of the experiments made by M. Du Bois Reymond with a magneto-electrometer of extraordinary sensitiveness, the Author can bear his personal testimony to the fact, that the electricity even of the corresponding fingers of the two hands is very seldom equally balanced, and that the existence of even the slightest scratch or abrasion of surface upon one of them produces a very marked disturbance.

being entirely dependent (as in Plants) upon the degree of *external* warmth to which their bodies are subjected. We shall now inquire, in the first place, into the amount of Heat thus generated by Man; and then into the sources of its production.

651. Our present knowledge of the ordinary Temperature of the Human body under different circumstances is chiefly due to the investigations of Dr. J. Davy.¹—The first series of his observations included 114 individuals of both sexes, of different ages, and among various races, in different latitudes, and under various temperatures; the external temperature, however, was in no instance very low, and the variations were by no means extreme. The mean of the ages of all the individuals was 27 years. The following is a general statement of the results, the temperature of the body having been ascertained by a thermometer placed under the tongue:—

Temperature of the air	60°	Average temperature of the body	98.28°
“ “	69°	“ “ “	98.15°
“ “	78°	“ “ “	98.85°
“ “	79.5°	“ “ “	99.21°
“ “	80°	“ “ “	99.67°
“ “	82°	“ “ “	99.9°
Mean of all the experiments	74°	Mean of all the experiments	100°
Highest temperature of air	82°	Highest temperature of body	102°
Lowest temperature of air	60°	Lowest temperature of body	96.5°

From this we see that the variations noted by Dr. Davy, which were evidently in part the consequence of variations in external temperature, but which were also partly attributable to individual peculiarities, amounted to $5\frac{1}{2}$ degrees; the lower extreme might be found to undergo still further depression, if the inquiries were carried on in very cold climates.—Dr. Davy's subsequent inquiries have been directed to the determination of the various influences which tend to produce a departure from the average; and it will be advantageous to present his results in a systematized form, in combination with those of other observers. The most important of these variations seem to be those dependent upon Age, Period of the Day, Exercise or Repose, Ingestion of Food or Drink, and External Temperature.

a. The temperature of *Infants*, according to the observations of Dr. Davy, M. Roger,² and of Dr. G. C. Holland,³ is somewhat higher than that of adults,⁴ provided that they are placed in conditions favorable to its sustenance; but, as will be shown hereafter, infants and young children are very inferior to adults in their power of resisting the depressing influence of external cold (§ 664). Their temperature, when examined immediately after birth by a thermometer in the axilla, is nearly 100°; but it quickly falls to about 95.5°, and gradually rises in the course of the next twenty-four hours to about 97.7° in weakly subjects, and to 99.5° in strong infants. Between four months and six years of age, M. Roger found the average temperature to be 98.9°; and between six and fourteen years of age, 99.16°.—The temperature of *aged* persons, from the observations of Dr. J. Davy, does not seem to be below that of persons in the vigor of life, provided that there be no external depressing influences: but they

¹ See his successive Memoirs in the “Philosophical Transactions” for 1814 (republished in Dr. D.'s “Anatomical and Physiological Researches”), 1844, 1845, and 1850.

² “Archiv. Gén. de Méd.,” 1844.

³ “Inquiry into the Laws of Life,” 1829.

⁴ Dr. W. F. Edwards (“On the Influence of Physical Agents on Life,” p. 115) gives as the result of his observations, which were only ten in number, that the temperature of infants is lower than that stated above; but it is obvious that these observations were made during the period of depression which occurs in the first days, whilst the respiratory function is becoming established.

seem, like infants and young children, to have less power of resisting external cold, the temperature of their bodies being more easily and considerably reduced by it than is that of adults; and hence probably it has happened, that popular opinion assigns to them an habitually inferior temperature.

b. A slight *diurnal* variation in the temperature of the body appears usually to take place, quite irrespectively of external heat or cold; but this does not seem to be very constant either in its period or its degree, and is seldom very considerable. Thus Dr. Davy found, from a long series of observations carried on upon himself whilst in England, that the body was warmest in the morning, and coldest at night; whilst the reverse was the case in Barbadoes. The following table gives his average results:—

Mean temperature under the tongue.				Temperature of Room.		
England	{ 7-8 A. M. 98.74°	2-4 P. M. 98.52°	12 P. M. 97.92°	7-8 A. M. 50.9°	2-4 P. M. 54.7°	12 P. M. 62°
Barbadoes	{ 6-7 A. M. 98.07°	12-2 P. M. 98.9°	9-11 P. M. 99°	6-7 A. M. 76.7°	12-2 P. M. 83.6°	9-11 P. M. 79°

From the observations of M. Chossat on Birds, in which the diurnal variation amounts to $1\frac{1}{2}$ Fahr., it seems that the maximum is pretty constantly at noon, and the minimum near midnight; and this corresponds well with what has already been pointed out, with regard to the relative activity of respiration at different periods of the twenty-four hours (§ 564, i). Probably there is a less capacity for generating heat during the night; so that, if the body be insufficiently protected by clothing, or be exposed to a low degree of external temperature, its own temperature will be more readily lowered: and thus the minimum of the whole day may come to present itself at this part of it, in a temperate climate; whilst in a tropical climate, the light bed-covering and free circulation of air usual in the sleeping-room, together with the depressing influence of repose, would tend to render the early morning temperature the lowest.

c. That an increase in the heat of the body is produced by *exercise*, and that repose tends to its reduction, is a matter of familiar experience; but the observations of Dr. Davy show that there is scarcely any perceptible difference in the heat of the deep-seated parts, the augmentation and depression being confined to the extremities. Thus, on one occasion recorded by him, the temperature of the air of the room before walking being 60°, that of the feet (the thermometer being placed between the toes) being only 66°, that of the thermometer under the tongue being 98°, and that of the urine 100°—the temperature after a walk in the open air at 40°, the exercise having diffused a feeling of gentle warmth through the body, was 96.5° in the feet, 97° in the hands, 98° under the tongue, and 101° in the urine. So on another occasion, the temperature having been 66° in the room, 75° in the feet, 81° in the hands, 98° under the tongue, and 100° in the urine—after a walk in air at 50°, the temperature was 99° in the feet, 98° in the hands, 98° under the tongue, and 101.5° in the urine.

d. The influence of *ingestion of food* upon the temperature of the body has not yet been duly investigated. Common experience leads to the conclusion, that after a meal, as after exercise, there is a greater warmth in the extremities; but Dr. Davy's observations show that, in his own case, whilst in England, there was usually an appreciable depression immediately after dinner, though in Barbadoes the effect of a moderate meal was to produce an elevation. In both cases, however, Dr. D. observed that the ingestion of *wine* has a positively depressing influence on the temperature of the body, which increases with the quantity taken; and it may have been the constant employment of wine

with his dinner which was the real cause of the depression observed in England.¹

e. The influence of *external temperature* is sufficiently apparent in the observations already cited; for although external cold may act in a different degree on different individuals, according to their respective ages, powers of resistance, &c., yet there is ample proof that on the whole a continued exposure to it reduces the temperature of the body somewhat below its ordinary standard, whilst continued exposure to heat occasions a slight elevation in the temperature of the body. The influence of cold is, of course, most powerfully exerted when the body is at rest; and under such circumstances Dr. Davy found the temperature of his own body to be reduced, on an average of four observations, to 96.7° , the average temperature of the surrounding air having been 37° . On comparing the bodily temperature of different individuals working in rooms of various temperatures in the same factory, Dr. Davy found the tongue-thermometer rise to 100° in one man, and to 100.5° in another, who had been working for some hours in a room at 92° ; whilst it was 99° in a young woman who worked in a room at 73° , and only 97.5° in another who worked in a temperature of 60° . The effects of seasonal change are less marked in Man than they are in the lower animals, which are more exposed to extremes of temperature; but it seems principally exerted in modifying the heat-producing power. For it has been shown by Dr. W. F. Edwards (Op. cit.), that warm-blooded animals are more speedily killed by extreme cold in summer than in winter; and it seems probable, therefore, that we are partly to attribute the peculiar chilling influence of a cold day in summer, and the oppressiveness of a warm day in winter, to the seasonal change in the body itself; although the effect is doubtless referable in part to the effect of contrast upon our own feelings.

652. The usual Temperature of the body occasionally undergoes considerable alteration in *disease*; and this in the way either of increase or of diminution. Thus in maladies which involve an acceleration of pulse and a quickening of the respiration, the temperature is generally higher than usual, even though a large portion of the lung may be unfit for its function. This is often remarkably seen in the last stages of phthisis, when the inspirations are extremely rapid, and the pulse so quick as scarcely to admit of being counted; the skin, in such cases, often becomes almost painfully hot. On the other hand, in diseases of the contrary character, such as "*morbis cceruleus*," asthma, and cholera, the temperature of the body falls; a reduction to 78° having been noticed in the former maladies, and to 67° in the latter. The range observed by M. Andral in diseases which less affected the calorifying function, was from 95° to 107.6° ; and by M. Roger (loc. cit.), in diseases of children, from 74.3 to 108.5. Prof. Dunglison² speaks of having seen the thermometer at 106° in scarlatina and typhus; and Dr. Francis Home³ found it to stand at 104° in two individuals in the cold stage of an intermittent, whilst it afterwards fell to 101° , and subsequently to 99° , during the sweating stage. Dr. Edwards mentions a case of tetanus, in which the temperature of the body rose to $110\frac{1}{2}^{\circ}$. The following

¹ This difference in effect noted by Dr. Davy, between a moderate quantity of wine taken with dinner in England and in Barbadoes, seems readily explicable by the fact that the presence of Alcohol in the blood diminishes for a time the energy of the proper combusive process (§ 264, *h*). For, when the temperature of the atmosphere is considerably below that of the body, this retardation of the combusive process occasioned by the wine will allow the heat of the body to be lowered by it, notwithstanding the tendency to increased activity of the circulation and respiration which the meal alone would exert. In a warm climate, on the other hand, the cooling influence of the external air would not be sufficient to produce this reduction in the temperature of the body, notwithstanding the retarding influence of the wine upon the combusive process.

² "Human Physiology," 7th edit., vol. ii. p. 225.

³ "Medical Facts and Experiments," London, 1759.

observations have been made on this subject by M. Donné:¹ in a case of puerperal fever, the pulse being 168, and the respiration 48 per minute, the temperature was 104°; in a case of hypertrophy of the heart, the pulse being 150 and the respirations 34, the temperature was 103°; in a case of typhoid fever, the pulse being 136, and the respirations 50, the temperature was 104°; and in a case of phthisis, the pulse being 140, and the respirations 62, the temperature was 102°; on the other hand, in a case of jaundice, in which the pulse was but 52, the temperature was only 96.40°; but the same temperature was observed in a case of diabetes, in which the pulse was 84. These limited observations, whilst they clearly indicate that a *general* relation exists between the temperature of the body and the rapidity of the pulse, also show that this relation is by no means invariable, but that it is liable to be affected by several causes, of which our knowledge is as yet very limited.—It is not a little remarkable that the temperature of the body should sometimes rise considerably after death; and this not merely in such diseases as Cholera, in which it has undergone an extreme depression during the latter part of life; but even in the case of febrile disorders, in which the temperature during life has been above the usual standard. This has been ascertained by Dr. Bennett Dowler² of New Orleans, on the bodies of those yellow-fever subjects which have already been referred to as exhibiting a remarkable degree of *molecular* life after *somatic* death (§§ 328, 552). In one case, for example, the highest temperature during life was in the axilla, 104°; ten minutes after death it had risen to 109° in the axilla; fifteen minutes afterwards it was 113° in an incision in the thigh; in twenty minutes the liver gave 112°; in one hour and forty minutes, the heart gave 109°, and the thigh in the former incision 109°; and in three hours after the removal of all the viscera, a new incision in the thigh gave 110°. It is curious that the maximum of the heat observed after death should have been in the thigh, and the minimum in the brain; as is shown in the following table of the highest amount of temperature noted in eight different regions in five subjects:—

Thigh.	Epigastrium.	Axilla.	Chest.	Heart.	Brain.	Rectum.	Liver.
113°	111°	109°	107°	109°	102°	111°	112°
109°	110°	109°	106.5°	106°	101°	109°	109°
109°	109°	108°	106°	105°	101°	107°	108°
109°	109°	108°	106°	104°	100°	107°	107°
108°	109°	107°	105°	104°	99°	106°	106°
Mean 109.6°	109.6°	108.2°	106.1°	105.6°	100.6°	108°	108.4°

653. Although there appears to be, for all species of animals, a distinct limit to the variations of bodily temperature, under which their vital operations can be carried on, this limitation does not prevent animals from existing in the midst of great diversities of external conditions; since they have within themselves the power of compensating for these, in a very extraordinary degree. This power seems to exist in Man to a higher amount than in most other animals; since he cannot only support but enjoy life, under extremes, of which either would be fatal to many. In many parts of the tropical zone, the thermometer rises every day, through a large portion of the year, to 110°; and in British India it is said to be seen occasionally at 130°. On the other hand, the degree of cold frequently sustained by Arctic voyagers, and quite endurable under proper precautions, appears much more astonishing; by Captain Parry, the thermometer has been seen as low as —55°, or 87° below the freezing point; by Captain Franklin at —58°, or 90° below the freezing point; and

² "Western Journal of Medicine and Surgery," June and Oct., 1844; cited in "Philadelphia Medical Examiner," June, 1845, and in Prof. Dunglison's "Human Physiology," 7th edit., vol. ii. p. 718.

by Captain Back at -70° , or 102° below the freezing point. In both cases, the effect of the atmospheric temperature on the body is greatly influenced by the condition of the air as to motion or rest; thus, every one has heard of the almost unbearable oppressiveness of the "sirocco," or hot wind of Sicily and Italy, the actual temperature of which is not higher than has often been experienced without any great discomfort, when the air is calm: and, on the other side, it may be mentioned that, in the experience of many Arctic voyagers, a temperature of -50° may be sustained, when the air is perfectly still, with less inconvenience than is caused by air in motion at a temperature fifty degrees higher.¹ This is quite conformable to what might be anticipated on physical principles.

654. Again, the degree of moisture contained in a heated atmosphere makes a great difference in the degree of elevation of temperature, which may be sustained without inconvenience. Many instances are on record, of a heat of from 250° to 280° being endured in dry air for a considerable length of time, even by persons unaccustomed to a particularly high temperature; and persons whose occupations are such as to require it can sustain a much higher degree of heat, though not perhaps for any long period. The workmen of the late Sir F. Chantrey were accustomed to enter a furnace in which his moulds were dried, whilst the floor was red-hot, and a thermometer in the air stood at 350° ; and Chabert, the "Fire-king," was in the habit of entering an oven whose temperature was from 400° to 600° .² It is possible that these feats might be easily matched by many workmen who are habitually exposed to high temperatures; such as those employed in Iron-foundries, Glass-houses, and Gas-works. In all these instances, the dryness of the air facilitates the rapidity of the vaporization of the fluid, whose secretion by the Cutaneous glandulæ is promoted by heat applied to the surface; and the large amount of caloric which is consumed in this change is for the most part withdrawn from the body, the temperature of which is thus kept down. Exposure to a very elevated temperature, however, if continued for a sufficient length of time, does produce a certain elevation of that of the body; as might be expected from the statements already made, in regard to the variation in the heat of the body with changes in atmospheric temperature (§ 651). In the experiments of MM. Berger and Delaroche,³ it was found that, after the body had been exposed to air of 120° during 17 minutes, a thermometer placed in the mouth rose nearly 7° above the ordinary temperature; it may be remarked, however, that, as the body was immersed in

¹ The Author has been informed by Sir John Richardson, that in his last Arctic Expedition, whilst at winter quarters, he was accustomed to go from his sitting-room, to the magnetic observatory at a short distance (about an ordinary street's breadth), without feeling it necessary even to put on a great-coat; although the temperature of the former was about 50° , and that of the air through which he had to pass to the latter was -50° , the difference being 100° . This immunity from chilling influence was chiefly attributable to the *dryness* and *stillness* of the atmosphere; but it is worthy of note that Sir J. R. and the whole of his party on this expedition, abstained entirely from alcoholic liquors; and the Author has received his personal assurance, that his experience on this occasion fully bore out his previous conviction, that continued severe cold is *much better* borne without recourse to these liquors, than under the employment of them.

² The wonderful feats performed by many individuals from time to time—of dipping the hand into melted lead, laying hold of a red-hot iron, &c.—have been recently shown by M. de Boutigny to be explicable upon very simple principles. For in all such cases, a thin film of aqueous fluid in the "spherical state" intervenes between the skin and the heated surface; and a hand which is naturally damp, or which has been slightly moistened, may be safely passed into the stream of molten iron as it flows from the furnace; as was demonstrated by M. de Boutigny at the recent meeting of the British Association at Ipswich (1851).

³ "Expériences sur les Effets qu'une forte Chaleur produit sur l'Economie;" Paris, 1805: and "Journal de Physique," tomes lxiii., lxxi., et lxxvii.

a close box, from which the head projected (in order to avoid the direct influence of the heated air on the temperature of the mouth), the air had probably become charged with the vapor exhaled from the surface, and had, therefore, somewhat of the effects of a moist atmosphere. At any rate, the temperature of the body does not appear to rise, under any circumstances, to a degree very much greater than this. In one of the experiments of Drs. Fordyce and Blagden,¹ the temperature of a Dog, that had been shut up for half an hour in a chamber of which the temperature was between 220° and 236°, was found to have risen from 101° to about 108°. MM. Delaroche and Berger tried several experiments on different species of animals, in order to ascertain the highest temperature to which the body could be raised without the destruction of life, by inclosing them in air heated from 122° to 201°, until they died: the result was very uniform, the temperature of the body at the end of the experiment only varying in the different species between 11° and 13° above their natural standard: whence it may be inferred that an elevation to this degree must be fatal. This elevation would be attained comparatively soon in a moist atmosphere; partly because of the greater conducting power of the medium; but principally on account of the check which is put upon the vaporization of the fluid secreted by the skin. Even here, however, custom and acquired constitution have a very striking influence; for whilst the inhabitants of this country are unable to sustain, during more than 10 or 12 minutes, immersion in a vapor-bath of the temperature of 110° or 120°, the Finnish peasantry remain for half an hour or more in a vapor-bath the temperature of which finally rises even to 158° or 167°.—Accurate experiments are yet wanting to determine the influence of humidity on the effects of cold air. From experiments on young Birds incapable of maintaining their own temperature, of which some were placed in cold dry air, and others in cold air charged with moisture, it was found by Dr. Edwards that the loss of heat was in both instances the same; the effect of the evaporation from the surface in the former case being counterbalanced in the latter by the depressing influence of the cold moisture. This influence, the existence of which is a matter of ordinary experience, is probably exerted directly upon the nervous system.

655. Having thus considered the general facts which indicate the faculty possessed by the living system, in the higher Animals, of keeping up its temperature to an elevated standard, and of preventing it from being raised much beyond it by any degree of external heat, we have next to inquire to what this faculty is due.—In forming an opinion upon this point, it is of fundamental importance to bear in mind that the production of Heat is not peculiar to Animals, but is exhibited also by Plants, in parts in which certain vital operations that involve the production of carbonic acid, are taking place with unusual rapidity, and under circumstances which tend to prevent the dissipation of the heat thus generated. This is pre-eminently the case during the periods of germination and flowering; as may be seen in the act of malting, where a number of germinating seeds being heaped together, the thermometer in the midst of them has been observed to rise to 110°; whilst during the flowering of the Arum tribe, whose blossoms are crowded together on spadixes, and these are inclosed in protective spathes, a thermometer placed in the midst of twelve spadixes has been seen to rise to 121°, the temperature of the surrounding air being only 66°.² In all such cases, the elevation of temperature is found to be a very constant ratio to the amount of carbonic acid which is produced by the union of atmospheric oxygen with carbon set free from the vegetable tissues;³

¹ "Philosophical Transactions," 1775.

² See "Princ. of Phys., Gen. and Comp.," §§ 615, 616, *Am. Ed.*

³ This has been made yet more certain by the recent observations of M. Garreau ("Ann. des Sci. Nat.," 3me série, Botan., tom. xvi. p. 250), who has noted the temperature of

so that it is scarcely possible to entertain a reasonable doubt, that the production of Heat in Plants is dependent upon a process of slow combustion.—When the general phenomena of Calorification in Animals are carefully examined, they are found to harmonize with this view. Throughout the whole kingdom, a close and exact conformity may be perceived between the amount of Oxygen consumed and of Carbonic acid given off, and the degree of Heat liberated. In the cold-blooded animals, whose temperature is almost entirely dependent upon that of the surrounding element, the respiration is feeble; being carried on, for the most part, through the medium of water. In the warm-blooded Vertebrata, however, which have the power of keeping up the heat of their bodies to an elevated standard, even when that of the surrounding air is far beneath it, the quantity of oxygen consumed is very large; and that required by Birds is more, in proportion to their size, than that employed by Mammalia, as we should expect from the more elevated temperature of the former. In the class of Insects, we have a very remarkable illustration of the same general fact. It appears, from the researches of Mr. Newport,¹ that Insects, during their larva and pupa states, and even in their perfect condition when at rest, are to be regarded as truly cold-blooded animals; their temperature rising and falling with that of the surrounding medium, and being at no time more than a degree or two above it. In a state of activity, however, the temperature of the body attains a considerable elevation; frequently as much as 10° or 15° above that of the air. It must be remembered that, owing to their larger extent of surface in proportion to their bulk, small animals are cooled much more rapidly than large ones; and the temperature of insects would probably rise much higher, if it were not for the loss they are thus continually experiencing, which is greatly increased by the action of the wings. In one of Mr. N.'s experiments, a single Humble-bee, in a state of violent excitement, communicated to three cubic inches of air as much as 4° of heat within five minutes; its own temperature being raised 7° in the same time. When several individuals in a state of excitement, however, are clustered together, so that the loss of heat is prevented, the elevation of temperature is much more considerable; thus, a thermometer introduced among seven “nursing-bees” stood at 92½°, whilst the external air was only 70°; and the temperature of a hive was raised by disturbing it, during winter, from 48½° to 102°, the temperature of the air being only 34½° at the time.—In all these instances, the amount of Oxygen consumed bears an exact proportion to that of the Heat evolved.

these spadixes, hour by hour, during the “paroxysm” of flowering, and the quantity of oxygen consumed during the same periods, with the following result; the amount of heat developed being expressed by the number of degrees (Cent.) shown by the thermometer above the temperature of the surrounding air, and the quantity of oxygen consumed being stated in multiples of the volume of each spadix.

	No. 1.		No. 2.		No. 3.	
	Heat produced.	Oxygen consumed.	Heat produced.	Oxygen consumed.	Heat produced.	Oxygen consumed.
1st hour	3.2	1.11	4.2	16.5	3.5	10.0

¹ “Philosophical Transactions,” 1837.

656. We have seen that in Man, as in the lower animals, exercise has a considerable though a more limited effect in producing an elevation of temperature; and that this is not merely due to the acceleration of the circulation is shown by the fact that the exercise of a particular muscle will cause an increase in the heat liberated from it (§ 330).¹ It may be stated as a general fact, that every change in the condition of the organic components of the body, in which their elements enter into new combinations with oxygen, must be a source of the development of Heat. And as we have seen that a considerable part of the carbonic acid and water which are exhaled in Respiration, is formed within the body by the metamorphosis of its own tissues, and that this metamorphosis is promoted by the active exercise of the nervo-muscular apparatus, it follows that in animals whose habits of life are peculiarly active, whilst the temperature of the surrounding medium is sufficiently high to prevent its exerting any considerable cooling influence over them, the combusive process thus maintained may be adequate for the maintenance of the temperature of the body at its normal standard. This seems to be the case with the great Carnivorous quadrupeds of warm climates, and with certain races of Men who lead a life of incessant activity like theirs. But whenever the cooling influence of the atmosphere is greater, or the retrograde metamorphosis of tissue takes place with less activity, some further supply of heat-producing material is required; and this is derived either directly from the food, or from a store previously laid up in the body. Although the albuminous and gelatinous components of the food may be made, by decomposition within the body, to yield saccharine and oleaginous compounds, which serve as an immediate *pabulum* to the combusive process, yet this metamorphosis involves a great waste of valuable nutritive material; and the needed supply is much more advantageously derived at once from those farinaceous or oleaginous substances which are furnished in abundance by the Vegetable kingdom, the latter also by the Animal. No reasonable doubt can any longer be entertained, that the production of Heat by the combusive process is the purpose to which these substances are destined to be subservient in the bodies of Herbivorous animals and of Man; and the results of experience in regard to their relative heat-producing powers are in precise accordance with the indications afforded by their chemical composition (§ 401).

657. Our knowledge of the dependence of all the vital processes in warm-blooded animals upon the Heat of their bodies, and of the dependence of their calorifying power upon the due supply of material for the combusive process, has received some remarkable additions from the experiments of M. Chossat upon Starvation.² He found that Birds, when totally deprived of food and drink, suffered a progressive, though slight, daily diminution of temperature. This diminution was not so much shown by a fall of their maximum heat, as by an increase in the diurnal variation, which he ascertained to occur even in the normal state (§ 651, *b*). The average variation in the *inanitiated* state was about 6° (instead of $1\frac{1}{2}^{\circ}$), gradually increasing as the animal became weaker; moreover, the gradual rise of temperature, which should have taken place between midnight and noon, was retarded; whilst the fall subsequently to noon commenced much earlier than in the healthy state; so that the *average* of the whole day was lowered by about $4\frac{1}{2}^{\circ}$ between the *first* and the *penultimate* days of this

¹ It was affirmed by Dr. Granville ("Phil. Trans.," 1825) that the temperature of the uterus during parturition sometimes rises as high as 120° . In some observations made at the Philadelphia Hospital, however, at the desire of Prof. Dunglison, the temperature of the uterus was not found to be much above that of the vagina; the former being, in three cases, 100° , 102° , and 100° , whilst the latter was 100° , 100° , and 105° . (Prof. Dunglison's "Human Physiology," 7th edit., vol. ii. p. 226.)

² "Recherches Expérimentales sur l'Inanition," Paris, 1843; an analysis of this work will be found in the "Brit. and For. Med. Rev.," April, 1844.

condition. On the *last* day, the production of heat diminished very rapidly, and the thermometer fell from hour to hour, until death supervened; the whole loss on that day being about 25° Fahr., making the *total* depression about $29\frac{1}{2}^{\circ}$. This depression appears, from the considerations to be presently stated, to be the *immediate* cause of Death. On examining the amount of loss sustained by the different organs of the body, it was found that 93 per cent. of the *Fat* had disappeared; being all, in fact, which *could* be removed; whilst the nervous centres scarcely exhibited any diminution in weight (§ 416). From the constant coincidence between the entire consumption of the fat, and the depression of temperature—joined to the fact that the duration of life under the inanitiating process evidently varied (other things being equal) with the amount of fat previously accumulated in the body—the inference seems irresistible, that the calorifying process depended chiefly, if not entirely, on the materials supplied by this substance. Whenever, therefore, the store of combustible matter in the system was exhausted, the inanitated animals died, by the cooling of their bodies consequent upon the loss of calorifying power.

658. That this is the real explanation of the fact is shown by the results of a series of very remarkable experiments performed by M. Chossat, with the purpose of testing the correctness of this view. When inanitated animals whose death seemed impending (in several instances death actually took place, whilst the preliminary processes of weighing, the application of the thermometer, &c., were being performed), were subjected to artificial heat, they were almost uniformly restored from a state of insensibility and want of muscular power to a condition of comparative activity; their temperature rose, their muscular power returned, they flew about the room and took food when it was presented to them; and if the artificial assistance was sufficiently prolonged, and they were not again subjected to the starving process, most of them recovered. If they were left to themselves too early, however, the digestive process was not performed, and they ultimately died. Up to the time when they began to take food, their weight continued to diminish; the secretions being renewed, under the influence of artificial heat, sometimes to a considerable amount. It was not until digestion had actually taken place (which, owing to the weakened functional power, was commonly many hours subsequently to the ingestion of the food), that the animal regained its power of generating heat; so that, if the external source of heat was withdrawn, the body at once cooled; and it was not until the quantity of food actually *digested* was sufficient to support the wants of the body, that its independent power of calorification returned. It is to be remembered that, in such cases, the resources of the body are on the point of being completely exhausted, when the attempt at re-animation is made; consequently it has nothing whatever to fall back upon; and the leaving it to itself *at any time* until fresh resources have been provided for it, is consequently as certain a cause of death, as it would have been in the first instance.

659. It can scarcely be questioned, from the similarity of the phenomena, that Inanitation, with its consequent depression of temperature, is the immediate cause of death in various diseases of Exhaustion: and it seems probable that there are many cases, in which the depressing cause is of a temporary nature, and in which a judicious and timely application of artificial heat might prolong life until it has passed off, just as artificial respiration is serviceable in cases of narcotic poisoning (§ 208). It is especially, perhaps, in those forms of Fever, in which no decided lesion can be discovered after death, that this view has the strongest claim to reception; and the beneficial result of the administration of Alcohol in such conditions, and the large amount in which it may be given with impunity, may probably be accounted for on this principle. That it acts as a specific stimulus to the nervous system, cannot be doubted from its effects on the healthy body; but that it serves as a *fuel* to keep up the calori-

fyng process, appears equally certain. Its great efficacy in such cases seems to depend upon the readiness with which it will be taken into the circulation by a simple act of endosmotic imbibition, when the special Absorbent process, dependent upon the peculiar powers of the cells of the villi (§ 461), are in abeyance. There is no other combustible fluid, whose miscibility and whose density, relatively to that of the Blood, will permit of its rapid absorption by the simple physical process adverted to.¹

660. That the oxidation of certain components of the food or of the tissues is the fundamental source of Animal Heat, is further indicated by the close conformity which we everywhere find between the activity of the Respiratory process and the amount of Heat which is generated; and this not merely when we compare different tribes of animals with each other, but also when we compare the amount of oxygen absorbed and of carbonic acid exhaled by the same individuals under different degrees of external temperature (§ 564, a). For we find that the system possesses within itself a regulating power, by which the combustive process is augmented in activity when the cooling influence of the surrounding medium is considerable, so that this influence is resisted; whilst the internal fire (so to speak) is slackened, whenever the temperature of the outer air rises so much, as to render the same generation of heat no longer requisite. The appetite for food, and especially for those particular forms of it which best afford the combustive pabulum, varies in the same degree; and thus, when supplied with appropriate nutriment, Man is able to brave the severest cold, without suffering any considerable depression in his bodily temperature. —It would seem that the Cutaneous Respiration, small as it is, promotes those molecular changes on which the maintenance of Animal Heat depends; for it was found by MM. Becquerel and Breschet,² that when the hair of Rabbits was shaved off, and a composition of glue, suet, and resin (forming a coating impermeable to the air) was applied to the whole surface, the temperature rapidly fell, notwithstanding the obstacle thus offered to the evaporation of the sweat, whereby, it might be supposed, the temperature of the body would be considerably elevated. In the first rabbit, which had a temperature of 100° before being shaved and plastered, it had fallen to 89½° by the time the material spread over him was dry. An hour after, the thermometer placed in the same parts (the muscles of the thigh and chest) had descended to 76°. In another rabbit, prepared with more care, by the time that the plaster was dry, the temperature of the body was not more than 5½° above that of the surrounding medium, which was at that time 69½°; and in an hour after this, the animal died.—These experiments place in a very striking point of view the importance of the cutaneous surface as a respiratory organ, even in the higher animals; and they enable us to understand how, when the secreting power of the lungs is nearly destroyed by disease, the heat of the body is kept up to its natural standard by the action of the Skin. A valuable therapeutic indication, also, is derivable from the knowledge which we thus gain, of the importance of the cutaneous respiration; for it leads us to perceive the desirableness of keeping the skin moist, in those febrile diseases in which there are great heat and dryness of the surface, since secretion cannot properly take place through a dry membrane. Of the relief afforded by cold or tepid sponging in such cases, experience has given ample evidence.

661. It has been held that the Chemical theory of Calorification is insufficient

¹ The Author has stated the very striking results of observations which he has had the opportunity of making upon this point, in his Prize Essay "On the Use and Abuse of Alcoholic Liquors," § 215, *Am. Ed.*

² "Comptes Rendus," Oct., 1841. These experiments have been repeated and confirmed by Magendie ("Gazette Médicale," Dec. 6, 1843).

to account for the total amount of Heat generated by a warm-blooded animal in a given time; this assertion being founded upon the experimental results obtained by M. Dulong. It has been shown by Prof. Liebig, however, that the estimates originally made require correction for the true calorific equivalents of carbon and hydrogen; and that, this correction having been made, the heat produced by the combustion of the Carbon which is contained in the carbonic acid expired, and by the combustion of such a proportion of the Hydrogen contained in the exhaled water as may be fairly considered to have undergone oxygenation within the system (§ 569), proves to be adequate to compensate for that which would be dissipated by the evaporation of all the water transpired from the skin and lungs, and also to maintain the temperature of the body itself in an atmosphere of ordinary coolness.¹ And to the combustion heat of carbon and hydrogen, we should also add that of those relatively minute quantities of Phosphorus and Sulphur, which also undergo oxidation within the system, whereby a small additional amount of heat must be generated.—Through whatever diversity of combinations or successive stages of oxidation these elements respectively pass, in their progress to complete or final oxidation, it may be regarded as an indisputable fact, that *they give out precisely the same amount of heat in the whole, as if they had undergone the most rapid combustion in pure oxygen*; and thus we may look to almost every molecular change in the body, although pre-eminently to those which are concerned in the *disintegration* of its textures and in the elimination of their products by Respiration, as participating in the function of Calorification.

662. It cannot be denied, however, that there are certain phenomena which seem at first sight to be completely opposed to this doctrine, and which can scarcely be explained in accordance with it, save by a considerable modification in our usual ideas. The class of facts to which reference is here made, are those which indicate that the Nervous system has a very important concern in the process, and that it is, in fact, one of the immediate instruments in the development of heat. Thus it was experimentally shown by Sir B. Brodie,² that when the Brain is cut off from the spinal cord, or its functions are suspended by the agency of a narcotic, and artificial respiration is practised, so that the circulation is maintained, the body not only loses heat rapidly, but may even cool *more rapidly* than the body of an animal similarly treated, but in which artificial respiration is not performed. Now it is certainly true, as was subsequently pointed out by Drs. Wilson Philip and Hastings,³ and by Dr. C. Williams,⁴ that the effect of the artificial performance of respiration depends in some degree upon the mode in which it is accomplished; for that if, as in most of Sir B. Brodie's experiments, the insufflation be repeated 30 times or more in a minute, the cooling effect of the air thus introduced is greater than the warming effect of the imperfect respiratory change to which it becomes subservient; whilst if the insufflation be repeated only 12 times in a minute, the cooling of the body, as compared with that of a body in which the circulation is not thus maintained, is retarded, instead of being accelerated. But still it is evident from Sir B. Brodie's experiments, that the withdrawal of the influence of the Encephalon has a positively depressing effect upon the Calorific function; for the rapid fall of temperature took place even in cases in which the amount of carbonic acid exhaled during the performance of artificial respiration, was fully equal to the normal quantity; and the subsequent experiments of MM.

⁴ "Edinb. Med.-Chir. Trans.," vol. ii. p. 192.

Le Gallois¹ and Chossat² are decidedly confirmatory of this conclusion, whilst they extend it to other lesions of the Nervous centres, the influence of which upon the calorific function appears to be proportional to their severity.—Various pathological phenomena, moreover, indicate that the withdrawal of nervous influence from any part of the body usually tends to produce a depression of its temperature, and this especially in the extremities; thus, Mr. H. Earle³ found the temperature of paralyzed limbs slightly lower than that of sound limbs; so Prof. Dunglison has noticed that in one case of hemiplegia of five months' standing, the temperature of the axilla was $96\frac{1}{2}^{\circ}$ on the sound side, and 96° on the paralyzed, whilst that of the hand was 87° on the sound side and only $79\frac{1}{2}^{\circ}$ on the paralyzed; and in another case of only a fortnight's duration, the temperature of the axilla was 100° on the sound side, and only $98\frac{1}{4}^{\circ}$ on the paralyzed, whilst that of the hand was 94° on the sound side, and 90° on the paralyzed.⁴ But it is a remarkable fact, that the disturbance of temperature produced by severe injuries of the Nervous system occasionally shows itself in the opposite direction. Thus, it has been noticed by many experimenters that one of the first effects of division of the spinal cord in the back, in warm-blooded animals, is to raise the temperature of the posterior part of the body, this elevation continuing for some hours. A case is recorded by Sir B. Brodie, in which, the spinal cord having been so seriously injured in the lower part of the cervical region that the whole of the nerves passing off below were completely paralyzed, the heat of the body, as shown by a thermometer placed on the inside of the groin, was not less than 111° ; and this notwithstanding that the respiratory function was very imperfectly performed, the number of inspirations being considerably reduced, and the countenance being livid.⁵ And Prof. Dunglison states that, notwithstanding the usual depression of the thermometer on the hemiplegic side, it is not unfrequently found to be more elevated than on the sound side.⁶ According to the recent experiments of M. Cl. Bernard,⁷ it appears that an elevation of temperature constantly takes place on one side of the face, when the trunk which unites the Sympathetic ganglia of the neck on that side is cut through; this increase being not only perceptible to the touch, but showing itself by a thermometer introduced into the nostrils or ears, even to the extent of from 7° to 11° Fahr. When the superior cervical ganglion is removed, the same effect is produced, but with yet greater intensity. This difference is maintained for many months, and is not connected with the occurrence of inflammation, congestion, œdema, or any other pathological change in the part; moreover, it is not prevented from manifesting itself by the division of any of the cerebro-spinal nerves of the face. It is remarkable that the sensibility of the parts thus affected should be no less augmented than their temperature.

[Dr. Brown-Sequard has observed the same remarkable phenomena as those detailed by M. Cl. Bernard, but he regards them as mere results of the paralysis, and of the consequent dilatation of the bloodvessels. In consequence of this dilatation, the blood reaches the part supplied by the nerve in larger quantities; the nutrition is therefore more active. The increased sensibility is a result of the augmented vital properties of the nerves when their nutrition is increased. Dr. Brown-Sequard has likewise noticed the increase of temperature of the ear over that of the rectum, to the amount of one or two degrees Fahr.; but it must be remembered that the temperature of the rectum is a little lower than that of the blood, and as the ear is gorged with that fluid, it

⁶ "Amer. Med. Intelligencer," Oct. 18, 1838. ⁷ "Gazette Médicale," Fevr. 21, 1852.

is easy to understand why it should possess its temperature. Many facts prove that the degree of temperature and sensibility in a part are in direct ratio with the amount of blood circulating in it.

If galvanism be applied to the superior portion of the sympathetic nerve after it has been cut in the neck, the vessels of the face and ear, after a short time, begin to contract, and subsequently resume their normal condition, if they do not even diminish. Coincidentally with this diminution, there is a decrease of the temperature and sensibility of the face and ear, until the palsied and sound side are alike in this respect.

When the galvanic current ceases to act, the vessels again dilate, and all the phenomena discovered by M. Bernard reappear. It hence appears that the only direct effect of section of the cervical portion of the sympathetic is the paralysis and consequent dilatation of the bloodvessels. Another deduction from these experiments is, that the sympathetic sends motor fibres to many of the bloodvessels of the head.¹

663. The influence which conditions of the Nervous System are thus shown to possess over the function of Calorification has led some Physiologists and even Chemists to the conclusion that the production of Heat is essentially dependent upon Nervous agency, of which it is one of the manifestations. But, as Prof. Liebig justly observes, "if this view exclude chemical action, or changes in the arrangement of the elementary particles, as a condition of nervous agency, it means nothing else than to derive the presence of motion, the manifestation of force, from nothing. But no force, no power, can come of nothing."² That the production of heat in living bodies may take place without any possible assistance from nervous agency, is manifest from the phenomena of Vegetable heat already referred to (655); and there can be no reasonable doubt, that the source of this production is a true combustive process. And the evidence afforded by the *post-mortem* production of heat in the Human subject (§ 652) conclusively points to the same result; more particularly as the elevation of temperature observed in the brain was uniformly *less* than that which was manifested in other large organs.—But the phenomena just enumerated (and many others that might be cited) can scarcely be accounted for, without admitting that the Nervous system exerts an important modifying power upon the temperature of the body, which may be either elevated or depressed through its agency; and the question now arises whether this operation takes place through the influence which the Nervous system exerts over the molecular processes of Nutrition, Secretion, &c., or through some more direct method. It can scarcely be denied that the first of these channels affords not merely a possible, but also a probable means, for the exercise of such influence; but still it is difficult to conceive that any great effect can be thus produced, since, as already shown, it is not so much in the growth as in the disintegration of textures, that heat is produced by the oxidation of their components. On the other hand, from the close relation which has been shown to exist between the Vital and Physical forces (CHAP. III. SECT. 2), it can scarcely be regarded as improbable that the Nervous force, generated by molecular changes in the Nervous substance, may manifest itself under the form of Heat, just as we know that it manifests itself (as in the Electric fishes) under that of Electricity.³ And thus it is quite conceivable that one mode in which alimentary materials may be applied to the maintenance of Animal Heat, may consist in their subservience to these molecular changes, which seem to take place in the Nervous substance with more activity than in any other tissue; and thus a large measure of caloric may be

¹ Vide Phil. Med. Exam., N. S., vol. viii. No. viii., August, 1852.

² "Animal Chemistry," 3d edit., p. 39.

³ See "Princ. of Phys., Gen. and Comp.," §§ 635-639, *Am. Ed.*

generated through the immediate instrumentality of the Nervous system, notwithstanding that the ultimate source of its development lies (as in the Chemical theory) in the oxidation of the elements of the food.—Such an hypothesis will be found consistent, the Author believes, with all the well-ascertained facts of the case; for whilst it assigns their full value to all those proofs, which establish (in his mind) the necessary dependence of Calorification upon the changes to which the Respiration is subservient, and thus upon the supply of combustible material on the one hand, and of oxygen on the other, it also assigns a definite *modus operandi* to the Nervous system, as an instrument largely concerned in the production and distribution of the heat thus generated—this *modus operandi*, moreover, being in such complete harmony with the other manifestations of Nervous power, that its existence might almost have been predicated upon general considerations.¹

664. We have now to inquire whether the power of generating Heat is possessed by the Human subject in an equal degree at all ages; this question being very different from that of the usual temperature of the body at the various periods of life; since an individual who can maintain a high temperature when the surrounding air is moderately warm, may have very little power of bearing continued exposure to severe cold. Important analogical evidence on this point has been supplied by the experiments of Dr. W. F. Edwards upon the lower Mammalia, Birds, &c.² It appears from these to be a general fact that, the younger the animal, the less is its independent calorifying power. The development of the embryo of oviparous animals is entirely dependent upon the amount of external warmth supplied to it; and there are many kinds of Birds, which, at the time they issue from the egg, are so deficient in the power of generating heat, that their temperature rapidly falls when they are removed from the nest and placed in a cold atmosphere. It was shown by collateral experiments, that the loss of heat was not to be attributed to the absence of feathers, nor to the extent of surface exposed in comparison with the bulk of the body; and that nothing but an absolute deficiency in the power of generating it, would account for the fall of temperature. This is quite conformable to facts well ascertained in regard to Mammalia. The foetus, during intra-uterine life, has little power of keeping up its own temperature; and in many cases it is much dependent on external warmth, for some time after birth. The degree of this dependence, however, differs greatly in the various species of Mammalia, as among Birds; being less in proportion as the general development is advanced. Thus, young Guinea-pigs, which can run about and pick up food for themselves, almost as soon as they are born, are from the first independent of parental warmth; whilst, on the other hand, the young of Dogs, Cats, Rabbits, &c., which are born blind, and which do not, for a fortnight or more, acquire the same development with the preceding, rapidly lose their heat when withdrawn from contact with the body of the mother.—In the Human species, it is well known that external warmth is necessary for the Infant, its body rapidly losing heat when exposed to the chilling influence of a low temperature; but the fact is too often neglected (under the erroneous idea of hardening the constitution) during the early years of childhood. It is to be carefully remembered, that the development of Man is slower than that of any other animal, and that his calorifying power is closely connected with his general bodily vigor; and though the infant becomes more independent of it as development advances, it is many years before the standard can be maintained without assistance, throughout the ordinary vicissitudes of external temperature. Especial care is required with regard to the maintenance of the bodily heat by artificial warmth, in the case of children

¹ See the Author's Memoir "On the Mutual Relations of the Vital and Physical Forces," in "Phil. Trans." 1850.

² "On the Influence of Physical Agents on Life," Part iii. Chap. i.

prematurely born; for the earlier the period of embryonic life, the less is the power of calorification that exists for some time after birth. The temperature of a seven months' child, though well swathed and near a good fire, was found by Dr. W. Edwards, within two or three hours after its birth, to be no more than 89.6°. And in some of the recorded instances in which the birth has taken place before the completion of the sixth month, it has not been found possible to maintain the warmth of the infant by exposure to the radiant-heat of a fire, the contact of the warm body of another person being the only effectual means of keeping up its temperature.—The fullest measure of calorifying power is possessed by adults; but even in them it is sometimes weakened by previous exertion, so that death by the cooling of the body may occur when the body is exposed to cold of no great intensity, but in a state of exhaustion of nervous power; a fact which remarkably confirms the views advanced in the preceding paragraph. A decrease of calorifying power takes place in advanced age. Old people complain that their "blood is chill;" and they suffer greatly from exposure to cold, the temperature of the whole body being lowered by it. These facts have a very interesting connection with the results of statistical inquiries, as to the average number of deaths at different seasons; the following are recorded by M. Quetelet,¹ as occurring at Brussels, the *mean* monthly mortality at each age being reckoned as 100.

	First Month.	2—3 Years.	8—12 Years.	25—30 Years.	50—65 Years.	90 Years and above.
January	1.39	1.22	1.08	1.05	1.30	1.58
February	1.28	1.13	1.06	1.04	1.22	1.48
March	1.21	1.30	1.27	1.11	1.11	1.25
April	1.02	1.27	1.34	1.06	1.02	0.96
May	0.93	1.12	1.21	1.02	0.93	0.84
June	0.83	0.94	0.99	1.02	0.85	0.75
July	0.78	0.82	0.88	0.91	0.77	0.64
August	0.79	0.73	0.82	0.96	0.85	0.66
September	0.86	0.76	0.81	0.95	0.89	0.76
October	0.91	0.78	0.76	0.93	0.90	0.74
November	0.93	0.91	0.80	0.97	1.00	1.03
December	1.07	1.01	0.96	0.97	1.15	1.29

We see from this table that, during the first months of infant life, the external temperature has a very marked influence; for the average mortality during each of the three summer months being 80, that of January is nearly 140, and the average of February and March is 125. This is confirmed by the result obtained by MM. Villermé and Milne-Edwards in their researches on the mortality of the children conveyed to the Foundling Hospitals in the different towns in France; for they not only ascertained that the mortality is much the greatest during the first three months in the year, but also that it varies in different parts of the kingdom, according to the relative severity of the winter.² As childhood advances, however, the winter mortality diminishes, whilst that of the spring undergoes an increase; this is probably due to the greater prevalence of certain epidemics at the latter season; for the same condition is observed, in a

¹ "Essai de Physique Sociale," tom. i. p. 197.

² Dr. Emerson has shown that, in the Southern and Middle States of North America, the *high summer* temperature is the greatest cause of infant mortality; the proportion of deaths during the first year of childhood, occurring in the months of June, July, and August, being about *four* times greater than that occurring during the same months in any subsequent year up to the age of 20. The winter mortality under the second year scarcely exceeds the average of subsequent years. ("Amer. Journ. of Med. Sci.," Nov. 1831.)

still more remarkable degree, between the ages of 8 and 12 years—the time when children are most severely affected by such epidemics. As the constitution acquires greater vigor, and the bodily structure attains its full development, the influence of the season upon mortality becomes less apparent; so that, at the age of from 25 to 30 years, the difference between the summer and winter mortality is very slight. This difference reappears, however, in a very marked degree, at a later period, when the general vigor and the calorifying power undergo a gradual diminution. Between the ages of 50 and 65 it is nearly as great as in early infancy; and it gradually becomes more striking, until, at the age of 90 and upwards, the deaths in January are 158 for every 74 in July (a proportion of $2\frac{1}{2}$ to 1); and the average of the three winter months is 145, whilst that of the three summer months is only 68, or less than one-half.—The results of the comparisons which have now been carried out for many successive years, in the Reports of the Registrar-General, between the variations in the weekly rate of mortality in the metropolis and the range of atmospheric temperature, present a close coincidence with the foregoing: it being especially to be noted that the rate of mortality (save during the prevalence of any fatal epidemic) is almost invariably the highest during the winter months; that the increase of deaths at that period is most marked amongst children and old people; and that any extraordinary severity of winter cold constantly produces a great augmentation in the mortality, the weekly number of deaths rising from the average of 1000 (or thereabouts) to 1200, when the mean temperature of the twenty-four hours falls a degree or two lower than the freezing-point.

665. Having thus considered the means by which the degree of Heat necessary for the performance of the functions of the Human system is generated, we have to inquire how its temperature is prevented from being raised too high; in other words, what *frigorifying* means there are, to counterbalance the influence of causes which, in excess, would otherwise be fatal, by raising the heat of the body to an undue degree (§ 654). How is it, for example, that, when a person enters a room whose atmosphere is heated to one or two hundred degrees above his body, the latter does not partake of the elevation, even though exposed to the heat for some time? Or, since the inhabitants of a climate, where the thermometer averages 100° for many weeks together, are continually generating additional heat in their own bodies, how is it that this does not accumulate, and raise them to an undue elevation?—The means provided by Nature for cooling the body when necessary, are of the simplest possible character. From the whole of its soft moist surface, simple *Evaporation* will take place at all times, as from an inorganic body in the same circumstances; and the amount of this will be regulated merely by the condition of the atmosphere, as to warmth and dryness. The more readily watery vapor can be dissolved in atmospheric air, the more will be lost from the surface of the body in this manner. In cold weather, very little is thus carried off, even though the air be dry: and a warm atmosphere, already charged with dampness, will be nearly as ineffectual. But simple evaporation is not the chief means by which the temperature of the body is regulated. The Skin, as already mentioned (646), contains a large number of glandulæ, the office of which is to secrete an aqueous fluid; and the amount of this *Exhalation* appears to depend solely or chiefly upon the temperature of the surrounding air. Thus, when the external heat is very great, a considerable amount of fluid is transuded from the skin; and this, in evaporating, carries off a large quantity of the free caloric, which would otherwise raise the temperature of the body. If the atmosphere be hot and dry, and also be in motion, both exhalation and evaporation go on with great rapidity. If it be cold, both are checked, the former almost entirely so; but, if it be dry, some evaporation still continues. On the other hand, in a hot atmosphere, saturated with moisture, exhalation continues, though evaporation is almost entirely checked; and the

fluid poured out by the exhalant glands accumulates on the skin. There is reason to believe that the secretion continues, even when the body is immersed in water, provided its temperature be high.—We learn from these facts the great importance of not suddenly checking Exhalation, by exposure of the surface to cold, when the secretion is being actively performed; since a great disturbance of the circulation will be likely to ensue, similar to that which has been already mentioned, as occurring when other important secretions are suddenly suspended.

3.—*Evolution of Light.*

666. Although the evolution of Light from the living Human subject is an exceptional phenomenon, which has only been observed in morbid states of the body, yet its occasional occurrence is fraught with interest to the Physiologist, on the one hand from its relation to the Luminosity so common among the lower animals, and on the other from the indications which it affords of the possibility of the formation, even during life, of peculiar phosphuretted compounds, which, being products of incipient decomposition, have been usually supposed to be generated only after death.—There is no doubt that luminous exhalations frequently ascend from burial-grounds; and that the superstitions of many nations respecting “corpse-lights” have to this extent a foundation in fact. A very decided luminosity has been observed to proceed from dissecting-room subjects, the light thus evolved being sufficient to render the forms of the bodies, as well as those of muscles and other dissected parts (which are peculiarly bright), almost as distinct as in the day-light. That this proceeds from the production of a peculiar phosphorescent compound, is shown by the fact, that the luminosity may be communicated to the fingers, or to towels, &c., by contact with the luminous surfaces.¹—Dr. W. Stokes narrates the case of a patient who was under his observation, some years since, in the Old Meath Hospital, having been admitted on account of an enormous cancer in her breast, which was in an advanced stage of ulceration, the edges being irregular and everted; every part of the base and edges of this cavity was strongly phosphorescent, the light being sufficient to enable the figures on a watch-dial to be distinguished within a few inches; and here also it appeared that the luminosity was due to a particular exudation from the exposed surface. Three cases are recorded by Sir H. Marsh, in which an evolution of light took place from the living body, without any such obvious source of decomposition; all the subjects of these cases, however, were in the last stage of phthisis; and it cannot be doubted that here, as in other diseases of exhaustion, incipient disintegration was taking place during the later periods of life (§ 418). The light in each case is described as playing around the face, but not as directly proceeding from the surface; and in one of these instances, which was recorded by Dr. D. Donovan,² the luminous appearance was not only perceptible over the head of the patient’s bed, but luminous vapors passed in streams through the apartment. It can scarcely be doubted that it was here the *breath* which contained the luminous compound, more especially as in one of the cases it was observed to have a very peculiar smell; and the probability that the luminosity was due to the presence of phosphorus in progress of slow oxidation, is greatly increased by the fact already referred to (§ 570), that the injection of phosphuretted oil into the bloodvessels gives rise to a similar appearance. In repeating this experiment, Sir H. Marsh states that when half an ounce of olive oil, holding two

¹ See Sir Herbert Marsh on “The Evolution of Light from the Living Human Subject” (Dublin, 1842), p. 20.—From this interesting pamphlet, most of the statements in this paragraph are derived.

² “Dublin Medical Press,” Jan. 15, 1840.

grains of phosphorus in solution, was injected into the crural vein of a dog, a dense white vapor began to issue from the nostrils even before the syringe was completely emptied, which became faintly luminous on the removal of the lights: and, the injection being repeated with the same quantity, the expiration immediately became beautifully luminous, resembling jets of pale-colored flame pouring forth from the nostrils of the animal. And the luminosity which has been occasionally observed in the urine,¹ may fairly be imputed to an increase in the quantity of unoxidized phosphorus which it seems normally to contain; its liberation taking place at a more rapid rate than its conversion into phosphoric acid (§ 641), either through excessive excretion or through impeded respiration. A case has been recorded by Kaster (loc. cit.) in which the body-linen was rendered luminous by the perspiration after any violent exercise; and here, too, the cause may be presumed to have been the same.—On the whole, then, we may conclude the occasional evolution of Light from the Human subject to be the consequence (when not an *electrical* phenomenon) of the production of a phosphorescent compound at the expense of the disintegrating tissues; which compound passes off through one of the ordinary channels of excretion.

4.—*Evolution of Electricity.*

667. When the vast variety of changes of condition to which the components of the living body are subjected during the performance of its vital operations, and the impossibility of the occurrence of any of these without some disturbance of electric equilibrium,² are duly considered, the wonder is, not that such disturbance should be occasionally so considerable as to make itself apparent, but that it should be ordinarily so obscure as only to be detected by the most careful search, and with the assistance of the most delicate instruments.—The researches of Prof. Matteucci, M. du Bois-Reymond, and others, however, have now made it apparent, that there are no two parts of the body (save those which correspond on the opposite sides) whose electrical condition is precisely the same; and that the differences between them are greater in proportion to the diversity of the vital processes which are taking place in them, and to the activity with which these are being carried on. Thus, Donn found that the skin and most of the internal membranes are in opposite electrical states; and Matteucci observed a considerable deflection of the needle of a delicate galvanometer, when the liver and stomach of a rabbit were connected with its platinum electrodes.³ More recently, Mr. Baxter has found that if one of the electrodes be placed upon any part of the intestinal surface, and the other be inserted into

¹ "Casper's Wochenschrift," 1849, No. 15.—A case has been recently put on record (Bchner's Repert. B. viii. p. 342), in which the urine and semen of a patient who was under treatment for impotence and spermatorrhea, and who was employing phosphorus as a remedy both internally and externally, were observed to be luminous.

² There is probably no instance of *chemical union* or decomposition, in which the electric condition of the bodies concerned is not altered. Simple *change of form*, from solid to liquid, or from liquid to gaseous, is attended with electric disturbance; and this is greatly increased when any separation takes place between substances that were previously united, as when water containing a small quantity of saline matter is caused to evaporate and to leave it behind. *Heat*, again, is continually generating Electricity; for not only is a current produced by the heating of two dissimilar metals in contact, but also by the unequal heating of two parts of the same bar; and though the effect is most striking in the case of metals, it is by no means limited to them. And so constantly is Electricity generated by the retardation of *motion*, as in friction, that it is not possible to rub together any two substances, excepting such as are of the most perfect homogeneity (such as the fractured surfaces of a broken bar) without the production of electric change, as well as of heat.

³ See M. Becquerel's "Traite de l'Electricit," tom. i. p. 327, and tom. iv. p. 300.

the branch of the mesenteric vein proceeding from it, a decided deflection of the needle was produced, indicating a positive condition of the blood; but that no effect was produced when the second electrode was inserted into the artery of the part instead of into its vein. These effects were found to cease after the death of the animals; and could not be attributed, therefore, to mere chemical differences between the blood and the secreted product; but must have arisen from electric disturbance taking place in the very act of secretion.¹—That the process of Nutrition, as well as of Secretion, in parts which are undergoing rapid molecular change, gives rise to electric disturbance, is proved by the experiments of Matteucci and Du Bois-Reymond upon the relative electrical states of different parts of muscles and nerves. If the two extremities of a muscle, removed from the body of an animal very recently killed, be applied to the two electrodes of a delicate galvanometer, there is usually some deflection of the needle; this being greater in proportion to the difference in the arrangement of the muscular and tendinous elements of the two extremities. Although the direction of the current is constant for each muscle, yet there is no constant relation between the direction of the currents and the position of the muscles in the body; thus, in the *gastrocnemius* of the Frog's leg, the direction is from the foot towards the body, whilst in the *sartorius* it is the reverse. Taking all the muscles of a part together, however, there is usually such a want of balance between the opposite currents, that a constant current is established in the direction of the strongest and most numerous of the separate muscular currents; this, in the Frog, passes uniformly from the hind-feet towards the head, and was at one time supposed to be peculiar to that animal; but a similar current may almost always be detected in other animals. The muscular current grows feebler and feebler, the longer the muscle has been removed from the body; it is affected by any agents which tend to lower its vitality, and becomes extinct as soon as its contractility ceases. From the experiments of M. du Bois-Reymond, to be presently described (§ 670), it may be concluded that the current in the arm of Man, when at rest, is from the shoulder towards the points of the fingers.

668. The conditions of the "muscular current" have been made the subject of special investigation by M. du Bois-Reymond; and the following is an outline of the results at which he has arrived, for whose due comprehension, however, it is requisite that the terms employed by him should be first defined.—The entire muscle being composed of a mass of fibres, having a generally parallel direction, and attached at their extremities to tendinous structure, which has in itself but little or no electro-motor power, but is a conductor of electricity, it follows that the tendon or tendinous portion of a muscle represents a surface formed by the *bases* of the muscular fibres considered as prisms, which may be designated its *natural transverse section*. On the other hand, the fleshy surface of the muscle, which is formed only by the *sides* of the fibres considered as prisms, may be regarded as the *natural longitudinal section* of the muscle. Again, if a muscle be divided in a direction more or less perpendicular to its fibres, an *artificial transverse section* will be made; whilst if the muscle be torn lengthways in the direction of its fibres, an *artificial longitudinal section* will be made; and these artificial sections show the same electric conditions with their corresponding natural sections. Now experiments repeated in a great variety of modes demonstrate that *every point in the natural or artificial longitudinal section of a muscle is positive in relation to every part of its transverse section, whether natural or artificial*; the most powerful influence on the galvanometer being produced, when a portion of the surface (or natural longitudinal section) of a muscle is laid upon one of the electrodes, and a portion of the

¹ "Philosophical Transactions," 1848, p. 243.

surface formed by cutting the muscle across (or artificial transverse section) is placed against the other. When the two tendinous extremities of a muscle, whose form is symmetrical or nearly so, are placed against the electrodes, the deflection of the needle of the galvanometer is but slight; and the same is the case with two transverse sections taken at equal distances from the two ends of the muscle, and also with two points of the longitudinal section which are equally distant from the middle of its length. But if the two points of the longitudinal section applied to the electrodes be not equally distant from the centre of the muscle, then the point which is nearest to the centre is positive to the one which is nearest to the end; and, in like manner, when the different parts of the transverse section are tested in regard to each other, the points lying nearest the surface of the muscle are found to be positive to those nearer its interior. The intensity of the current, however, between any two points in the *same* section—whether transverse or longitudinal—is always incomparably less than that of the currents which are obtained between two points in *different* sections, one in the longitudinal and the other in the transverse. These results may be obtained, not merely with the entire muscle, but with insulated portions of it; and even, as we are assured by M. du Bois-Reymond, with a single primitive fasciculus. Hence it seems unquestionable that every integral particle of the muscular substance must be a centre of electro-motor action, and must contain within itself positive and negative elements; and the variations both of intensity and direction in the muscular current, under certain circumstances, are so sudden and so extensive, that it appears impossible to account for them by any change of larger heterogeneous elements, or in any other way than by assuming corresponding changes of position in almost infinitely small centres of action. It is indifferent what form is assigned to these electromotive molecules; but it would seem that they must have two negative polar zones, and a positive equatorial zone; a combination of such elements being able to produce all the electrical effects of a muscle in a state of rest. It seems altogether best to suit the phenomena, to suppose that each of these *peripolar* molecules is formed by the combination of two *dipolar* molecules, touching each other by their positive poles—as in the subjoined table, which represents a band of four series, A, B, C, D, each series containing four dipolar molecules.

1	$\left\{ \begin{array}{c} \overline{-} \\ + \\ \overline{-} \end{array} \right\}$	$\left\{ \begin{array}{c} \overline{-} \\ + \\ \overline{-} \end{array} \right\}$	$\left\{ \begin{array}{c} \overline{-} \\ + \\ \overline{-} \end{array} \right\}$	$\left\{ \begin{array}{c} \overline{-} \\ + \\ \overline{-} \end{array} \right\}$	1
2	$\left\{ \begin{array}{c} \overline{-} \\ + \\ \overline{-} \end{array} \right\}$	$\left\{ \begin{array}{c} \overline{-} \\ + \\ \overline{-} \end{array} \right\}$	$\left\{ \begin{array}{c} \overline{-} \\ + \\ \overline{-} \end{array} \right\}$	$\left\{ \begin{array}{c} \overline{-} \\ + \\ \overline{-} \end{array} \right\}$	2
3	$\left\{ \begin{array}{c} \overline{-} \\ + \\ \overline{-} \end{array} \right\}$	$\left\{ \begin{array}{c} \overline{-} \\ + \\ \overline{-} \end{array} \right\}$	$\left\{ \begin{array}{c} \overline{-} \\ + \\ \overline{-} \end{array} \right\}$	$\left\{ \begin{array}{c} \overline{-} \\ + \\ \overline{-} \end{array} \right\}$	3
4	$\left\{ \begin{array}{c} \overline{-} \\ + \\ \overline{-} \end{array} \right\}$	$\left\{ \begin{array}{c} \overline{-} \\ + \\ \overline{-} \end{array} \right\}$	$\left\{ \begin{array}{c} \overline{-} \\ + \\ \overline{-} \end{array} \right\}$	$\left\{ \begin{array}{c} \overline{-} \\ + \\ \overline{-} \end{array} \right\}$	4

669. The current shown by the entire muscle, when made to form part of a circuit, is only a *derived* current produced by incomparably more intense currents circulating in the interior of the muscle around these ultimate particles, and will vary greatly in intensity, according to the mode in which these particles are arranged; generally speaking, however, it increases both with the length and with the thickness of the muscle. There is, however, another cause of a

very remarkable nature, which influences both its intensity and its direction; this, according to M. du Bois-Reymond, is the existence of a thin layer of muscular substance, beneath the tendinous expansion, whose electromotive power is exactly opposite to that of the rest, so that its action tends to reverse the general law of the muscular current. For when the *gastrocnemius* of a frog is placed between the two electrodes, so as to touch them only with its tendinous extremities, it gives a weak upward current; but if the frog have been previously cooled, there will probably be no current at all; or if it have been frozen, there may actually be a current in the opposite direction. If, now, a drop of any liquid capable of corroding the muscular tissue (such as alcohol, creosote, acids, alkaline solutions, &c.), be placed upon the aponeurosis of the tendo-Achillis, the ordinary upward current of the muscle is evolved; and the same effect is produced by completely removing a thin layer of muscular substance at the natural transverse section. This effect is accounted for by M. du Bois-Reymond, on the supposition that, at the tendinous extremities of the muscular fibres, the linear series of peripolar elements is terminated by a single dipolar element, whose positive pole is thus free, instead of the negative pole being so; and he has shown that by an apparatus of zinc and copper, constructed after this plan, all the electric phenomena of the muscle at rest may be imitated.

670. That a change in the electric state of a muscle takes place in the act of contraction, had been ascertained by the experiments of Prof. Matteucci (§ 330); but, as he was only able to detect this by the galvanoscopic frog (the galvanometer which he employed not giving unquestionable indications of it), he was not able to determine its nature with accuracy. This has been accomplished, however, by M. du Bois-Reymond, who has shown that during contraction the muscular current is not increased (as supposed by Matteucci), but is diminished and even reduced to zero. In order to exhibit this phenomenon satisfactorily, it is found advantageous to cause the muscle to contract powerfully or uninterruptedly for as long a time as possible, that is, to *tetanize* it; and this may be effected by acting violently on its nerve by heat, chemical agents, or a succession of electric shocks; or by poisoning the animal with strychnia. In whatever mode the tetanized state is induced, the same result follows;—the needle of the galvanometer passes over to the negative side. This, however, does not indicate (as might be at first supposed) the development of a new current during the contraction, in a direction opposite to that which prevails during rest; but it is the consequence of the “secondary polarity”¹ which is evolved in the platinum electrodes, as soon as the muscular current is diminished; the needle passing from the positive to the negative side, as soon as the current of the secondary polarity becomes more powerful than the original muscular current. This negative deflection of the needle at the moment of contraction is always proportional to the actual intensity of the current of the muscle while at rest; and it ceases as soon as the tetanic contraction ceases, after which the muscular current gradually recovers its previous intensity.—Thus, then, it appears that the contraction of a muscle is attended with a *marked diminution of its*

¹ When the electromotor body is removed, and the two electrodes (platinum plates immersed in a saturated solution of common salt) are connected by some imperfectly conducting body, a secondary current is manifested in the reverse direction to the first, the needle being deflected to the other side; this is caused by the electro-chemical reaction of the substances which the current of animal electricity has evolved on the platinum plates by means of its electrolytic action; and its occurrence is often a useful and valuable confirmation of the first result, as showing that the primary deflection really was the consequence of the presence of an electromotor. When the electromotive action, moreover, is very weak, it may be made more evident by reversing the position of the electromotor, without first replacing the connector; so that the action which it will then exert in the reverse direction will be strengthened by the secondary current developed by the previous action.

electromotive power; a fact which seems to harmonize well with the general views formerly adverted to in regard to the "correlation of forces;" the changes which operate to produce disturbance of electric equilibrium whilst the muscle is at rest, being concerned in the development of motor power when it is thrown into contraction. This alteration has been demonstrated by M. du Bois-Reymond in the living animal, after the following manner. The two feet of a live frog were immersed in the two connecting vessels, but one of the legs was paralyzed by division of its sciatic plexus; the muscular currents of the muscles of the two limbs neutralized each other, so long as they remained at rest; but upon the frog being poisoned with strychnia, so that tetanic convulsions occurred in one limb whilst the other remained motionless, the current in the former limb was weakened, whilst that of the other remained unaffected, and a deflection of the needle took place, indicating an upward current in the paralyzed limb and a downward current in the tetanized one. The same thing may be shown in the Human subject, by dipping the forefingers of the two hands into the two conducting vessels connected with the galvanometer, so that the two arms are included in opposite directions in the circuit; when if, after the needle (which usually undergoes a temporary disturbance on their first immersion) has come to a state of rest, all the muscles of one of the arms be strongly and permanently contracted, so as to give them the greatest possible tension without changing the position of the arm, the needle is instantly deflected, always indicating a current from the hand to the shoulder, that is, an *upward* current in the contracted arm. Hence, according to the explanation just given, the contracted arm plays the part of the negative metal in the circuit, in regard to the arm whose muscles remain in the state of relaxation, showing that the normal current will be a downward one.—This change, however, is so extremely slight, that a very delicate galvanometer is requisite to render it perceptible. Its intensity depends very much on the muscular energy of the experimenter; and even the greater power which the right arm usually possesses becomes perceptible in the greater deflection of the needle when it is put in action.¹

671. The discovery that an electric current exists in *nerves*, the conditions of which are in most respects similar to that of the Muscular current, is entirely due to M. du Bois-Reymond. When a small piece of a nerve-trunk is cut out from the recently killed body, and is so placed upon the electrodes that it touches one of them with its surface (or natural *longitudinal* section), and the other with its cut extremity (or artificial *transverse* section), a considerable deflection of the index is produced, the direction of which always indicates the passage of a current from the interior to the exterior of the nerve-trunk. It is indifferent in regard to the direction of the current, whether the central or the peripheral cut extremity be applied to the electrode; and in fact the most powerful effect is obtained by doubling the nerve in the middle, and applying both transverse sections to one electrode, whilst the loop is applied to the other. On the other hand, if the two cut extremities be applied to the two electrodes respectively, no decided effect is produced; and the same neutrality exists between any two points of the surface of the trunk, equidistant from the middle of its length;

¹ Of this very remarkable experiment, which was first made by M. du Bois-Reymond, the Author has himself (through that gentleman's kindness) been a witness; and he gladly bears his testimony to its highly satisfactory character, and withdraws the doubt previously expressed (on the authority of Prof. Matteucci's negative statements) in regard to the reality of this phenomenon (§ 330, note).—The success of M. du Bois-Reymond in these and similar investigations, is doubtless due in great part to the marvellous sensitiveness of the galvanometer he employs, the coils of which consist of *three miles* of wire, as well as to the perfection of the various arrangements by which he is enabled to avoid or eliminate sources of error; but it must be attributed in great part also to the philosophic method on which his inquiries are planned, and to the skill and perseverance with which they are carried out.

but if the points be not equidistant, then a slight deflection is produced, indicating that the parts nearer the middle are positive to those nearer the extremities. It has not been found possible, owing to the small size of the nerve-trunks experimented on, to test in a similar manner the relative state of different points of their transverse section; but there can be little doubt, from the complete conformity which exists in other respects between the nervous and muscular currents, that the same law will be found to prevail in this as in the former case; namely, that the points nearer the surface are positive to those nearer the centre. There is no difference between the motor and the sensory nerves in regard to the direction of this current, the existence of which has been proved by M. du Bois-Reymond, not only by the galvanometer, but also by the excitement of contractions in the limb of the galvanoscopic frog.—The “nervous current,” like the muscular, must be considered as derived from the electromotive action of the molecules of the nerve; and, for the reasons already pointed out, the intensity of the current in the immediate neighborhood of the molecules may be infinitely greater than that which is shown by the galvanometer to exist in the trunk of the nerve.

672. We have now to follow M. du Bois-Reymond through his investigations on the change in the condition of the “nervous current,” whilst the nerve is in a state of functional activity, whether motorial or sensorial. For the examination of this, it is desirable to induce a state of continuous action in the nerve, analogous to the tetanic contraction of muscle; and this condition in the motor nerve is manifestly that which induces tetanus in its muscle; whilst in sensory nerves it is that in which a violent sensation is uninterruptedly kept up. No means of exciting such a state are so certain and simple as electric currents; but it is necessary in the first place to determine the modification which these

Fig. 169.

currents may themselves produce in the proper “nervous current.” If a portion of nerve-trunk be so placed (Fig. 173), that it touches one of the electrodes by its transverse section (which may be designated T), and the other by its surface or longitudinal section (L), and a portion of its continuation be included in a galvanic circuit, so that a current shall pass in the direction $Z \rightarrow P$, which is the same in its direction as that between $T \rightarrow L$, then the intensity of the “nervous current” $T \rightarrow L$, as indicated by the deflection of the needle of the galvanometer, will be found to undergo an increase; whilst on the other hand, if the electric current be passed in the contrary direction $P \rightarrow Z$, the intensity of the “nervous current” $T \rightarrow L$ will decrease.—The portion $Z \rightarrow P$ of the nerve, which is included in the electric circuit, is termed the *excited* portion, and the current passed through it is the *exciting current*; on the other hand, the portion $T \rightarrow L$ in-

cluded between the electrodes of the galvanometer is the *derived* portion; and the altered condition of this part, which is produced by the extraneous current (this current having been experimentally proved by M. du Bois-Reymond to exert no direct influence on the galvanometer), is termed the *electrotonic state* of the nerve. When the intensity of the “nervous current” is increased, the nerve is said to be in the *positive phase* of this electrotonic state; and when it is diminished, the nerve is in the *negative phase* of that state.—By a proper arrangement, the same exciting current may be made to produce the positive phase in one part of a nerve-trunk, and the negative phase in another. Thus if the two extremities of a nerve (Fig. 170, p and c) be so connected with two galvanometers, that both shall develop the “nervous current,” and an inter-

mediate portion be excited by the transmission of an electric current in the direction $z \Rightarrow p$, the nervous current in the "derived" portion c will be increased in intensity, whilst that in the portion p will be diminished.—Hence it may be inferred that when any portion of the length of a nerve is traversed by an electric current, besides the usual electromotive action of the nerve, a new electromotive action takes place in every point of the nerve, by a polarization of its electromotive elements, which action has the same direction as the exciting current itself; and a current is thus produced in the "derived" portion which is added to the original "nervous current" at that end of the nerve at which the direction of this new current and of the nervous current coincide, and is subtracted at that end at which the directions are different. These variations in the intensity of the "nervous current" continue as long as the "exciting current" lasts, and immediately cease when the circuit of that current is broken. It is to the induction of the electrotonic state in the nerve supplying it that the contraction of a muscle is due, which ensues on the completion of the circuit; and to the cessation of this state, that the muscular contraction is due which is consequent upon the interruption of the circuit. Hence the electrotonic changes in the condition of nerves may be observed without previously dividing them.—When, on the other hand, a nerve is "tetanized" by passing an interrupted and alternating current through a portion of it, the effect is, as in the case of muscle, to produce a *diminution* in its own proper current; the needles of *both* galvanometers, in the arrangement last described, being deflected to the negative side, instead of one going back to zero, and the positive deflection of the other being increased, as happens when the "excited portion" is subjected to a continuous and uniform current. The same negative variation of the nervous current has been demonstrated by M. du Bois-Reymond in nerves tetanized by other means, as by the use of strychnia. And the phenomena both of the "electrotonic state," and of the "negative variation" are precisely the same, whether motor or sensory nerves be subjected to the experiment; thus making it appear that nerve-force may be transmitted in either direction along each of these orders of nerves.—A very remarkable modification of the "nervous current" has been shown by M. du Bois-Reymond to follow severe injuries of the nerve, by mechanical, chemical, or thermal agencies. If, for instance, a piece of hot metal be brought near to the nerve without touching it, the nervous current will be seen to sink rapidly, and to have its direction reversed, during which the property possessed by the nerve of conveying irritation to the muscle, though somewhat impaired, will not be destroyed; and if, whilst in this abnormal state, the nerve be divided, every transverse section is found neutral or positive to the longitudinal section, instead of negative. If the nerve-trunk be then placed between muscles, so as to recover its natural moisture, it will at the same time recover its usual electromotive power.¹

Fig. 170.

¹ The materials of the five preceding paragraphs have been derived from the sketch of M. du Bois-Reymond's researches, which has been recently published by Dr. Bence Jones ("On Animal Electricity: being an Abstract of the Discoveries of Emil du Bois-Reymond"). Having himself had the opportunity of witnessing a considerable number of the experiments above referred to, the Author feels it due to M. du Bois-Reymond to state, that their results correspond so precisely with his predictions in every instance, as to prove that he had ac-

673. Some of the most important parts of the body being thus in a state of constant *disequilibrium* with regard to each other, it is not surprising that the electric state of the whole should be ordinarily in *disequilibrium* with that of surrounding bodies. This difference, however, is usually prevented from manifesting itself, in consequence of the restoration of the equilibrium by the free contact which is continually taking place between them; and it is for the most part only when the Human body is insulated, that it becomes apparent. The galvanometer is then affected, however, by the contact of one of its electrodes with the person insulated, and the other with any neighboring uninsulated body; and also by the contact of the electrode with the hands of two persons both insulated, who join their other hands together, a difference in the electrical states of the two individuals being thus indicated. The electricity of man is most frequently positive, and irritable men of sanguine temperament have more free electricity than those of phlegmatic character; the electricity of women is more frequently negative than that of men. There are persons who scarcely ever pull off articles of dress which have been worn next the skin, without sparks and a crackling noise being produced; especially in dry weather, when the electricity of the body is retained, instead of being rapidly dissipated as it is by a damp atmosphere. The effect is usually heightened, if silk stockings and other silken articles have been worn, since these act as insulators. It is doubtless in part attributable to the friction of the articles of dress against each other and against the body; but we can scarcely doubt that it is partly due to the generation of electricity in the body itself, since it bears no constant relation to the former of these supposed causes. Thus a Capuchin friar is mentioned by Dr. Schneider,¹ who, on removing his cowl, always found a number of shining crackling sparks to pass from his scalp; and this phenomenon continued still perceptible after a three weeks' illness. The most remarkable case of the generation of Electricity in the Human subject at present known, was recorded some years since in America.² The subject of it, a lady, was for many months in an electric state so different from that of surrounding bodies, that, whenever she was but slightly insulated by a carpet or other feebly conducting medium, sparks passed between her person and any object she approached; when most favorably circumstanced, four sparks per minute would pass from her finger to the brass ball of the stove at the distance of $1\frac{1}{2}$ inch. From the pain which accompanied the passage of the sparks, her condition was a source of much discomfort to her. The circumstances which appeared most favorable to the generation of the electricity were an atmosphere of about 80° , tranquillity of mind, and social enjoyment; whilst a low temperature and depressing emotions diminished it in a corresponding degree. The phenomenon was first noticed during the occurrence of an Aurora Borealis; and though its first appearance was sudden, its departure was gradual. Various experiments were made, with the view of ascertaining if the electricity was generated by the friction of articles of dress; but no change in these seemed to modify its intensity.

quired a thorough mastery over the conditions of the phenomena. And he may mention the experimental demonstration of the "nervous current," as most fully satisfactory.—It may be stated with confidence, that the course of investigation which is being followed out by M. du Bois-Reymond, is one pre-eminently calculated to develop results of importance in Physiology; and is the only one out of which definite indications in regard to the Therapeutic applications of Electricity can be expected to arise.

CHAPTER XIV.

OF THE FUNCTIONS OF THE NERVOUS SYSTEM.

1.—*General Summary.*

674. THE Nervous System of Man, as of Vertebrated animals generally, consists of an aggregation of separate ganglionic centres, which are more or less intimately connected with each other by commissural fibres, and which are called into consentaneous activity in a large proportion of the operations of which this apparatus is the instrument. Hence, notwithstanding the abundant evidence that these several centres differ in their respective endowments, there is considerable difficulty in the determination of their special functions; since the destruction or removal of any one portion of the Nervous system not only puts a stop to the phenomena to which it is itself directly subservient, but so deranges the general train of nervous activity, that it often becomes impossible to ascertain, by any such method, what is its real share in the entire performance. In this difficulty, however, we may advantageously have recourse to the study of the structure and actions of those forms of the Nervous system presented to us among the lower animals, in which its ganglionic centres are fewer and less intimately connected, and in which, therefore, it is more easy to gain an acquaintance with their several endowments. And from an extensive survey of these, we seem able to deduce the following conclusions, which afford the most valuable guidance in the study of the Nervous System of Man.¹

I. The Nervous System, in its lowest and simplest form, may consist of but a single ganglionic centre,² with afferent and motor nerves (§ 350), whose function is essentially *internuncial*; impressions made upon the afferent fibres exciting respondent movements in the muscles supplied by the motor, without any necessary intervention of consciousness. Such movements are properly distinguished as *excito-motor*.

II. A repetition of such ganglionic centres may exist to any extent, without heterogeneity of function, or any essential departure from the simple mode of action just indicated; each of these centres may be specially connected by afferent and motor fibres with one segment or division of the body, and may minister peculiarly to its actions; but the several centres may be so intimately connected by commissural fibres, that an impression made upon the afferent nerves of any one of them may excite respondent motions in other segments. This we see effected through the annular gangliated cord of the higher Radiata, and through the longitudinal gangliated cord of the Articulata; the disposition of the ganglia and of their connecting cords having reference simply to the general plan of the body.

III. A higher form of Nervous System is that in which the multiplication of

¹ For a general view of the facts on which these conclusions are based, see "Princ. of Phys., Gen. and Comp.," CHAP. XX., *Am. Ed.*

² It may, perhaps, be doubted whether any Animal really exists, possessing such nervous system, and yet not endowed with consciousness. It is quite certain, however, that animals do exist (the Tunicated Mollusca, for example), in which the actions above referred to are the only ones of which we have any distinct evidence from observation of their habits.

ganglionic centres has reference, not to the multiplication of similar parts which are to be alike supplied with nervous power, but to the exercise of adversity of functions, through the instrumentality of different structures; thus, in the higher Articulated and Molluscous tribes, we find ganglionic centres specially set apart for the actions of deglutition and respiration, as well as for those of locomotion; but the *modus operandi* is still the same, these actions being all "excito-motor," that is, being performed through the "reflex" agency of their several ganglionic centres, without the necessary intervention of consciousness. These centres are connected with each other commissurally, when they are required to act with consentaneousness; and it is frequently to be observed in the most developed forms of each type, that they come into actual coalescence, their functional distinctness being still indicated, however, by the distribution of their nervous trunks.

IV. In all but the very lowest Invertebrata, the nervous system includes, in addition to the foregoing, certain ganglionic centres, situated in the neighborhood of the entrance to the digestive cavity, and connected with certain organs, which, from their more or less close resemblance to our own instruments of special sense, we conclude to be organs of sight, smell, hearing, &c. Now as we know from our own experience, that impressions made upon these organs produce no further change unless we become *conscious* of them, and as the Invertebrata possess no distinct ganglionic centres of a higher character, it seems to be a legitimate inference that these "sensorial" ganglia are the instruments by which the animals furnished with them are rendered cognizant of such impressions, and through which the sensations thus called into existence serve to prompt and direct their movements. What is commonly designated as the "brain" of Invertebrata (more properly their "cephalic ganglia") cannot be shown to consist of anything else than an assemblage of sensorial centres; and its actions appear to be entirely of a "reflex" character, such of the movements of these animals as are not excito-motor being performed (there is strong reason to believe) in response to sensations excited by internal or external impressions. Such movements, therefore, may be designated as *sensori-motor*, or *consensual*. Like the preceding, they must be accounted purely "automatic," since neither emotion, reason, nor will has any participation in them; and the proportion which they bear to the actions of the excito-motor kind seems to correspond pretty closely with the relative development of the cephalic ganglia and of the rest of the nervous system, is very obvious when the larva and imago states of Insects are compared. However disjoined the various excito-motor centres may be amongst each other, we uniformly find them connected with the cephalic ganglia by commissural tracts; and this anatomical fact, with many phenomena which observation and experiment upon their actions have brought to light, makes it apparent, that besides the reflex actions which are performed through their own direct instrumentality, the sensory ganglia have a participation in those performed through other ganglionic centres. Thus it seems probable that a stimulus transmitted downwards from the sensory ganglia, to one of the ganglia of the trunk of a Centipede, excites the efferent nerves of that ganglion to call into contraction the muscles supplied by them, just as the excitor influence arriving at that ganglion through its own afferent nerve would do.

675. The whole Nervous System of Invertebrated animals, then, may be regarded as ministering entirely to *automatic* action; and its highest development, as in the class of Insects, is coincident with the highest manifestations of the "instinctive" powers, which, when carefully examined, are found to consist entirely in movements of the excito-motor and sensori-motor kinds. When we attentively consider the habits of these animals, we find that their actions, though evidently adapted to the attainment of certain ends, are very far from evincing a *designed* adaptation on the part of the beings that perform them,

such as that of which we are ourselves conscious in our own voluntary movements, or which we trace in the operations of the more intelligent Vertebrata. For, in the first place, these actions are invariably performed in the same manner by all the individuals of a species, when the conditions are the same; and thus are obviously to be attributed rather to a uniform impulse, than to a free choice; the most remarkable examples of this being furnished by the economy of Bees, Wasps, and other "social" Insects, in which every individual of the community performs its appropriate part, with the exactitude and method of a perfect machine. The very perfection of the adaptation, again, is often of itself a sufficient evidence of the unreasoning character of the beings which perform the work; for, if we attribute it to their own intelligence, we must admit that this intelligence frequently equals, if it does not surpass, that of the most accomplished Human reasoner.¹ Moreover, these operations are performed without any guidance from experience; for it can be proved in many cases, that it is impossible for the beings which execute them to have received any instruction from their parents; and we see that they do not themselves make any progressive attempts towards perfection, but accomplish their work as well when they first apply themselves to it, as after any number of repetitions of the same acts. It is interesting to observe, moreover, that as these instinctive operations vary at different periods of life; so is there a corresponding variation in the structure of the Nervous system. Thus we see that, in the *larva* of the Insect, these operations are entirely directed towards the acquisition of food; and its organs of sense and locomotive powers are only so far developed as to serve this purpose. But in the *imago* or perfect Insect, the primary object is the continuance of the race; and the sensorial and motor endowments are adapted to enable the individual to seek its mate, and to make preparations (frequently of a most elaborate kind) for the nurture of the offspring. Hence we can scarcely fail to arrive at the conclusion, that the *adaptiveness* of the instinctive operations of Insects, &c., lies in the original construction of their nervous system, which causes particular movements to be executed in direct response to certain impressions and sensations. And this view is confirmed by the comparison of these movements with those which have been always recognized as "instinctive" in the Human being; thus, the act of sucking in the infant requires the combined exertion of a considerable number of muscles, which combination is clearly not the result of intelligence and will, but is a purely "reflex"

¹ Of this we have a most remarkable example in the architecture of the common Hive-Bee.—The *hexagonal* form of the cell is the one in which the greatest strength, and the nearest approach to the cylindrical cavity required for containing the larva, are attained, with the least expenditure of material. But the instinct which directs the Bees in the construction of the partition that forms the bottom or end of the cell, is of a nature still more wonderful than that which governs its general shape. The bottom of each cell rests upon three partitions of cells upon the opposite side of the comb; so that it is rendered much stronger, than if it merely separated the cavities of two cells opposed to one another. The partition is not a single plane surface; but is formed by the union of three rhomboidal planes, uniting in the centre of each cell. The angles formed by the sides of these rhombs were determined by the measurements of Miraldi to be $109^{\circ} 28'$ and $70^{\circ} 32'$; and these have been shown, by mathematical calculation, to be *precisely* the angles, at which the greatest strength and capacity can be attained, with the least expenditure of wax. The solution of the problem was first attempted by Koenig, a pupil of the celebrated Bernouille; and as his result proved to differ from the observed angle by only two minutes of a degree, it was presumed that the discrepancy was due to an error of observation, which it was easy to account for by the smallness of the surfaces whose inclination had to be measured. The question has been since taken up, however, by Lord Brougham (Appendix to his Illustrated edition of "Paley's Natural Theology"); who has worked it out afresh, and has shown that, when certain small quantities, neglected by Koenig, are properly introduced into the calculation, the result is exactly accordant with observation—the Bees being thus proved to be *right*, and the *Mathematician wrong*.

act (§ 423); and the same may be said of the acts of coughing and sneezing (§ 555), the *purpose* of which is most obvious, and the adaptation to that purpose most complete, yet these acts are most assuredly *not* performed with any notion of their purpose, but at the prompting of an irresistible impulse, which, originating in an excitation applied to a sensory surface and conveyed to the automatic centres, becomes the immediate source of all the separate muscular contractions which combine to accomplish the prearranged result.¹

676. Thus, then, the type of psychical perfection among Invertebrated animals, which is manifested in the highest degree in the Social Insects, consists in the exclusive development of the *Automatic* powers; in virtue of which, each individual performs those actions to which it is directly prompted by the impulses arising out of impressions made upon its afferent nerves, without any self-control or self-direction; so that it must be regarded as entirely a creature of necessity, performing its instrumental part in the economy of Nature from no design or will of its own, but in accordance with the plan originally devised by its Creator. On turning to the Vertebrated series, on the other hand, we find that perfection consists in the highest development of the *Intelligence*, and in the supreme domination of the *Will*, to which all the automatic movements, save those which are absolutely essential to the maintenance of the organic functions, are brought under subjection; so that each individual becomes an independent, self-moving, and self-controlling agent, all whose actions are performed with a definite purpose which is distinctly before his own view, and are adapted to the attainment of their end by his own reason. This, however, is only true of Man in his highest state of psychical development; for not only do the actions of the lower Vertebrata appear to be nearly as much under the direction of automatic impulses as are those of the Invertebrated classes, but the same is true of those of the Human species in infancy and early childhood; and a very close correspondence may be traced between the gradual development of the Intelligence and the progressive acquirement of Volitional dominance, in the ascending series of Vertebrated animals, and in the advance of Man from the mental state of childhood (which is permanently retained, as to all its essential characters, in many adults, and even in whole races of the least cultivated order) to the highest elevation which his nature is capable of displaying in his present sphere of existence.—The superaddition of these more elevated psychical endowments is coincident with the addition of a peculiar ganglionic centre, the Cerebrum, to the automatic apparatus of Vertebrated animals; and the relative proportion which this bears to the automatic centres, both as to size and complexity of structure, corresponds so closely with the degree of predominance which the Intelligence and Will possess over the Instinctive propensities, that it is scarcely possible to doubt that the Cerebrum is the instrument through which these higher psychical powers are exercised. Even in Man, however, the Automatic division of the Nervous system still constitutes

¹ We have not, perhaps, any right to affirm that there is *nothing whatever* analogous in the Invertebrata to the Reasoning powers and Will of higher animals; but if these faculties have any existence among them, they must be regarded as in a merely rudimentary state, corresponding with the undeveloped condition of the Cerebrum. In none of the Articulata has any trace of this organ been discovered; a rudiment of it, however, has been supposed to exist in the Cuttle-fish. The only distinct indication of intelligence displayed by Invertebrata is the slight degree of capacity of "learning by experience" which some of them display; this capacity being limited to the mere formation of *associations* between the mental states called up by different objects of sense, which we observe to be the first stage in the development of the mental powers in the Human infant. And it is interesting to remark that this educability is less displayed by Insects, in which we may consider the Automatic tendencies as attaining their highest development, than it is in Spiders, which present in several points of their conformation an approximation towards the Vertebrated series.

its fundamental and essential part; for not only is it the instrument of all those actions which are directly excited by sensations or impressions derived from without, many of these being necessary to the maintenance of his organic functions; but it is also the connecting link between the Cerebrum and the external world. For, as will appear hereafter, the Cerebrum receives all its stimulus to action through the sensorial ganglia, to which all the proper sensory nerves are traceable; whilst on the other hand, in carrying into effect the mandates of the will, it does not operate directly upon the muscles, but affects them through the instrumentality of the Automatic motor apparatus.

677. The dominant character of the Nervous System in Vertebrated animals is marked by the subserviency of the whole organism to its purposes. In a large proportion of the Invertebrata, the Nervous system seems like an appendage to the rest of the structure, a mechanism superadded for the sake of bringing its various parts into more advantageous relation; and we do not find any special adaptation of the organs of support for its protection. But in all the Vertebrated classes, we find that the internal osseous skeleton, whose existence supplies the most distinctive character of the group, is adapted not merely to furnish the most complete and efficient protection to the Nervous centres, but also to afford points of attachment to the Muscles, as well as a system of inflexible levers on which they may exert the contractile power called forth by the nerves; so that the development of the neuro-skeleton (thus designated in contradistinction to the dermo-skeleton) has a constant relation to that of the Nervomuscular apparatus. This is most remarkably seen in Man; in whom the "archetype" or fundamental plan of the Vertebral skeleton is most departed from, in order that it may be adapted to his special requirements.¹ And it is in him, too, that the Nervous system presents the greatest proportionate development, and that, by the intimate connections which subsist between its several parts, it is made so far to constitute *one whole*, that the determination of their respective functions is attended with the greatest difficulty. It has been, in fact, through the too exclusive attention commonly paid to Human Anatomy, that the meaning of the facts brought to light by dissection has been very commonly misapprehended; and that many of the physiological interpretations based upon them, have been completely negatived by more extended inquiry.—It is only, in fact, by studying the Cerebro-Spinal apparatus in its lowest, as well as in its highest form, and by bringing the intervening grades into comparison with both extremes, that it is possible to establish what are its fundamental or essential, and what its accessory parts; and in this way only can such a correspondence be established between the development of a particular structure, and the manifestation of a certain psychical endowment, as may enable the latter to be attributed with any degree of probability to the former. In fact, there is no part of the Human Organism, as to which the advantages of such a comparison are so striking, or in which the value of the "experiments ready prepared for us by Nature" is so much above that of the results of artificial mutilations.

678. Under the guidance, then, of these principles, we find that we may distinguish, as the fundamental part of the Nervous system of Man, the *Cranio-Spinal Axis*, consisting of the Spinal Cord, the Medulla Oblongata, and the Sensory Ganglia, and altogether constituting the centre of automatic movement.—The Spinal Cord, consisting of a tract of vesicular matter inclosed within strands of longitudinal fibres, and giving off successive pairs of intervertebral nerves which are connected at their roots with both of these components, is obviously homologous with the gangliated ventral column of the Articulata, differing from it only in the continuity of the ganglionic substance which occupies

¹ See "Princ. of Phys., Gen. and Comp.," § 326, *k*, *Am. Ed.*

its interior; and each segmental division of it, which serves as the centre for its own pair of nerves, may be considered, like each ganglion of the ventral column of the Articulata, as a repetition of the single "pedal" or locomotive ganglion of the Mollusca.—The Medulla Oblongata consists of a set of strands, which essentially correspond with the cords that pass round the œsophagus in Invertebrated animals, connecting the cephalic ganglia with the first sub-œsophageal ganglion; but, as the whole cranio-spinal axis in the Vertebrata lies *above* the alimentary canal (the trunk being supposed to be in a horizontal position), there is no such divergence of these strands, the only separation between them being that which is known as the "fourth ventricle." Interposed among the commissural fibres of the Medulla Oblongata, however, are certain collections of vesicular matter, which serve as the ganglionic centres for the movements of respiration and deglutition, and which thus correspond with the respiratory and stomato-gastric ganglia of Invertebrated animals. This incorporation of so many distinct centres into one system would seem destined in part to afford to all of them the protection of the vertebral column; and in part to secure that consentaneousness of action and that ready means of mutual influence which are peculiarly requisite in beings in whom the activity of the Nervous system is so predominant. Thus the close connection which is established in the higher Vertebrated animals, between the respiratory and the general locomotive apparatus, is obviously subservient to the use which the former makes of the latter in the performance of its functions; whilst, on the other hand, the control which their encephalic centres possess over the actions of the respiratory ganglia enables the will to regulate the inspiratory and expiratory movements in the manner required for the acts of vocalization.—Under the term Sensory Ganglia may be comprehended that assemblage of ganglionic masses lying along the base of the skull in Man, and partly included in the Medulla Oblongata, in which the nerves of the "special senses," Taste, Hearing, Sight, and Smell, have their central terminations; and with these may probably be associated the two pairs of ganglionic bodies known as the Corpora Striata and Thalami Optici, into which may be traced the greater proportion of the fibres that constitute the various strands of the Medulla Oblongata, and which seem to stand in the same kind of relation to the nerves of Touch or "common sensation," that the Olfactive, Optic, Auditory, and Gustative ganglia bear to their several nerve-trunks.

679. Now it is not a little interesting, that this Cranio-Spinal axis, which represents in Vertebrated animals the whole nervous system of the Invertebrata (with the exception of the rudiment of the Sympathetic which they possess), should exist in the lowest known Vertebrated animal without any superaddition, and should be sufficient for the performance of all its actions. Such is the case in the curious *Amphioxus*,¹ which presents not the slightest trace of either Cerebrum or Cerebellum, and in which even the sensory ganglia and the organs of special sense have only a rudimentary existence; and in which, too, the spinal cord is composed of a series of ganglia that are obviously distinct from each other, although in close approximation. And even in the lower Cyclostome Fishes, the condition of the nervous centres is very little above this, save as regards the larger development of the sensory ganglia. This condition has its parallel, even in the Human species, in the case of Infants which are occasionally born without either Cerebrum or Cerebellum; such have existed for several hours or even days, breathing, sucking, crying, and performing various other movements; and there is no physiological reason why their lives should not be prolonged, if they be nurtured with sufficient care (§ 373).

¹ "Princ. of Phys. Gen. and Comp.," § 321, *Am. Ed.*

680. In Man, however, as in all the higher Vertebrata, we find superimposed (as it were) upon the Sensory ganglia, and constituting the principal mass of the Encephalon, the bodies which are known as the *Cerebral Hemispheres*, or *Hemispheric Ganglia*. Now when these are so greatly developed as to cover in and obscure the Sensory ganglia to the degree which presents itself in Man, it is not surprising that the fundamental importance of the latter should not be generally recognized; in Fishes, however, the proportion between the two sets of centres is entirely reversed, the rudiments of the Cerebral Hemispheres (Fig. 171, B) being usually inferior in size to the Optic ganglia (C) alone. Indeed, of the pair of ganglionic masses to which that designation is usually applied, it may be almost positively stated that the greater part is homologous with the Corpora Striata of the Human brain; it being only in the higher Cartilaginous fishes that a ventricular cavity exists in each of these bodies, separating the thin layer of true Cerebral substance which overlies it, from the ganglionic mass which forms its floor. Between these two extremes, a regular gradation is presented in the intermediate tribes.—Now it is a point especially worthy of note, that no sensory nerves terminate directly in the Cerebrum, nor do any motor nerves issue from it; and there seems a strong probability that there is not, as formerly supposed, a direct continuity between any or all of the nerve-fibres distributed to the body, and the medullary substance of the Cerebrum. For, whilst the nerves of “special” sense have their own ganglionic centres, it cannot be shown that the nervous fibres of “general” sense which either enter the cranium as part of the cephalic nerves, or which pass up from the Spinal cord, have any higher destination than the Thalami Optici. So the motor fibres which pass forth from the cranium either into the cephalic nerve-trunks or into the motor columns of the Spinal cord, cannot be certainly said to have a higher origin than the Corpora Striata. And we shall find strong physiological ground for the belief that the Cerebrum has no communication with the external world, otherwise than by the Sensori-motor apparatus which ministers to the automatic actions; and that even the movements which are usually designated as “voluntary” are only so as regards their original source, the power which calls the muscles into contraction being even then immediately derived from the Cranio-Spinal axis, as it is in the purely automatic movements excited by an external impression.

681. Wherever a Cerebrum is superimposed upon the Sensory Ganglia, we find another ganglionic mass, the *Cerebellum*, superimposed upon the Medulla Oblongata. The development of this organ bears a general, but by no means a constant relation to that of the Cerebrum; for in the lowest Fishes it is a thin lamina of nervous matter on the median line, only partially covering in the “fourth ventricle;” whilst in the higher Mammalia, as in Man, it is a mass of considerable size, having two lateral lobes or hemispheres in addition to its central portion. The direct communication which the Cerebellum has with both columns of the Spinal cord, and the comparatively slight commissural connection which it possesses with the higher portions of the Encephalic centres, justify the supposition that it is rather concerned in the regulation and co-ordination of the actions of the former, than in any proper psychical operations; and it will hereafter be shown that the evidence afforded by Comparative Anatomy, by Experimental inquiry, and by Pathological observation, all tends to support this view of its function.

682. Now although every segment of the Spinal Cord and every one of the

D, cerebellum.

Sensory Ganglia, may be considered, in common with the Cerebrum, as a true and independent centre of nervous power, yet this independence is only manifested when these organs are separated from each other, either structurally—by actual division, or functionally—by the suspension of the activity of other parts. In their state of perfect integrity and complete functional activity, they are all (at least in Man) in such subordination to the Cerebrum, that they only minister to its actions, except in so far as they are subservient to the maintenance of the organic functions, as in the automatic acts of breathing and swallowing. With regard to every other action, the Will, if it possess its due predominance, can exercise a determining power; keeping in check every automatic impulse, and even repressing the promptings of emotional excitement. And this seems to result from the peculiar arrangement of the nervous apparatus; which causes the excitor *impression* to travel in the *upward* direction, if it meet with no interruption, until it reaches the Cerebrum, without exciting any reflex movements in its course. When it arrives at the Sensorium, it makes an impression on the consciousness of the individual, and thus gives rise to a *sensation*; and the change thus induced, being further propagated from the sensory ganglia to the Cerebrum, becomes the occasion of the formation of an *idea*. If with this idea any pleasurable or painful feeling should be associated, it assumes the character of an *emotion*; and either as a simple or as an emotional idea, it becomes the subject of *intellectual operations*, whose final issue is in a *volitional determination*, or act of the Will, which may be exerted in producing or checking a muscular movement, or in controlling or directing the current of thought.

683. But if this ordinary upward course be anywhere interrupted, the impression will then exert its power in a *transverse* direction, and a "reflex" action will be the result, the nature of this being dependent upon the part of the Cerebro-Spinal axis at which its ascent had been checked. Thus, if the interruption be produced by division or injury of the Spinal Cord, so that its lower part is cut-off from communication with the encephalic centres, this portion then acts as an independent centre, and impressions made upon it through the afferent nerves proceeding to it from the lower extremities, excite violent reflex movements, which, being thus produced without sensation, are designated as "excitomotor."—So, again, if the impression should be conveyed to the Sensorium, but should be prevented by the removal of the Cerebrum, or by its state of functional inaction, or by the direction of its activity into some other channel, from calling forth ideas through its instrumentality, they may react upon the motor apparatus by the "reflex" power of the Sensory ganglia themselves; as seems to be the case with regard to those locomotive actions which are maintained and guided by sensations during states of profound abstraction, when the attention of the individual is so completely concentrated upon his own train of thought that he does not *perceive* external objects, although his movements are obviously guided through the visual and tactile senses. Such actions, being dependent upon the prompting of sensations, are "sensori-motor" or "consensual."—But further, there is evidence that even the Cerebrum may respond (as it were) automatically to impressions fitted to excite it to "reflex" action, when from any cause the Will is in abeyance, and its power cannot be exerted either over the muscular system or over the direction of the thoughts. Thus in the states of Dreaming, Somnambulism, and even Reverie, whether spontaneous or artificially induced (Sect. 7), *ideas* which take possession of the mind, and from which it cannot free itself, may excite respondent movements; and this may happen also when the force of the idea is morbidly exaggerated, and the will is not suspended but merely weakened, as in many forms of Insanity. With these ideas, moreover, Emotional states may be mixed up, and even Intellectual processes may be prompted by them; so long, however, as these psychical operations take place at the mere *suggestion* of antecedent impressions (the particular changes which these

suggestions excite being determined by the mental constitution and habits of thought of the individual), so long must the actions proceeding from them be considered as manifestations of the "reflex" power of the Cerebrum, and consequently as no less automatic in their character, than are those which result from the reflex power of the Cranio-Spinal axis. Those actions which proceed from simple ideas, without any excitement of feeling, may be designated as *ideo-motor*; whilst those which spring from a passion or emotion may be termed *emotional*. The automatic nature of the purely emotional actions can scarcely be denied; when the passions are strongly excited, their impulses even acquire the mastery over the strongest exertion of the Will; and it is in individuals in whom the habitual control of the will is the weakest, that we observe the emotions to act most powerfully on the bodily frame.

684. The dominant power of the Will, not only over every act of the nervo-muscular apparatus which is not immediately concerned in the maintenance of the vital functions, but over the course of purely psychical action, is probably the most distinctive attribute of the Human mind in its highest phase of development; and it is that which gives to each individual the freedom of action, which every one is conscious to himself that he is capable of exerting. Notwithstanding the evidences of rationality which many of the lower animals present, and the manifestations which they display of emotions that are similar to our own, there is no ground to believe that they have any of that controlling power over their psychical operations which *we* possess: on the contrary, all observation seems to lead to the conclusion, that they are under the complete domination of the ideas and emotions by which they are for the time possessed, and have no power either of repressing these by a forcible act of Will, or of turning the attention, by a like voluntary effort, into another channel. In this respect, then, their condition resembles that of the dreamer, the somnambule, or the insane patient, in all of whom this voluntary control is suspended, and who (when their minds are susceptible of external impressions) may be so "played upon" by the suggestion of ideas, that any respondent action consistent with the habitual mental state of the individual, may be evoked by an appropriate stimulus; just as we see in the case of animals that are trained to the performance of particular sets of movements, which are executed in response to certain promptings conveyed to them through their sensorium. Now between the complete want of this controlling power of the Will, and the most perfect possession of it, every intermediate gradation is presented by the several individuals which make up the Human species; some persons being so much accustomed, in consequence of the weakness of their Will, to act directly upon intellectual or emotional suggestions, that they can scarcely be said to be voluntary agents; and others allowing certain dominant ideas or habitual feelings to gain such a mastery over them, as to exercise that determining power which the Will alone ought to exert. This gradation may be perfectly traced in children, in whose education the development of the faculty of "self-control" should be a leading object; and it is also displayed in some of those phases of mental Imbecility, which result from a deficiency of the power of fixing the attention upon any object of consciousness, and of withdrawing it from external objects that tend to distract the mind by suggesting new ideas and trains of thought. On this power of self-direction, indeed, all the higher developments of intellectual power almost essentially depend; and we shall hereafter see how largely it is concerned in that progressive exaltation of the Moral nature, which, even more than Intellectual capacity, tends to bring the Human soul into relation with its Creator.

685. This directing power of the Will seems to be most strongly exerted, however, over those actions which are most closely connected with *psychical* changes, and which are exclusively *Cerebral* in their seat. It has been already pointed out, that the Cranio-spinal axis not merely serves as the channel for the

reception of the impressions which excite the activity of the Hemispheric ganglia, and as the instrument whereby the results of their operation are brought to bear upon the muscular system; but that it is also the centre of reflexion through which various automatic movements are called forth, that are immediately concerned in the maintenance of the organic functions. The impressions which excite these movements do not in general pass on to the Cerebrum; for we only perceive them when we specially direct our attention to them, or when they exist in unusual potency. Thus we are unconscious of the “*besoin de respirer*” by which our ordinary movements of respiration are prompted; and it is only when we have refrained from breathing for a few seconds, that we experience a sensation of uneasiness which impels us to make forcible efforts for its relief. Notwithstanding, however, that the Cerebrum is thus unconcerned in the ordinary performance of these automatic movements, yet it can exert a certain degree of control over many of them, so as even to suspend them for a time; but in no instance can it carry this suspension to such an extent as seriously to disarrange the organic functions; thus, when we have voluntarily refrained from breathing for a few seconds, the inspiratory impulse so rapidly increases in strength with the continuance of the suspension, that it at last overcomes the most powerful effort we can make for the repression of the movements to which it prompts. Now in this and similar cases, it would seem as if the Will interfered to prevent that direct transverse passage of the stimulus from the afferent to the efferent nerves, through the Cranio-Spinal axis, which constitutes the ordinary line of action for impressions having their origin in the necessities of the organic or vegetative life of the individual. That the Will should have a certain degree of control over these movements, is necessary in order that they may be rendered subservient to various actions which are necessary for the due exercise of Man’s psychical powers; but that they should not be left dependent upon its exercise, and should even be executed in opposition to it, when the wants of the system imperatively demand their performance, constitutes a wise provision for securing Life against the chances of inattention or momentary caprice.

686. The general views here put forth in regard to the independent and connected actions of the several primary divisions of the Cerebro-Spinal apparatus, may perhaps be rendered more intelligible by the following Table, which is intended to represent the ordinary course of operation when the whole is in a state of complete functional activity (§ 682), and the character of the “*reflex*” actions to which each part is subservient, when it is the highest centre that the impression can reach (§ 683).

687. Having thus considered the principal attributes of the ganglionic centres of the Cerebro-Spinal system, we have next to inquire into those of the nerve-trunks which are connected with them. It is only in the Vertebrata that the difference between the *afferent* and *efferent* fibres of the nerves has been satisfactorily determined. The merit of this discovery is almost entirely due to Sir C. Bell, who was led to it by a chain of reasoning of a highly philosophical character; and although his first experiments on the Spinal nerves were not satisfactory, he virtually determined the respective functions of their two roots, by experiments and pathological observations upon the cranial nerves, some of which contain only one class of fibres to the exclusion of the other, before any other physiologist came into the field.¹ Subsequently his general views were confirmed by the very decided experiments of Müller; but until very recently, some obscurity hung over a portion of the phenomena. It was from the first maintained by Magendie, and has been subsequently asserted by other physiologists, that the anterior and posterior roots of the nerves were *both* concerned in the reception of impressions and in the production of motions; for that, when the anterior roots were touched, the animal gave signs of pain, at the same time that convulsive movements were performed: and that, on touching the posterior roots, not only the sensibility of the animal seemed to be affected, but muscular motions were excited. These physiologists were not willing, therefore, to admit more than that the anterior roots were *especially* motor, and the posterior *especially* sensory. But the knowledge we now possess of the reflex function of the Spinal Cord enables the latter portion of these phenomena to be easily explained. The motions excited by irritating the posterior roots are found to be entirely dependent upon their connection with the Spinal Cord, and upon the integrity of the anterior roots and of the trunks into which they enter; whilst they are not checked by the separation of the posterior roots from the peripheral portion of the trunk: it is evident, therefore, that excitation of the posterior roots does not act immediately upon the muscles through the trunk of the nerve, which they contribute to form; but that it excites a motor impulse in the Spinal Cord, which is propagated through the anterior roots to the periphery of the system. The converse phenomenon, the apparent sensibility of the anterior roots, has been explained by the experiments of Dr. Kroneberg,² which seem to prove that it is dependent upon a branch from the posterior roots passing into the anterior roots at their point of inosculation, and then directing itself towards the cord (§ 692).

688. Every fibre, there is reason to believe, runs a distinct course between the central organ, in which it loses itself at one extremity, and the muscle or organ of sense in which it terminates at the other. Each nervous trunk is made up of several fasciculi of these fibres; and each fasciculus is composed of a large number of the ultimate fibres themselves. Although the fasciculi occasionally intermix and exchange fibres with one another (as occurs in what is termed a *plexus*), the fibres themselves never inosculate. Each fibre would seem, therefore, to have its appropriate office, which it cannot share with another. —Several objects appear to be attained by the plexiform arrangement. In some instances it serves to intermix fibres, which have endowments fundamentally different; for example, the Spinal Accessory nerve, at its origin, appears to be exclusively motor, and the roots of the Pneumogastric to be as exclusively afferent; but by the early admixture of these, a large number of motor fibres are imparted to the Pneumogastric, and are distributed in variable proportion, with its different branches; whilst few of its sensory filaments seem to enter the Spinal Accessory.—In other instances, the object of a plexus appears to be

¹ See "Brit. and Foreign Med. Review," vol. ix. p. 140, &c.

² "Müller's Archiv.," 1839, Heft v.; and "Brit. and For. Med. Rev.," vol. ix. p. 547.

to give a more advantageous distribution to fibres, which all possess corresponding endowments. Thus the brachial plexus mixes together the fibres arising from five segments of the spinal cord, and sends off five principal trunks to supply the arm. Now, if each of these trunks had arisen by itself, from a distinct segment of the spinal cord, so that the parts on which it is distributed had only a single connection with the nervous centres, they would have been much more liable to paralysis than at present. By means of the plexus, every part is supplied with fibres arising from each segment of the spinal cord; and the functions of the whole must therefore be suspended, before complete paralysis of any part can occur from a cause which operates above the plexus. Such a view is borne out by direct experiment; for it has been ascertained by Panizza that in Frogs, whose crural plexus is much less complicated than that of Mammalia, section of the roots of one of the three nerves which enter into it produces little effect on the general movements of the limb; and that, even when two are divided, there is no paralysis of any of its actions, all being weakened in a nearly similar degree.—But, as Dr. Gull has pointed out,¹ one use of such a plexus as the brachial or the crural appears to be, to bring the muscles which derive their nervous supply from it, into relation with different ganglionic segments of the Spinal Cord; each of which may exert a diverse action, either in virtue of its own endowments, or of the influence of the will upon it; so that groups of muscles may thus be associated for combined actions. All consideration of the mode in which we make use of our muscles, and of the power which we have over them, leads to the conclusion that each ganglionic centre has a specific and limited sphere of influence, producing certain movements and no others; hence for the execution of a variety of movements in harmonious combination with each other, it seems requisite that the nervous supply of each muscle should be derived from several different centres; and thus it is that the complication of plexuses comes to be related to the variety of movements of the parts supplied through them.—It is not a little interesting to remark that arrangements of a similar kind should present themselves among the higher Invertebrata. Thus, in Hymenopterous Insects (as first pointed out by Mr. Newport), there is a plexiform interlacement between the nerves of the anterior and of the posterior pairs of wings, which act very powerfully together; whilst in the Coleoptera, in which the anterior wings are converted into elytra, and are motionless during flight, the nerves supplying each pair run their course distinctly. In the Octopus, or Poulp, again, the trunks which radiate from the cephalic mass to the eight large arms surrounding the head are connected by a circular band, forming a kind of plexus, which seems to contribute to the very powerful and harmonious movements of the arms of this Cephalopod.

689. The following statements, in which the doctrines of Prof. Müller² are adopted with some modifications and additions, embody the general principles ascertained by experiment, respecting the transmission of sensory and motor impressions along the nerves which respectively minister to them. Their *rationale* will be at once understood, from the facts already mentioned in regard to the isolated character of each fibril, and the identity of its endowments through its whole course.

1. When the whole trunk of a *sensory* nerve is irritated, a sensation is produced, which is referred by the mind to the parts to which its branches are ultimately distributed; and if only part of the trunk be irritated, the sensation will be referred to those parts only which are supplied by the fibrils it contains. This is evidently caused by the production of a change in the sensorium, corresponding with that which would have been transmitted from the peripheral

¹ "Gulstonian Lectures on the Nervous System," in "Medical Times," 1849, p. 372.

² "Elements of Physiology," translated by Dr. Baly; pp. 680, 686.

origins of the nerves, had the impression been made upon them. Such a change only requires the integrity of the afferent trunk, between the point irritated and the sensorium, and is not at all dependent upon the state of the peripheral part to which the sensations are referred; for this may have been paralyzed by the division or other lesion of the nerve, or may have been altogether separated as in amputation, or the relative position of its parts may have been changed, as in autoplasmic operations. So, when different parts of the thickness of the same trunk are separately and successively irritated, the sensations are successively referred to the several parts supplied by these divisions. This may be easily shown by compressing the ulnar nerve in different directions, where it passes at the inner side of the elbow-joint.—Still the mind undoubtedly does possess a certain power of discriminating the part of the nerve-trunk on which the impression is made; for whilst this impression is such as to produce sensations that are referred to its peripheral extremities, pain is at the same time felt in the spot itself; and it would seem as if slight impressions are *only* felt in the latter situation, at least in the normal condition of the trunk or fibre. Thus, as it has been well remarked by Volkmann, “if a needle’s point be drawn in a straight line across the back, or the thigh, or any part in which the nerves are widely placed, the mind perceives the line of irritation as a straight one; whereas, if it referred all impressions to the ends of irritated fibres, this mode of irritation should be felt in sensations variously scattered about the line, at the points where the nerve-fibres crossed by the needle terminate.”¹

II. The sensation produced by irritation of a branch of the nerve is confined to the parts to which that branch is distributed, and does not affect the branches which come off from the nerve higher up. The rationale of this law is at once intelligible: but it should be mentioned that there are certain conditions, in which the irritation of a single nerve will give rise to sensations over a great extent of the body. This “radiation of sensations” seems rather due, however, to a particular state of the central organs, than to any direct communication among the sensory fibres.

III. The *motor* influence is propagated only in a centrifugal direction, never in a retrograde course. It may originate in a spontaneous change in the central organs, or it may be excited by an impression conveyed to them through afferent nerves, but in both cases its law is the same.

IV. When the whole trunk of a motor nerve is irritated, all the muscles which it supplies are caused to contract. This contraction evidently results from the similarity between the effect of an artificial stimulus applied to the trunk in its course, and that of the change in the central organs by which the motor influence is ordinarily propagated. But when only a part of the trunk or a branch is irritated, the contraction is usually confined to the muscles which receive their nervous fibres from it; in this instance, as in the other, there is no lateral communication between the fibrils. An exception exists, however, in regard to galvanic irritation, which may be transmitted laterally when its ordinary course is checked; as has been shown by the following ingenious experiment of M. du Bois-Reymond. If any motor nerve be selected which divaricates into two branches (as, for example, the sciatic nerve of a frog, which divides above the bend of the knee into the tibial and peroneal branches), and a galvanic stimulus be applied to either of these branches, this having been first divided above its insertion into the muscles, the electrotonic state will be developed, not merely in the portion of the trunk continuous with that branch,

¹ “Kirkes and Paget’s Handbook of Physiology,” p. 375.—It does not seem improbable, however, that in the case of the compression or other irritation of a large nerve-trunk the *local* pain may be produced through the instrumentality of *nervi nervorum*, the existence of which is scarcely less probable than that of *vasa vasorum*.

but also in that which is continuous with the other branch, as will be made apparent by the contraction in the muscles supplied by the latter. That this experiment may be free from the possible fallacy resulting from the excitement of reflex action, the trunk of the sciatic nerve should be divided high up, or the spinal cord be destroyed.

690. Various methods of determining the functions of particular nerves present themselves to the Physiological inquirer.—One source of evidence is drawn from their *peripheral distribution*. For example, if a nervous trunk is found to lose itself entirely in the substance of Muscles, it may be inferred to be chiefly, if not entirely, *motor* or *efferent*. In this manner, Willis long ago determined that the Third, Fourth, Sixth, Portio dura of the Seventh and Ninth cranial nerves, are almost entirely subservient to muscular movement; and the same had been observed of the fibres proceeding from the small root of the Fifth pair, before Sir C. Bell experimentally determined the double function of that division of the nerve into which alone it enters. Again, where a nerve passes through the muscles, with little or no ramification among them, and proceeds to a Cutaneous or Mucous surface, on which its branches are minutely distributed, there is equal reason to believe that it is of a *sensory*, or rather of an *afferent*, character. In this manner, Willis came to the conclusion that the Fifth pair of cranial nerves differs from those previously mentioned, in being partly sensory. Further, where a nerve is *entirely* distributed upon a surface adapted to receive impressions of a *special* kind, as the Schneiderian membrane, the retina, or the membrane lining the internal ear, it may be inferred that it is not capable of transmitting any other kind of impressions; for experiment has shown that the *special sensory* nerves do not possess common sensibility. The case is different, however, in regard to the sense of taste, which originates in impressions not far removed from those of ordinary touch; and it is probable that the same nerves minister to both.—Anatomical evidence of this kind is valuable also, not only in reference to the functions of a principal trunk, but even as to those of its several branches, which, in some instances, differ considerably. Thus, some of the branches of the Pneumogastric are especially motor, and others almost exclusively afferent; and anatomical examination, carefully prosecuted, not only assigns the reasons for these functions when ascertained, but is in itself nearly sufficient to determine them. For the superior laryngeal branch is distributed almost entirely upon the mucous surface of the larynx, the only muscle it supplies being the crico-thyroid; whilst the inferior laryngeal or recurrent is almost exclusively distributed to the muscles. From this we might infer that the former is an afferent, and the latter a motor nerve; and experimental inquiries (as we have seen, § 553) fully confirm this view. In like manner, it may be shown that the Glosso-pharyngeal is chiefly an afferent nerve, since it is distributed to the *surface* of the tongue and pharynx, and scarcely at all to the muscles of those parts; whilst the pharyngeal branches of the Pneumogastric are chiefly, if not entirely, motor (§ 427). Lower down, however, the branches of the Glosso-pharyngeal cease, and the œsophageal branches of the Pneumogastric are distributed both to the mucous surface and to the muscles, from which it may be inferred that they are both afferent and motor; a deduction which experiment confirms (§ 428).—We perceive, therefore, that much knowledge of the function of a nerve may be obtained, from the attentive study of its ultimate distribution; but it is necessary that this should be very carefully ascertained before it is made to serve as the foundation for physiological inferences. As an example of former errors in this respect, may be mentioned the description of the Portio dura of the Seventh, at first given by Sir C. Bell; he stated it to be distributed to the skin as well as to the muscles of the face, and evidently regarded it as in part an afferent nerve, subservient to respiratory

impressions as well as to motions. In the same manner, from inaccurate observation of the ultimate distribution of the Superior Laryngeal nerve, it was long regarded as that which stimulated to action the constrictors of the glottis.

691. But the knowledge obtained by such anatomical examinations alone is of a very general kind; and requires to be made particular—to be corrected and modified—by other sources of information. One of these relates to the *connection of the trunks with the central organs*. The evidence derived from this source, however, is seldom of a very definite character; and, in fact, Physiologists have rather been accustomed to judge of the functions of particular divisions of the nervous centres by those of the nerves with which they are connected, than to draw aid from the former in the determination of the latter. Still, this kind of examination is not without its use, when there is reason to believe that a particular tract of fibrous structure has a certain function, and when the office of a nerve whose roots terminate in it is doubtful. Here, again, however, very minute and accurate examination is necessary, before any sound physiological inferences can be drawn from facts of this description; and many instances might be adduced to show that the real connections of nerves and nervous centres are often very different from their apparent ones.

692. Most important information as to the functions of particular nerves may be drawn from *experimental inquiries*; but these also are liable to give fallacious results, unless they are prosecuted with a full knowledge of all the precautions necessary to insure success. Some of these will be here explained.—In the first place, the endowments of the *trunk* and of the *roots* of a nerve may differ; owing to the admixture, in the former, of fibres derived by inosculation from another nerve (§ 688). Hence, in order to attain satisfactory results, a comparative set of experiments should always be made upon each.—A nerve-trunk may be too hastily considered as *motor*, on account of the excitation of muscular movements by irritation of its trunk, whilst still in connection with its centre; for such movements may be called forth, not only by the direct influence of the nerve upon the muscles, but also by reflex stimulation, acting through the ganglionic centre upon some other nerve. The real nature of such movements can only be determined by dividing the trunk, and irritating each of the cut extremities. If, upon irritating the end *separated* from the centre, muscular contractions are produced, it may be safely inferred that the nerve is, in part at least, of an *effrent* character. Should no such result follow, this would be improbable. If, on the other hand, muscular movement should be produced by irritating the extremity *in connection with* the centre, it will then be evident, that it is occasioned by an impression conveyed *towards* the centre by *this* trunk, and propagated to the muscles by some other; in other words, to use the language of Dr. M. Hall, this nerve is an “*excitor*” of motion, not a direct motor nerve. The Glosso-pharyngeal has been satisfactorily determined, by experiments of this kind, performed by Dr. J. Reid (§ 427), to be chiefly, if not entirely, an afferent nerve.—It has been from the want of a proper mode of experimenting that the functions of the *posterior* roots of the Spinal nerves have been regarded as in any degree motor. If they be irritated, without division of either root, motions are often excited; but if they be divided, and their separated trunks be then irritated, no motions ensue; nor are any movements produced by irritation of the roots in connection with the spinal cord, if the *anterior* roots have been divided. Hence it appears that these fibres do not possess any direct motor powers, but that they convey impressions to the centre, which are reflected to the muscles through the anterior roots.—The same difficulties do not attend the determination of the *sensory* endowments of nerves. If, when the trunk of a nerve is pricked or pinched, the animal exhibit signs

of pain, it may be concluded that the nerve is capable of receiving and transmitting sensory impressions from its peripheral extremity. But not unfrequently this capability is derived by inosculation with another nerve; as is the case with the Facial, which is sensory after it has passed through the parotid gland, having received there a twig from the Fifth pair. A similar inosculation explains the apparent sensibility of the *anterior* roots of the Spinal nerves. If these be irritated, the animal usually gives signs of uneasiness; but, if they be divided, and the cut ends nearest the centre be irritated, none such are exhibited; whilst they are still shown when the farther ends are irritated, but not if the posterior roots are divided. This seems to indicate that, from the point of junction of the two roots, sensory fibres derived from the posterior root pass backwards (or towards the centre) in the anterior; and thus its apparent sensory endowments are entirely dependent upon its connection with the posterior column of the spinal cord, through the posterior roots.

693. The fallacies to which all experiments upon the nerves are subject, arising from the partial loss of their power of receiving and conveying impressions, and of exciting the muscles to action, after death, are too obvious to require more particular mention here; yet they are frequently overlooked. Of a similar description are those arising from severe disturbance of the system, in consequence of operations; which also have not been enough regarded by experimenters. As a general rule, *negative* results are of less value than *positive*; but very careful discrimination is often required to determine what *are* negative, and what positive results. Each particular case has *its* own sources of fallacy, which require to be logically scrutinized; and the only satisfactory proof is derived from the concurrence of every kind of evidence, which the nature of the inquiry admits of. Thus, in the determination of the functions of a particular nerve-trunk, it should be shown that a certain effect is constantly produced by its excitation (under the conditions laid down in the preceding paragraph), and that a corresponding interruption in the action to which it is hence inferred to be subservient, takes place when its continuity has been interrupted: by this double proof, the Glosso-pharyngeal and the Pneumogastric are shown to be the principal, but not the sole, exciters of the movements of Deglutition and Inspiration respectively. But the evidence afforded solely by the interruption of a particular function, after the division of a certain nerve, or the destruction or removal of a nervous centre, is by no means so satisfactory; for this may be occasioned rather by the general effects of the operation than by the simple lesion of the nervous apparatus. In order to get rid, so far as possible, of this source of fallacy (which particularly affects experiments upon the Encephalic centres, and upon the influence of the nerves upon the viscera), it is desirable to perform comparative experiments, in which the general injury shall be as nearly as possible the same, and the only difference shall lie in the lesion of the nervous system; and to subtract from the general result all that can be thus shown to be attributable to the general disturbance produced by the operation. But, even then, it may happen that the function is only suspended for a time by the shock which has been induced by the injury to the nerve; and if it should be subsequently renewed, without any reunion of the trunk, we have the most convincing proof that, whatever degree of participation the nerve may have in it, the action is not essentially dependent upon the integrity of that portion of the nervous apparatus. Such we have seen to be the case in regard to the relation of the Pneumogastric nerves to the secretion of gastric fluid in the walls of the stomach (§§ 445-447).

694. All our positive knowledge of the functions of the Nervous System in general, save that which results from our own consciousness of what passes within ourselves, and that which we obtain from watching the manifestations of

disease in Man, is derived from observation of the phenomena exhibited by animals made the subjects of experiments; and in the interpretation of these, great caution must be exercised.—In the first place it must be constantly borne in mind that, except through the *movements* consequent upon them, we have no means of ascertaining whether or not particular changes in the Nervous System, whose character we are endeavoring to determine, are attended with Sensation; since we have no power of judging whether or not this has been excited, save by the cries and struggles of the animal made the subject of experiment. Now although such cries and struggles are ordinarily considered as indications of pain, yet it is not right so to regard them in every instance; and the only unequivocal evidence is derived from observation of the corresponding phenomena in the Human subject; since we can there ascertain, by the direct testimony of the individual affected, what impressions produce sensation, and what excite movements independently of sensation (§ 674). Further, we are not justified in assuming that Consciousness is excited by an irritation, still less that Intelligence and Will are called into exercise by it, merely because movements, evidently tending to get rid of its source, are performed in response to it. We know that the contractions of the heart and alimentary tube are ordinarily excited by a stimulus, without any sensation being involved; and these movements, like all that are concerned in the maintenance of the Organic functions, have an obvious design, when considered either in their immediate effects, or in their more remote consequences. The character of *adaptiveness*, then, in Muscular movements excited by external stimuli, is no proof that they are performed in obedience to sensation; much less, that they have a voluntary character. In no case is this adaptiveness more remarkable than in some of those actions which are not only performed without any effort of the will, but which the will cannot imitate. This is the case, for example, with the act of Deglutition (§§ 427, 428), the muscles concerned in which cannot be thrown into contraction by a voluntary impulse, being stimulated only by impressions conveyed from the mucous surface of the fauces to the Medulla Oblongata, and thence reflected along the motor nerves. No one can swallow, without producing an impression of some kind upon this surface, to which the muscular movements will immediately respond. Now it is impossible to conceive any movements more perfectly adapted to a given purpose, than those of the parts in question; and yet they are independent not only of volition but of sensation, being still performed in cases, in which consciousness is completely suspended, or entirely absent. The act of Sucking in the infant, again, is one in which a number of muscles are called into combined contraction, in a manner which shows a most complete adaptation to a given purpose; and yet it is impossible to suppose this adaptation to be *purposive* on the part of the infant itself; more especially as it is shown, both by the occurrence of monstrosities, and by experiments made with this object (§ 423), that no part of the Cranio-spinal axis above the Medulla Oblongata is necessary to it. And in the acts of Coughing and Sneezing (§ 555), we have examples of the most *adaptive* movements, executed by a marvellous combination of separate muscular actions, with the obvious purpose of removing a source of irritation from the air-passages; and yet we know by personal experience, that this combination is *not* made with any design of our own.

695. In addition to the Cerebro-Spinal system of ganglionic centres and nerve-trunks, all but the lowest Vertebrated animals possess a system of ganglionic centres scattered in different parts of the body, but mutually connected with each other, as well as with the Cerebro-spinal system; this is commonly termed the *Sympathetic* system; but not unfrequently, from the position of its principal centres, and their evident functional relation to the

Fig. 172.

apparatus of Organic life, the *Visceral* system. To this system, which seldom presents itself in a distinctly recognizable form in Invertebrated animals, we are probably to refer not only the Semi-lunar and Cardiac ganglia (which seem to be its principal centres), with the chain of cranial, cervical, thoracic, lumbar, and sacral ganglia, which are in nearer connection with the cerebro-spinal system, but also numerous minute ganglia, which are to be found on its branches in various parts, and, in addition, the ganglia upon the posterior roots of the spinal nerves; and if such be the case, those fibres contained in the cerebro-spinal nerves, which have these as their ganglionic centres, must also be accounted as belonging to the Sympathetic system. On the other hand, there unquestionably exist numerous fibres in the Visceral system, which proceed into it from the Cerebro-spinal system; these, however, are not uniformly distributed, for some of the Visceral nerves contain few or none of them, whilst in others they are numerous. The branches by which the Sympathetic system communicates with the Cerebro-spinal, and which were formerly considered as the *roots* of the Sympathetic system, contain fibres of both kinds;—i. e., Cerebro-spinal fibres passing into the Sympathetic, and Sympathetic fibres passing into the Cerebro-spinal. The latter are chiefly, if not entirely, transmitted into the *anterior* branches of the Spinal nerves; the *posterior*

branches being apparently supplied with sympathetic fibres from the ganglia on their own posterior roots. Some of these last fibres also pass from the cerebro-spinal into the Sympathetic system. By these communications, the two systems of fibres are so blended with each other, that it is impossible to isolate them.—The branches proceeding from the Semilunar ganglia are distributed upon the abdominal viscera; and those of the Cardiac ganglia upon the heart and the vessels proceeding from it. The latter seem to accompany the arterial trunks through their whole course, ramifying minutely upon their surface; and it can scarcely be doubted that they exercise an important influence over their functions. What the nature of that influence may be, however, will be a subject for future inquiry. It is so evidently connected with the operations of nutrition, secretion, &c., that the designation of “nervous system of organic life,” as applied to this system, does not seem objectionable, provided that we do not understand it as denoting the *dependence* of these functions upon it.—Even in Vertebrata, however, we

do not always find the distribution of the visceral trunks distinct from that of the cerebro-spinal. In the Cyclostome Fishes, the par vagum supplies the intestinal canal along its whole length, as well as the heart; and no appearance of a distinct sympathetic can be discovered. In Serpents, again, the lower part of the alimentary canal is supplied from the spinal cord, and the upper part by the par vagum; and though the lateral cords of the sympathetic may be traced, they are almost destitute of ganglia. Even in the highest Vertebrata, some of the glands, of which the secretion is most directly influenced by the condition of the mind, are supplied with most of their nerves from the cerebro-spinal system; thus, the lachrymal and sublingual glands receive large branches from the fifth pair, and the mammary glands from the intercostal nerves.

2. Of the Spinal Cord and Medulla Oblongata;—their Structure and Actions.

696. In our more detailed consideration of the functions of the several divisions of the Nervous System, it is desirable, for several reasons, to commence with the *Cranio-Spinal Axis*; which, as already pointed out (§ 678), may be considered as constituting the fundamental portion of this apparatus. The entire Axis is divided into its Cranial and its Spinal portions, the passage of the Cord through the foramen magnum of the occipital bone being considered

to mark the boundary between them; and although the separation of the Medulla Spinalis from the Medulla Oblongata which is thus established, is in itself purely artificial, yet it will be found to correspond completely with the natural division founded on their respective physiological attributes. The *Spinal Cord*,¹ then, which extends from the margin of the foramen magnum to the first or second lumbar vertebra, and which is prolonged as the *filum terminale*² to the extremity of the sacral canal, is almost completely divided by the *anterior* and *posterior median fissures* (Fig. 174), into two lateral and symmetrical halves. The "anterior median fissure" (*a*) is more distinct than the posterior, being wider at the surface; but it only penetrates to about one-third of the thickness of the Cord, its depth increasing, however, towards its lower part. The sides of the "posterior median fissure" (*p*), on the other hand, are in closer approximation; but the division commonly extends to about half the thickness of the cord, being deeper towards its upper than towards its lower end. The two halves, therefore, are only united by a commissural band which occupies the central part of the cord, and this is traversed by the "Spinal canal" (*f*), which is continued downwards from the fourth ventricle.³ At a little distance from either side of the posterior median fissure, and corresponding with the line of attachment of the posterior roots of the nerves, is the *posterior lateral furrow*; a shallow, longitudinal depression, which marks out the "posterior columns" of the cord as distinct from the "antero-lateral columns." A corresponding furrow has been sometimes described as traversing the Cord in the line of the anterior roots of the nerves on either side; but this can scarcely be said to have a real existence; and the separation of the "antero-lateral columns" into the "anterior" and the "lateral" columns, is only marked externally by the attachment of the nerve-roots, but is made more obvious internally by the peculiar distribution of the gray matter. These columns are entirely composed of nerve-fibres, whose general direction is longitudinal; and of these fibres it is quite certain that some are directly continuous with those which constitute the roots of the spinal nerves. It has been generally considered by Anatomists, that the anterior roots are chiefly connected with the anterior columns, but that some of their fibres are also continuous with the lateral columns; and that the posterior roots are in like manner connected chiefly with the posterior, but also with the lateral columns. Some have maintained, on the other hand, that both sets of nerve-roots are connected with the lateral columns exclusively. According to the most recent researches, however, it appears that the anterior roots are directly connected with the anterior columns only, and the posterior roots with the posterior columns alone; but of those fibres from both these roots which pass at first into the gray matter, a certain proportion emerge from this and enter the lateral columns.—To what extent any of these fibres proceed along the columns of the Spinal Cord, no precise anatomical evidence has yet been obtained; and although there are appearances which may be regarded as sanctioning the idea that a direct and continuous communication is established by their means between the roots of the nerves

¹ The sketch given in the text of the anatomy of the Spinal Cord is chiefly derived from the statements of Prof. Kolliker in his "Mikroskopische Anatomie" (Band ii. §§ 115, 116), and of Mr. J. L. Clarke in the "Philosophical Transactions," 1851; between which there is a general accordance.

² The structure of the "filum terminale" is in every respect essentially the same as that of the proper Spinal Cord, save that no nerve-roots are connected with it.

³ The spinal canal is much more obvious in Fishes; and the commissural connection between the two halves of their spinal cord is far less distinct than in higher Vertebrata. The canal can only be distinguished in Man, being no more than 1-100th of an inch in diameter, by submitting thin transverse sections of the Cord to microscopic examination.

and the encephalic centres, yet there are difficulties, in such a view of the case, which must be taken into account in our physiological consideration of it (§ 700).

697. The "gray matter" of the Spinal Cord is readily brought into view by making transverse sections in different parts: and although its distribution is by no means uniform, yet on the whole it may be described as constituting (when thus exposed) two somewhat crescent-shaped masses (Fig. 174), whose convexities are turned towards each other, and are connected by the gray commissure, whilst their cornua are directed towards the surface of the cord; the posterior peak on either side reaching the posterior lateral furrow, whilst the anterior, though the larger cornu, does not approach quite so near to the surface. This gray matter, however, is by no means uniform in its texture throughout. A considerable part of the posterior cornua is destitute of vesicular or ganglionic corpuscles, and is known under the name of *substantia gelatinosa* (*g*); it has been lately shown by Mr. J. L. Clarke, however, that a tract of vesicular matter does exist on either side (*e*), in intimate connection with the posterior roots of the nerves, and that this may be traced continuously from the lower extremity of the spinal cord to the medulla oblongata where it terminates, and that it increases in size in the lumbar and cervical enlargements. The gray matter of the anterior cornua, which has been distinguished as the *substantia spongiosa*, contains a large amount of vesicular structure (*d, d*), the number of

Fig. 174.

vesicles being constantly in direct proportion to the size of the nerve-roots in connection with it. The vesicles are of the stellate character, each having several prolongations which seem to unite with those of other vesicles; and

hitherto it has not been found possible to trace any direct passage of these prolongations into nerve-fibres. The commissure is formed entirely, according to Mr. J. L. Clarke, by the fibrous portion of the gray matter, neither the anterior nor the posterior columns having any direct connection by transverse fibres; and the central part of it is stated by him to consist of a layer of fine fibrous tissue surrounding the wall of the spinal canal, which is lined with a layer of columnar epithelium. The fibres of the gray substance and even those of the *substantia gelatinosa* are tubular, but are of extremely minute size, their average diameter not exceeding 1-10,000th of an inch, and some of them measuring as little as 1-15,000th or 1-16,000th. The course of the fibres which constitute the roots of the Spinal Nerves, as seen in transverse sections of the Cord, is thus described by Mr. J. L. Clarke. The bundles of fibres which form the *posterior* root (Fig. 174, c, c) are much larger, but less numerous than those of the anterior; the fibres themselves are mostly finer and more delicate, their average diameter being about 1-7000th of an inch. On entering the posterior columns of the Cord, the fasciculi traverse them obliquely inwards, interlacing and forming with each other an intricate plexus. From this plexus, straight and distinct bundles enter the posterior cornua along their whole breadth, and cross the "*substantia gelatinosa*" both obliquely and at right angles; some being immediately continuous with fibres of the transverse commissure, some passing to the vesicular tract, while others break up and form a finer network which extends towards the anterior cornua. Some of these fibres, after traversing the gray substance, pass out again into the posterior and lateral white columns; and many of those of the "*substantia gelatinosa*" seem to become longitudinal. The fasciculi of fibres which constitute the *anterior* roots, on the other hand, traverse the anterior columns of the Cord somewhat obliquely, and in straight and distinct bundles, which do not interlace with each other, but proceed directly to the anterior gray cornu. On reaching this, they break up into smaller bundles and separate fibres, which diverge in various directions; of those proceeding towards the external border of the cornu, some pass out again into the antero-lateral column, whilst others, after winding round groups of caudate vesicles, curve inwards and join the fibres of the transverse commissure; of those proceeding along the inner border of the cornu, a few pass into the white column at the side of the median fissure, while others, entering the anterior portion of the transverse commissure, cross to the opposite side; and the remainder, plunging into the central portion of the cornu, and winding among its vesicles, seem to lose themselves in its substance, some of them probably changing their direction and becoming longitudinal. According to Stilling, an absolute continuity is thus established between certain of the anterior and posterior root-fibres of the same side; and also between the anterior fibres of one side and the posterior of the other, through the transverse commissure. The evidence which he has adduced in favor of this doctrine, however, is by no means satisfactory; and for the present it must be regarded as hypothetical. That an actual decussation of the fibres of the Cord is effected by means of the transverse commissure, although denied by Hannover, seems to have been fully proved by Mr. J. L. Clarke; this decussation, however, is limited, as already stated, to the fibres of the gray matter.¹

698. The Spinal Cord is by no means of uniform dimensions throughout its

¹ Mr. J. L. Clarke has succeeded in preparing transverse sections of the Cord of sufficient thinness to enable them to be seen under high powers with transmitted light; whereas the statements of Stilling, and of other observers who have used his method, have been founded upon observations made upon comparatively opaque sections seen under low powers, and often with reflected light, whereby the nature of the several structures was often left in obscurity.

length, but presents an enlargement at the origins of the large nerves forming the brachial and crural plexuses. This enlargement is produced by an increase in the quantity both of the gray and of the white substances; and it is obviously comparable to the enlargement of the ganglia of the ventral cord of *Articulata*, which presents itself in connection with the nerves of the special locomotive organs, as we well see in tracing the alterations which this cord undergoes between the "larva" and "imago" states of the Insect.¹ Its relation to the functions of these nerves is further indicated by the constancy with which it presents itself, through the entire Vertebrated series, in those parts of the Cord from which the largest supply is transmitted to the locomotive organs. In most Fishes, for example, the body being propelled through the water rather by the lateral action of the flattened trunk and tail (with that of the median fins), than by the movements of the extremities, which serve principally to guide it, the size of the Cord usually varies but little through its whole length; and this is especially the case with the Eel and other vermiform apodal fishes. But in the Flying-fish, and others whose pectoral fins are unusually powerful, a distinct ganglionic enlargement of the cord presents itself where their nerves are given off. In Serpents, again, the spinal cord is nearly uniform throughout its entire length; whilst in *Amphibia* it is so during the Tadpole condition, but presents enlargements corresponding to the anterior and posterior extremities, when these are developed; at the same time becoming much shortened, as the tail is less important to locomotion, or is altogether atrophied. In Birds, the ganglionic enlargements are generally very perceptible, and bear a close relation in size with the development of the locomotive organs with which they are connected: thus in birds of active flight, and short powerless legs, the anterior enlargement is the principal; but in those which are more adapted to run on land than to wing their way through the air, such as the whole tribe of Struthious birds, the size of the posterior enlargement is very remarkable; and this exactly corresponds with what has been observed in the Articulated classes, and especially in watching the metamorphosis of Insects. In Birds and Mammalia, however, the whole amount of the gray matter in the spinal cord does not bear so large a proportion to the bulk of the nerves proceeding from it, as in the lower Vertebrata; and the reason of this seems obvious. The actions of the locomotive organs are less and less of a reflex character, and are more directly excited by the will, and consequently by the brain, than in the inferior tribes; and just in proportion, therefore, to the development of the Brain, will it become the moving spring of all the actions performed by the animal, and the Spinal Cord be merely its instrument. Still, in all the Mammalia, as in Man, do we find these

ganglionic enlargements of the spinal cord; and in Man it is the posterior one (or rather the inferior), which contains the largest quantity of gray matter.

699. No doubt is now entertained amongst Physiologists that the Spinal Cord is to be regarded under a double aspect;—on the one hand, as an independent centre of nervous power, on which excitor impressions operate to produce reflex movements;—and, on the other, as the channel of communication between the roots of the spinal nerves and the encephalic centres, whereby sensory impressions are transmitted upwards to the sensorium, and motor influences originating in the brain are transmitted downwards to the efferent nerves. But with regard to what may be termed the mechanism by which this is effected, there is at present a considerable diversity of opinion; which arises out of the difficulty of determining, on the one hand, whether any of the root-fibres actually terminate in the gray matter of the Cord, and, on the other, whether the longitudinal fibres of the white columns are actually continuous from the Medulla Oblongata to the roots of the Spinal nerves. Three distinct notions of this mechanism at present have their several advocates amongst Anatomists of distinction.

I. According to the first view, which may be regarded as a modification of the doctrine which was current before the independent power of the Spinal Cord had been distinctly recognized, *all* the root-fibres of the Spinal nerves are brought by means of its longitudinal columns into direct continuity with the *Encephalic* centres; so that sensory impressions are transmitted upwards to the sensorium, and motor impulses are transmitted downwards from the seats of volition, emotion, &c., without any interruption. But these fibres *pass through* the gray substance of the Spinal Cord, in their transit from the white columns to the nerve roots, and are thus subjected to the influence of its vesicular matter, which is capable of exerting an independent operation through them, especially when their continuity with the Brain is interrupted.

II. According to the second view, the *Spinal Cord* is the real ganglionic centre of *all* the root-fibres of the nerves issuing from it; each pair of nerves being thus directly connected only with its own segment of the cord, or with other segments a little above or below this; and the function of the white or longitudinal columns being to establish a commissural connection between the several segments of the Cord, and to bring them into connection also with the Encephalic centres. On this hypothesis, no sensory impressions pass directly from the Spinal nerves to the Sensorium, and no motor impulse is directly transmitted from any part of the Encephalon to these nerves, the vesicular matter of the Spinal Cord being in each case the immediate recipient of the change, and serving (so to speak) as a fresh starting-point for the nerve-force; whilst, if the connection of any segment with the Encephalon be interrupted, that segment reacts upon impressions transmitted to it, in virtue of the direct connection of the nerve-roots with its own ganglionic centre.

III. The third view is a combination of both the preceding doctrines; for it is considered by those who advocate it, that certain of the root-fibres, passing continuously along the longitudinal columns of the Cord, establish a direct connection, for sensory and motor purposes, between the Spinal nerves and the Encephalic centres; while certain other fibres have their central termination in the gray matter of the Cord itself. It is considered, on this hypothesis, that the fibres which minister to sensory impressions do so in virtue of their direct and continuous passage from the peripheral surface to the sensorium; whilst the fibres which transmit downwards from the Encephalic centres the motor impulses originating in them, pass continuously to the muscles which they call into play. On the other hand, each segment of the Cord is considered to minister to its own reflex action; the different segments, however, possessing such a commissural connection with each other, that an impression made upon one of

them may be transmitted to many others, and may excite reflex movements through them. Among those who hold this view, however, there is a very considerable difference of opinion with regard to the real centre of the Encephalic fibres; some maintaining that they *pass through* the Corpora Striata, Thalami Optici, and other Sensory Ganglia, to the peripheral vesicular matter of the Cerebrum; whilst others hold that the real *termination* of all of them is in the Sensory Ganglia, and that the Cerebrum has therefore no connection with them, otherwise than through the intermediation of those bodies. Although this question may be considered as rather related to the structure and functions of the Encephalic centres, than to that of the Spinal Cord, yet it has such a bearing upon the function assigned to the longitudinal fibres of the Cord that it must be taken into account in the present discussion.

700. The principal argument for the doctrine (which seems to have originated with the anatomical researches of Stilling and Wallach,¹ and to have been first put forth on a physiological basis by Messrs. Todd and Bowman²) that the Spinal Cord is the real centre of all the nerve-fibres connected with it, arises from the asserted difficulty of supposing that its longitudinal columns *can* transmit any considerable number of nerve-fibres from the Encephalon to the Spinal nerve-roots. Thus it is urged by Dr. Todd, that it is highly improbable that the only channel by which the Will can influence the spinal nerves should be (as generally admitted) that afforded by the Anterior Pyramids; since the whole bulk of these pyramids on *both* sides, taken together, scarcely equals that of *one* of the anterior portions of the antero-lateral columns. Moreover, if there were a gradual giving-off of Encephalic fibres from the longitudinal columns into the roots of the nerves, the size of these columns ought progressively to diminish from above downwards; whereas it is asserted by Volkmann, who has strenuously upheld this doctrine,³ that the size of the white columns presents no such diminution, but that it is everywhere proportional to the quantity of gray matter in the Cord. Thus in Serpents, the Spinal cord (as already noticed) is remarkable for its uniformity of dimension through its entire length, the absence of limbs preventing the necessity for an increase in the quantity of gray matter in any part, and the fibrous columns presenting a similar uniformity throughout; whereas, if the latter be really Encephalic, they should gradually dwindle away from the head to the tail. Moreover, it has been estimated by Volkmann, that the area of the whole Spinal Cord of a Boa, at its anterior part, is not more than *one-eleventh* part of the united area of the 221 pairs of nerves which are given off from it. Further, it is urged by Volkmann, that the white columns are absolutely smaller in the cervical region than they are in the lower part of the cord, so that they would not suffice to convey even the lumbar columns upwards to the Encephalon, much less to transmit the fibres of all the intervening nerves in addition. Thus, having weighed four pieces of a Horse's spinal cord, all of the same length, and taken respectively from below the second, eighth, nineteenth, and thirtieth pairs of nerves, he found that their weights were respectively 219, 293, 163, and 281 grains; and that the transverse sections of the gray matter gave respectively the area of 13, 28, 11, and 25 square lines, whilst those of the white matter measured 109, 142, 89, and 121 square lines. Hence the greatest amount of fibrous as well as of gray substance is found in those enlargements of the cord which are the ganglionic centres of the nerves of the extremities; these being the parts from which the second and fourth segments were taken in the preceding experiment. On the other hand, in the middle dorsal region, the amount of fibrous structure appears

¹ "Untersuchungen über die Textur des Rückenmarks," Leipzig, 1842.

² "Physiological Anatomy and Physiology of Man," *Am. Ed.*

³ See his valuable article "Nervenphysiologie," in Wagner's "Handwörterbuch der Physiologie."

reduced to its minimum; and in the upper cervical region it is considerably less than in the segments below.—These and similar statements, however, have been recently met by Prof. Kölliker,¹ who inclines to the first of the doctrines stated in the preceding paragraph; his own researches having led him to a conclusion opposed to that of Volkmann, although he was at one time disposed to coincide with it. He has assured himself that in Man the thickness of the white columns augments from below upwards, and that the increase in the diameter of the Cord at the ganglionic enlargements is due to the augmentation of the gray matter only. Moreover, the diameter of the nerve-tubes in the Cord, especially at its upper part, is so much smaller than the diameter of the nerve-tubes of the Nerve-roots, that a large allowance must be made for this difference in estimating the relative number of nerve-tubes in the fibrous columns of the Cord and in the spinal Nerves; and he asserts, from actual measurement, that it is by no means impossible for the fibrous strands of the former to contain all the nerve-tubes which issue from them in the latter. He has found himself unable, moreover, to detect *any* termination of nerve-fibres in the vesicular substance of the spinal cord; and hence he thinks it probable that they all pass upwards to the brain.

701. The researches of Prof. Kölliker have thus shown it to be quite possible that many of the nerve-fibres (to say the least) do pass continuously between the Encephalon and the nerve-roots; whilst there is an antecedent probability, derived from the relation of these fibres to the vesicular substance of the Cord, and from the attributes of each segment of the cord as an independent ganglionic centre, that some of them terminate there. This probability becomes very strong when the Spinal Cord is compared with the ventral column of the Articulata; for it may be stated, with certainty, that some of the root-fibres of the nerves proceeding from the latter have their ganglionic centres in the vesicular matter of the ganglia; whilst it is equally certain that some of the fibres pass along the purely fibrous tract of the cord, directly to the cephalic ganglia, which they thus connect with the roots of all the nerves.² But this fibrous tract terminates in the Cephalic ganglia, which are homologous, as already remarked (§ 674), not with the whole Encephalon of Vertebrata, but with their “sensory ganglia” alone; and thus analogy would lead us to suppose that the fibrous strands of the Spinal Cord do *not* pass on continuously to the Cerebrum, but really extend no further upwards than the Corpora Striata, Thalami Optici, and the other ganglionic centres in connection with them, which lie along the floor of the cranial cavity. This view will be hereafter shown (Sect. 3) to be in harmony with anatomical and physiological facts, which indicate that the Cerebrum only receives its impulses to action through the medium of the Sensory Ganglia, and that it reacts upon the muscular apparatus only through the same channel. That some of the afferent fibres of the spinal nerves should pass continuously upwards to the ganglia of tactile sense in Man and other Vertebrata, as well as in Articulated animals, would seem a legitimate deduction from the fact that such continuity obviously exists between the olfactive, visual, and auditory nerves, and *their* respective ganglionic centres, no intermediate apparatus of vesicular matter being interposed in their course; and there seems no reason why the motor fibres which are instrumental in those movements that are dependent upon antecedent or coexistent sensations, should not pass continuously from these sensorial centres to the muscles which are called into action. If such

¹ “Mikroskopische Anatomie,” Band ii. § 116.

² See “Princ. of Phys., Gen. and Comp.,” § 768, *Am. Ed.*—The important facts here referred to, have been chiefly substantiated by the researches of Mr. Newport; a very important addition to his statements, however, has been recently made by M. Gunther, who has demonstrated the actual continuity between the nerve-fibres and the caudate vesicles, in the ganglia of the ventral cord of the Leech.

be the case, it does not seem at all improbable that there should be a difference in different tribes of animals, as to the proportion of fibres which have their centres in the Spinal cord and in the Sensorial centres respectively; for in those whose ordinary movements of progression, &c., are independent of sensation, being performed through the reflex action of the spinal cord, it might be expected that the chief connection of the spinal nerves should be with its own ganglionic substance, and that the bulk of the fibrous columns should be composed of commissural fibres resembling those which intervene between the separate portions of the ganglionic tract of the ventral cord of Articulata; whilst in like manner it might be anticipated that in Man, so large a part of whose movements are performed in obedience to a mental stimulus and under the guidance of sensation, the longitudinal strands should be chiefly composed of fibres that directly connect the sensorial centres with the roots of the spinal nerves. Such a difference would appear, from the comparative researches of MM. Volkmann and Kölliker, to exist between the structure of the Spinal cord of the Horse and that of Man.

702. Of the three doctrines previously stated, then, the third appears to be most in conformity with the analogy of the lower animals; whilst it is fairly justified by all that is certainly known of the anatomical structure of the Spinal Cord in Man. When originally advanced by Mr. Grainger,¹ its novelty chiefly consisted in the idea that *any* of the root-fibres of the spinal nerves have their central termination in the Spinal Cord; and no doubt was at that time entertained by Anatomists or Physiologists, that the Encephalic fibres pass onwards continuously to the peripheral surface of the Cerebrum, and directly minister to voluntary movement as well as to sensation. Consequently, Mr. Grainger's view of the constitution of the Spinal Cord was considered by many Physiologists (among whom the Author is not ashamed to have himself ranked) as affording the needed structural confirmation to Dr. Marshall Hall's hypothesis of a system of nerve-fibres ministering to the reflex action of the Cord, physiologically distinct from those which are subservient to sensation and voluntary movement. But when that distinction is made between the several Encephalic centres which there now appears ground for relying on, those fibres which connect them with the Spinal nerves are no longer to be accounted Cerebral, nor to be regarded as ministering to volition; but, on the other hand, are to be considered as merely Sensorial, and as belonging, no less than the fibres which link together the several segments of the Spinal Cord itself, to the "automatic apparatus" (§ 677).—Thus the view here advocated has a close *physiological* resemblance to the doctrine of Messrs. Todd and Bowman, Volkmann, &c.; whilst it is in full conformity with the *anatomical* facts supplied by Prof. Kölliker; for, whilst it recognizes the white columns of the Spinal Cord as chiefly composed of fibres which form a continuous connection between the nerve-roots and certain Encephalic centres, it regards these fibres as really *of the same order* with those which are generally admitted to pass from the nerves of one segment of the Spinal Cord to other segments above and below it, the only difference being that they extend themselves to its cranial segments: and it considers the entire "automatic apparatus" as receiving all the terminations of the nerves, so that all impressions upon the afferent nerves first operate upon it (affecting the consciousness, or not, according as they reach the sensory ganglia, or are arrested in their progress thither); and all motor impulses, whether simply reflex, or originating in emotional or volitional excitement, are issued from it through the nerve-trunks to the muscles.

703. In considering the functions of the Spinal Cord, we have to regard it under two aspects; in the first place, as a *conductor* of nervous force between

¹ "Observations on the Structure and Functions of the Spinal Cord," 1837.

the Nerve-trunks and the Encephalic centres; and in the second place, as itself *an independent centre* of nervous power. As a mere conductor of nervous force, its functions are the same as those of a nerve-trunk; for, if it be divided, all the parts of the body which are solely supplied by nerves coming off below the point of section are completely paralyzed as far as regards sensibility and voluntary movement; no impressions made upon them having the least power to affect the consciousness, and no exertion of the will being able to determine contraction of their muscles. This state of *paraplegia*, which may be experimentally induced in animals, is frequently exhibited in Man as a result of injury or of disease which seriously implicates the Spinal Cord; and, as it has been shown that among the lower animals complete reunion of the Cord may take place after complete division, as indicated by the entire restoration of its functional powers and the complete redintegration of its structure (§ 349), so have we reason to believe that a similar regeneration may take place to a considerable extent in Man, this being marked by the gradual return of sensibility and power of voluntary movement in the lower limbs which had been at first completely paralyzed. This regeneration is of course less likely to occur in cases of disease, when the parts around are in an unhealthy state, than when the paralysis is due to injury, which all the restorative powers of the system are engaged in repairing: but it is to be remembered that, as the injuries which are likely to cause such lesions of the Cord are nearly always attended with severe concussion (it being very rare for it to be accidentally wounded by the penetration of a sharp instrument between the vertebræ, in the mode in which experiments are made upon animals), some of their first effects are attributable to the *shock* which it has sustained; so that the partial recovery which takes place at an early period must not be regarded as the result of regeneration of nervous tissue, which requires a much longer time for its completion.

704. The conducting power of the entire Spinal Cord being thus established, we have next to inquire whether any difference in endowment can be shown to exist in its several columns. By Sir C. Bell, it was supposed that the anterior columns possess the same endowments as the anterior roots of the nerves, and the posterior columns the same as the posterior roots; and this view is supported by the experiments of Longet,¹ who deduces from them the conclusion, that irritation of the *posterior* columns, as of the posterior nerve-roots, gives rise to excruciating pain, without exciting any other movements than such as are called into action in reflex response to the impression, and that irritation of the *anterior* columns excites movements directly (or without reflexion), and is not a source of pain. Again, he found that when the Spinal Cord was completely divided, and time was allowed for the reflex activity of the cord to subside (this disappearing rapidly in adult warm-blooded animals), the application of an electric current to the posterior columns of the separated part occasioned no movement whatever, whilst its transmission through the anterior columns called forth vigorous movements. Moreover, he states that the effects of the reversal of the electric current, transmitted through the anterior columns, were the same as those of the same reversal when the currents were transmitted through the anterior roots of the spinal nerves; whilst they differed from those produced by the same change in the direction of the currents, transmitted through a nerve of mixed endowments.—The researches of Van Deen² lead on the whole to the same conclusions: but they tend, in his opinion, to show that the conducting power both of the anterior and posterior columns is very imperfect, if their white strands be completely separated from their gray matter. His experiments

¹ "Anatomie et Physiologie du Système Nerveux," 1842; and "Traité de Physiologie," 1850, tom. ii. pp. 184-8.

² "Traité et Découvertes sur la Physiologie et la Moëlle Epinière," Leide, 1841.

appear to have conclusively established that the gray matter, as well as the white, possesses conducting powers; as we might indeed anticipate from the circumstance, that it contains a large amount of the fibrous form of nerve-tissue, and that the commissural connection between the two lateral halves of the Cord is established (according to Mr. J. L. Clarke, § 696) by its gray substance alone. That a ready transverse communication exists, is proved not merely by the fact that an impression made upon a nerve of one side will very commonly excite reflex movements on both; but also by the experiment of completely dividing one-half of the cord as far as the median line, and dividing the other half to the same extent a short distance below the first section; for this operation does interrupt the transmission of sensory impressions, although it seems doubtful whether motor influences can be thus propagated.¹—The experimental results of Stilling,² again, are on the whole in harmony with the preceding; but he lays yet greater stress than Van Deen on the importance of the gray matter to even the conductive power of the white.—These deductions, however, are strongly opposed by Longet, who affirms that he could never obtain any evidence either of sensibility or of motor power, on irritating the gray substance alone by the electric current; and that, on the other hand, the entire destruction of the gray matter for a considerable length, by means of a rod introduced into the interior of the Cord, did not seem in any degree to impair the conducting power of its columns. It must be borne in mind, however, that there are numerous pathological phenomena, which it is very difficult to reconcile with the foregoing conclusions regarding the relative functions of the anterior and posterior columns of the Spinal Cord; cases having occurred, in which complete destruction of the anterior columns appeared to have taken place, without loss of voluntary motion in the parts below; whilst a similar destruction of the posterior columns has occurred without corresponding lesion of sensibility.³ But it must be borne in mind that we are still far from having an accurate knowledge of the degree of structural change in the nervous centres, which is incompatible with the continued performance of their functions; and that there are instances in which the whole thickness of the cord has undergone softening and apparent disintegration, without the destruction of the functional connection between the Encephalon and the parts below the seat of the disease.⁴

¹ A case is cited by Longet from Begin, in which a man was stabbed at the back of the neck, the point of the knife passing obliquely forwards between the sixth and seventh cervical vertebræ, dividing the antero-lateral and anterior columns of the Spinal Cord on the right side. He survived the injury six days; and suffered from complete paralysis of motion of the corresponding lower extremity, with incomplete paralysis of motion of the right arm; the sensibility remaining perfect. This case seems to show that the Will has no power to direct its motor impulses across the cord; since the parts deriving their nerves from the part of the cord below the partial section were entirely withdrawn from its influence.

² "Untersuchungen über die Functionen des Rückenmarks und die Nerven," Leipzig, 1842.

³ See especially the case recorded by Mr. Stanley in "Med.-Chir. Transact.," vol. xxiii. and by Dr. Webster, *Op. cit.*, vol. xxvi.

⁴ See, for example, the case of "Softening of the Spinal Marrow," recorded by Dr. Nairne in the "Med.-Chir. Trans.," vol. xxxiv.; in which a portion of the Cord at least an inch long, situated opposite the third and fourth dorsal vertebræ, was "so soft that the slightest pressure of the finger broke it up," being nearly in a fluid state through its whole thickness; yet the patient felt *pain* in his lower limbs, showing that the power of *upward* transmission remained; and, although he had lost all voluntary control over the muscles of the lower part of the body, yet they were affected with incessant *choreic* movement (which, as will be shown hereafter, Sect. 7, appears to originate in the Sensory Ganglia), and these movements were affected in such a marked manner by *emotions*, as plainly to indicate a *downward* transmission of motor power.

[The experiments of Dr. Brown-Sequard, witnessed by the editor, are also confirmatory of the results obtained by Van Deen, Stilling, Longet, and Clarke. Section of the posterior column on either side diminished the sensibility of the opposite side, at the same time that the operation caused great pain. Section of the whole of the white matter of the cord, however, did not destroy sensibility entirely, so long as the central gray matter was uninjured, thus showing that it, as well as the white matter, was a medium for the conduction of sensory impressions. An interesting fact has been witnessed in connection with these experiments, viz.: a degeneration of the tract of white fibres on the opposite side from the wound, evidenced by the deposition of granular cells, the beginning of a metamorphosis to be perfected after a lapse of time. This degeneration has been shown by Dr. Turek, of Vienna, to be a consequence of abrogation of function, the result either of disease or experiment;¹ and it manifests itself both in the sensory and motor tracts, whenever the transmission of motor impulses or sensory impressions has been arrested. The gray matter is not subject to the formation within it of these abnormal cells, from which, however, no conclusion can be absolutely drawn with regard to its power of conduction.—ED.]

705. It is difficult to reconcile with the experimental results already cited, those of other Physiologists, which appear to show that the anterior and posterior divisions of the Spinal Cord respectively minister to the motions of flexion and extension. This notion, which originated with Bellingeri,² was afterwards advocated by Valentin,³ who inferred from his experiments that, if the *posterior* column of the Spinal Cord of the Frog be irritated at the point at which the nerves of either extremity are given off, that extremity is *extended*, and that if the *anterior* column be irritated, the extremity is *flexed*; so that, since he admitted the anterior columns to be chiefly motor, and the posterior to be for the most part sensory, it would appear that the motor fibres of the extensors pass from the anterior into the posterior column, whilst those of the flexors are continued onwards in the anterior column. Confirmation of this inference was obtained by Valentin from experiments on Mammalia; and it is borne out according to him, by pathological phenomena observed in Man. According to this eminent physiologist, also, relaxation of the sphincters is analogous to the extended state of the extremities; and he has noticed a manifest relaxation of the sphincter ani in the frog, when the superior part of the spinal cord was irritated, so as to produce extension of the limbs. The experiments of Budge⁴ and Engelhardt,⁵ however, led them to an opposite conclusion; for it appeared to them that, in Mammalia, the nerve-fibres which act upon the *extensor* muscles are contained in the *anterior* columns, and those of the *flexor* muscles in the *posterior* columns; whilst, as regards the Frog, the nerve-fibres connected with the extensor muscles appeared to be situated posteriorly to those of the flexors. The experiments of Harless,⁶ again, have led him to regard the *upper* part of the spinal cord in the Frog, between the 2d and 4th vertebræ inclusive, as specially concerned in the *flexion* both of the anterior and posterior extremities; and the *lower* part, from the 5th to the 8th vertebræ inclusive, as in like manner concerned in their *extension*. All these results can only at present be accepted as indicating that some such special arrangement of the nerve-fibres in the Spinal Cord, having reference to the combination of different muscular actions in groups, may have a real existence; there is far too little accordance,

¹ "Über Secundäre Erkrankung einzelner Rückenmarksstränge und ihren Fortsetzungen zum Gebirne," Vienna, 1851.

⁶ "Müller's Archiv.," 1846.

however, among the phenomena described by different observers, to enable even a probable statement to be hazarded in regard to the nature of this arrangement; and it seems quite possible that it may vary in different animals, in accordance with their respective modes of progression. As far as Man is concerned, we have no evidence but that of pathological phenomena; and we certainly may find, in many forms of convulsive action, an indication that there is some common centre or tract of motor impulse for the extensor muscles generally, and another such centre or tract for the flexors.

706. We have now to consider the Spinal Cord as an independent centre of nervous power, and to inquire whether the movements which are excited through its "reflex activity really involve sensation. These movements are most characteristically displayed, when the Spinal Cord is cut off from communication with the higher Nervous centres; probably rather because the nerve-force excited by the impression reacts through the Spinal ganglion to which it is conveyed, when it can no longer pass on to the Encephalic centres (§ 683), than because (as some suppose) the impulse to reflex movement is ordinarily neutralized and rendered inoperative by an effort of the will. It is true that those reflex actions of the Spinal Cord which are necessary to the maintenance of Organic life, and which are equally performed whether the Spinal axis be in communication with the higher Encephalic centres or not, are continually modified or temporarily suspended by the Will; but this is only when we consciously bring the Will to bear upon them; and it is no less certain that we are *not* continually making any such exertions, in order to antagonize movements, which (as we learn from Pathological evidence), would be continually excited but for this neutralizing influence, if such a doctrine were correct. The readiest demonstration of the independent power of the Spinal Cord is derived from the motions exhibited by the limbs of animals, when irritation is applied to them after section of the Spinal Cord at some point above the entrance of their nerves; the fact that these movements are reflected through the Cord, and are not the product of direct stimulation applied to the part irritated, being shown by their complete cessation when the nerve-trunks are divided, or the substance of the Spinal Cord is broken down. Further, it is to be observed that a slight irritation applied to the peripheral *extremities* of the afferent nerves, is a more powerful excitor of reflex action than a much stronger impression, which occasions acute pain, applied to their *trunks*; thus, Mr. Grainger found that he could remove the entire hind-leg of a Salamander with the scissors, without the creature moving, or giving any expression of suffering, if the Spinal Cord had been first divided; yet that by irritation of the foot, especially by heat, in an animal similarly circumstanced, violent convulsive actions in the legs and tail were excited. This fact is important, not only as showing the comparatively powerful effect of impressions upon the cutaneous surface, but also as proving how little relation the amount of reflex action has to the intensity of sensation. [When the cutaneous surface is removed, reflex action can scarcely be excited at all by impressions, even of the most irritating character, as we have seen repeatedly in frogs whose inferior extremities have been denuded of cuticle.—ED.] That the movements executed by the limbs of the lower animals, when these are no longer connected by the Spinal Cord with the Encephalon, but remain connected with the Cord itself, do not take place through the intermediation of sensation, might be supposed to be sufficiently proved by the simple fact that division of the Cord, in Man, and hence by inference in the lower animals, reduces the parts below to a state of complete insensibility. But, on the other hand, the very performance, by decapitated animals of inferior tribes, of actions which had not been witnessed in Man under similar circumstances, has been held to indicate that the spinal cord in them has an endowment which *his* does not possess. The possibility of such an explanation, however unconformable to that analogy

throughout organized nature, which, the more it is studied, the more invariably is found to guide to truth, could not be disproved. Whatever experiments on decapitated animals were appealed to, in support of the doctrine that the Brain contains the only seat of sensibility, could be met by a simple denial that the Spinal Cord is everywhere as destitute of that endowment as it appears to be in Man. The cases of profound sleep and apoplexy might be cited as examples of reflex action without consciousness; but these have been met by the assertion that in such conditions sensations are *felt*, though they are not *remembered*. It is difficult, however, to apply such an explanation to the case of anencephalous human infants (in which all the ordinary reflex actions have been exhibited, with an entire absence of brain), without supposing that the Medulla Oblongata is the seat of a sensibility which we know that the lower part of the Spinal Cord does not possess; and of this there is no evidence whatever. Experiments on the lower animals, then, and observation of the phenomena manifested by apoplectic patients and anencephalous infants, *might* lead to the conclusion that the Spinal Cord does not itself possess sensibility, and that its reflex actions are independent of sensation. At this conclusion, Unzer, Prochaska, Sir G. Blane, Flourens, and other physiologists, had arrived; but it was not until special attention was directed to the subject by Dr. M. Hall, that facts were obtained by which a positive statement of it could be supported. For the question might have been continually asked—If the Spinal Cord in Man be precisely analogous in function to that of the lower Vertebrata, why are not its reflex phenomena manifested, when a portion of it is severed from the rest by disease or injury? The answer to this question is twofold. In the first place, simple division of the cord with a sharp instrument leaves the separated portion in a state of much more complete integrity, and therefore in a state much more fit for the performance of its peculiar functions, than it ordinarily is after disease or violent injury; and as the former method of division is one with which the Physiologist is not likely to meet in Man as a result of accident, and which he cannot experimentally put in practice, the cases in which reflex actions would be manifested are likely to be comparatively few. But, secondly, a sufficient number of such instances *have* now been accumulated, to prove that the occurrence is by no means so rare as might have been supposed; and that nothing is required but patient observation, to throw a great light on this interesting question, from the phenomena of disease. A most valuable collection of such cases, occurring within his own experience, has been published by Dr. W. Budd;¹ and the leading facts observed by him will be now enumerated.

707. In the first case, paraplegia was the result of angular distortion of the spine in the dorsal region. The sensibility of the lower extremities was extremely feeble, and the power of voluntary motion was almost entirely lost. "When, however, any part of skin is pinched or pricked, the limb that is thus acted on jumps with great vivacity; the toes are retracted towards the instep, the foot is raised on the heel, and the knee so flexed as to raise it off the bed; the limb is maintained in this state of tension for several seconds after the withdrawal of the stimulus, and then becomes suddenly relaxed." "In general, while one leg was convulsed, its fellow remained quiet, unless stimulus was applied to both at once." "In these instances, the pricking and pinching were perceived by the patient; but *much more violent* contractions are excited by a stimulus, of *whose presence he is unconscious*. When a feather is passed lightly over the skin, in the hollow of the instep, as if to tickle, convulsions occur in the corresponding limb, much more vigorous than those induced by pinching or pricking; they succeed one another in a rapid series of jerks, which are repeated as long as the stimulus is maintained." "When any part of

¹ "Medico-Chirurgical Transactions," vol. xxii.

the limb is irritated in the same way, the convulsions which ensue are very feeble, and much less powerful than those induced by pricking or pinching." "Convulsions, identical with those already described, are at all times excited by the acts of defecation and micturition. At these times, the convulsions are much more vigorous than under any other circumstances, insomuch that the patient has been obliged to resort to mechanical means to secure his person while engaged in these acts. During the act of expulsion, the convulsions succeed one another rapidly, the urine is discharged in interrupted jets, and the passage of the feces suffers a like interruption." The convulsions are more vigorous, the greater the accumulation of urine; and involuntary contractions occur whenever the bladder is distended, and also when the desire to relieve the rectum is manifested. "In all these circumstances, the convulsions are perfectly involuntary; and he is unable, by any effort of the will, to control or moderate them." The patient subsequently regained, in a gradual manner, both the sensibility of the lower extremities, and voluntary power over them; and as voluntary power increased, the susceptibility to involuntary movements, and the extent and power of these, diminished.—This case, then, exhibits an increased tendency to perform reflex actions, when the control of the brain was removed; and it also shows that a slight impression upon the surface, of which the patient was not conscious, was more efficacious in exciting reflex movements, than were others that more powerfully affected the sensory organs.—It should be added that, in the foregoing case, the nutrition of the lower extremities was not impaired, as in most cases of paraplegia; the rationale of this phenomenon, which is to be constantly observed when the reflex actions of the part remain entire, will be understood by reference to § 325.

708. In another case, the paralysis was more extensive, having been produced by an injury (resulting from a fall into the hold of a vessel) at the lower part of the neck. There was at first a total loss of voluntary power over the lower extremities, trunk, and hands; slight remaining voluntary power in the wrists, rather more in the elbows, and still more in the shoulders. The intercostal muscles did not participate in the movements of respiration. The sensibility of the hands and feet was greatly impaired. There were retention of urine, and involuntary evacuation of the feces. Recovery took place very gradually; and during its progress, several remarkable phenomena of reflex action were observed. At first, tickling one sole excited to movement that limb only which was acted upon; afterwards, tickling either sole excited both legs, and, on the 26th day, not only the lower extremities, but the trunk and other extremities also. Irritating the soles, by tickling or otherwise, was at first the only method, and always the most efficient one, by which convulsions could be excited. From the 26th to the 69th day, involuntary movements in all the palsied parts continued powerful and extensive, and were excited by the following causes: in the lower extremities only, by the passage of flatus from the bowels, or by the contact of a cold urinal with the penis; convulsions in the upper extremities and trunk, attended with sighing, by plucking the hair of the pubes. On the 41st day, a hot plate of metal was applied to the soles, and found a more powerful excitor of movement than any before tried. The movements continued as long as the hot plate was kept applied; but the same plate, at the common temperature, excited no movements after the first contact. The contact was distinctly felt by the patient; but *no sensation of heat* was perceived by him, although the plate was applied hot enough to cause vesication. At three different intervals, the patient took one-eighth of a grain of strychnia three times a day. Great increase of susceptibility to involuntary movements immediately followed, and they were excited by the slightest causes. No convulsions of the upper extremities could ever be produced, however, by irritating their integument; though, under the influence of strychnia, pulling the

hair of the head, or tickling the chin, would occasion violent spasmodic actions in them. Spontaneous convulsions of the palsied parts, which occurred at other times, were more frequent and more powerful after the use of strychnia. On the first return of voluntary power, the patient was enabled to restrain in some measure the excited movements : but this required a distinct effort of the will ; and the first attempts to walk were curiously affected, by the persistence of the susceptibility to excited involuntary movements. When he first attempted to stand, the knees immediately became forcibly bent under him ; this action of the legs being excited by contact of the soles with the ground. On the 95th day this effect did not take place, until the patient had made a few steps ; the legs then had a tendency to bend-up, a movement which he counteracted by rubbing the surface of the belly ; this rubbing excited the extensors to action, and the legs became extended with a jerk. A few more steps were then made ; the manœuvre repeated, and so on. This susceptibility to involuntary movements from impressions on the soles, gradually diminished ; and on the 141st day, the patient was able to walk about, supporting himself on the back of a chair which he pushed before him ; but his gait was unsteady, and much resembled that of chorea. Sensation improved very slowly : it was on the 53d day that he first slightly perceived the heat of the metal plate.—Now in this case, the abolition of common sensation was not so complete as in the former instance ; but of the peculiar kind of impression, which was found most efficacious in exciting reflex movements, *no consciousness whatever was experienced*. Not less interesting was the circumstance, that convulsions could be readily excited by impressions on surfaces *above* the seat of injury : as, by pulling the hair of the scalp, a sudden noise, and so on. This proves two important points : first, that a lesion of the cord may be such as to intercept the transmission of voluntary influence, and yet may allow the transmission of that reflected from incident nerves. Secondly, that all influences from impressions on incident nerves are diffused through the cord ; for, in the instance adduced, the reflected influence was undoubtedly not made to deviate into the cord by the morbid condition of that organ, but followed its natural course of diffusion, being rendered manifest in this case by the convulsions which were excited, in consequence of increased activity of the motor function of the cord. It is further interesting to remark, that, in the foregoing case, the reflex actions were very feeble during the first seven days, in comparison with their subsequent energy ; being limited to slight movements of the feet, which could not always be excited by tickling the soles. In another case of very similar character, it was three days after the accident before any reflex actions could be produced. It is evident, then, that the spinal cord must have been in a state of concussion, which prevented the manifestation of its peculiar functions, so long as this effect lasted ; and it is easy, therefore, to perceive, that a still more severe shock might permanently destroy its power, so as to prevent the exhibition of any of the phenomena of reflex action.

709. So many cases of this kind have now occurred, that it may be considered as a demonstrated fact, that the Spinal Cord, or insulated portions of it, may serve in Man, no less than in the lower animals, as the centre of very energetic reflex actions, when the Encephalic power which ordinarily operates through it is suspended or destroyed, or when it is prevented from influencing the Spinal nerves by such an injury to the Cord above their points of connection with it, as prevents the transmission of nervous polarity : and it is further evident that these movements are not more dependent upon sensation, than they are upon the will, since they may be excited without the consciousness of the individual, even when this is fully directed to the part.¹ And we thus have

¹ The Author is informed by his friend Mr. Paget, that among the notes left by John Hunter (which furnished some of the materials for the admirable Catalogue of the Pa-

adequate ground for the assertion, that the movements which may be called forth by stimulation in the states of profound Sleep or Coma, are not to be held to indicate that sensation is even momentarily excited; since we know that the reflex power of the Spinal Cord may be called into action by impressions which do not travel onwards to the sensorium, or which are powerless to affect the consciousness even when they arrive there. [That the source of the reflex faculty is to be looked for in the spinal cord itself, may be shown by the simple experiment of rapidly exciting reflex action in a decapitated animal. It will be found that, after exhausting it entirely, it will reappear and become as energetic as before, provided the circulation is kept up in the cord. Moreover, if the action of the spinal cord be rapidly excited, it is capable of producing an amount of muscular contraction in a frog's leg sufficient to raise, in divided portions, a weight of twelve pounds to a height of two lines. In a pigeon it can produce an amount of contraction sufficient to raise, also in divided portions, fifty pounds to the height of two inches in the course of an hour. That the reflex power is not derived from the medulla oblongata, as was supposed by Arnold and Flourens, is shown by the fact that it (the reflex power) is very weak in frogs immediately after the separation of the cord from the medulla oblongata, and that it increases afterwards to such a degree as to elevate by muscular contraction more than double the weight which the influence of the will could accomplish before the division.

The injection of blood into the carotid of an animal recently dead by hemorrhage, and in whom reflex action had ceased, is speedily followed by a return of that faculty of the cord, even after its separation.¹—Ed.] These reflex actions of the Spinal Cord have much more regularity and apparent *purposiveness* in the lower Vertebrata, approaching in this respect to the reflex actions of the ganglionic column of Articulata, than they have in Man. For we see that when a portion of *his* Spinal Cord is withdrawn from the influence of the Cerebrum, the reflex actions that may be excited in the limbs with which it has nervous connection, are disorderly and purposeless in their character, notwithstanding that they may be powerful; whilst, on the other hand, if a Frog be decapitated, its body is still supported on its limbs in the usual position, and will recover this if it be disturbed; irritation of the feet will cause it to leap; tickling the cloaca with a probe will excite efforts to push away the instrument; in fact, the movements altogether show almost as much adaptiveness and regularity, as if the mind of the animal were engaged in directing them. It would seem absurd, however, to attribute any psychical agency to the Spinal Cord; since, to remove these movements from the category of *automatic* actions, we must attribute to that organ a power, not merely of feeling, but also of choosing and directing movements with a conscious design; and all our knowledge of the functions of the Nervous System tends to the belief that such attributes belong only to the Brain. Hence, the adaptiveness of the reflex actions performed by many of the lower tribes of animals can only be held to indicate that a larger share of such adaptation is effected in them by what may be termed the *mechanism* of their nervous centres, and that less is left to voluntary choice and direction, which can only be safely trusted where a considerable amount of Intelligence exists to guide it. That the existence of even the most perfectly adapted combination of different muscular actions, all obviously bearing upon a definite object, does not in itself justify the attributing this combination to a design or voluntary choice.

thological portion of the Hunterian Museum drawn up by Mr. Paget), there was the record of a case of paraplegia, in which it appeared that Hunter had witnessed reflex movements of the legs in which sensation did not participate. When the patient was asked whether *he felt* the irritation by which the motions were excited, he significantly replied—glancing at his limbs—"No, Sir, but you see *my legs* do."

¹ [Phil. Med. Examiner, N. S. vol. viii. No. xcii. p. 482.]

in the individual that executes it, is sufficiently proved by the existence of such a combination in various automatic movements, most essential to the maintenance of the organic functions, which are performed with the utmost regularity, not only without our bestowing any volitional effort upon them, but also under circumstances which indicate that not even our consciousness has any share in developing or directing them. Such are the ordinary and extraordinary movements of Respiration, the movements of Deglutition and Defecation, &c.

710. *Medulla Oblongata*.—The cranial prolongation of the Spinal cord, which is distinguished by this appellation, has been regarded by some Physiologists as the peculiar seat of vitality; since, although the other Encephalic masses may be withdrawn from above, and nearly the whole of the Spinal Cord may be removed from below, without the destruction of life, yet a complete stop is put to the current of vital action when the Medulla Oblongata is destroyed.—[The arrest of vital action does not take place in frogs, or in other animals that respire largely by the general surface, as for instance amphibia and reptilia, for in them life continues for weeks, or even months, after complete removal of the Medulla Oblongata; circulation, digestion, and secretion going on with an activity but little impaired; death finally occurring from the diminution of the respiratory functions.¹—Ed.] But the dependence of the vital activity of the body generally upon the functional integrity of this part of the nervous system is simply consequent upon the fact that the Medulla Oblongata contains the gan-

glionic centre of the Respiratory movements; upon the continuance of which, as already shown (CHAP. X. SECT. 3), the continuance of the Circulation is dependent, and, with this, the maintenance of the Organic functions generally. In no other essential respect does the Medulla Oblongata differ from the Medulla Spinalis than in its ministration to certain classes of reflex movements which are

¹ [Vide Phil. Med. Examiner, N. S., Vol. viii., No. xcii., in which will be found an account of the experiments of Dr. Brown-Séquard upon this subject.]

specially destined to afford the conditions requisite for the performance of the functions of Respiration and Deglutition, instead of exerting its reflex power in the ordinary locomotive actions of the body; but the arrangement of its fibrous strands and of its nuclei of gray matter is peculiar; and a brief notice of its structure, and of the connections of its parts, is consequently desirable.—Four principal strands of nerve-fibres may be distinguished in each of its lateral halves; these are—I. The Anterior Pyramids or *Corpora Pyramidalia*;—II. The Olivary Bodies, or *Corpora Olivaria*; III. The Restiform Bodies, or *Corpora Restiformia*; otherwise called *Processus a Cerebello ad Medullam Oblongatam*; IV. The Posterior Pyramids, or *Corpora Pyramidalia Posteriora*.—The connections of these with the Brain above, and with the Spinal Cord below, will be presently traced.¹ The vesicular substance, on the other hand, is principally aggregated in three pairs of ganglionic centres; of which the *anterior* forms the nucleus of the Olivary body, the *lateral* of the Restiform, and the *posterior* of the Posterior Pyramidal.

711. The *Anterior Pyramids* (I) consist entirely of fibrous structure, and establish a communication between the “motor tract” (Fig. 178, *mt*) of the *Crura Cerebri*, and the anterior and antero-lateral columns of the Spinal Cord. The principal part of their fibres decussate; and these, as they pass from above downwards, dip away from the anterior surface of the Cord, and connect themselves with its *middle* or *lateral* columns, instead of with its anterior, as was pointed out by Rosenthal,² and more fully described by Dr. J. Reid.³ A small part of the fibres of the pyramidal columns, however, do not decussate, but proceed downwards on the same side, into the corresponding *anterior* columns of the Spinal Cord. II. The *Olivary* bodies are composed of fibrous strands, enclosing a gray nucleus (Fig. 178, *og*) on either side. The upward continuation of the for-

¹ Great diversities will be found in the accounts given of those connections by different authors; some of which are attributable to a variation in the use of terms, which must not pass unnoticed. By the majority of Anatomists, the name of *Corpora Restiformia* is given to the *Cerebellar* Columns; and this designation, therefore, it seems advisable to retain. Some, however, and amongst them Dr. J. Reid, in his very excellent description of the Anatomy of the Medulla Oblongata (“Edinb. Med. and Surg. Journal,” Jan. 1841), give that name to the columns that pass up from the posterior division of the spinal cord into the crura cerebri—which are here called (after Sir C. Bell) the posterior pyramids; and apply the term Posterior Pyramids to the Cerebellar column. The truth is that, as Sir C. Bell has justly observed, *all* the tracts of fibrous matter connecting the Brain with the Spinal Cord have a somewhat *pyramidal* form; and it might be added that all have something of a *restiform* or cord-like aspect.

mer divides, while passing through the Pons Varolii, into two bands, one of which proceeds upwards and forwards as a part of the "motor tract" (*m t*) of the Crus Cerebri, whilst the other (*o*) proceeds upwards and backwards to reach the Corpora Quadrigemina (*c, d*). The olivary columns are continuous inferiorly with the *anterior* columns of the Spinal Cord; and afford attachments to the anterior roots of the 1st and 2d cervical nerves. The vesicular nucleus, which is known as the *corpus dentatum*, seems to be especially connected with the origins of the nerves concerned in the regulation of the movements of the tongue; thus we find that anteriorly a portion of the roots of the Hypoglossal, which is the motor nerve of the tongue, issue from it; whilst posteriorly a portion of the roots of the Glosso-pharyngeal, which is one of the sensory nerves of that organ, seem to terminate in it.—III. The *Restiform* bodies, in like manner, each consist of fibrous strands (*F*) inclosing a gray nucleus. The

fibrous strands pass upwards into the Crura Cerebelli; whilst below they are chiefly continuous with the *posterior* columns of the Spinal Cord, having also some connection with the posterior part of the *middle* columns. These Cerebellar columns also communicate, however, with the *anterior* columns of the

Spinal Cord, by a band of "arciform" fibres, whose connections were first distinctly described by Mr. Solly;¹ of these there is a superficial set which unites itself with the pyramidal columns, and a deep set which comes into relation with the olivary. Their gray nucleus, or "restiform ganglion," appears to be the ganglionic centre of the Pneumogastric nerves, and of a portion of the roots of the Glosso-pharyngeal. IV. The *Posterior Pyramids* are scarcely distin-

guishable externally from the Restiform bodies, of which they were formerly described as a constituent part; they, however, form the immediate boundaries of the posterior median fissure; and whilst superficially marked-off from the Restiform bodies by a slight groove, are more completely separated from them by their anatomical relations to the parts above and below. Their fibres establish a connection between the sensory tract (Fig. 178, *st, st*) of the Crura Cerebri, and the posterior part of the *lateral* columns of the Spinal Cord, some of them passing also into its posterior columns. These fibrous tracts are stated by Mr. Solly¹ and Dr. Radclyffe Hall² to decussate, partially at least, whilst passing through the Pons Varolii.³ The gray nuclei of the Posterior Pyramids, situated immediately beneath the "fourth ventricle" (which is nothing else than the space left by the divergence of the Restiform and Posterior Pyramidal tracts), are the ganglionic centres of the Auditory nerves, or the proper *Auditory ganglia*; and it is interesting to observe that their seat precisely corresponds with that of the rudimental organ of hearing in many Invertebrata.

712. The Medulla Oblongata is usually considered as terminating at the lower border of the Pons Varolii; but it will be convenient here to trace up-

wards the strands by which it is connected with the higher Encephalic centres, as a clearer idea of its anatomical and physiological relations will thus be obtained.—The Pons is chiefly composed of transverse fibres which constitute the great commissure of the Cerebellum; and these fibres not only *surround* the

¹ "The Human Brain," 2d edit., p. 243.

² "Edinb. Med. and Surg. Journ.," July, 1847, Plate VII.

³ A decussation of the Posterior Pyramids was described by Sir C. Bell as occurring at the same level with the decussation of the Anterior Pyramids (Fig. 133, c); there can be no doubt, however, that this is an error, which probably originated in his having misinterpreted the appearance presented by the posterior aspect of the anterior decussation.

longitudinal bands which connect the Cerebral mass with the Spinal Cord, but *pass through* them; so as in some degree to isolate the two lateral halves from one another, and to form a complete septum between the anterior and posterior portions of each. These *anterior* and *posterior* tracts of the Crura Cerebri are respectively subservient to the *motor* and the *sensory* functions; as is clearly indicated by the endowments of the nerves which are connected with each.¹ The *Motor* tract is brought into view, by simply raising the superficial layer of the Pons, and tracing upwards and downwards the longitudinal fibres which present themselves. It is then found that these fibres may be traced *upwards* into the Corpora Striata; and *downwards* into the Anterior Pyramids and a portion of the Olivary columns; so that they connect the Corpora Striata with the *anterior*, and with the anterior portion of the *lateral* columns of the Spinal Cord. With this tract we find connected—passing from below upwards—the roots of the Spinal Accessory, the Hypoglossal, the Facial or Portio Dura of the 7th, the 6th or Abducens oculi, the smaller root of the 5th (which can be traced to the part of the Olivary column that passes upwards to the Corpora Quadrigemina), the 4th or Trochlearis (which is attached to the same part of the tract), and the 3d or Oculo-motor nerves; all of which are purely motor in their endowments. The *Sensory* tract is displayed by opening the Medulla Oblongata on its posterior aspect; and then separating and turning aside the Restiform columns, so as to bring into view the posterior pyramids.

[Fig. 181*.

¹ This was first clearly shown by Sir C. Bell in the "Philos. Transact.," 1835.

Its fibres may be traced *upwards* into the Thalami Optici; whilst they pass through the Posterior Pyramids into the posterior portion of the *lateral* columns, and also into the *posterior* columns of the Spinal Cord. With this tract are connected nearly the whole of the roots of the Pneumogastric and Glossopharyngeal nerves, and the larger or sensory root of the 5th pair. The greater part of the motor tract decussates where the Anterior Pyramids become continuous with the lateral columns of the Spinal Cord; on the other hand, the greater part of the Sensory tract decussates in its passage through the Pons Varolii [Fig. 181*]. The following tabular view may assist in conveying a

713. *Nerves of the Spinal Axis.*—With the Spinal Cord (in its limited sense) there are connected thirty-one pairs of nerves; each of these corresponding to a vertebral segment of the body, and having a double set of roots, as already described (§ 696). The anterior roots are usually the smaller; and this is particularly the case with those of the cervical nerves, in which the posterior roots are of remarkable comparative size. In the first Cervical “or sub-occipital” pair, the anterior roots are sometimes wanting; but there is then a derivation of fibres from the Spinal Accessory, or from the Hypoglossal, or from both. The two roots of the ordinary Spinal nerves unite immediately beyond the ganglion, which is situated on the posterior one; and the trunk thus formed separates immediately into two divisions—the anterior and posterior—each of which contains both afferent and motor fibres. These divisions, of which the anterior is by far the larger, proceed to the anterior and posterior parts of the body respectively; and are chiefly distributed to the skin and the muscles. The anterior branch is that which communicates with the Sympathetic nerve. In addition to these, however, the cranial prolongation of the Spinal Axis is the centre of all the cephalic nerves, save those of special sensation, which terminate in their respective ganglia; and as these cephalic nerves are for the most part distinguished by the peculiarity of their endowments, they require to be separately noticed.

714. The pair of nerves commonly designated as the *Fifth* of the Cephalic series, or as the *Trigeminus*, is the one which more nearly resembles the ordinary Spinal nerves (as was long since pointed out by Sir C. Bell), than does any other of those originating within the cranium. It possesses two distinct sets of roots, of which one is much larger than the other; on the larger root, as on the posterior and larger root of the Spinal nerves, is a distinct ganglion; and the fibres arising from the smaller root do not blend with the others, until after the latter have passed through this ganglion. The trunk of the nerve separates, as is well known, into three divisions—the Ophthalmic, the Superior Maxillary, and the Inferior Maxillary; and it can be easily shown, by careful dissection, that the fibres of the smaller root pass into the last of these divisions alone. When the distribution of this nerve is carefully examined, it is found that the first and second divisions of it proceed almost entirely to the skin and mucous surfaces, only a very small proportion of their fibres being lost in the muscles; whilst of the branches of the third division, a large number are distinctly muscular. Hence analogy, and the facts supplied by anatomical research, would lead to the conclusion that the first two divisions are nerves of sensation only, and that the third division combines sensory and motor endowments. Such an inference is fully borne out by experiment. When the whole trunk is divided within the cranium by the penetration of a sharp instrument (which Magendie, by frequent practice, has been able to accomplish), evident signs of acute pain are given. After the incision has been made through the skin, the animal remains quiet until the nerve is touched; and when it is pressed or divided, doleful cries are uttered, which continue for some time, showing the painful effect of the irritated state of the cut extremity. The common sensibility of all the parts supplied by this nerve is entirely destroyed on the affected side. The jaw does not hang loosely, because it is

partly kept up by the muscles of the other side; but it falls in a slight degree; and its movements are seen, when carefully observed, to be somewhat oblique. If the trunk be divided on each side, the whole head is deprived of sensibility, and the animal carries it in a curious vacillating manner, as if it were a foreign body. If the anterior or *Ophthalmic* branch only be divided, all the parts supplied by it are found to have lost their sensibility, but their motions are unimpaired; and all experiments and pathological observations concur in attributing to it sensory endowments only.

Fig. 183.

A representation of some of the nerves of the orbit, especially to show the lenticular ganglion (Arnold). 1. Ganglion of the fifth. 2. Ophthalmic nerve. 3. Upper maxillary. 4. Lower maxillary. 5. Nasal branch, giving the long root to the lenticular ganglion. 6. Third nerve. 7. Inferior oblique branch of the third connected with the ganglion by the short root. 8. Optic nerve. 9. Sixth nerve. 10. Sympathetic on the carotid artery.

The only apparent exception is in the case of the naso-ciliary branch, since there is good reason to believe that the long root of the ciliary ganglion and the long ciliary nerves possess motor powers; but these appear to be derived from the Sympathetic or from the 3d pair. When the whole nerve, or its anterior branch, is divided in the rabbit, the pupil is exceedingly contracted, and remains immovable; but in dogs and pigeons it is dilated. The pupil of the other eye is scarcely affected; or, if its dimensions be changed, it soon returns to its natural state. The eyeball, however, speedily becomes inflamed; and the inflammation usually runs on to suppuration and complete disorganization. The commencement of these changes may be commonly noticed within twenty-four hours after the operation; and they appear to be due to the want of the protective secretion, which (as will be explained

when the direct influence of the nervous system upon the organic functions is considered) is necessary to keep the mucous surface of the eye in its healthy condition, and which is not formed when the sensibility of that surface is destroyed. The *Superior Maxillary* branch, considered in itself, is equally destitute of motor endowments with the ophthalmic; but its connections with other nerves, through the sphenopalatine ganglion and its anastomosing twigs, may introduce a few motor fibres into it. The *Inferior Maxillary* branch is the only one which possesses motor as well as sensory endowments from its origin; but its different subdivisions possess these endowments in varying proportions, some being almost exclusively motor, and others as completely of a sensory character. The latter is probably the nature of the Lingual branch; and there seems good reason to believe, as will hereafter be shown (§ 717), that this ministers not only to the tactile sensibility of the tongue, but to the sense of Taste. The muscles put in action by this division are solely those concerned in the masticatory movements. The 5th pair is connected in different parts of its course, with a number of small ganglia belonging to the Sympathetic system. One of the most interesting of these ganglia is the *Ophthalmic* or *Ciliary* (Fig. 183), which is the centre whence the eyeball derives its supply of nerves, sensory, motor, and sympathetic. This ganglion derives its sensory fibres by its "long root" from the nasal branch of the Ophthalmic division of the 5th pair; its motor fibres, by the "short root," from the 3d pair;

whilst by another small root it is connected with the cavernous plexus of the Sympathetic system: thus presenting a sort of miniature representation of the entire series of Sympathetic ganglia, and of their connections with the Cerebro-spinal system.¹

715. The *Third*, *Fourth*, and *Sixth* pairs, together make up the apparatus of motor nerves, by which the muscles of the Orbit are called into action. The 3d pair supplies the greater number of the muscles; the 4th being confined to the Superior Oblique, and the 6th to the External Rectus. Of these nerves, the 3d pair is the only one which exhibits any appearance of sensibility, when its trunk is irritated; but this sensibility is not nearly so great as that of the 5th pair; and as there is no reason to believe that it is really possessed by the 3d in virtue of its direct connection with the nervous centres, it is probably imparted by the anastomosis of that nerve with the 5th—some filaments of which may pass backwards as well as forwards, so as to confer sensibility on the trunk of the 3d, above as well as beyond their point of entrance.—The peculiar mode in which those motor nerves ordinarily excite the muscles to action, under the guidance of the visual sense, will be considered in the next Section. Although commonly ranked as cephalic nerves, they have no direct connection with the Cerebrum; their real origin being from the upper part of the Spinal Axis (§ 712). The roots of the third pair may be traced into direct connection with the Corpora Quadrigemina; a fact of considerable physiological importance, as will hereafter appear.—The chief actions of a purely *reflex* nature, to which this group of nerves ordinarily ministers, are the government of the diameter of the pupil, which is accomplished through the Third pair; and the rolling of the eyeball beneath the upper lid during sleep, as well as in the efforts of sneezing, coughing, &c. But irregular movements of the eyeballs, which must be referred to the same group, are continually seen to accompany various other forms of convulsive action.

716. The *Portio Dura* of the *Seventh* pair, or *Facial* nerve, has been considered, since the first researches of Sir C. Bell, to be a nerve of motion only; but some physiologists have maintained, that it both possesses sensory endowments, and arises by a double root. According to Valentin, however, who

¹ The functions of this ganglion have been made the subject of particular investigation by Dr. C. Radcliffe Hall ("Edinb. Med. and Surg. Journal," 1846-48), whose most important results are as follows:—

1. The size of the ciliary ganglion is always in direct proportion to the activity of the iris, which in turn always bears a direct relation to the strength and acuteness of vision, and to the nocturnal habits of the animal, and implies a proportionate development of the internal vascular apparatus of the eye.

2. The ganglion is always more intimately connected with the 3d pair than with any other, the size of the short root being always in direct relation to that of the ganglion; and the ganglion being sometimes a mere swelling on the trunk of the nerve.

3. The fibres derived from the 5th pair do not terminate in the ganglion, but pass onwards through it to the ciliary plexus.

4. In the Rabbit, the iris receives fibres from the 6th pair, which do not pass through the ganglion; and it is through this that the contraction of the pupil is produced in that animal by irritation of the 5th pair, which will not produce any effect upon the pupil of the Dog, Cat, or Pigeon, so long as it does not affect the brain to the extent of producing vertigo, nor affect the visual sense in any other way.

5. Irritation of the 5th nerve does not in any animal affect the action of the iris *after* the division of the cerebral connections of all the other ocular nerves; so that its influence over the movements of the iris must be reflected through the encephalic centres, not through the ophthalmic ganglion.

6. The function of the ganglionic centre itself, as a part of the Sympathetic system, is to bring the "organic actions" of the eyeball, especially its supply of blood, into harmony with its functional activity; this harmony being produced by the passage of the cerebro-spinal nerves through the ganglion, which excites the synergetic action of its own vesicles and nerve-fibres.

experimented on the roots exposed within the cranium, it possesses no sensory endowments at its origin; since, when these roots were touched, the animals gave no signs of pain, though violent muscular movements were excited in the face. Subsequently to its first entrance into the canal by which it emerges,

Fig. 184.

The *Nerves of the Orbit* seen from the outer side: after Arnold.—1. Section of the frontal bone; immediately behind the numeral is the frontal sinus, and, in front, the integument. 2. The superior maxillary bone; the section in front of the numeral exhibits the maxillary sinus. 3. Part of the sphenoid bone. 4. The levator palpebræ and superior rectus muscles. 5. The superior oblique muscle. 6. The inferior oblique muscle. 7. The ocular half of the external rectus muscle drawn forwards. 8. The orbital half of the external rectus muscle turned downwards. On this muscle the sixth nerve is seen dividing into branches. 9. The inferior rectus muscle. 10. The optic nerve. 11. The internal carotid artery emerging from the cavernous sinus. 12. The ophthalmic artery. 13. The third nerve. 14. The branch of the third nerve to the inferior oblique muscle. Between this and the sixth nerve (7) is seen the branch which supplies the inferior rectus; its branch to the ophthalmic ganglion is seen proceeding from the upper side of the trunk of the nerve, at the bottom of the orbit. 15. The fourth nerve. 16. The trunk of the fifth nerve. 17. The Gasserian ganglion. 18. The ophthalmic nerve. 19. The superior maxillary nerve. 20. The inferior maxillary nerve. 21. The frontal nerve. 22. Its division into branches to supply the integument of the forehead. 23. The lachrymal nerve. 24. The nasal nerve; the small nerve seen in the bifurcation of the nasal and frontal nerve is one of the branches of the upper division of the third nerve. 25. The nasal nerve passing over the internal rectus muscle to the anterior ethmoidal foramen. 26. The infra-trochlear nerve. 27. A long ciliary branch of the nasal; another long ciliary branch is seen proceeding from the lower aspect of the nerve. 28. The long root of the ophthalmic ganglion, proceeding from the nasal nerve, and receiving the sympathetic root which joins it at an acute angle. 29. The ophthalmic ganglion, giving off from its fore part the short ciliary nerves. 30. The globe of the eye.

however, it anastomoses with other nerves; and thus *sensory* fibres are introduced into it from many different sources—anteriorly, from the 5th pair, and posteriorly, from the cervical nerves—which cause irritation of several of its branches to produce pain. The number and situation of the anastomoses vary much in different animals; so that it is impossible to make any very comprehensive statement in regard to them.—Experimental researches leave no doubt that the Portio Dura is the *general motor* nerve of the face; ministering to the influence of Volition and of Emotion, and also being the channel of the reflex movements concerned in respiration and other automatic actions of the muscles; but not being in the least concerned in the act of mastication.

717. The functions of the *Glosso-Pharyngeal* nerve have been heretofore alluded to in part; but there still remain several questions to be discussed in regard to them. Reasons have been given for the belief that it is chiefly an afferent nerve—scarcely having any *direct* power of exciting muscular contrac-

tion, but conveying impressions to the Medulla Oblongata, which produce reflex movements of the motor nerves concerned in deglutition (§ 427). This view of its function was deduced by Dr. J. Reid from minute anatomical investigation, and from a large number of experiments. Some experimenters assert that

Fig. 185.

The distribution of the *Facial* nerve, and the branches of the *Cervical* plexus.—1. The facial nerve, escaping from the stylo-mastoid foramen, and crossing the ramus of the lower jaw; the parotid gland has been removed in order to see the nerve more distinctly. 2. The posterior auricular branch; the digastric and stylo-mastoid filaments are seen near the origin of this branch. 3. Temporal branches, communicating with (4) the branches of the frontal nerve. 5. Facial branches, communicating with (6) the infra-orbital nerve. 7. Facial branches, communicating with (8) the mental nerve. 9. Cervico-facial branches, communicating with (10) the superficialis colli nerve, and forming a plexus (11) over the submaxillary gland. The distribution of the branches of the facial in a radiated direction over the side of the face constitutes the *pes anserinus*. 12. The auricularis magnus nerve, one of the ascending branches of the cervical plexus. 13. The occipitalis minor, ascending along the posterior border of the sterno-mastoid muscle. 14. The superficial and deep descending branches of the cervical plexus. 15. The spinal accessory nerve, giving off a branch to the external surface of the trapezius muscle. 16. The occipitalis major nerve, the posterior branch of the second cervical nerve.

they have succeeded in exciting direct muscular actions through its trunk; but these actions seem to be limited to the stylo-pharyngei and to the palato-glossi muscles. Much controversy has taken place on the question whether this nerve is to be regarded as ministering, partly or exclusively, to the sense of Taste; and many high authorities have ranged themselves on each side. The question involves that of the function of the Lingual branch of the 5th pair; and it is partly to be decided by the anatomical relations of the two nerves respectively. The Glosso-pharyngeal is principally distributed on the mucous surface of the fauces, and on the back of the tongue; but, according to Valentin, it sends a branch forwards, on either side, somewhat beneath the lateral margin, which supplies the edges and inferior surface of the tip of the tongue, and inosculates with the Lingual branch of the 5th. On the other hand, the upper surface of the front of the tongue is supplied by this Lingual branch. The experiments of Dr. Alcock, whose conclusions are borne out by Dr. J. Reid, decidedly support the conclusion that the gustative sensibility of *this* part of the tongue is chiefly due to the latter nerve, being evidently impaired by division of it. On the other hand, it is equally certain that the sense of taste is not destroyed by

section of the Lingual nerve on each side ; and it seems also well ascertained, that it is impaired by section of the Glosso-pharyngeal nerve.—The pathological evidence bearing upon this point appears somewhat contradictory. Numerous cases have been recorded,¹ in which both common and gustative sensation were destroyed in the parts of the tongue supplied by the 5th pair, when that nerve was paralyzed ; in some of these, the loss of the sense of taste appeared to extend itself to the base of the tongue, but then there was evidence that the Glosso-pharyngeal was involved in the paralysis. On the other hand, cases of paralysis of the 5th pair are related by Mr. Noble and by Vogt,² in which common sensation was lost, whilst the sense of taste remained in the same parts ; and Mr. Noble relates another case,³ in which there was loss of taste without impairment of common sensation. The cases of Mr. Noble and Vogt would seem to indicate that the 5th pair does not minister to the sense of Taste ; but, as Dr. J. Reid has justly observed, we have no evidence that *all* the filaments of the 5th Pair sent to the tongue were affected ; and there is believed to be no case on record, in which the whole of the 5th pair, or of its 3d branch, was found to be diseased after death, and in which during life the sense of Taste had been retained in the anterior and middle parts of the tongue. Hence these cases only serve to indicate what is probable on other grounds ; viz., that the filaments which convey gustative impressions are not the same with those that minister to common sensation.—On the whole, then, it seems to be proved by anatomical and experimental evidence, that both the Glosso-pharyngeal and the Fifth pair minister alike to the tactile and to the gustative sense ; and there is nothing in the pathological facts just noticed that militates against this conclusion. There seems good reason to believe the Glosso-pharyngeal to be exclusively the nerve, through which the impressions made by disagreeable substances taken into the mouth are propagated to the Medulla Oblongata, so as to produce nausea and to excite efforts to vomit.

718. The functions of the *Pneumogastric* nerve at its roots have been made the subject of particular examination by various experimenters ; some of whom (for instance, Valentin, Longet, and Morganti) have concluded that it *there* possesses no motor power, but is entirely a sensory or rather an afferent nerve. According to these, if the roots be carefully separated from those of the Glosso-pharyngeal, and (which is a matter of some difficulty) from those of the Spinal Accessory nerve, and be then irritated, no movements of the organs supplied by its trunk can be observed : whilst, if the roots be irritated when in connection with the nervous centres, muscular contractions, evidently of a reflex character, result from the irritation ; and strong evidences of their sensibility are also given. It has been further asserted that, when the roots of the Spinal Accessory nerve are irritated, no indications of sensation are given ; but that the muscular parts supplied by the Pneumogastric, as well as by its own trunk, are made to contract, even when the roots are separated from the nervous centres ; so that these roots must be regarded as the channel of the motor influence, transmitted to them from the Medulla Oblongata. Where the Pneumogastric swells into the jugular ganglion, an interchange of fibres takes place between it and the Spinal Accessory ; and it seems clear that the pharyngeal branches, which are among the most decidedly motor of all those given off from the Pneumogastric, may in great part be traced backwards into the Spinal Accessory.—But, on the other hand, an equally numerous and trustworthy set of experimenters (among whom may be mentioned J. Reid, Müller, Volkmann, Stilling, Wagner,

A view of the distribution of the Glosso-Pharyngeal Pneumogastric and Spinal Accessory Nerves, or the Eighth pair: 1, the inferior maxillary nerve; 2, the gustatory nerve; 3, the chorda tympani; 4, the auricular nerve; 5, its communication with the portio dura; 6, the facial nerve coming out of the stylo-mastoid foramen; 7, the glosso-pharyngeal nerve; 8, branches to the stylo-pharyngeus muscle; 9, the pharyngeal branch of the pneumogastric nerve descending to form the pharyngeal plexus; 10, branches of the glosso-pharyngeal to the pharyngeal plexus; 11, the pneumogastric nerve; 12, the pharyngeal plexus; 13, the superior laryngeal branch; 14, branches to the pharyngeal plexus; 15, 15, communication of the superior and inferior laryngeal nerves; 16, cardiac branches; 17, cardiac branches from the right pneumogastric nerve; 18, the left cardiac ganglion and plexus; 19, the recurrent or inferior laryngeal nerve; 20, branches sent from the curve of the recurrent nerve to the pulmonary plexus; 21, the anterior pulmonary plexus; 22, 22, the oesophageal plexus.

and Bernard) are opposed to this opinion; maintaining that the Pneumogastric has motor roots of its own; and affirming that irritation of the roots of the Spinal Accessory produces little or no effect on the muscles supplied by the trunk of the Par Vagus.—The fact appears to be that the roots of these two nerves are so commingled, that it is difficult to say what belongs exclusively to each. Some of the fibres usually considered to belong to the Spinal Accessory are occasionally seen to connect themselves with the roots of the Pneumogastric, even before the ganglion is found upon it. And it seems most probable that, while the roots of the Spinal Accessory are entirely motor, those of the Pneumogastric are *chiefly* afferent; that they inosculate with each other, in a degree which may vary in different species, and even in different individuals; and that the Pneumogastric may thus derive additional motor fibres from the Spinal Accessory, whilst it supplies that nerve with afferent fibres. Further, from the researches of M. Cl. Bernard, to be presently noticed (§ 719), it appears probable that the motor fibres properly belonging to the Pneumogastric are adequate to the regulation of those movements of the larynx and other portions of the air-passages, which are concerned in the *passive* act of Respiration.—In regard to its *trunk*, there can be no doubt that the Pneumogastric is to be considered as a nerve of double endowments; although it is certain that these endowments are very differently distributed amongst its branches. That the nerve is capable of conveying those impressions, which become *sensations* when communicated to the sensorium, is experimentally proved by the fact that, when its trunk is pinched, the animal gives signs of acute pain: but it is also evident from the painful consciousness we occasionally have of an abnormal condition of the organs which it supplies. Thus, the suspension of the respiratory movements gives rise to a feeling of the greatest uneasiness, which must be excited by impressions conveyed through this nerve from the lungs; and an inflamed state of the walls of the air-passages causes the contact of cold and dry air to produce distressing pain and irritation. Yet of the ordinary impressions conveyed from these organs, which are concerned in producing the respiratory movements, and in regulating the actions of the glottis, we are not conscious. The same may be said of the portion of the nerve distributed upon the alimentary tube. The pharyngeal branches are almost exclusively motor, the afferent function being performed by the Glosso-pharyngeal; whilst the œsophageal and gastric are both afferent and motor, conveying impressions which excite reflex movements in the muscles of those parts, but which do not become sensations except under extraordinary circumstances.—The participation of this nerve in the operations of Deglutition, Digestion, Circulation, and Respiration, and the effects of injury to its trunk or branches, have already been considered in the account of those functions.

719. In regard to the functions of the *Spinal Accessory* nerve, also, there has been great difference of opinion; the peculiarity of its origin and course having led to the belief that some very especial purpose is answered by it. The roots of this nerve arise from the side of the Spinal Cord as low down as the 5th or 6th cervical nerve; and the trunk formed by them ascends into the cranium between the anterior and posterior roots of the spinal nerves. From the recent researches of Mr. J. L. Clarke,¹ it appears that these roots may be traced into a special tract of vesicular matter, which descends as far as the lumbar enlargement. The predominance of motor fibres in its roots, its inosculatation with the Pneumogastric, and its probable reception of sensory fibres from the latter whilst imparting to it motor filaments, have been already referred to (§ 718). As its trunk passes through the foramen lacerum, it divides into two branches; of which the internal, after giving off some filaments

¹ "Philosophical Transactions," 1851, p. 613.

that assist in forming the pharyngeal branch of the Pneumogastric, becomes incorporated with the trunk of that nerve; whilst the external proceeds outwards, and is finally distributed to the sterno-cleido-mastoideus and trapezius muscles, some of its filaments inosculating with those of the cervical plexus. When the external branch is irritated, before it perforates the sterno-mastoid muscle, vigorous convulsive movements of that muscle and of the trapezius are produced; and the animal does not give any signs of pain, unless the nerve be firmly compressed between the forceps, or be included in a tight ligature. Hence it may be inferred that the functions of this nerve are chiefly motor, and that its sensory filaments are few in number. Further, when the nerve has been cut across, or firmly tied, irritation of the lower end is attended by the same convulsive movements of the muscles; whilst irritation of the upper end, in connection with the spinal cord, is unattended with any muscular movement. Hence it is clear that the motions occasioned by irritating it are of a direct, not of a reflex character. The same muscular movements are observed on irritating the nerve in the recently-killed animal, as during life.—According to Sir C. Bell, the Spinal Accessory is a purely Respiratory nerve, whose office it is to excite the involuntary or automatic movements of the muscles it supplies, which share in the act of respiration; and he states that the division of it paralyzes, as muscles of respiration, the muscles to which it is distributed; though they still perform the voluntary movements, through the medium of the spinal nerves. Both Valentin and Dr. J. Reid, however, positively deny that this is the case; and Dr. Reid's method of experimenting was well adapted to test the truth of the assertion.¹ The functions of this nerve have been made the subject of special examination by M. Cl. Bernard,² who has arrived at the conclusion that the Spinal Accessory is a purely motor nerve, whose action is not essential to the *ordinary* movements of respiration, these being provided for by the Pneumogastric and ordinary Spinal nerves; but that its special function is to bring the respiratory movements into accordance with the requirements of Animal life, adapting the actions of the muscles of the larynx and thorax to the production of *voice*, or to general muscular *effort*. The internal branch, which is especially distributed, with the fibres of the Pneumogastric, to the pharynx and larynx, is peculiarly subservient to the former of these purposes; and the external to the latter. This conclusion is sufficiently in accordance with the results obtained by other experimenters, to be received as a probable explanation of the facts which have been observed by them.

720. The *Hypoglossal* nerve, or *Motor Linguae*, is the only one which, in the regular order, now remains to be considered. That the distribution of this nerve is restricted to the muscles of the tongue is a point very easily established by anatomical research; and accordingly, we find that long before the time of Sir C. Bell, Willis had spoken of it as the nerve of the motions of articulation, whilst to the Lingual branch of the 5th pair he attributed the power of exercising the sense of taste; and he distinctly stated that the reason of this organ being supplied with two nerves is its double function. The inference that it is chiefly, if not entirely, a *motor* nerve, which has been founded upon its anatomical distribution, is supported also by the nature of its origin, which is usually from a single root, corresponding to the anterior root

¹ See his "Physiol., Pathol., and Anat. Researches," p. 151; and "Edinb. Med. and Surg. Journ.," Jan., 1838.

² "Recherches Expérimentales sur les Fonctions du Nerf Spinal," in "Archives de Médecine," 1844. This memoir, having gained the prize given by the Académie des Sciences for experimental physiology in 1845, has been printed in the "Recueil des Savants étrangers," tom. xi., 1851; and the author states that since the first publication of his researches, he has confirmed his original conclusions by the repetition and variation of his experiments.

of the Spinal nerves. Experiment shows that, when the trunk of the nerve is stretched, pinched, or galvanized, violent motions of the whole tongue, even to its tip, are occasioned; and also, that similar movements take place after division of the nerve, when the cut end most distant from the brain is irritated. In regard to the degree in which this nerve possesses sensory properties, there

Fig. 188.

The course and distribution of the Hypoglossal or Ninth pair of nerves; the deep-seated nerves of the neck are also seen: 1, the hypoglossal nerve; 2, branches communicating with the gustatory nerve; 3, a branch to the origin of the hyoid muscles; 4, the descendens noni nerve; 5, the loop formed with the branch from the cervical nerves; 6, muscular branches to the depressor muscles of the larynx; 7, a filament from the second cervical nerve, and 8, a filament from the third cervical, uniting to form the communicating branch with the loop from the descendens noni; 9, the auricular nerve; 10, the inferior dental nerve; 11, its mylo-hyoidean branch; 12, the gustatory nerve; 13, the chorda tympani passing to the gustatory nerve; 14, the chorda tympani leaving the gustatory nerve to join the submaxillary ganglion; 15, the submaxillary ganglion; 16, filaments of communication with the lingual nerve; 17, the glosso-pharyngeal nerve; 18, the pneumogastric or par vagum nerve; 19, the three upper cervical nerves; 20, the four inferior cervical nerves; 21, the first dorsal nerve; 22, 23, the brachial plexus; 24, 25, the phrenic nerve; 26, the carotid artery; 27, the internal jugular vein.

is some difference of opinion amongst physiologists, founded, as it would seem, on a variation in this respect between different animals. Indications of pain are usually given, when the trunk is irritated after its exit from the cranium; but these may proceed from its free anastomosis with the cervical nerves, which not improbably impart sensory fibres to it. But in some Mammalia, the hypoglossal nerve has been found to possess a small posterior root with a ganglion; this is the case in the Ox, and also in the Rabbit; and in the latter animal, Valentin states that the two trunks pass out from the cranium through separate orifices, and that, after their exit, one may be shown to be sensory, and the other to be motor. Hence, this nerve, which is the lowest of those that originate in the cephalic prolongation of the spinal cord generally known as the medulla oblongata, approaches very closely in some animals to the regular type of the spinal nerves; and though in Man it still manifests an irregularity in having only a single root, yet this irregularity is often shared by the first cervical nerve, which also has sometimes an anterior root only. The Hypoglossal nerve is distributed not merely to the tongue, but to the muscles of the neck, which are concerned in the movements of the larynx; and the purpose of this distribution is probably

to associate them in those actions which are necessary for articulate speech. Though *all* the motions of the tongue are performed through the medium of this nerve, yet it would appear, from pathological phenomena, to have at least two distinct connections with the nervous centres; for in many cases of paralysis, the masticatory movements of the tongue are but little affected, when the power of articulation is much injured or totally destroyed; and the converse may be occasionally noticed. When this nerve is paralyzed on one side, in hemiplegia, it will be generally observed that the tongue, when the patient is directed to put it out, is projected *towards* the palsied side of the face: this is due to the want of action of the lingual muscles of that side, which do not aid in pushing forward the tip; the point is consequently directed only by the muscles of the other side, which will not act in a straight direction, when unantagonized by their fellows. It is a curious fact, however, that the Hypoglossal nerve seems not to be always palsied on the same side with the Facial, but sometimes on the other. This has been suggested to be due to the origination of the roots of this nerve from near the point at which the pyramids of the medulla oblongata decussate, so that some of its fibres come off, like those of the spinal nerves, without crossing, whilst others are transmitted to the opposite side, like those of the higher cephalic nerves; and the cause of paralysis may affect one or other of these sets of roots more particularly. Whatever may be the validity of this explanation, the circumstance is an interesting one, and well worthy of attention.¹

721. The *general character and arrangement* of the Cephalic nerves, as distinguished from the ordinary Spinal, constitute a study of much interest, when considered in relation to Comparative Anatomy, and to Embryology. It appears, from what has been already stated, that the Pneumogastric, Spinal Accessory, Glosso-pharyngeal, and Hypoglossal nerves, may be considered nearly in the light of ordinary Spinal nerves. They all take their origin exclusively in the Medulla Oblongata; and the want of correspondence in position, between their roots and those of the Spinal nerves, is readily accounted for by the alteration in the direction of the columns of the Spinal cord, which not only decussate laterally, but, as it were, antero-posteriorly (§ 711). The Hypoglossal, as just stated, not unfrequently possesses a sensory in addition to its motor root. The Glosso-pharyngeal, which is principally an afferent nerve, has a small motor root; but most of the motor fibres which answer to it are to be found in the Pneumogastric. That the Pneumogastric and Spinal Accessory together represent a spinal nerve, may be regarded as probable from what has been already said of their relations.

722. Leaving these nerves out of the question, therefore, we proceed to the rest. Comparative anatomy, and the study of Embryonic development, alike show that the Spinal Cord and Medulla Oblongata constitute the most essential part of the nervous system in Vertebrata; and that the Cerebral Hemispheres are superadded, as it were, to this. At an early period of development, the Encephalon consists chiefly of four vesicles, which correspond with the ganglionic enlargements of the nervous cord of the Articulata, and mark four divisions of the Cerebro-Spinal axis; and, in accordance with this view, the Osteologist is able to trace, in the bones of the cranium, the same elements which would form four vertebræ, in a much expanded and altered condition.² However improba-

¹ It may be questioned, however, whether the Hypoglossal is really paralyzed on the opposite side from the Facial in such cases. An instance has been communicated to the Author by Dr. W. Budd, in which the hypoglossal nerve was completely divided on one side; and yet the tip of the tongue, when the patient was desired to put it out, was sometimes directed *from* and sometimes *towards* the palsied side; showing that the muscles of either half are sufficient to give any required direction to the whole.

² See "Princ. of Phys., Gen. and Comp.," *Am. Ed.*, § 320, *i*; and Prof. Owen's "Archetype Skeleton."

ble such an idea might seem, when the cranium of the higher Vertebrata alone is examined, it at once reconciles itself to our reason, when we direct our attention to that of Reptiles and Fishes; in which classes the size of the Cerebral

[Fig. 188*.

The drawing exhibits the cerebral connection of all the cerebral nerves except the 1st. It is from a sketch taken from two dissections of this part. *b*. Posterior optic tubercle. The generative bodies of the thalamus are just above it. *E*. Cerebellum. *H*. Spinal cord. *i*. Tuber cinereum. *K*. Optic thalamus divided perpendicularly. *w*. Corpus restiforme. *x*. Pons Varolii. *b b*. Optic nerves: this nerve is traced on the left side back beneath the optic thalamus and round the crus cerebri. It divides into four roots; the first (*g g*) plunges into the substance of the thalamus, the next runs over the external geniculate body and surface of the thalamus, the third goes to the anterior optic tubercle, the fourth runs to *D*, the testis or posterior optic tubercle. *c*. Third pair common oculo-muscular, arising by two roots like the spinal roots of the spinal nerves, the upper from the gray neurine of the locus niger, the lower from the continuation of the pyramidal columns in the crus cerebri and Pons Varolii, *p t*. *d*. Fourth pair, apparently arising from the inter-cerebral commissure (*i c*), but really plunging down to the olivary tract (*o f*) as it ascends to the optic tubercles. *e m*. Motor or non-ganglionic root of the fifth pair, arising from the posterior edge of the olivary tract. *e*. Sensory root of the fifth pair running down between the olivary tract and restiform body to the sensory tract. *f*. Sixth pair, or abducens, arising from the pyramidal tract. *g*. Seventh pair, facial nerve, or portio dura, arising by an anterior portion from the olivary tract and by a posterior portion from the cerebellic fibres of the anterior columns as they ascend on the corpus restiforme, *w*. *h*. Eighth pair, portio mollis, or auditory nerve, with its two roots embracing the restiform body. *i*. Ninth pair, or glosso-pharyngeal; and *j*. Tenth pair, or par vagum, plunging into the restiform ganglion. *j j*. Fibres of the optic nerve plunging into the thalamus; immediately below these letters is the corpus geniculatum externum. *k*. Eleventh pair, or lingual nerve; the olivary body has been nearly sliced off and turned out of its natural position; some of the filaments of the lingual nerve are traced into the deeper portion of the ganglion, which is left in its situation; others which are the highest are evidently connected with the pyramidal tract.¹—Ed.]

or hemispheric ganglia is very small, in comparison with that of the ganglia of Special Sensation; and in which the latter evidently form but a continuation of the Spinal Cord, modified in its function: so that, when we trace upward the cavity of the spinal column into that of the cranium, we encounter no material change, either in its size or direction. The four pairs of nerves of special sen-

¹ ["Solly on the Brain," *Am. Ed.*]

sation—Auditory, Gustatory, Optic, and Olfactory—make their way out *through* these three cranial vertebræ respectively. At a later period of development, other nerves are interposed *between* these; which, being *intervertebral*, are evidently more analogous to the Spinal nerves, both in situation and function. A separation of the primitive fibres of these takes place, however, during the progress of development, so that their distribution appears irregular. Thus the greater part of the sensory fibres are contained in the large division of the Trigemini: whilst of the motor fibres, the anterior ones chiefly pass forwards as the Oculomotor and Patheticus; and of the posterior, some form the small division of the Trigemini, and others unite with the first pair from the Medulla Oblongata to form the Facial. This last fact explains the close union, which is found in Fishes and some Amphibia, between that nerve and those proceeding more directly from the Medulla Oblongata. According to Valentin, the Glosso-pharyngeal is the sensory portion of the first pair from the Medulla Oblongata, of which the motor part is chiefly comprehended in the Facial nerve. Although we are accustomed to consider the Fifth pair as *par excellence* the Spinal nerve, of the head, the foregoing statements, founded upon the history of development,¹ show that the nerves of the Orbit really belong to its motor portion; they may consequently be regarded as altogether forming the *first* of the *intervertebral* nerves of the cranium. The Facial and Glosso-pharyngeal appear to constitute the *second*; whilst the Par Vagus and Spinal Accessory, forming the *third* pair, intervene between this and the true Spinal, of which the Hypoglossal may be considered as the first.

723. *Functions of the Spinal Axis.*—Whatever view we may take of the structure of the Spinal Cord, no doubt can be fairly entertained that it must be physiologically treated on the one hand as a true centre (or rather as an aggregation of separate centres) of nervous power, and on the other as a medium of conduction between the Encephalic centres and the roots of the Spinal nerves. And although its attributes as an independent centre become most obvious when it is separated from the rest, yet there can be no reasonable doubt that it is always acting as such, even when every part of the Nervous System is in a state of complete vigor. It may, in fact, be said to supply, by its “reflex power,” *the conditions requisite for the maintenance of the various Organic processes*; and, as Dr. M. Hall has pointed out, it especially governs the various orifices of ingress and egress. Thus the act of Deglutition is entirely dependent upon the Spinal Axis and the nerves proceeding from it; the Will being in no other way concerned in it than by originating the necessary stimulus; and even sensation not being a necessary link in the chain of excito-motor action (§§ 426—428). The action of the cardiac sphincter, again—and probably that of the pyloric sphincter also—is dependent upon its nervous connection with the Spinal Axis; and is entirely regulated without sensorial excitement (§ 428). And there is much reason to believe that certain of the movements of the Stomach itself are in like manner dependent upon its connection with the Medulla Oblongata (§ 430); although it unquestionably possesses an independent motor activity of its own. The movements of the Intestinal tube are undoubtedly influenced by the Spinal Cord, although essentially independent of it (§§ 432, 433); but the sphincter which surrounds its orifice of egress is undoubtedly placed under its guardianship, although partly subjected (in Man) to the control of the Will. The same may be said of the *expulsor* muscles concerned in the act of Defecation; and of the *expulsors* and sphincter which effect and control the act of Urination (§ 434).—Looking, again, at the movements which are subservient to the Respiratory process, we find that all those

¹ See Prof. Valentin “De Functionibus Nervorum Cerebraliū et Nervi Sympathetici,” Bernæ, 1839; lib. iii. cap. i.

which are essential to its regular maintenance are performed through the intermediation of the Spinal Axis alone; that the Will has only such a limited power over them as to bring them into harmony with its other requirements, as in the acts of vocalization and in extraordinary muscular exertions; and that the stimulus by which they are commonly maintained does not even affect the consciousness, the "*besoin de respirer*" only becoming *sensible* when the respiratory process is being imperfectly performed (§§ 548—551). Not only are the ordinary respiratory movements performed through this channel, but the aperture of the Glottis is regulated by it in everything that concerns the respiration; and either by its spasmodic closure against the entrance of unfit substances, or by the expulsor effort of coughing, which is excited by them when they do find their way into the air-passages, these passages are kept free from solid, liquid, or gaseous particles, whose presence in them would be injurious.—In the expulsion of the Generative products, also, the reflex power of the Spinal Cord takes an important share. The muscular contractions which produce the *Emissio Seminis* are excitomotor in their nature; being independent of the Will, and not capable of restraint by it when once fully excited; and being (like those of Deglutition) excitable in no other way than by a particular local irritation. It has been shown by experiment, and also by pathological observation, that the separation of the lower portion of the Spinal Cord from the upper does not prevent these movements from being excited, although the act is then unaccompanied with sensation, which proves that sensation is not essential to its performance; on the other hand, the power of emission is annihilated by destruction of the lower portion of the Spinal Cord, or by section of the nerves which supply the genital organs. The act of Parturition, however, seems to be less dependent upon the Spinal Cord; for, as will be shown hereafter (CHAP. XIX.), the contractions of the Uterus, which are alone sufficient to expel the *foetus* when there is no considerable resistance, are not to be regarded as reflex; and it is only in the co-operation of those associated muscles which come into play in the second stage of labor, when the head is passing through the os uteri and is engaged in the pelvic cavity, that the assistance of the Spinal cord and its nerves is called in. These movements, like those of Defecation, may be to a certain extent promoted or restrained by voluntary effort; but when the exciting influence (the pressure of the head against the parietes of the vaginal canal) has once been fully brought into operation by the uterine contractions, the Will has little power over them, either in one way or the other. The antagonizing influence of the sphincter vaginæ seems, like that of the sphincter ani, to be dependent upon the Spinal Cord; and thus it happens that when its tension and that of other muscular parts have been destroyed by death, whilst the uterus still retains its contractility, the power of the latter has sufficed for the completion of the parturient process, the child being expelled after the respiratory movements have ceased.

724. The Spinal Cord is not merely the instrument whereby the movements essential to the maintenance of the Organic functions are sustained; it is also subservient to other muscular actions whose character is essentially *protective*. Thus it was ascertained by Dr. M. Hall¹ that, if the functions of the Brain be suspended or destroyed, without injury to the Spinal Cord and its nerves, the *Orbicularis* muscle will contract, so as to occasion the closure of the eyelids, upon their tarsal margin being touched with a feather. This fact is interesting in several points of view. In the first place, it is a characteristic example of pure reflex action, occurring under circumstances in which volition cannot be imagined to guide it, and in which there is no valid reason to believe that sensation directs it. Further, it explains the almost irresistible nature of the

¹ "Memoirs on the Nervous System," 1837, p. 61.

tendency to winking, which is performed at short intervals by the contraction of the Orbicularis muscle; this is evidently a Spinal action, capable of being in some degree restrained (like that of respiration) by the will, but only until such times as the stimulus (resulting perhaps from the collection of minute particles of dust upon the eyes, or from the dryness of their surface in consequence of evaporation) becomes too strong to be any longer resisted. Again, we have in sleep or in apoplexy an example of this purely spinal action, unbalanced by the influence of the will, which, in the waking state, antagonizes it by calling the levator palpebræ into action. As soon as the will ceases to act, the lids droop, and close over the eye in order to protect it; and if those of a sleeping person be separated by the hand, they will be found presently to return. Here, as in studying the respiratory and other movements, we are led to perceive that it is the Brain alone which is torpid during sleep, and whose functions are affected by this torpidity. As Dr. M. Hall very justly remarks, "the Spinal system never sleeps;" it is constantly in activity; and it is thus that, in all periods and phases of Life, the movements which are essential to its continued maintenance are kept up without sensible effort.—The closure of the pupil against a strong light is another movement of the same protective tendency. The channel through which that just named is performed is completed by the first branch of the Fifth and the Portio Dura of the seventh. The contraction of the pupil is immediately caused by the Third pair, or Motor Oculi, as is easily shown by irritating the trunk of that nerve and observing the result; but the stimulus which excites it is conveyed through the Optic nerve. But although the contraction of the pupil is usually in close accordance with the *sensation* occasioned by the impression of light upon the retina, yet there is evidence to prove that the sensation of light is not always necessary; for, even when the sight of both eyes has been entirely destroyed by amaurosis, the regular actions have been witnessed in the pupil, in accordance with varying degrees of light impinging on the retina. Such cases seem to indicate that the motion results from an *impression* upon the retina, which impression, being conducted to the Sensorium, ordinarily produces a sensation; but that even where no sensation is produced, on account of a disordered state of the part of the ganglionic centre in which the Optic nerve terminates, if the central tract which connects that nerve with the Third pair retain its integrity, a reflex action may be excited through it, although no sensation intervene. The rarity of the occurrence is easily accounted for, by the fact that in most cases of amaurosis, the disease lies in the retina or in the trunk of the nerve, and thereby checks both its spinal and its encephalic actions.—Although we are not at present acquainted with any similar protective movements, in the Human being, designed to keep the organ of Hearing from injury, yet there can be little doubt that those which we are constantly witnessing in other animals, possessing large external ears, are reflex actions excited by the irritation applied to them. In regard to the Nose, we find a remarkably complex action—that of Sneezing—adapted to drive off any cause of irritation (§ 555). The stimulus is conveyed, in this case, not through the Olfactory nerve, but through the Fifth pair; so that it is not dependent upon the excitement of the sensation of Smell. The act of Coughing, also, may be regarded as of a protective character; being destined to remove sources of irritation from the air-passages. Many of the automatic movements, performed by the limbs of Frogs and other animals, when their connection with the brain has been cut off, appear destined to remove these parts from sources of irritation or injury; and they may thus be rightly placed under the same category.

725. The fact that sensation is very commonly *associated with* the reflex actions we have been considering, being produced by the impression that excites them, has led many to suppose that it necessarily participates in them;—a doctrine which we have seen to be untenable. But the question not unnaturally

arises, *why* Sensation should so constantly participate in these operations, if not essential to them; and the answer to this question is to be found in the fact that it is only through sensation that a higher set of actions, mental and bodily, is called into play, which is essential to the *continued maintenance* of those belonging to the present category. Illustrations of this truth might be drawn from any one of the functions already noticed; but the Ingestion of food will supply us with one of the most apposite. We have seen that the act of Deglutition is in itself independent of sensation; anything that comes within the grasp of the pharyngeal constrictors being conveyed downwards by their reflex contraction, just as anything which touches the arms of a Polype is entrapped by them and drawn into the stomach. Now this action may be considered as attended with sensation, in the ordinary condition of the higher Animal, in order that it may be guided in the performance of those other movements of prehension, mastication, &c., by which the food may be brought within reach of the apparatus of deglutition; and the sensations which are linked with these are among the influences which prompt to those mental operations whereby food is provided for the digestive apparatus to make use of. The Zoophyte is dependent for its supplies of aliment upon what the currents in the surrounding fluid, or other chances, may bring into its neighborhood; and if these should fail, it starves. The encephalous Infant, again, can swallow, and even suck; but it can execute no other movements adapted to obtain the supply of food continually necessary for maintenance, because it has not a mind which sensations could awake into activity. The sensation connected with excito-motor actions has not only this important end, but it frequently contributes to enjoyment, as in Suction and Ejaculatio seminis. The sensation accompanying the actions of this class, moreover, frequently affords premonition of danger, or gives excitement to supplementary actions destined to remove it, as in the case of Respiration; for where anything interferes with the due discharge of the function, the uneasy sensation that ensues occasions unwonted movements, which are more or less adapted to remove the impediment, in proportion as they are guided by judgment as well as by consciousness. Again, sensation often gives warning against inconvenience, as in the Excretory functions; and here it is very evident that its purpose is not only (if it be at all) to excite the associated muscles necessary for the excretion, but actually to make the will set up the antagonizing action of the sphincters (§ 434).

726. We have now to inquire how far the independent action of the Spinal Cord is concerned in the general muscular movements of Man, and especially in the locomotive actions of his lower extremities. On this point it is obvious that we must not be guided by the analogy of the lower animals; since in Man the locomotive and other movements are for the most part volitional and purposive, and he has to acquire by experience that control over his muscular apparatus which is necessary to enable him to perform them; whilst in Invertebrata generally, and in a large part of the lower Vertebrata, it is evident that the movements of progression, &c., which are characteristic of each species, come under the general category of automatic actions, and are provided for in the original organization of its nervous centres, being performed without any education, and under circumstances which render the notion of a purpose on the Animal's own part quite untenable. In so far as these instinctive movements require the guidance and direction of sensations, they must be referred to the "consensual" group; but clear evidence is afforded by the continuance of many of them after the removal of the centres of sensation, that they are excito-motor in their character, and that they require no higher centre than the ganglia which correspond to the Spinal Cord of Man.¹ There can be little doubt that

¹ See "Princ. of Phys., Gen. and Comp.," §§ 769-771, *Am. Ed.*

the habitual movements of locomotion, and others which have become "secondarily automatic," may be performed by Man under particular circumstances through the agency of the Spinal Cord alone, under the guidance and direction of the Sensorial centres, or even without such guidance; the required condition being, that the influence of the Cerebrum shall be entirely withdrawn. There are numerous instances on record, in which soldiers have continued to *march* in a sound sleep; and the Author has been assured by an intelligent witness, that he has seen a very accomplished pianist complete the performance of a piece of music in the same state.¹ A case has been mentioned to him by his friend Dr. William Budd, of a patient who labored under that form of epilepsy in which there was simply a temporary suspension of consciousness without convulsion; and whenever the paroxysm came on, he persisted in the kind of movement in which he was engaged at the moment, having on one occasion fallen into the water through continuing to walk onwards, and having on several occasions (being a shoemaker by trade) wounded his fingers with the awl in his hand by a repetition of the movement by which he was endeavoring to pierce the leather. Such facts as these add great strength to the probability, that when the Cerebral power is not suspended, but merely directed into another channel, as in the states of reverie or abstraction, and the attention is entirely drawn off from the movements of locomotion, the continuance of these is due to the independent automatic action of the Spinal Cord, the direction being given to them by the Sensory Ganglia. This point, however, will be more fully considered hereafter (§ 749); at present it may be remarked that, when a regular train of movements is being performed under such conditions, each action may be probably regarded as affording the stimulus to the next; each contact of the foot with the ground, in the act of walking, exciting the muscular contractions which constitute the next step;² and each movement of the musician exciting that which has customarily followed it, after the same fashion. Now in all these cases, it seems reasonable to infer, that the same kind of connection between the excitor and motor nerves comes to be formed by a process of gradual development, as originally exists in the nervous systems of those animals whose movements are entirely automatic. Whether there is in any case an actual continuity of nerve-fibres, may be reasonably doubted. That such a peculiar continuity is not requisite, in order to allow an excitor impression made upon one part of the Cord to call forth motions through another, may be certainly inferred from the fact, that under particular circumstances we find the influence of such impressions radiating in every direction, and extending to nerves which they do not ordinarily affect (§ 728). Still there can be no doubt that the nerve-force is disposed to pass in special *tracks*; and it seems probable that, whilst some are originally marked out for the automatic movements, others may be gradually worn in (so to speak) by the habitual action of the Will; and that thus, when a train of sequential actions originally directed by the Will has been once set in operation, it may continue without any further influence from that source.

727. Another manifestation of the independent power of the Spinal Cord is seen in its influence on *Muscular Tension*.—The various muscles of the body, even when there is the most complete absence of effort, maintain, in the healthy

¹ In playing by memory on a musical instrument, the *muscular* sense often suggests the sequence of movements with more certainty than the *auditory*; and since the impressions derived from the muscles may prompt and regulate successional movements without affecting the consciousness, there is no such improbability in the above statement as might at first sight appear.

² The truth of this view seems to the Author to be strongly supported by observation of the mode in which infants learn to walk; for, long before they can stand, they will instinctively perform the movements of walking, if they be so supported that the feet touch the ground.

state of the system, a certain degree of firmness, by their antagonism with each other; and if any set of muscles be completely paralyzed, the opposing muscles will draw the part on which they act out of its position of repose; as is well seen in the distortion of the face which is characteristic of paralysis of the facial nerve on one side. This condition has been designated as the *tone* of the Muscles; but this term renders it liable to be confounded with their *tonic contraction* (§ 331), which is also concerned in maintaining their firmness, but which is a manifestation of the simple contractility of their tissue, and is exhibited alike by the striated and the non-striated forms of muscular fibre, but more especially by the latter. On the other hand, the condition now alluded to, which may perhaps be appropriately termed their *tension*, is the result of a moderate though continued excitement of that contractility, through the nervous centres. It has been proved by Dr. M. Hall that the Muscular Tension is not dependent upon the influence of the Brain, but upon that of the Spinal Cord; as the following experiments demonstrate: "Two Rabbits were taken; from one the head was removed; from the other also the head was removed, and the spinal marrow was cautiously destroyed with a sharp instrument: the limbs of the former retained a certain degree of firmness and elasticity; those of the second were perfectly lax." Again: "The limbs and tail of a decapitated Turtle possessed a certain degree of firmness or tone, recoiled on being drawn from their position, and moved with energy on the application of a stimulus. On withdrawing the spinal marrow gently out of its canal, all these phenomena ceased. The limbs were no longer obedient to stimuli, and became perfectly flaccid, having lost all their resilience. The sphincter lost its circular form and contracted state, becoming lax, flaccid, and shapeless. The tail was flaccid, and unmoved on the application of stimuli."¹ It is further remarked, by Messrs. Todd and Bowman, that "a decapitated frog will continue in the sitting posture through the influence of the spinal cord; but immediately this organ is removed, the limbs fall apart."—This operation of the Spinal Cord is doubtless but a peculiar manifestation of its ordinary reflex function. We shall hereafter see (§ 750) how much the influence of the Will in producing the active contraction of a muscle is connected with sensations received from it; and it seems highly probable that the impression of the state of the muscle, conveyed by the afferent fibres proceeding from it to the spinal cord, is sufficient to excite this state of moderate tension through the motor nerves arising from the latter. Such a view derives probability from the fact, which must have fallen under the observation of almost every one, that most reflex actions become increased in energy if resistance be made to them. Of this we have familiar examples in the action of the expulsor muscles, which operate in defecation, urination, and parturition, if, when they are strongly excited, their efforts be opposed by spasmodic contraction of the sphincters, or by mechanical means. Many forms of convulsive movement exhibit the same tendency, their violence being proportional to the mechanical force used to restrain them.² Here it is evident that the *impression of resistance*, conveyed to the Spinal Cord, is the source of the increased energy of its motor influence; from which we may fairly infer that the moderate resistance, occasioned by the natural antagonism of the muscles, is the source of their continued and moderate tension, whilst they are under the influence of the Spinal Cord. This constant though gentle action serves to keep up the nutrition of the muscles, which are paralyzed to the will; and this is still more completely maintained, if the portion of the nervous centres, with

¹ "Memoirs on the Nervous System," 1837, p. 93.

² Hence the absurdity of the common practice of endeavoring to *prevent* the movements of the limbs and body, in convulsive paroxysms, by mechanical constraint. Nothing should be attempted but what is requisite to prevent the sufferer from doing himself an injury.

which they remain connected, be so unduly irritable, that the muscles are called into contraction upon the slightest excitation, and are thus continually exhibiting twitchings, startings, or more powerful convulsive movements. It is upon the state of nutrition of the muscles that their contractility depends (§ 313); and hence the Spinal Cord has an indirect influence upon this peculiar property, which is more likely to be retained, when the muscle is still subject to the influence of the Spinal Cord, though cut off from that of the Brain, than when it is completely paralyzed by the entire separation of its connection with the nervous centres.

728. The functional activity of the Spinal Cord is capable of being morbidly diminished or augmented. It may even be for a time almost completely suspended, as in Syncope; which state may be induced by sudden and violent impressions, either of a mental or physical nature, that operate upon the whole nervous system at once—commencing, however, in the Brain. It is to be remarked that, in recovering from these, it is the Spinal system of which the activity is first renewed; the respiratory movements recommencing, and the power of swallowing being restored, before any voluntary actions can be performed. A corresponding state may be induced in particular portions of the system by Concussion; as is seen in severe injuries of the Spinal Cord, which are almost invariably followed for a time by the suspension of its functions. Again, the power of the whole Spinal Cord may be diminished by various causes, such as enfeebled circulation, pressure, &c.; and then we have torpidity and imperfect nutrition of the whole muscular system.¹ If oppression exist in the Brain, the functions of the Medulla Oblongata will be especially affected; and if it be prolonged and sufficiently severe, Asphyxia will result from the interruption of the respiratory movements which it occasions.—On the other hand, the excitability of the whole Cord, or of particular parts of it, may be morbidly increased.² This is especially seen in ordinary Tetanus, and in the

¹ A case has been for some time under the Author's observation, in which the males of a family have been successively affected with a general muscular debility, commencing in the lower extremities, which is pretty obviously traceable to deficient functional activity of the Spinal Cord. The affection has manifested itself during the earlier years of childhood; and in the two elder sons has advanced until it has produced an almost complete general paralysis, with fatty degeneration of the muscles. In a younger son, in whom the same affection had distinctly begun to manifest itself, it has been kept in check by very careful attention to every means that can favor healthy nutrition and development of nervous power; among which, constant exercise, and the frequent transmission of feeble electrical currents down the spine and from the spine to the limbs, have seemed the most effectual.

² It has been pointed out by Messrs. Todd and Bowman ("Physiological Anatomy," p. 281, *Am. Ed.*) that the Spinal Cord of the male frog, at the season of copulation, naturally possesses a state of most extraordinary excitability. The thumb of each anterior extremity, at this season, becomes considerably enlarged; as is well known to Naturalists. "This enlargement is caused principally by a considerable development of the papillary structure of the skin which covers it; so that large papillæ are formed all over it. A male frog, at this season, has an irresistible propensity to cling to any object, by seizing it between his anterior extremities. It is in this way that he seizes upon, and clings to the female; fixing his thumbs to each side of her abdomen, and remaining there for weeks, until the ova have been completely expelled. An effort of the Will alone could not keep up the grasp uninterrupted for so long a time; yet so firm is the hold, that it can with difficulty be relaxed. Whatever is brought in the way of the thumbs, will be caught by the forcible contraction of the anterior limbs; and hence we often find frogs clinging blindly to a piece of wood, or a dead fish, or some other substance which they may chance to meet with. If the finger be placed between the anterior extremities, they will grasp it firmly; nor will they relax their grasp until they are separated by force. If the animal be decapitated, whilst the finger is within the grasp of its anterior extremities, they still continue to hold on firmly. The posterior half of the body may be cut away, and yet the anterior extremities will still cling to the finger; but immediately that the segment of the cord, from which the anterior extremities derive their nerves, has been removed, all their motion ceases. This curious instinct only exists during the period of sexual excitement; for at other periods the excitability of the anterior extremities is considerably less than that of the posterior."

artificial Tetanus induced by Strychnine; in which the slightest external stimulus is sufficient to induce reflex actions in their most terrific forms. It is interesting to remark that, in this formidable disease, the functions of the muscles controlling the various orifices are those most affected; and it is by the spasms affecting the organs of respiration or deglutition, that life is commonly terminated. In some forms of Hysteria, also, there is a morbid excitability of the same kind, so that various kinds of convulsions are brought on by very slight stimuli; and Infantile convulsions are generally attributable to the same kind of disorder of the nervous centres, which is frequently induced by bad air, unwholesome food, or some other cause that affects the purity of the blood (§ 583). Not only is the general muscular system of Animal life involved in these abnormal actions, but various parts of the apparatus of Organic life have their normal functions seriously perverted by the same condition of the Spinal Cord; being connected with it through the medium of the Sympathetic system of nerves, whose motor powers are chiefly, if not entirely, derived from that source (Sect. 6).—Various remedial agents will probably be found to operate, by occasioning increased excitability in some particular segments of the Cord; so that the usual stimuli applied to the parts connected with these will occasion increased muscular tension. This seems to be the case, for example, in regard to the influence of aloes on the rectum and uterus, cantharides on the neck of the bladder and adjoining parts, and secale cornutum on the uterus. The mode of influence of cantharides is illustrated by a curious case, related by Dr. M. Hall, of a young lady who lost the power of retention of urine, in consequence of a fatty tumor in the spinal canal, which gradually severed the Spinal Cord, and induced paraplegia. The power of retaining the urine was always restored *for a time* by a dose of tincture of cantharides, which seems to have acted by augmenting the excitability of that segment of the Cord with which the sphincter vesicæ is connected.

3.—Of the Sensory Ganglia and their Functions.—Consensual Movements.

729. At the base of the Brain in Man, concealed by the Cerebral Hemispheres, but still readily distinguishable from them, we find a series of ganglionic masses; which are in direct connection with the nerves of Sensation; and which appear to have functions quite independent of those of the other components of the Encephalon.—Thus anteriorly we have the *Olfactive* ganglia, in what are commonly termed the bulbous expansions of the Olfactive nerve. That these are real ganglia is proved by their containing gray or vesicular substance; and their separation from the general mass of the Encephalon, by the peduncles or footstalks commonly termed the trunks of the Olfactory nerves, finds its analogy in many species of Fish. The ganglionic nature of these masses is more evident in many of the lower Mammalia, in which the organ of Smell is highly developed, than it is in Man, whose olfactive powers are comparatively moderate.—At some distance behind these, we have the representatives of the *Optic* ganglia, in the Tubercula Quadrigemina, to which the principal part of the roots of the Optic nerve may be traced. Although these bodies are so small in Man, in comparison with the whole Encephalic mass, as to be apparently insignificant, yet they are much larger, and form a more evidently important part of it in many of the lower Mammalia; though still presenting the same general aspect.—The *Auditory* ganglia do not form distinct lobes or projections; but are lodged in the substance of the Medulla Oblongata. Their real character is most evident in certain Fishes, as the Carp; in which we trace the Auditory nerve into a ganglionic centre as distinct as the Optic ganglion. In higher animals, however, and in Man, we are able to trace the Auditory nerve into a small mass of vesicular matter, which lies on each side of the Fourth Ventricle; and although this

is lodged in the midst of parts whose function is altogether different, yet there seems no reason for doubting that it has a character of its own, and that it is really the ganglionic centre of the Auditory nerve.—In like manner, we may

Fig. 189.

Section of the cerebrum, displaying the surfaces of the corpora striata, and optic thalami, the cavity of the third ventricle, and the upper surface of the cerebellum.—*a e.* Corpora quadrigemina,—*a* testis, *e* nates. *b.* Soft commissure. *c.* Corpus callosum. *f.* Anterior pillars of fornix. *g.* Anterior cornu of lateral ventricle. *k k.* Corpora striata. *l l.* Optic thalami. * Anterior tubercle of the left thalamus. *z* to *s.* Third ventricle. probably fix upon a collection of vesicular matter, imbedded in the Medulla Oblongata—which is considered by Stilling to be the nucleus of the Glosso-pharyngeal nerve, and to which a portion of the sensory root of the Fifth pair may be also traced—as representing the *Gustatory* ganglion.

730. At the base of the Cerebral Hemispheres, we find two other large ganglionic masses, on either side; through which nearly all the fibres appear to pass that connect the Hemispheres with the Medulla Oblongata. These are the *Thalami Optici* and the *Corpora Striata*. Now, although these are commonly in the light of appendages, merely, to the Cerebral Hemispheres, it is evident, from the large quantity of vesicular matter they contain, that they must rank as independent ganglionic centres; and this view is supported alike by the evidence of Comparative Anatomy, and by that afforded by the history of Development. For it is certain that the size of the Thalami Optici and Corpora Striata presents no more relation, in different tribes of animals, to that of the Cerebrum, than does that of the ganglia of Special Sense; and they may even present a considerable development, when the condition of the Cerebrum is quite rudimentary. Thus in the Osseous Fishes, a careful examination of the relations of the body which is known as the Optic lobe (Fig. 171, c) makes it ap-

parent that this is not merely the representative of the proper Optic Ganglion of Man, but also of the Thalamus Opticus; whilst, again, the mass which is designated as the Cerebral lobe (B) is chiefly homologous with the Corpus Striatum of higher animals. The nature of the latter body is made apparent in the higher Cartilaginous Fishes, by the presence of a ventricle in its interior; the floor of this cavity being formed by the Corpus Striatum, whilst the thin layer of nervous matter which forms its roof is the only representative of the Cerebral

¹ ["Solly on the Brain," *Am. Ed.*]

hemisphere. So in the Human embryo of the 6th week, we find a distinct vesicle for the *Thalami Optici*, interposed between the vesicle of the *Corpora Quadrigemina* and that which gives origin to the *Cerebral Hemispheres*; whilst the *Corpora Striata* constitute the floor of the cavity or ventricle which exists in the latter, this being as yet of comparatively small dimensions. Now, as already pointed out, we may distinguish in the *Medulla Oblongata* and *Crura Cerebri*, a *sensory* and *motor* tract, by the endowments of the nerves which issue from them. The sensory tract may be traced upwards, until it almost entirely spreads itself through the substance of the *Thalamus*. Moreover, the *Optic nerves*, and the *peduncles of the Olfactive*, may be shown to have a distinct connection with the *Thalami*; the former by the direct passage of a portion of their roots into these ganglia; and the latter through the medium of the *Fornix*. Hence we may fairly regard the *Thalami Optici* as the chief focus of the *Sensory* nerves, and more especially as the ganglionic centre of the nerves of *common* sensation, which ascend to it from the *Medulla Oblongata* and *Spinal Cord*.—On the other hand, the *Corpora Striata* are implanted on the *Motor* tract of the *Crura Cerebri*, which descend into the *Pyramidal columns*; and their relation to the fibres of which that tract is composed appears to be essentially the same as that which the *Thalami* bear to the sensory tract. Upon the precise nature of that relation, Anatomists are not agreed; but there are several considerations which render it probable that there is *not* that continuity between the fibres of the *Crura Cerebri*, and those which radiate from the *Thalami Optici* and *Corpora Striata* to the surface of the *Hemispheres*, which a superficial examination would seem to indicate; but that the fibres which ascend from the *Crura Cerebri* for the most part, if not entirely, terminate in the vesicular substance of the former bodies, and that the radiating fibres of the latter take a fresh departure from them.¹ At any rate, as we shall see hereafter, there is a complete *physiological* separation between the *Cerebrum* and the *Sensory Ganglia* upon which it is superposed.

731. The *Thalami Optici*, and the *Corpora Striata*, as is well known, are very closely connected with each other by commissural fibres; and, if the preceding account of their respective offices be correct, they may be regarded as having much the same relation to each other as that which exists between the posterior and anterior peaks of vesicular matter in the *Spinal Cord*;² the latter issuing motor impulses in response to sensations excited through the former. They are also closely connected with other ganglionic masses in their neighborhood, such as the *Locus Niger*, and the vesicular matter of the *Tuber Annulare*; which again are in close relation with the vesicular matter of the *Medulla Oblongata*.—Altogether it is very evident that a series of true ganglionic centres exists at the base of the *Encephalon*, and that these are really as distinct from either the *Cerebrum* or *Cerebellum* as the latter are from each other; and we have next to inquire, what functions are to be assigned to them.

732. The determination of these may seem to be the more difficult, as it is impossible to make any satisfactory experiments upon the ganglionic centres in question by isolating them completely from the *Cerebral Hemispheres* above, and from the *Medulla Oblongata* and *Spinal Cord* below. But the evidence derived from *Comparative Anatomy* appears to be in this case particularly clear; and, rightly considered, affords us nearly all the information we require. In the series of "experiments prepared for us by nature," which is presented to us in the descending scale of *Animal life*, we witness the effects

¹ See especially Messrs. Todd and Bowman's "*Physiological Anatomy*," p. 251, *Am. Ed.*, and Prof. Kölliker's "*Mikroskopische Anatomie*," band ii. § 118.

² This was first pointed out by Messrs. Todd and Bowman in their "*Physiological Anatomy*," p. 308, *Am. Ed.*

of the gradual change in the relative development of the Sensory ganglia and Cerebral Hemispheres, which are presented to us in the Vertebrated classes; and the results of the entire withdrawal of the latter, and of the sole operation of the former, which are presented in the higher Invertebrata. For the sensory ganglia gradually increase, whilst the Cerebral Hemispheres as regularly diminish, in relative size and importance, as we descend from the higher Mammalia to the lower—from these to Birds—thence to reptiles—from these, again, to the higher Fishes, in which the aggregate size of the Sensory ganglia equals that of the Cerebrum—thence to the lower Fishes, in which the size of the Cerebral lobes is no greater than that of a single pair of sensory ganglia, the Optic, and frequently even inferior—and lastly, to the *Amphioxus* or Lancelot, the lowest Vertebrated animal of which we have any knowledge, in which there is not the rudiment of a Cerebrum, the Encephalon being only represented by a single ganglionic mass, which, from its connection with the nerves of sense, must obviously be regarded as analogous to the congeries of ganglia that we find in the higher forms of the class.—Descending to the Invertebrated series, we find that, except in a few of those which border most closely upon Vertebrata (such, for example, as the Cuttle-Fish), the whole Cephalic mass appears to be made up of ganglia in immediate connection with the Nerves of Sense. These may appear to form but a single pair; yet they are in reality composed of several pairs, fused (as it were) into one mass. Of this we may judge by determining the number of distinct pairs of nerves which issue from them; and also by the investigation of the history of their development, the results of which bear a close correspondence with those obtained in the preceding method.—It is further to be remarked that the development of the Cephalic ganglia in the Invertebrata always bears an exact proportion to the development of the eyes; the other organs of special sense being comparatively undeveloped; whilst these, in all the higher classes at least, are instruments of great perfection, and are evidently connected most intimately with the direction of the movements of the animals. Of this fact we have a remarkable illustration in the history of the metamorphosis of Insects; the eyes being almost rudimentary, and the Cephalic ganglia comparatively small, in most Larvæ; whilst both these organs attain a high development in the Imago, to whose actions the faculty of sight is essential.¹

733. Thus we are led by the very cogent evidence which Comparative Anatomy supplies, to regard this series of Ganglionic centres as constituting the real *Sensorium*; each ganglion having the power of communicating to the mind the impressions derived from the organ with which it is connected, and of exciting automatic muscular movements in response to these sensations. If this position be denied, we must either refuse the attribute of consciousness to such animals as possess no other encephalic centres than these; or we must believe that the addition of the Cerebral hemispheres, in the Vertebrated series, alters the endowments of the Sensory ganglia—an idea which is contrary to all analogy.

734. So far as the results of Experiments can be relied on, they afford a corroboration of this view. The degree in which animals high in the scale of organization can perform the functions of life, without any other centre of action than the Ganglia of Special sense, the Medulla Oblongata, and the Cerebellum, appears extraordinary to those who are accustomed to regard the Cerebral Hemispheres as the centre of all energy. From the experiments of Flourens,² Hertwig,³ Magendie,⁴ Longet,⁵ and others, it appears that not only Reptiles, but

Birds and Mammals, may survive for many weeks or months (if their physical wants be duly supplied) after the removal of the entire Cerebrum. It is difficult to substantiate the existence in them of actual sensation; but some of their movements appear to be of a higher kind than those resulting from mere excito-motor action. One of the most remarkable phenomena exhibited by such a being is the power of maintaining its equilibrium, which could scarcely exist without consciousness. If it be laid upon the back, it rises again; if pushed, it walks. If a Bird thus mutilated be thrown into the air, it flies; if a Frog be touched, it leaps. It swallows food and liquid, when they are placed in its mouth; and the digestive operations, the acts of excretion, &c., take place as usual. In the case of a Pigeon experimented on by Malacorps, which is recorded by Magendie, there appears sufficient proof of the persistence of a certain amount of sensation. Although the animal was not affected by a strong light suddenly made to fall upon its eyes, it was accustomed, when confined in a darkened or partially illuminated room, to seek out the light parts; and *it avoided objects that lay in its way*. In the same manner, it did not seem to be affected by sudden noises; but at night, when it slept, with closed eyes and its head under its wing, it would raise its head in a remarkable manner, and open its eyes, on the slightest noise; speedily relapsing into a state of complete unconsciousness. Its principal occupation was to prune its feathers and scratch itself. And Longuet mentions that a Pigeon from which he had removed the entire Cerebrum gave many indications of consciousness of light; not only the pupil contracting, but the lids closing, when a strong light was suddenly made to fall upon the eye, the animal having been previously kept in darkness; and *when a lighted candle was made to move in a circle before it, the animal executed a corresponding movement with its head*.¹—The condition of such beings seems to resemble that of a Man, who is in a slumber sufficiently deep to lose all distinct *perception* of external objects, but who is yet conscious of *sensations*, as appears from the movements occasioned by light or by sounds, or from those which he executes to withdraw the body from an uneasy position (§ 787).

735. The results of other Experiments made upon the Sensory ganglia themselves, and upon the organs from which they derive their impressions, confirm this view; by showing that the ordinary movements are seriously perturbed, and that in some instances a new set of automatic movements is induced, when the ordinary relations between the sensory and motor apparatus are disarranged. Among the ganglia of special sensation, the functions of the Optic Lobes, or *Corpora Quadrigemina*, have been chiefly examined experimentally. The researches of Flourens and Hertwig have shown that their connection with the visual function, which might be inferred from their anatomical relations, is thus substantiated. The partial loss of the ganglion on one side produces partial loss of power and temporary blindness on the opposite side of the body, without necessarily destroying the mobility of the pupil; but the removal of a larger portion or complete extirpation of it, occasions permanent blindness and immobility of the pupil, with temporary muscular weakness on the opposite side. This temporary disorder of the muscular system sometimes manifests itself (as already stated) in a tendency to move on the axis, as if the animal were giddy. No disturbance of consciousness appears to be produced; and Hertwig states that he never witnessed the convulsions which Flourens mentions as a consequence of the operation, and which were probably occasioned by his incision having been carried too deeply. As Longuet has justly remarked, it is difficult,

¹ It must not be forgotten that, in such experiments, the severity of the operation will of itself occasion a suspension or disturbance of the functions of parts that remain; so that the *loss* of a power must not be at once inferred from the absence of its manifestations. But the *persistence* of a power, after the removal of a particular organ, is a clear proof that it cannot be the peculiar attribute of that organ.

if not impossible, to remove one or both of these ganglionic masses, without doing such an injury to the Crura Cerebri on which they repose, as shall in great degree account for such disturbed movements (§ 738). Irritation of *one* of the Tubercula Quadrigemina has been observed, both by Flourens and Longet, to produce contraction of the pupils of *both* eyes.—These results of experiment are partly confirmed by Pathological phenomena in Man; for there are many instances on record in which blindness has been one of the consequences of diseased alterations in one or both tubercles; and in some of the cases in which the lesion extended to parts seated beneath the tubercles, disturbed movements were observed.—The subservience of these bodies to the exercise of the visual sense appears, on the whole, to be the point best established in regard to their functions; and considering the degree in which this sense is concerned in the regulation of the general movements of the body, it is not surprising that lesions of its centre should occasion a perversion of these movements. This appears the more probable from the fact that, in animals whose Sensory ganglia bear so large a proportion to the whole Encephalon, that we must look upon them as the principal centres of motor activity, instead of being chiefly concerned (as in Man) in the mere guidance of movements whose origin is Cerebral, lesions of the organ of sense, from which the impressions that excite the sensori-motor impulses are derived, produce a corresponding disturbance. Thus Flourens found that a vertiginous movement may be induced in Pigeons by simply blinding one eye; and Longet produced the same effect by evacuating the humors of the eye.

736. It is probably on the same principle that we are to account for the remarkable results obtained by Flourens (Op. cit.) from section of the portion of the Auditory nerve proceeding to the Semicircular canals. Section of the horizontal semicircular canal in Pigeons, on both sides, induces a rapid, jerking, horizontal movement of the head from side to side; and a tendency to turn to one side, which manifests itself whenever the animal attempts to walk forwards. Section of a vertical canal, whether the superior or inferior, of both sides, is followed by a violent vertical movement of the head. And section of the horizontal and vertical canals, at the same time, causes horizontal and vertical movements. Section of either canal on one side only is followed by the same effect as when the canal is divided on both sides; but this is inferior in intensity. The movements continue to be performed during several months. In Rabbits, section of the horizontal canal is followed by the same movements as those exhibited by Pigeons; and they are even more constant, though less violent. Section of the anterior vertical canal causes the animal to make continued forward “somersets;” whilst section of the posterior vertical canal occasions continual backward “somersets.” The movements cease when the animal is in repose; and they recommence when it begins to move, increasing in violence as its motion is more rapid.—These curious results are supposed by M. Flourens to indicate that the nerve supplying the semicircular canals does not minister to the sense of hearing, but to the direction of the movements of the animal; but they are fully explained upon the supposition that the normal function of the semicircular canals is to indicate to the animal the *direction* of sounds, and that its movements are partly determined by these; so that a destruction of one or other of them will produce an irregularity of movement (resulting, as it would seem, from a sort of giddiness on the part of the animal), just as when one of the eyes of a bird is covered or destroyed, as in the experiments previously cited.

737. The numerous Experiments which have been made for the purpose of determining the functions of the Thalami Optici and Corpora Striata, have not yielded any very satisfactory results; and this on account of the impossibility of completely isolating them in such a manner as to limit the operation (whether this be section, removal, or irritation) to them alone. Thus it is impossible to

remove them, either separately or conjointly, without first removing the Cerebral Hemispheres; and the Thalami cannot be entirely removed, without dividing the stratum of fibres which passes through their deeper portion in their passage to the Corpora Striata. The evidence afforded by Pathology, too, is far from being self-consistent; and this, it may be surmised, from the circumstance that the effects of morbid changes (particularly of sanguineous effusions) in any part of the Encephalon extend themselves to other parts than those in which the obvious lesions are found; as is abundantly proved by the great variety of phenomena which present themselves as the results of lesions apparently similar, and the similarity of the phenomena that are frequently consequent upon lesions of very different parts.—The Thalami Optici have not that relation to the visual sense which their designation would imply; for (according to the affirmation of Longuet) they may be completely destroyed in Mammals and Birds, without destruction of sight or loss of the activity of the pupil; and irritation of one or both of them produces no contraction of the pupil. It seems probable, therefore, that the loss of sight, with dilatation and immobility of the pupil, which is frequently observed in cases of apoplectic effusion into the substance of the Thalami, is really due to the compression of the Optic nerves which lie beneath them. These bodies appear, however, to possess a very decided influence on the power of voluntary movement; for, although an animal maintains its balance, and can be made to move onwards, after the removal of the Cerebral Hemispheres, and even after the removal of the Corpora Striata, yet if either of the Thalami Optici be removed, the sensibility and power of voluntary movement are destroyed on the *opposite* side of the body, and the animal consequently falls over to that side (Longuet). If, instead of the entire removal of one of the Thalami, an incision be made in it without the previous removal of the Cerebrum, the animal keeps turning to one side in a circular manner (*evolution du manège*): according to Longuet and Lafargue, this movement is directed in the rabbit towards the opposite side; whilst Flourens states that in the frog its direction is towards the injured side; and according to Schiff¹ the destruction of the three anterior fourths of this organ in the rabbit determines this movement towards the injured side, whilst that of the posterior fourth determines the movement towards the opposite side. No mechanical irritation of the Thalami produces either signs of pain or muscular movement; and this fact might at first appear to negative the doctrine that these organs are the ganglia of common sensation. But it must be borne in mind that the production of pain by mechanical injuries is by no means a universal phenomenon in the case of the nerve-trunks which minister to sensation, the olfactive, optic, and auditory nerves being exempted; and it need occasion still less surprise, therefore, that a nervous *centre* should be destitute of this kind of impressibility.—The effects of lesions of the Corpora Striata are less distinctly marked. It was affirmed by Magendie that there exists in them a motor power, which excites *backward* movement, and that a corresponding power of exciting *forward* movement exists in the Cerebellum; and these two powers ordinarily balance each other; but that, if either organ be removed, the power of the other will occasion a continual automatic movement, the removal of the Corpora Striata causing an irresistible tendency to forward progression, whilst the division of the peduncles of the Cerebellum (according to him) occasions the reverse movement. These assertions, however, have not been confirmed by other experimenters. According to Longuet (*Op. cit.*), Schiff,² and Lafargue,³ the results of removal of the Corpora Striata with the anterior part of the Cerebral hemispheres are for the most part negative; for

¹ Roser's und Wunderlich's "Archiv. für Physiol., Heilkunde," 1846, § 667.

² "De vi motoria baseos encephali," Bockenheimii, 1845.

³ "Essai sur la valeur des localisations encéphaliques," &c., Thèse inaug., Paris, 1838.

the animal usually remains in a state of profound stupor, although still retaining the erect position; and it is only when irritated by pinching or pricking, that it will execute any rapid movements. No mechanical irritation of the Corpora Striata produces either signs of pain or muscular movement.—No distinct evidence regarding the special functions of either of these ganglionic masses can be gained from Pathological phenomena. So far as is yet known, extensive disease of either the Thalamus Opticus or the Corpus Striatum of one side produces hemiplegia, or paralysis both of sensation and motion, on the opposite side. The same result very commonly follows an apoplectic effusion into the substance of either; and although it has been maintained that, when the lesion is limited to the Corpus Striatum, the posterior member is peculiarly or alone affected, and that lesion of the Thalamus Opticus alone has a special tendency to occasion paralysis of the anterior member, yet the careful analysis which has been made by Andral¹ into the pathological phenomena afforded by seventy-five cases of paralysis in which the apoplectic effusion was limited to one or other of these bodies, does not afford the least countenance to any such doctrine. And it is affirmed by Longet, that injury or removal of the Corpus Striatum of one side did not, in his experiments, affect the posterior more than the anterior limb; nor could he detect any difference in the condition of these limbs after the removal of the Thalamus.

738. When the fibrous tracts which connect these ganglionic masses with the Medulla Oblongata, and which are commonly (but erroneously) designated as the *Crura Cerebri*, are completely divided, the result, as might be anticipated, is the annihilation of sensibility and of the power of voluntary movement in the body generally.² When, however, the *Crura Cerebri* of a rabbit are not completely divided, but one of them is partially cut through, a little in front of the Pons Varolii, the animal is said by Longet and Schiff to exhibit a constant tendency to turn towards the side opposite to that of the lesion, so that it performs the circular *evolution du manège*; the diameter of its circle of movement being smaller, in proportion as the incision approaches the edge of the Pons. But if one of the *Crura* be completely divided, the animal then falls over on the opposite side; the limbs of that side being paralyzed to the influence of the Encephalic centres, though they may be still caused to exhibit reflex motions. Hence it appears that the circular movements which are performed after incomplete lesions of the *Crura Cerebri* and Thalamus Opticus of either side, are due to the weakening of the sensori-motor apparatus of the opposite side, whereby the balance of the muscular actions of the two sides is destroyed. Nearly the same results have been obtained on this point by Longet, Lafargue, and Schiff. —Considerable importance is attached by some Physiologists to the part of the Encephalon known as the *Tuber Annulare*, to which the name of *Mesocephale* has also been given. This is not altogether synonymous with the *Pons Varolii*, as some Anatomists have represented it; for, while the latter consists of transverse fibres, which form the commissure between the hemispheres of the Cerebellum, surrounding and passing between the longitudinal fibres of the Sensory and Motor tracts which constitute the *Crura Cerebri*, the *Tuber Annulare* (which exists in animals whose Cerebellum has no hemispheres) is a projection from the surface of the proper Medulla Oblongata, containing a considerable nucleus of vesicular matter. The experiments of Longet have led him to the conclusion

¹ "Clinique Médicale," tom. ii. p. 664, et seq.

² It is considered by Longet that these functions are not *completely* destroyed, because the animals on whom this operation has been performed still retain some power of movement, and respond by cries to impressions that ordinarily produce pain. There is no proof, however, that such actions are other than "excito-motor;" they certainly cannot in themselves be admitted as proving the persistence of consciousness in the lower segment of the Cerebro-Spinal axis.

that this ganglionic mass is an independent centre of sensation and of motor power; but they do not afford any clear information as to its special attributes. He states, however, that convulsive movements are excited by irritating it, and especially by the transmission of an electric current through its substance. These movements, however, according to the testimony of Dr. Todd, appear to be of a different character from those which are excited by the application of the same stimulus to the Spinal Cord and Medulla Oblongata; for he states that, whilst the convulsions excited by the transmission of the current of the magneto-electric machine through the parts just named are *tetanic*, the muscles being thrown into a state of *fixed* contraction—those which ensue when the current is transmitted through the region of the Mesocephale and Corpora Quadrigemina are *epileptic*, being combined movements of *alternate* contraction and relaxation, flexion and extension, affecting the muscles of all the limbs, of the trunk, and of the eyes, which roll about just as in epilepsy.¹

[Dr. Brown-Séquard, whose experimental researches have been frequently quoted, has published the following *resumé* of the phenomena produced by injuries of the nervous system.²

Pourfour du Petit and Méhée de la Touche were the first experimenters who witnessed turning produced by an injury of the nervous centres. But the first valuable researches on this phenomenon were made by Magendie and Flourens.

The parts of the cerebro-spinal centre which may be injured without producing turning, are: the cerebral hemispheres, the cerebellum, the corpora striata, the corpus callosum, the spinal marrow, and the olfactive and optic nerves.³ Injuries of all the other parts of the cerebro-spinal centres may produce turning or rolling.

These circulatory or rotatory movements take place sometimes on the same side of the body, and sometimes on the side opposite to that portion of the encephalon which has been injured.

A puncture of one of the following parts produces turning or rolling on the injured side:—

1. The anterior extremity of the thalami optici, according to Schiff.
2. The crura cerebri, according to Magendie.
3. The bi-, or quadrigeminal tubercles, according to Flourens.
4. The pons Varolii.
5. The posterior part of the processus cerebelli ad pontem.
6. The auditive nerve, according to Brown-Séquard.
7. The medulla oblongata at the point of insertion of the facial nerve, according to the experiments of Brown-Séquard, in common with Dr. Martin-Magron.
8. The medulla oblongata outside of the anterior pyramids, according to Magendie.
9. A great part of the posterior face of the medulla oblongata, according to Brown-Séquard.

The parts of the encephalon which produce turning or rolling on the opposite side are:—

1. The posterior extremity of the thalami optici, according to Schiff.
2. The crura cerebri, according to Lafargue.
3. The anterior part of the processus cerebelli ad pontem.
4. A small part of the medulla oblongata before the nib of the calamus scriptorius.

¹ Lumleian Lectures "On the Pathology and Treatment of Convulsive Diseases," in "Medical Gazette," May 11, 1849.

² ["Phil. Med. Examiner," August 1852.]

³ [The three nerves of the superior senses, the olfactive, the optic, and the auditive, are considered, by the author of the article here quoted, as a part of the nervous centres.—Ed.]

torius and behind the corpora olivaria, according to Brown-Séquard's experiments in common with Dr. Martin-Magron.

Some of these two series of parts ordinarily produce turning, and others rolling. But these two kinds of movements can be produced by the puncture of a single part of the encephalon. Rolling is nothing but the exaggeration of turning; thus, after a puncture of the medulla oblongata, the animal at first rolls, and after some instants, instead of rolling, it turns. If, when it is turning, a slight puncture is made anew, close to the first, then the animal rolls.

1. *Turning and Rolling caused by tearing the Facial Nerve.*—Dr. Martin-Magron and Dr. Brown-Séquard have discovered that, if the facial nerve of a rabbit or a guinea-pig be exposed at its exit from the stylo-mastoid foramen, and then drawn away from the cranium, so as to tear it asunder near its origin, the animal begins in about five minutes to turn itself round and round, the movement being from left to right when the nerve has been thus torn on the left side, and from right to left when it has been torn on the right side. This rotation is generally preceded by convulsive movements of the eyes, of the jaws, and of the head upon the trunk: and the body is then bent (as in pleurosthotonos) towards the injured side, by the contraction of all the longitudinal muscles of that side, the power of which is such as to resist considerable force applied to extend them. The movement at first takes place in a small circle; but the circle generally enlarges more and more, until at last, after twenty or thirty minutes, the animal walks in a straight line. There is no paralysis of any muscles, save the facial. The effect is not produced, unless the nerve be torn close to its origin.

When the nerve on the other side also is torn, even after a long interval, instead of the tendency to turn to one side, there is, at first, a rolling of the body on its longitudinal axis, which takes place towards the side last operated on. After this has continued, however, for twenty minutes or more, the animal recovers its feet, and begins to *turn*, as after the first operation, but towards the other side. This movement soon ceases.

Dr. Martin-Magron and the author think that the cause of these phenomena does not exist in the facial nerve itself, but in the part of the medulla oblongata from which this nerve originates.¹

2. *Turning and Rolling produced by an Injury to the Medulla Oblongata.*—M. Magendie² says: "Having raised up the cerebellum, I make a section perpendicularly to the surface of the fourth ventricle, and at three or four millimetres from the median line. If I cut on the right, the animal will turn on the right side; if I cut on the left, it will turn on the left side."

If we suppose a plane cutting the medulla oblongata transversely at the distance of nearly two lines before the nib of the calamus scriptorius, the posterior face of the medulla oblongata will be divided into two parts: one before that plane which the author calls superior, and the other behind, or inferior.

Now, every puncture on that superior part produces turning or rolling on the side which has been punctured. The slightest puncture on the processus cerebelli ad medullam oblongatam will produce a violent and very rapid rolling. As long as the animal lives after the operation, it rolls or it turns every time it tries to walk.

When (as Dr. Martin-Magron and the author have discovered) a deep section is made on the inferior part of the posterior face of the medulla oblongata, before the nib of the calamus scriptorius, turning is produced on the side of the body

¹ [See "Gaz. Méd. de Paris," 1849, t. iv. p. 879.]

² ["Précis Elém. de Physiol.," Paris, 1836, t. i. p. 414.]

opposite to the punctured side of the medulla. A rabbit, which lived thirteen days after the operation, had still the circulatory movement a few hours before dying; although sometimes the animal could walk nearly straight for a few seconds.

3. *Turning produced by a Puncture or a Section of the Acoustic Nerve.*—Flourens has discovered that, after the section of the semicircular canals, turning sometimes takes place.

The author has found all the facts detailed in relation to this subject. It was interesting to know if a puncture or the section of the auditive nerve would produce turning. As it was impossible to operate on that nerve in mammals, he experimented on frogs. In these amphibia, it is easy to find the nerve and to act upon it. He found that, after a puncture or a section on the trunk of the nerve, the animal begins instantly to turn. As long as the frogs live, after a puncture of the acoustic nerve, they turn; but the circle of turning is much smaller a short time after the operation than afterwards. He has kept such frogs alive for months.

4. *On a New Mode of Turning.*—The same experimenter has discovered a mode of turning which has some of the characters of both turning and rolling.

In the circulatory movement called turning (*mouvement de manège*), the body of the animal is bent on one of the lateral sides. It has the shape of an arch, and this arch is generally a part of the circumference described by the animal when turning. The smaller the radius of that arch, the smaller is the circle of turning.

In the new mode of turning, the body of the animal is not bent, and when it walks it moves laterally, instead of going forwards. In turning, it describes a circle, but the longitudinal axis of its body, instead of being then a part of the circumference, is a part of a radius, so that its head is at the circumference, and its tail towards the centre of the described circle.

This mode of turning has been performed by animals on whom the quadrigeminal tubercles and the pons Varolii, on one side, had been punctured by a pin. One of the eyes was convulsed; the other was in its normal condition. The convulsed eye was the right one, and the tubercles punctured were those of the left side.

5. *On the Causes of Turning and Rolling.*—1. As the slightest puncture of certain parts of the encephalon is sufficient to produce turning or rolling, it is evident that those rotating movements do not exist in consequence of an hemiplegia, as Lafargue, Longet, and Schiff believe they do. Another reason is that every degree of hemiplegia exists in man without being accompanied by turning or rolling. Besides, these phenomena have been observed in persons who had no paralysis at all.

2. The theories of Magendie and Flourens are also opposed by the fact that a slight puncture is sufficient to produce turning or rolling.

3. As to the theory of Henle, which is based upon the existence of convulsions in the eye, producing a kind of vertigo, it has against it the facts that, on one side, convulsions may exist in the eyes without any other disorder in the movements; and, on the other side, sometimes turning or rolling exists without any convulsion in the eyes.¹

Nevertheless, in many cases, the vertigo consequent on convulsions of the eyes is one element of the cause of turning. And in certain cases, paralysis of some parts of the body may facilitate the rotatory movements. But their great cause is the existence of a convulsive contraction in some of the muscles,

¹ [See a very remarkable case observed by Dr. Leuret, in "Comptes Rendus et Mémoires de la Soc. Biologie," année 1850, Paris, 1851, t. ii. p. 7.]

on one side of the body. These convulsive contractions are to be found in every case of circulatory or rotatory movement. As to the cause of these contractions, it exists in the irritation produced in certain parts of the encephalon.—Ed.]

739. *Nerves of Special Sense.*—Having thus taken a general survey of the information supplied by Comparative Anatomy, Experiment, and Pathological phenomena, in regard to the functions of this division of the Encephalon, we shall next inquire into the attributes of the Nerves of which they are obviously the ganglionic centres.—Through the First pair, or *Olfactory* nerves, are transmitted the impressions made by odorous emanations upon the surface it supplies; and it is not susceptible to impressions of any other kind. Anatomical examination of the distribution of this nerve proves that it is not one which directly conveys motor influence to any muscles, since all its branches are distributed to the membrane lining the nasal cavity; and experimental inquiry leads to the same result, for no irritation of the peduncles or branches excites any muscular movement. Further, no irritation of any part of this nerve excites reflex actions through other nerves. Again, it is not a nerve of common sensation; for animals exhibit no sign of pain, when it is subjected to any kind of irritation. Neither the division of the nerve, nor the destruction of the olfactive ganglia, seems to inconvenience them materially. They take their food, move with their accustomed agility, and exhibit the usual appetites of their kind. The “common” sensibility of the parts contained in the olfactive organ is in no degree impaired, as is shown by the effect of irritating vapors; but the animals are destitute of the sense of smell, as is shown by the way in which these vapors affect them. At first they appear indifferent to their presence, and then suddenly and vehemently avoid them, as soon as the Schneiderian membrane becomes irritated. Moreover, if two dogs, with the eyes bandaged, one having the olfactory nerves and ganglia sound, and the other having had them destroyed, are brought into the neighborhood of the dead body of an animal, the former will examine it by its smell; whilst the latter, even if he touches it, pays no attention to it. This experiment Valentin¹ states that he has repeated several times, and always with the same results. Further, common observation shows that sensibility to irritants, such as snuff, and acuteness of the power of smell, bear no constant proportion to one another; and there is ample pathological evidence, that the want of this sense is connected with some morbid condition of the olfactory nerves or ganglia.—It is well known that Magendie has maintained that the Fifth pair in some way furnishes conditions requisite for the enjoyment of the sense of smell; asserting that, when it is cut, the animal is deprived of this. But his experiments were made with irritating vapors, which excite sternutation or other violent muscular actions, not through the Olfactory nerve, but through the Fifth pair; and the experiments of Valentin, just related, fully prove that the animals are not sensitive to *odors*, strictly so called, after the Olfactory nerve has been divided. It is highly probable, however, that the acuteness of the true sense of smell may be diminished by section of the Fifth pair; since the Schneiderian membrane is no longer duly moistened by its proper secretion; and, when dry, it is not so susceptible of the impressions made by those minute particles of odoriferous substances, to which the excitement of the sensation must be referred.

740. That the Second pair, or *Optic* nerves, have an analogous character, appears alike from anatomical and experimental evidence. No chemical or mechanical stimulus of the nerve produces *direct* muscular motion; nor does it give rise, so far as can be ascertained, to indications of pain; whence it may be con-

¹ “De Functionibus Nervorum Cerebraliū,” &c., Bernæ, 1839.

cluded that this nerve is not one of common sensation. That the ordinary sensibility of the eyeball remains, when the functions of the Optic nerve are completely destroyed, is well known; as is also the fact that division of it puts an end to the power of vision. Valentin states that, although the Optic nerve may, like other nerves, be in appearance completely regenerated, he has never been able to obtain any evidence that the power of sight has been in the least degree recovered. He remarks that animals suddenly made blind exhibit great mental disturbance, and perform many unaccustomed movements; and that the complete absence of the power of vision is easily ascertained. Morbid changes are sometimes observed to take place in eyes whose Optic nerve has been divided; but these are by no means so constant or so extensive as when the Fifth pair is paralyzed; and they may not improbably be attributed to the injury, occasioned by the operation itself, to the parts within the orbit.

741. The Optic nerve, though analogous to the Olfactory in all the points hitherto mentioned, differs from it in one important respect;—that it has the power of conveying impressions which excite *reflex* muscular motions. This is especially the case in regard to the Iris, the ordinary actions of which are regulated by the degree of light impinging on the retina. When the Optic nerve is divided, a contraction of the pupil takes place; but this does not occur, if the connection of this nerve with the third pair, through the nervous centres, be in any way interrupted. After such division (if complete), the state of the pupil is not affected by variations in the degree of light impinging on the retina; except in particular cases, in which it is influenced through other channels. Thus, in a patient suffering under amaurosis of one eye, the pupil of the affected eye is often found to vary in size, in accordance with that of the other eye; but this effect is produced by the action of light on the retina of the sound eye, which produces a motor change in the third pair on both sides. Further, as already shown (§ 724), the *impression* only of light upon the retina may give rise to contraction of the pupil, by reflex action, when the optic nerve is itself sound; whilst no *sensations* are received through the eye, in consequence of disease in the sensorial portion of the nervous centres. Although the contraction of the pupil is effected by the influence of motor fibres, which proceed to the sphincter of the Iris from the third pair of nerves, *through* the Ophthalmic ganglion, there is evidence that its dilatation depends rather upon the influence it derived from that ganglion itself, and from the Sympathetic system, of which it forms part.—Some have attempted to show that the actions of the iris are in a slight degree voluntary, because, by an effort of the will, they could occasion contraction of the pupil; but this so-called voluntary contraction is always connected with a change in the place

The infundibulum. 5. The Pons Varolii. 6. The medulla oblongata. The figure is on the right corpus pyramidale. 7. The 3d pair, motores oculi. 8. 4th pair, pathetici. 9. 5th pair, trigemini. 10. 6th pair, abducentes. 11. 7th pair, auditory and facial. 12. 8th pair, pneumogastric, spinal accessory, and glosso-pharyngeal. 13. 9th pair, hypoglossal.

of the eyeball itself, occasioned by an action of some of its muscles. It is principally noticed under the two following conditions: 1. When an object is brought very near the eye, and we steadily fix our attention upon it, the axes of the two eyes are made to converge; and if this convergence be carried to a considerable extent, so that the pupils of both eyes are sensibly directed towards the inner canthus, a contraction of the pupil takes place. The final cause or purpose of this contraction is very evident. When an object is brought near the eye, the rays proceeding from it would enter the pupil (if it remained of its usual size) at an angle of divergence so much greater than that which would allow them to be properly refracted to a focus, that indistinct vision would necessarily result. By the contraction of the pupil, however, the extreme or most divergent rays are cut off, and the pencil is reduced within the proper angle. The principle is precisely the same as that on which the optician applies a *stop* behind his lenses, which reduces their aperture in proportion to the shortness of their focal distance. 2. Contraction of the pupil is also noticed, when the eyeball is performing that rotation upwards and inwards, which, when it occurs along with violent respiratory actions, or during sleep, must be regarded as involuntary. (This rotation also takes place, to a slight degree, when the eyelid is depressed, as in ordinary winking; and it is obvious that, in this manner, the surface of the eye is more effectually swept free from impurities which may have gathered upon it, than it would be by the downward motion of the lid alone.) But the pupil is *not* contracted, when the eyeball is *voluntarily* rotated upwards and inwards. Besides the contractions of the pupil, another action of a "reflex" character is produced through the Optic nerve—the contraction of the Orbicularis muscle under the influence of strong light, or when a foreign body is suddenly brought near the eye. But this cannot be produced without a consciousness of the object; in fact, it is a movement of a "consensual" kind, produced by the painful effect of light, which gives rise to the condition well characterized by the term *photophobia*. The involuntary character of it must be evident to every one who has been engaged in the treatment of diseases of the eyes; and the effect of it is aided by a similarly involuntary movement of the eyeball itself, which is rotated upwards and inwards, to a greater extent than the Will appears able to effect.—Another reflex movement excited through the visual sense is that of Sneezing, which is induced in many individuals by the sudden exposure of the eyes to a strong light: of the purely automatic character of this movement there can be no question, since it cannot be imitated voluntarily; and that it is not excito-motor is proved by the fact that it is not excited unless the light is *seen*.¹

742. There is a further peculiarity, of a very marked kind, attending the course of the Optic nerves; this is the crossing or decussation which they undergo, more or less completely, whilst proceeding from their ganglia to the eyes. In some of the lower animals, in which the two eyes (from their lateral position) have entirely different spheres of vision, the decussation is complete; the whole of the fibres from the right optic ganglion passing into the left eye, and *vice versa*. This is the case, for example, with most of the Osseous Fishes (as the cod, halibut, &c.); and also, in great part at least, with Birds.² In the Human subject, however, and in animals which, like him, have the two eyes looking in the same direction, the decussation seems less complete; but there is a very remarkable arrangement of the fibres, which seems destined to bring the two eyes into peculiarly consentaneous action. The *posterior* border of the Optic Chiasma is formed exclusively of *commissural* fibres, which pass from one optic

¹ A patient was for some time in the London Hospital, in whom there was such an undue impressibility of the retina that she could not remain in even a moderate light without a continual repetition of the act of Sneezing.

² See Solly on "The Human Brain," *Am. Ed.*

ganglion to the other, without entering the real optic nerve. Again, the anterior border of the Chiasma is composed of fibres, which seem, in like manner, to act as a commissure between the two *retinæ*; passing from one to the other, without any connection with the optic ganglia. The tract which lies between the two borders, and occupies the middle of the Chiasma, is the true Optic Nerve; and in this it would appear that a portion of the fibres decussates, whilst another portion passes directly from each Optic ganglia into the corresponding eye. The fibres which proceed from the ganglia to the *retinæ*, and constitute the proper Optic Nerves, may be distinguished into an internal and an external tract. Of these, the external on each side passes directly onwards to the eye of *that* side; whilst the internal crosses over to the eye of the opposite side. The distribution of these two sets of fibres in the retina of each eye respectively, is such that, according to Mr. Mayo, the fibres from either optic ganglion will be distributed to *its own side of both eyes*;¹ the right optic ganglion being thus exclusively connected with the outer part of the retina of the right eye, and with the inner part of the retina of the left eye; and the left optic ganglion being, in like manner, connected exclusively with the outer side of the left retina, and with the inner side of the right. Now, as either side of the eye receives the images of objects which are on the other side of its axis, it follows, if this account of their distribution be correct, that in Man, as in the lower animals, each ganglion receives the sensations of objects situated on the opposite sides of the body. The purpose of this decussation may be, to bring the visual impressions, which are so important in directing the movements of the body, into proper harmony with the motor apparatus; so that, the decussation of the motor fibres in the pyramids being accompanied by a decussation of the optic nerves, the same effect is produced as if neither decussated—which last is the case with Invertebrated animals in general.

743. The functions of the *Auditory* nerve, or *Portio Mollis* of the 7th, are easily determined, by anatomical examination of its distribution, and by observation of pathological phenomena, to be analogous to those of the two preceding. Atrophy or lesion of the trunk destroys the sense of Hearing; whilst irritation of it produces auditory sensations, but does not occasion pain. From experiments made upon the nerve before it leaves the cranial cavity, it appears satisfactorily ascertained that this nerve is not endowed either with common sensibility, or with the power of directly stimulating muscular movement. Nor can any obvious reflex actions be executed by irritation of this nerve; but it seems nevertheless by no means improbable, that the muscles which regulate the tension of the tympanum are called into action by impressions made upon it and reflected through the auditory ganglion, in the same manner

Fig. 191.

¹ This arrangement was first hypothetically suggested by Dr. Wollaston ("Philos. Trans.," 1824), as facilitating the explanation of some of the phenomena of vision, and more particularly single vision with two eyes. We shall hereafter see, however, that the singleness of the impression resulting from the formation of two pictures upon our *retinæ* is not attributable to any such anatomical arrangement, their combination being a mental process, and the fusion of two dissimilar pictures being requisite to enable us to exercise one of the highest attributes of the visual sense, the perception of *projection*. (See CHAP. xv. SECT. 5.)

Fig. 192.

A view of the origin and distribution of the Portio Mollis of the Seventh pair or Auditory Nerve: 1, the medulla oblongata; 2, the pons Varolii; 3, 4, the crura cerebelli of the right side; 5, the eighth pair of nerves; 6, the ninth pair; 7, the auditory nerve distributed to the cochlea and labyrinth; 8, the sixth pair of nerves; 9, the portio dura of the seventh pair; 10, the fourth pair; 11, the fifth pair.

nerves are irritated; which movements are capable of a different explanation (§ 736).

744. The nerves which minister to the sense of *Taste* are destitute of the peculiarities which distinguish the preceding; being no other than certain branches of ordinary afferent nerves—the Fifth Pair and Glosso-pharyngeal (§ 717)—the peculiar endowments of which seem to depend rather upon the structure and actions of the papillæ at their peripheral extremities than upon anything special in their own characters; for, as in the case of the ordinary nerves of “common” sensation, mechanical irritation applied to them calls forth indications of pain.—From the observations and experiments of M. Cl. Bernard,¹ it appears that the Facial nerve (portio dura of the 7th) supplies some condition requisite for the sense of Taste, through the branch known as the Chorda Tympani, which is the motor nerve of the Lingualis muscle. When paralysis of the Facial exists in Man, the sense of taste is very much impaired on the corresponding side of the tongue, provided the cause of the paralysis be seated above the origin of the Chorda Tympani from its trunk. Similar results have been obtained from experiments upon other animals. The nature of the influence afforded by this nerve is entirely unknown; and it is the more obscure, as the Chorda Tympani contains no sensory filaments.

745. To the sense of *Touch*, all the afferent nerves of the body (save the nerves of special sense) appear to minister; in virtue—according to the doctrine already propounded—of the direct connection of certain of their fibrils with the *Sensorium commune*. But the degree in which they are capable of producing Sensations does not bear any constant relation to their power of exciting reflex actions. Thus, the Glosso-pharyngeal is not nearly so *sensitive* as the Fifth pair; though more powerful as an *excitor* nerve. The Par Vagus appears to have even less power of arousing sensory changes; although it is the most important of all the excitors to reflex action. So, again, the afferent nerves of the inferior extremities, in Man, are less concerned in ministering to sensations, than are those of the superior; and yet they appear to be much more efficient as excitors to muscular action.—These differences may be accounted for, by supposing that the proportion which the fibres, having their centre in the

as the diameter of the pupil is regulated through the Optic nerve. In the involuntary start, however, which is occasioned by a loud and sudden sound, we have an example of a *consensual* movement excited through the Auditory nerve, which is evidently analogous to the closure of the eyes to a strong light. In certain morbidly impressible states of the nervous system, as will be shown hereafter, the effect of sounds on the motor apparatus is far more remarkable.—It has been attempted by Flourens to show that the division of the Auditory nerve, which proceeds to the Semicircular canals, has functions altogether different from that portion which supplies the Vestibule and Cochlea. This inference, however, is grounded only upon the movements exhibited by animals in which these

¹ “Archives Générales de Médecine,” 1844.

ganglionic matter of the Spinal Cord, bears to that of the fibres which pass on to the Sensorium, is not constant, but is liable to variation; the former predominating in the Par Vagus and the Glosso-pharyngeal, whilst the latter are more numerous in the Fifth Pair, and in most of the Spinal nerves.

746. To the reflex actions of the Sensory Ganglia, all the *motor* fibres of the Cranio-spinal axis, save those which originate in its Spinal portion, may be considered as subservient; for, as we have seen, the motor columns from which proceed the anterior roots of the Spinal nerves and the motor Encephalic nerves, pass up into the Corpora Striata and Corpora Quadrigemina; and although the direct connection of the other ganglia of Special sense with the motor columns is at present a matter of presumption only, yet this presumption is strongly supported by the analogy of the Optic ganglia, the distinctness of the connection in this case being easily accounted for, when it is remembered in how great a degree the general movements of the body are guided by the visual sense. This anatomical evidence is fully borne out by the results of experiment; since, as we have seen (§ 738), convulsive movements of all parts of the body may be excited by the application of the electric stimulus to this division of the Encephalic centres.

747. *Functions of the Sensory Ganglia.*—We have now to consider what deductions may be drawn with regard to the functions of the Sensory Ganglia in Man, from the facts supplied by Comparative Anatomy, Experimental inquiry, and Pathological phenomena. Here, as in the case of the Spinal Cord, we have to distinguish between their operation as independent ganglionic centres, and their action in subservience to the Cerebrum, which is superposed upon them. We have seen reason to conclude that, in their former capacity, they are to be regarded as the true centres of *Sensation* (*i. e.* of the consciousness of external impressions), and as the instrument, in virtue of their own “reflex” power, of that class of Instinctive or Automatic movements, which require to be prompted and guided by sensations, and which cannot, therefore, be referred to the excito-motor group. But although it is sufficiently obvious that such movements constitute the highest manifestations of Animal life in the Invertebrata generally, and that they are but little modified by any higher principle of action even in the lower Vertebrata, yet it is no less obvious that in adult Man, in whom the Intelligence and Will are fully developed, we have comparatively little evidence of this independent reflex action of the Sensory Ganglia;—all those automatic actions which are *immediately* necessary for the maintenance of his Organic life being provided for by the excito-motor portion of the apparatus, so that, although sensation ordinarily accompanies most of them, it is not essential to them; whilst those which are necessary to provide more *remotely* for its requirements are for the most part committed to the guidance of his Reason. For the impressions which have been brought by the afferent nerves to his Sensorium, and which have there produced sensations, do not in general react at once upon the motor apparatus (as they do in those animals in which the Sensory Ganglia are the *highest* of the nervous centres), but usually transmit their influence upwards to the Cerebrum, through whose instrumentality they give rise to ideas and reasoning processes, which operate upon the motor apparatus either emotionally or volitionally. And it is for the most part only when this upward transmission is checked, either by the non-development or the functional inactivity of the Cerebrum, or by its complete occupation in some other train of action—or, on the other hand, when the reflex action of the Sensory ganglia is called into play with unusual potency—that we have any manifestations of the *sensori-motor* or *consensual* mode of operation in Man, at all comparable in variety or importance to those which are so remarkable in the lower animals.

748. Still, sufficient evidence of the existence of this class of reflex movements may be drawn from observation of the actions of Man in his ordinary

condition ; examples of it being furnished (as we have seen) by the closure of the eyes to a dazzling light, the start caused by a loud and unexpected sound, or the sneezing excited by sensory impressions on the Schneiderian membrane or the retina. To these may be added the vomiting produced by various sensory impressions, as the sight of a loathsome object, a disagreeable smell, a nauseous taste, or that peculiar feeling of want of support which gives rise to "sea-sickness," especially when combined with the sight of continually shifting lines and surfaces, which itself in many individuals disposes to the same state ; the involuntary laughter which is excited by tickling, and also that which sometimes involuntarily bursts forth at the provocation of some sight or sound to which no ludicrous idea or emotion can be attached ; the yawning which is excited by an internal sensation of uneasiness (usually arising from deficient respiration), or by the sight or sound of the act as performed by another ; and those involuntary movements of the body and limbs, excited by uneasy sensations (probably muscular), which are commonly designated as "the fidgets." When the reflex activity of the Sensory ganglia is more strongly excited, in consequence either of an unusual potency of the sensory impressions, or of an unusual excitability of this part of the nervous centres, a much greater variety of sensori-motor actions is witnessed. The powerful involuntary contraction of the orbicularis and of the muscles which roll the eyeball upwards and inwards, in cases of excessive irritability of the retina, is one of the best examples of this kind ; but another very curious illustration is afforded by the involuntary abridgment of the excito-motor actions of respiration when the performance of these is attended with pain—the dependence of this abridgment upon the direct stimulus of sensation, rather than upon voluntary restraint, being obvious from the fact that it often presents itself on *one* side only, a limitation which the Will cannot imitate. Again, there are certain Convulsive disorders which appear to depend upon an undue excitability of these centres, the paroxysms being excited by impressions which act through the organs of sense, and are not thus operative unless the patient be conscious of them ; thus in *Hydrophobia*, we observe the immediate influence of the sight, sound, or contact, of liquids, or of the slightest currents of air, in exciting muscular contractions ; and in many *Hysteric* subjects, the sight of a paroxysm in another individual is the most certain means of its induction in themselves. A remarkable case of this general exaltation of purely sensorial excitability has been recorded by Dr. Cowan, who gives the following account of the phenomena, which can scarcely be referred to any other than this category. "The shadow of a bird crossing the window, though the blind and bed-curtains are closed, the displacement of the smallest portion of the wick of a candle, the slightest changes in the firelight, induce a sudden jerking of the spinal muscles, extending to the arms and legs when violent, and this without the slightest mental emotion of any kind beyond a consciousness of the movement. At times the vocal organs are implicated, and a slight cry, quite involuntary, takes place. At these periods she is unusually susceptible of all noises, especially the least expected and least familiar. Movements in the next house inaudible to others, the slightest rattle in the lock of a door, tearing a morsel of paper, and a thousand little sources of sound not to be catalogued, induce results similar to those of visual impressions."¹

749. It is, however, when the Cerebrum is not in a state which renders it capable of receiving and acting upon Sensorial impressions, that we find the independent reflex activity of the Sensory ganglia most strikingly displayed. Thus in the *Infant*, for some time after its birth, it is obvious to an attentive observer that a large part of its movements are directly prompted by sensations to which it can as yet attach no distinct ideas, and that they do not proceed

¹ "Lancet," Oct. 4, 1845.

from that *purposive* impulse which is essential to render them voluntary. This is well seen in the efforts which it makes to find the nipple with its lips; being probably guided thereto at first by the smell, but afterwards by the sight also; when the nipple has been found, the act of suction is purely excito-motor, as already explained. So in the idiot, whose brain has never attained its normal development, the influence of sensations in directly producing respondent movements is obvious to all who examine them with discrimination; and a remarkable case will be cited hereafter (Sect. 7), in which an entire though temporary suspension of Cerebral power, reducing the subject of it to the condition of one of the lowest *Vertebrata*, gave a very satisfactory proof of the independent power of this division of the Encephalic centres.—But we do not require to go so far in search of characteristic examples of this kind of reflex action; since they are afforded, as already remarked, by the performance of *habitual* movements, which are clearly under Sensorial guidance, when the Cerebrum is occupied in some train of action altogether disconnected with them. An individual who is subject to “absence of mind” may fall into a reverie whilst walking the streets, his whole attention may be absorbed in his train of thought, and he may be utterly unconscious of any interruption in its continuity; and yet, during the whole of that time, his limbs shall have been in motion, carrying him along the accustomed path, whilst his vision shall have given the direction to these movements, which is requisite to guide him along a particular line, or to move him out of it for the avoidance of obstacles. As already remarked (§ 726), there seems strong reason for regarding the ambulatory movements of the limbs as in themselves excito-motor; but the guidance of these movements by the visual sense marks the participation of the Sensorium in this remarkable performance. It has been maintained by some Metaphysicians and Physiologists that these “secondarily automatic” actions always continue to be voluntary, because their performance is originally due to a succession of volitional acts, and because, in any particular case, it is the will which first excites them, whilst an exertion of the will serves to check them at any time. But this doctrine involves the notion, that the will is in a state of pendulum-like oscillation between the train of thought and the train of movement; whereas nothing is more certain to the individual who is the subject of both, than that the former may be as uninterrupted as if his body were perfectly at rest, and his reverie were taking place in the quietude of his own study. And as it commonly happens that the direction taken is that in which the individual is most in the habit of walking, it will not unfrequently occur that, if he had previously intended to pursue some other, he finds himself, when his reverie is at an end, in a locality which may be very remote from that towards which his walk was originally destined; which would not be the case, if his movements had been still under the purposive direction of the will. And although it is perfectly true that these movements can be at any time checked by an effort of the will, yet this does not really indicate that the will has been previously engaged in sustaining them; since, for the will to act upon them at all, the *attention* must be recalled to them, and the Cerebrum must be liberated from its previous self-occupation. And the gradual conversion of a volitional into an automatic train of movements, so that at last the train, once started, shall continue to run down of itself, will be found to be less improbable than it would at first appear, when it comes to be understood that the mechanism of both sets of actions is essentially the same, and that they merely differ as regards the nature of the stimulus which originally excites them (§ 757). That the same automatic movements are not excited by the same sensations, when the Cerebrum is in its ordinary state of functional connection with the Sensorium, is a fact entirely in harmony with the principle already laid down (§§ 683—6). The complete occupation of the mind in other ways, as in close conversation or argument, or even (it may be) in the voluntary

direction of some other train of muscular movements, is no less favorable than the state of reverie to that independent action of the Automatic centres which has been now described.

750. In the state of entire functional activity of the nervous centres of Man, however, there can be no doubt that the operation of the Sensory Ganglia is entirely subordinated to that of the Cerebrum; and that it furnishes an essential means of connection between the actions of the Cerebrum on the one hand, and those of the organs of Sense and Motion on the other, by the combination of which the Mind is brought into relation with the external world. For, in the first place, it may be affirmed with certainty that no mental action can be excited in the first instance, save by the stimulus of Sensations; and it is the office of the Sensory ganglia to form these out of the impressions brought to them from the organs of sense, and to transmit such sensorial changes to the Cerebrum. But they have a no less important participation in the downward action of the Cerebrum upon the motor apparatus; for no voluntary action can be performed without the assistance of a *guiding Sensation*, as was first prominently stated by Sir C. Bell.¹—In the majority of cases, the guiding or controlling sensation is derived from the muscles themselves, of whose condition we are rendered cognizant by the sensory nerves with which they are furnished; but there are certain cases in which it is ordinarily derived from one of the special senses, and in which the muscular sense can only imperfectly supply the deficiency of such guidance; whilst again, if the muscular sense be deficient, one of the special senses may supply the requisite information. The proof of this necessity is furnished by the *entire impossibility of making or sustaining voluntary efforts without a guiding sensation of some kind*. Thus, in complete anæsthesia of the lower extremities, without loss of muscular power, the patient is as completely unable to walk as if the motor nerves had also been paralyzed, unless the deficient sensorial guidance be replaced by some other; and in similar affections of the upper extremities, there is a like inability to raise the limb or to sustain a weight. But in such cases, the deficiency of the “muscular sense” may be made good by the visual; thus the patient who cannot feel either the contact of his foot with the ground, or the muscular effort he is making, can manage to stand and walk if he *look* at his limbs; and the woman who cannot feel the pressure of her child upon her arms, can yet sustain it as long as she keeps her eyes fixed upon it, but no longer—the muscles ceasing to contract, and the limb dropping powerless, the moment that the eyes are withdrawn from it. Thus it is, too, that when we are about to make a muscular effort, the amount of force which we put forth is governed by the mental conception of that which will be required, as indicated by the experience of former sensations; just as the contractions of the muscles of vocalization are regulated by the conception of the sound to be produced. Hence if the weight be unknown to us, and it prove either much heavier or much lighter than was expected, we find that we have put forth too little or too great a muscular effort.

751. There are two groups of muscular actions, however, which, although as voluntary in their character as the foregoing, are yet habitually guided by other sensations than those derived from the muscles themselves. These are the movements of the *eyeball*, and those of the *vocal apparatus*.—The former are directed by the visual sense,² by which the action of the muscles is guided and controlled, in the same manner as that of other muscles is directed by their own “muscular sense;” and hence it happens that, when we close our eyes, we cannot

¹ See his chapter “On the Nervous Circle which connects the voluntary muscles with the Brain,” in his work “On the Nervous System of the Human Body.”

² See Dr. Alison’s Memoir on the “Anatomical and Physiological Inferences from the Study of the Nerves of the Orbit,” in “Trans. of Roy. Soc. of Edinb.,” vol. xv.

move them in any required direction, without an effort that strongly calls forth the muscular sense, by which the action is then guided. In persons who have become blind after having once enjoyed sight, an association is formed by habit between the muscular sense and the contractile action, that enables the former to serve as the guide after the loss of the visual sense; but in those who are born *perfectly* blind, or who have become so in early infancy, this association is never formed, and the eyes of such persons exhibit a continued indefinite movement, and cannot by any amount of effort be steadily fixed in one spot, or be turned in any definite direction. A very small amount of the visual sense, however, such as serves merely to indicate the direction of light, is sufficient for the government of the movements of the eyeball.—In the production of vocal sounds, again, that nice adjustment of the muscles of the larynx, which is requisite to give forth determinate tones, is ordinarily directed by the auditory sense: being learned in the first instance under the guidance of the sounds actually produced; but being subsequently effected voluntarily, in accordance with the mental conception (a sort of inward sensation) of the tone to be uttered, which conception cannot be formed, unless the sense of hearing has previously brought similar tones to the mind. Hence it is that persons who are born *deaf*, are also *dumb*. They may have no malformation of the organs of speech; but they are incapable of uttering distinct vocal sounds or musical tones, because they have not the guiding conception, or recalled sensation, of the nature of these. By long training, however, and by imitative efforts directed by muscular sensations in the larynx itself, some persons thus circumstanced have acquired the power of speech: but the want of a sufficiently definite control over the vocal muscles is always very evident in their use of the organ. It is very rarely that a person who has once enjoyed the sense of hearing afterwards becomes so *completely* deaf as to lose all auditory control over his vocal organs. An example of this kind, however, has been made known to the public by a well-known author as having occurred in himself; and the record of his experiences¹ contains many points of much interest. The deafness was the result of an accident occurring in childhood, which left him for some time in a state of extreme debility; and when he made the attempt to speak, it was with considerable pain in the vocal organs. This pain probably resulted from the unaccustomed effort which it was necessary to make, when the usual guidance was wanting; being analogous to the uneasiness which we experience when we attempt to move our eyes with the lids closed. His voice at that time is described as being very similar to that of a person born deaf and dumb, but who has been taught to speak. With the uneasiness in the use of the vocal organs was associated an extreme mental indisposition to their employment; and thus, for some years, the voice was very little exercised. Circumstances afterwards forced it, however, into constant employment; and great improvement subsequently took place in the power of vocalization, evidently by attention to the indications of the muscular sense. It is a curious circumstance, fully confirming this view, that the words which had been in use previously to the supervention of the deafness, are still pronounced (such of them, at least, as are kept in employment) as they had been in childhood; the muscular movements concerned in their articulation being still guided by the original auditory conception, in spite of the knowledge derived from the information of others, that such pronunciation is erroneous. On the other hand, all the words subsequently learned are pronounced according to their spelling; the acquired associations between the muscular sensations and the written signs being in this case the obvious guide.

752. It is through the muscular sense, in combination with the visual and tactile, that those movements are regulated which are concerned alike in ordi-

¹ See the "Lost Senses," by Dr. Kitto; vol. i. chapters 2 and 3.

nary progression, and in the maintenance of the equilibrium of the body. That the visual sense has, in most persons, a large share in this regulation, is evident from the simple fact that no one who has not been accustomed to the deprivation of it can continue to walk straight-forwards, when blindfolded, or in absolute darkness, towards any point in the direction of which he may have been at first guided. But the blind man, who has been accustomed to rely exclusively upon his muscular sense, has no difficulty in keeping to a straight path; and moves onwards with a confidence which is in remarkable contrast with the gait of a man who has been deprived of sight for the occasion only. In fact, as Mr. Mayo has well remarked,¹ in our ordinary movements, "we lean upon our eyesight as upon crutches." And when our vision, instead of aiding and guiding us, brings to the mind sensations of an antagonistic character, our movements become uncertain, from the loss of that power of guidance and control over them which the harmony of the two sensations usually gives. Thus a person unaccustomed to look down heights *feels* insecure at the top of a tower or a precipice, although he *knows* that his body is properly supported; for the void which he sees below him contradicts (so to speak) the tactile sensations by which he is made conscious of the due equilibrium of his body. So, again, any one can walk along a narrow plank which forms part of the floor of a room, or which is elevated but a little above it, without the least difficulty, and even without any consciousness of effort. But let that plank extend across a chasm, the bottom of which is so far removed from the eye that the visual sense gives no assistance; and even those who have braced their nerves against all emotional distraction, feel that an effort is requisite to maintain the equilibrium during their passage over it; that effort being aided by the withdrawal of the eyes from the abyss below, and the fixation of them on a point beyond, which at the same time helps to give steadiness to the movements, and distracts the mind from the sense of its danger. The degree in which the muscular sense is alone sufficient for the guidance of such movements, when the mind has no consciousness of the danger, and when the visual sense neither affords aid nor contributes to distract the attention, is remarkably illustrated by the phenomena of Somnambulism; for the sleep-walker traverses, without the least hesitation, the narrow parapet of a house, and crosses narrow and insecure planks, clambers roofs, &c., under circumstances that clearly indicate the nature of the guidance by which he is directed (see Sect. 7).—The dependence of our ordinary power of maintaining our equilibrium upon the combination of the guiding sensations derived through the sight and the touch, is further well illustrated, as Mr. Mayo has pointed out (*loc. cit.*), by what happens to a landsman on first going to sea. "It is long before the passenger acquires his 'sea legs.' At first, as the ship moves, he can hardly keep his feet; the shifting lines of the vessel and surface of the water unsettle his visual stability; the different inclinations of the planks he stands on, his muscular sense. In a short time, he learns to disregard the shifting images and changing motions, or acquires facility in adapting himself (like one on horseback) to the different alterations in the line of direction in his frame." And when a person who has thus learned by habit to maintain his equilibrium on a shifting surface, first treads upon firm ground, he feels himself almost as much at fault as he did when he first went to sea; and it is only after being some time on shore, that he is able to resume his original manner of walking. Indeed, most of those who spend the greater part of their time at sea acquire a peculiar gait, which becomes so habitual to them that they are never able to throw it off.

753. But, further, there is very strong physiological evidence that the Sensory Ganglia are not merely the instruments whereby our voluntary movements

¹ "Outlines of Physiology," p. 355.

are directed and controlled, in virtue of the guiding sensations which they furnish, but that they are actually the immediate centres of the motor influence which excites muscular contractions, in obedience to impulses transmitted downwards from the Cerebrum. It has usually been considered that the Cerebrum acts directly upon the muscles through the motor nerves, in virtue of a direct continuity of fibres from the gray matter of its convolutions, *through* the Corpora Striata, the motor tract of the Medulla Oblongata, the anterior portion of the Spinal Cord, and the anterior roots of the nerves; and that in the performance of any voluntary movement, the Will determines the motor force to the muscle or set of muscles by whose instrumentality it may be produced. To this doctrine, however, the anatomical facts already stated (§ 730) constitute a very serious objection; for the motor tract cannot be stated with certainty to have any higher origin than the Corpora Striata; and it is impossible to imagine that the fibres which converge towards the surface of these bodies from all parts of the Cerebrum can be so closely compacted together as to be included in the motor columns of the Spinal Axis. The fact would rather seem to be that these converging fibres bear the same kind of anatomical relation to the Corpora Striata and the other Sensorial centres of motor power, as do the fibres of the afferent nerves which proceed to them from the Retina, the Schneiderian membrane, and other peripheral expansions of nervous matter; and hence we might infer that the nerve-force generated in the convolutions, instead of acting *immediately* on the motor nerves, is first directed towards the Automatic centres, and excites the same kind of motor response in them as would be given to an impression transmitted to them through a sensory nerve. We shall find that such a view of the structural arrangements of these parts is in remarkable accordance with their functional relations, as indicated by a careful analysis of the mechanism of what is commonly regarded as voluntary movement. The Cerebrum, as will be shown hereafter (Sect. 5), may thus call the Automatic apparatus into action, as the instrument either of *ideas*, of *emotions*, or of *volitional determinations*; but as both the *ideo-motor* and the *emotional* movements have much in common with the automatic, there is no occasion for at present specially inquiring into their mechanism, and we may limit our examination to *voluntary* movements alone, which have been usually regarded as in such complete antagonism to those of the automatic group, that even distinct sets of nerve-fibres have been thought requisite to account for the transmission of these two sets of motor impulses to the muscles.

754. Now in the first place it may be asserted with some confidence, that no effort of the Will *can* exert that direct influence on the muscles which our ordinary phraseology, and even the language of scientific reasoners, would seem to imply; but, on the other hand, that the Will is solely concerned in determining the *result*, the selection and combination of muscular movements required to bring about this result *not* being effected by the Will, but by some intermediate agency. If it were otherwise, we should be dependent upon anatomical knowledge for our power of performing the simplest movement of the body; whereas we find the fact to be, that the man who has not the least idea of the mechanism of muscular action can acquire the most perfect command over his movements, and can adapt them as perfectly to the desired end as the most accomplished anatomist could do. Further, we cannot, by any exertion of the will, single out a particular muscle and throw it into contraction by itself, unless that muscle be one which is alone concerned in an action that we can voluntarily perform; and even then we single it out by *willing* the action. Thus we can put the *levator palpebræ* in action by itself; but this we do, not by any conscious determination of power to the muscle itself, but by *willing* to raise the eyelids; and it is only by our anatomical knowledge that we know that but a single muscle is concerned in this movement. So far as our own consciousness can

inform us, there is no difference between the mechanism of this action and that of the flexion of the knee or elbow-joint; and yet in these latter movements, several muscles are concerned, not one of which can be singled out by an effort of the will, and thrown into action separately from the rest.—The idea that the will is *directly* exerted upon the muscles called into action to produce a particular movement, may seem to derive some support from the *sense of effort* of which we are conscious in making the exertion, and which we refer to the muscles which are concerned in it; but this sense of effort is nothing else than the “muscular sense” already alluded to, which has its origin in the state of tension of the muscles, and which is no more an indication of *mental* effort directed to them, than the sensation of light or sound is an indication of a determination of voluntary power to the eyes or ears.

755. There are two cases in which it is very easy to show that the Will is concerned with the result alone, and is not directly exerted upon the instruments by which that result is brought about. These are, the movements of the Eyes, and the production of Vocal tones. In neither of these are we conscious of any effort in the muscular apparatus, unless the contraction be carried beyond its accustomed extent; the ordinary movements being governed, as already remarked, not by the muscular sense, but by the visual and auditory senses respectively.—Nothing can be more simple, to all appearance, than the act of turning the eyes upwards or downwards, to one side or the other, in obedience to a determination of the Will; and yet the Will does not impress such a determination upon the muscles. That which the Will really does is to cause the eyeball to roll in a given direction, in accordance with a visual sensation; and it is only *when there is an object* towards which the eyes can be turned, that we can move them with our usual facility. When the eyelids are closed, and we attempt to roll the globes upwards or downwards, to one side or the other, we feel that we can do so but very imperfectly, and with a sense of effort referred to the muscles themselves,—this sense being the result of the state of tension in which the muscles are placed, by the effort to move the eyes without the guiding visual sensation. Now, on the other hand, the Will may determine to fix the eyes upon an object; and yet this very fixation may be only attainable by a muscular movement,—which movement is directly excited by the visual sense, without any exertion of voluntary power over the muscles. Such is the case when we look steadily at an object, whilst we move the head horizontally from side to side; for the eyeballs will then be moved in the contrary direction by a kind of instinctive effort of the external and internal recti, which tends to keep the retinae in their first position, and to prevent the motion of the images over them. So, when we look steadily at an object, and incline the head towards either shoulder, the eyeballs are rotated upon their antero-posterior axis (probably by the agency of the oblique muscles) apparently with the very same purpose,—that of preventing the images from moving over the retinae. Now we cannot refuse to this rotation any of the attributes which really characterize the so-called voluntary movements; and yet we are not even informed by our own consciousness that such a movement is taking place, and know it only by observation of others.

756. The muscular contractions which are concerned in the production of vocal tones are, in like manner, always accounted voluntary; and yet it is easy to show that the Will has no direct power over the muscles of the larynx. For we cannot raise or depress the larynx as a whole, nor move the thyroid cartilage upon the cricoid, nor separate or approximate the arytenoid cartilages, nor extend or relax the vocal ligaments, by simply *willing* to do so, however strongly. Yet we can readily do any or all these things by an act of the Will exerted for a specific purpose. We conceive of a tone *to be* produced, and we *will* to produce it; a certain combination of the muscular actions of the larynx then takes

place, in most exact accordance one with another; and the predetermined tone is the result. This anticipated or conceived sensation is the guide to the muscular movements, when as yet the utterance of the voice has not taken place; but whilst we are in the act of speaking or singing, the contractile actions are regulated by the present sensations derived from the sounds as they are produced. It can scarcely but be admitted, then, that the Will does *not* directly govern the movements of the Larynx; but that these movements are immediately dependent upon some other agency.

757. Now what is true of the two preceding classes of actions is equally true of all the rest of the so-called *voluntary* movements; for in all of them the power of the Will is really limited to the determination of the result; and the production of that result is entirely dependent upon the concurrence of a "guiding sensation," which is usually furnished by the very muscles that are called into action. It is obvious, therefore, that we have to seek for some intermediate agency, which *executes* the actions *determined* by the Will; and when the facts and probabilities already stated are duly considered, they tend strongly in favor of the idea that even Voluntary movements are executed by the instrumentality of the Automatic apparatus, and that they differ only from the automatic or instinctive in the nature of the stimulus by which they are excited—the determination of the Will here replacing, as the *exciting cause* of its action, the sensory impression which operates as such in the case of an instinctive movement, and which is still requisite for its guidance.

758. This view of the case derives a remarkable confirmation from the analysis of two classes of phenomena; the first consisting of cases in which movements that are ordinarily automatic are performed by voluntary determination, or simply in response to an idea; the second consisting of those in which movements originally voluntary come by habit to be automatically performed.—Of the first class, the act of Coughing is a good example. This action, which is ordinarily automatic, may also be excited by a voluntary determination; such a determination, however, is directed to the *result*, rather than exercised in singling out the different movements and then combining them in the necessary sequence; and it thus seems obviously to take the place of the laryngeal or tracheal irritation, as the *primum mobile* of the series, which, in its actual performance, is as automatic in the latter case as in the former. So, again, we know that many of the automatic movements which have been already referred to as examples of the sensori-motor group (§ 748), and which the Will cannot call forth, may be performed in response to *ideas* or *conceptions*, which are Cerebral states that seem to recal the same condition of the Sensorium as that which was originally excited by the Sensory impression. Thus it is well known that the act of Vomiting may be induced by the *remembrance* of some loathsome object or nauseous taste, which may have been excited by some act of "suggestion;" and the author has known an instance in which a violent fit of sea-sickness was brought on by the sight of a vessel tossed about at sea, which recalled the former experience of that state. So, the Hydrophobic paroxysm may be excited by the mention of the *name* of water, which of course calls up the idea; and a tendency to yawn is in like manner frequently induced by looking at a picture of yawners, or by speaking of the act, or by voluntarily commencing the act, which may then be automatically completed.—The automatic performance of actions which were originally voluntary has already been fully discussed (§ 749); and we have therefore only to remark here that the fact very strongly supports the view now advanced, as to the *singleness* of the mechanism which serves as the instrument of both classes of actions, and the essential uniformity of its operation in the two cases.—It would be difficult to explain either set of phenomena satisfactorily on the hypothesis that there is a "distinct system" of fibres

for the volitional and for the automatic movements; since it is not readily to be conceived how a set of movements originally performed by the one, can ever be transferred to the other; whilst, on the other hand, it is easy to understand how the same motorial action may be excited in the automatic centres, either by an *external* impression conveyed thither by an afferent nerve from a Sensory surface (as that of the irritation in the air-passages, which excites the act of coughing), or by a stimulus proceeding from the convoluted surface of the Cerebrum, and conveyed along those connecting fibres which Reil with great sagacity termed the “nerves of the *internal* senses.”

759. To sum up, then, we seem justified in concluding that the *Cranio-Spinal Axis* of Man and other Vertebrata—consisting of the Sensory Ganglia, Medulla Oblongata, and Spinal Cord—is (like the chain of cephalic and ventral ganglia of Articulata with which it is homologous) the immediate instrument of *all sensorial and motor changes*; that by its sole and independent action are produced all those movements which are ranked as automatic or *instinctive*, these being performed in response to external impressions which may or may not affect the consciousness; but that when acting in subordination to the Cerebrum, the Cranio-Spinal Axis transmits upwards to it the influence of Sensorial changes, and receives from it the downward impulses, which it directs automatically into the appropriate channel for the execution of the movements which the Mind has directed. The number of purely automatic actions diminishes in proportion to the development of the Cerebrum, and to the subjection of the Automatic apparatus to its control; but even in Man, those most closely connected with the maintenance of the organic functions, or most necessary for the conservation of the bodily structure, remain quite independent of any mental agency, and most of them do not require consciousness for their excitation. But when the activity of the Cerebrum is suspended or is otherwise directed, without any affection of the automatic apparatus, movements which have long been habitually performed in a particular sequence, may be kept up, when the will has once set them in action, through the automatic mechanism alone; the impressional or sensational change produced by each action supplying the stimulus which calls forth the next.—It may further be concluded that the Sensory Ganglia, which are the instruments whereby we are rendered *conscious* of external impressions, are also the seat of those simple *feelings* of pleasure and pain which are immediately linked on to that consciousness. For it can scarcely be doubted that such feelings must be associated with particular sensations, in animals that have no ganglionic centres above these; since we must otherwise regard the whole series of Invertebrated tribes as neither susceptible of enjoyment, nor capable of feeling pain or discomfort. And it is scarcely probable that a state of consciousness which we can scarcely ourselves distinguish from the sensation that induces it should have a separate centre in our Encephalon.

4.—Of the Cerebellum, and its Functions.

760. The Cerebellum is an organ which, though confined to the Vertebrated sub-Kingdom, is yet in peculiarly intimate relation with the Automatic apparatus. In that highest state of development which it presents in Man, we find it to consist of two *lateral lobes* or *hemispheres*, composed of nerve-fibres invested in a very peculiar manner by vesicular substance, and of a *central lobe*, also containing a combination of the vesicular and fibrous substances, which is known under the designation of the “*vermiform process*.” The hemispheres are not only connected with each other by this central lobe, but also by the fibrous commissure which passes beneath the Medulla Oblongata, and is known as the “*Pons Varolii*.” The commissural fibres form part of the “*Crura Cerebelli*,” but another portion is formed by the strands which connect the Cerebellum with

the anterior and posterior columns of the Spinal Cord and Medulla Oblongata (§ 711); and in addition to these, we find a fasciculus of fibres passing between the Cerebellum and the Corpora Quadrigemina, the “*iter a cerebello ad testes.*” The peduncle of its hemispheres on either side contains a mass of gray matter,

Fig. 193.

An under view of the cerebellum, seen from behind.—The medulla oblongata, *m*, having been cut off a short way below the pons. (*Reil*.) *c*. Pons Varolii. *d*. Middle crus of cerebellum. *e e*. which seems to be a ganglionic centre for the fibres that pass upwards to it from the Spinal Axis. Thus the Cerebellum has no direct connection with the Cerebrum, and its relations are entirely with the Automatic apparatus.

761. When we examine into the relative development of the Cerebellum in the different classes of Vertebrata, we find that it presents some very remarkable differences.¹ In its simpler forms, this organ is found to consist entirely of the representative of the *central* lobe of the Human Cerebellum, the hemispheres not making their appearance until we have ascended to the class of Birds. The proportional development of the Cerebellum is smallest in the Vermiform Fishes, which approach most nearly to the Invertebrata; but it is much greater in the higher Cartilaginous Fishes than it is in Reptiles, in which it is generally very low. Passing on to Birds, we remark that the average dimensions of the Cerebellum greatly surpass those of the organ in Reptiles; but that they do not exceed those occasionally met with in Fishes. The greatest size is not found in those species which approach most nearly to the Mammalia in general conformation, such as the Ostrich; but in those of most active and varied powers of flight. Lastly, on ascending the scale of Mammiferous animals, we cannot but be struck with the rapid advance in the proportional size of the Cerebellum which we observe as we rise from the lowest (which are surpassed in this respect by many Birds) towards Man, in whom it attains a development which appears enormous, even when contrasted with that of the Quadrumana.—Now on looking at the size of the Cerebellum in relation to the general motor activity of these classes respectively, and especially taking into account the *variety* of their respective movements, and the number of separate muscular actions which are combined in each, we can scarcely help noticing that it is in the tribes which are most distinguished in these respects, that the largest Cerebellum is usually found.

¹ The fullest information upon this point will be found in M. Serres's "*Anatomie Comparée du Cerveau*," and M. Leuret's "*Anat. Comp. du Système Nerveux.*"

Thus, of all classes of Vertebrata, Reptiles are the most inert; and their motions require the least co-ordination. The active predaceous Sharks far surpass them in this respect, and may be compared with Birds, in the energy of their passage through the water, and in their facility of changing their direction during the most rapid progression; their Cerebellum, accordingly, bears to their Spinal Cord very much the same proportion as it does in Birds. On the other hand, the Flat Fish, which lie near the bottom of the ocean, and which have a much less variety of movement, have a very much smaller Cerebellum; and the Vermiform Fishes, which are almost all completely destitute of fins, and whose

motions resemble those of the lower Articulata, have a Cerebellum so small as to be scarcely discoverable. On looking at the class of Birds, we observe that the active predaceous Falcons, and the swift-winged Swallows (the perfect control possessed by which over their complicated movements must have been observed by every one), have a Cerebellum much larger in proportion than that of the

Gallinaceous birds, whose powers of flight are small, or than that of the Struthious tribe, in which they are altogether absent. Lastly, on comparing its proportional size in the different orders of mammalia, with the number and variety of muscular actions requiring combined movements, of which they are respectively capable,

[Fig. 194*.

This figure exhibits those fibres from the anterior columns which, ascending to the cerebellum, connect the motor tract with that portion of the cerebral mass. E. Cerebellum. X. Pons Varolii. T. Pyramidal eminences. S. Olivary bodies. Ww. Corpus restiforme, its surface having been carefully scraped, in order to show the *superficial cerebellar fibres* of the anterior columns. we observe an even more remarkable correspondence. In the hoofed Quadrupeds, in which the muscular apparatus of the extremities is reduced to its greatest simplicity, and in which the movements of progression are simple, the Cerebellum is relatively smaller than it is found to be in some Birds; but in proportion as the extremities acquire the power of prehension, and together with this a power of application to a great variety of purposes—still more, in proportion as the animal becomes capable of maintaining the erect posture, in which a constant muscular exertion, consisting of a number of most elaborately combined actions, is required—do we find the size of the Cerebellum, and the complexity of its structure, undergoing a rapid increase. Thus, even between the Dog and the Bear there is a marked difference; the latter being capable of remaining for some time in the erect posture, and often spontaneously assuming it; whilst to

the former it is anything but natural. In the semi-erect Apes, again, there is a very great advance in the proportional size of the Cerebellum; and those which most approach Man in the tendency to preserve habitually the erect posture, also come nearest to him in the dimensions of this organ.

762. Now it is evident that Man, although far inferior to many of the lower animals in the power of performing various particular kinds of movement, far surpasses them all in the number and variety of the combinations which he is capable of executing, and in the complexity of the combinations themselves. Thus, if we attentively consider the act of *walking* in man, we shall find that there is scarcely a muscle of the trunk or extremities which is not actively concerned in it; some being engaged in performing the necessary movements, and others in maintaining the equilibrium of the body, which is disturbed by them. On the other hand, in the Horse or Camel, the muscular movements are individually numerous, but they do not require nearly the same perfect co-ordination. And in the Bird, the number of muscles employed in the movements of flight, and in directing the course of these, is really comparatively small; as may at once be perceived, by comparing the rigidity of the skeleton of the trunk of the Bird with that of Man, and by remembering the complete inactivity of the lower extremities during the active condition of the upper. In fact, the motions of the wings are so simple and regular as to suggest the idea that, as in Insects, their character is more automatic than directly voluntary—an idea which is supported by the length of time during which they can be kept up without apparent fatigue, and also by the important facts already mentioned, which experimental research has disclosed (§ 734).

763. We have next to inquire what evidence can be drawn from Experimental investigations on the same subject: and in reference to this it is desirable to remark, in the first place, that the experimental mode of inquiry is perhaps more applicable to this organ than to other parts of the Encephalon; inasmuch as it can be altogether removed, with little disturbance of the actions immediately essential to life; and the animals soon recover from the shock of the operation, and seem but little affected, except in some easily recognized particulars. The principal experimenters upon this subject have been Rolando, Flourens, Magendie, Hertwig, and Longet. It is not to be expected that there should be an exact conformity among the results obtained by all. Every one who has been engaged in physiological experiments is aware of the amount of difference caused by very minute variations in their circumstances; in no department of inquiry is this more the case than in regard to the Nervous System; and such differences are yet more likely to occur in experiments made upon its centres than in those which concern its trunks.—The investigations of Flourens are the most clear and decisive in their results; and of these we shall accordingly take a general survey. He found that, when the Cerebellum was mechanically injured, the animals gave no signs of sensibility, nor were they affected with convulsions. When the Cerebellum was being removed by successive slices, the animals became restless, and their movements were irregular; and by the time that the last portion of the organ was cut away, the animals had entirely lost the power of springing, flying, walking, standing, and preserving their equilibrium,—in short, of performing any combined muscular movements which are not of a simply reflex character. When an animal in this state was laid upon the back, it could not recover its former posture; but it fluttered its wings, and did not lie in a state of stupor. When placed in the erect position, it staggered and fell like a drunken man—not, however, without making efforts to maintain its balance. When threatened with a blow, it evidently saw it, and endeavored to avoid it. It did not seem that the animal had in any degree lost voluntary power over its several muscles; nor did sensation appear to be impaired. The faculty of *combining* the actions of the muscles in groups,

however, was completely destroyed; except so far as those actions (as that of Respiration) were dependent only upon the reflex function of the Spinal Cord. The experiments afforded the same results, when made upon each class of Vertebrated animals; and they have since been repeated, with corresponding effects, by Bouillaud and Hertwig. The latter agrees with Flourens, also, in stating that the removal of one side of the Cerebellum affects the movements of the opposite side of the body; and he further mentions that, if the mutilation of the Cerebellum have been partial only, its function is in great degree restored.¹

764. It was further affirmed by Magendie, that the removal of the Cerebellum, or the infliction of a deep wound of its substance on both sides, occasions the animal to move *backwards* as if by an irresistible impulse; and this he attributed to the retrograde power of the Corpora Striata, which now acts without its due balance. That such a movement does *sometimes* present itself after such injuries as have been described cannot be questioned, the fact having been confirmed by other experimenters; but it is a phenomenon of such rarity, that it cannot be rightly considered as having any direct dependence upon the injury of the Cerebellum, but must be rather set down to some accidental complication or concurrent disturbance; more especially since, as already pointed out (§ 737), the function attributed by Magendie to the Corpora Striata has no real existence.—But the results of section of one of the Crura Cerebelli, which were first obtained by Magendie, are much more constant; for the performance of this operation causes the animal to fall over upon one side, and to continue *rolling upon its longitudinal axis*, even as fast (in some instances) as sixty times in a minute, the movement going on for many days without intermission. There is a remarkable difference in the statements of different experimenters, however, as regards the direction of this rolling movement; for, whilst Magendie and Müller affirm that it takes place *towards* the injured side, Longet and Lafargue assert that it takes place *from* the injured side towards the opposite side. This discrepancy appears, from the experiments of Schiff,² to be due to a difference in the locality of the section; for he states that if the peduncle be divided from *behind*, the animal turns *towards* the side on which the section is made; whilst if the section be made *in front*, the animal turns *from* that side towards the opposite one. This difference is explained by Longet, by the difference in the course of the anterior and posterior fibres of the peduncles; for according to him the former communicate with the decussating, and the latter with the non-decussating portion of the motor tract; so that, when the former are injured, the animal loses control over the muscles of the opposite side, and when the latter, over the muscles of the same side. This rolling movement is attributed by some to the continued activity of the muscles of one side, now unbalanced by that of the muscles on the other; but if such were the case, as Longet justly remarks, it ought to occur more frequently than it does in cases of ordinary hemiplegia; and according to that experimenter, observation shows that it rather depends on a *twisting* movement of the spinal column, especially affecting its anterior portion, and dragging the posterior (as it were) after it.³

765. The information supplied by Pathological phenomena, when interpreted with the cautions formerly referred to, is found on the whole to coincide with

¹ All these results are objected to by those who assert that the Cerebellum is the seat of the sexual instinct, on the ground that the observed aberrations of the motor functions are sufficiently accounted for by the general disturbance which an operation so severe must necessarily induce. The fallacy of this objection, however, is shown by the fact that the much more severe operation of removing the Hemispheres does not occasion such an aberration; the power of performing the associated movements, and of maintaining the equilibrium, being remarkably preserved after the loss of them (§ 734).

² “De vi motoria baseos encephali inquisitiones experimentales;” Bockenhemii, 1845.

³ See his “Traité de Physiologie,” tom. ii. partie 2, pp. 216, 217.

that obtained from experiment. In the first place, it fully supports the conclusion that the Cerebellum is not in any way the instrument of *psychical* operations. Inflammation of the membranes covering it, if confined to that part, does not produce delirium; and its almost complete destruction by gradual softening does not appear necessarily to involve loss of intellectual power. "But," remarks Andral, "whilst the changes of intelligence were variable, inconstant, and of little importance, the lesions of motion, on the contrary, were observed in all the cases [of softening] except one; and in this it is not quite certain that motion was not interfered with." Yet the result of Andral's analysis of as many as ninety-three cases of disease of the Cerebellum,¹ is not favorable to the doctrine to which the results of experiments seem to point; but, as it has been justly remarked by Longet, the effects of disease are only partly comparable to those of experiment; since in a large proportion of chronic cases of the former, the change consists in the formation of a new product, such as a tubercular or cancerous deposit, or a cyst of some kind, the gradual development of which is quite consistent with the continued functional activity of the organ, as we see by parallel phenomena elsewhere; whilst in those instances in which hemorrhage occurs, this usually occasions either complete apoplexy or local paralysis, by its effects upon other organs. Still, several cases of chronic disease of the Cerebellum have been observed in which *unsteadiness of gait*, without paralysis, or only giving place to paralysis at last on the occurrence of hemorrhage, was a very marked symptom;² and these afford a strong confirmation of the doctrine based on the experimental researches already referred to. In a few cases in which both lobes of the Cerebellum have been seriously affected, the tendency to retrograde movement has been observed; and instances are also on record, of the occurrence of rotary movement, which has been found to be connected with lesion of the Crus Cerebelli on the same side.³ So far as they can be relied on, therefore, the results of the three methods of investigation bear a very close correspondence; and it can scarcely be doubted that they afford us a near approximation to truth.

766. It must not be allowed to pass unnoticed, that some Physiologists (as Foville, Pinel-Grandchamp, and Dugès) have regarded the Cerebellum as the centre of common Sensation; chiefly on the ground of its connection with the posterior columns of the Spinal Cord, and of the manifestations of pain which are called forth by touching the Restiform columns. Although these facts may lead us to admit that the Cerebellum is connected with the sensorial centres, and even that it is itself a seat of sensibility, yet it is impossible to regard it as the exclusive seat of sensibility, consistently with the facts with which experiment and pathological observation supply us; since neither the complete removal of this organ by operation, nor its complete destruction by disease,⁴ has been found to involve any loss of the ordinary sensorial powers.—There would seem much more probability in the idea that it is the special seat of the "muscular sense," which has so important a share in the guidance of the co-ordinated move-

¹ See his "Clinique Médicale," 2ème edit. tom. v. p. 735.

² Two such cases are recorded by Mr. Dunn in the "Med.-Chir. Trans.," vol. xxxii., and another by Dr. Cowan in the "Prov. Med. and Surg. Journ.," April 16, 1845; and the Author has been made acquainted with several others, by gentlemen under whose cognizance they have fallen.

³ A collection of such cases has been made by Dr. Paget, in his paper on "Morbid Rhythmical Movements," in the "Edinb. Med. and Surg. Journal," 1847, vol. lxxvii.—A case fell within the Author's knowledge a few years ago, in which a state of this kind, that lasted for some hours, appeared to depend upon an attack of indigestion; the symptoms being completely relieved by vomiting, and no further indication of encephalic disorder manifesting itself.

⁴ See the well-known case recorded by Combetti, in the "Revue Médicale," tom. ii. p. 57

ments; and this notion derives confirmation from the marked structural connection which exists between the Cerebellum and the Optic Ganglia (*corpora quadrigemina*), the purpose of which may be not unfairly surmised to be, to communicate the guidance of the *visual* sense to the organ by which the co-ordination of motions is effected, in the same manner as the impressions appertaining to the muscular sense are transmitted upwards by the Restiform columns. The chief objection to such a view would seem to lie in the strong similarity between the "muscular" sense and "common" or "tactile" sensation, which makes it difficult to conceive that they should have different seats in the *Sensorium commune*. But this difficulty is diminished if not removed by the reflection, that the Restiform columns appear to have the same endowments as the remainder of the Sensory tract derived from the posterior columns of the Spinal Cord; and that no explanation can be given of their extreme sensitiveness to impressions (as shown by experiment), unless it be admitted that the organ in which they terminate is itself a centre of a form of sensation closely allied to that of the common or tactile kind. Possibly, however, the true termination of these fibres is in the "corpus dentatum" of the *Crura Cerebelli*; and the Cerebellum may only react upon impressions thence transmitted to it, without being itself the instrument of communicating such impressions to the consciousness.

767. We have now to examine, however, another doctrine regarding the functions of the Cerebellum, which was first propounded by Gall, and which is supported by the Phrenological school of physiologists. This doctrine, that the Cerebellum is the organ of the sexual instinct, is not altogether incompatible with the other; and by some it has been held in combination with it. The greater number of Phrenologists, however, regard this instinct as the *exclusive* function of the Cerebellum; and assert that they can judge of its intensity by the degree of development of the organ. We shall now examine the evidence in support of this position, afforded by the three methods of inquiry which have been already indicated. In the first place, it may be remarked that the sexual propensity is very closely connected with various emotional states of mind to which "organs" are assigned by Phrenologists, and of which the Cerebrum is universally admitted to be the seat; such, for instance, as "love of offspring," "adhesiveness," and in the lower animals more particularly with "combateness;" and in Man it has a continual operation upon the reasoning faculties and the Will. Yet the anatomical connections of the Cerebellum are peculiarly unfavorable to any such influence; these being, as we have seen, rather with the lower than with the higher portion of the Cerebro-spinal axis.—Again, the results of fair observation as to the comparative size of the Cerebellum in different animals can scarcely be regarded as otherwise than very unfavorable to the doctrine in question. In the greater number of Fishes, it is well known that no sexual congress takes place; the seminal fluid being merely effused, like any other excretion, into the surrounding water; and being thus brought into only accidental contact with the ova, of which a large proportion are never fertilized. But there are certain Fishes, as the Sharks, Rays, and Eels, in which copulation takes place after the ordinary method. Now on contrasting these groups, we find no corresponding difference in the size of the Cerebellum. It is true that this organ is of large size in the Sharks; but it is smaller in the Rays, and almost rudimentary in the Eels; in this respect bearing a precise correspondence with the variety and complexity of their movements. Further, in many ordinary Fishes, which do *not* copulate, such as the Cod, the Cerebellum is not only larger, but more complex in structure, than it is in the generality of Reptiles, in which the sexual instinct is commonly strong; the whole spinal system of the Frog possessing, at the season of reproduction, an extraordinary degree of excitability, which is evidently destined to aid in the performance of the function. Again, on comparing the Gallinaceous Birds, which are poly-

gamous with the Raptorial and Insectorial tribes which live in pairs, we find that the former, instead of having a larger Cerebellum, have one of inferior size. Further, on looking at the Mammalia, the same disproportion may be noticed. A friend who kept some Kangaroos in his garden informed the author that they were the most salacious animals he ever saw; yet their Cerebellum is one of the smallest to be found in the class. Every one knows, again, the salacity of Monkeys; there are many which are excited to violent demonstrations by the sight even of a human female; and there are few which do not practise masturbation, when kept in solitary confinement; yet in them the Cerebellum is much smaller than in Man, in whom the sexual impulse is much less violent. It has been supposed that the large size of the organ in Man is connected with his *constant* possession of the appetite, which is only *occasional* in others; but this does not hold good, since among domestic animals there are many which are ready to breed throughout the year, Cats and Rabbits, for instance, and in these we do not find any peculiar difference in the size of the Cerebellum.¹

768. It is asserted, however, that the results of observation in Man lead to a positive conclusion that the size of the Cerebellum is a measure of the intensity of the sexual instinct in the individual. This assertion has been met by the counter-statement of others that no such relation exists. It is unfortunate that here, as in many other instances, each party has registered the observations favorable to its own views, rather than those of an opposite character; so that until some additional evidence of a less partial nature shall have been collected, we must consider the question as *sub judice*. It may be safely affirmed, however, that no evidence upon the affirmative side of this proposition has yet been adduced, which can be in the least degree satisfactory to the mind of any Anatomist who is competent to judge of its value. For nearly all the observations which have been paraded by Phrenologists in support of Gall's doctrine have been based, *not* upon the actual *determination* of the size or weight of the Cerebellum in different individuals, but upon the *estimation* of its proportional development from the external conformation of the skull. Now any one who has even cursorily examined those principal types of cranial conformation which are characteristic of some of the chief subdivisions of the Human species, must perceive that there is a no less characteristic difference between these different types in the occipital, than there is in the frontal region. For whilst the occipital projection is much *greater* in the "prognathous" skull than it is in the "elliptical," it is as much *less* in the "pyramidal;" and thus while the first would be considered, according to phrenological rules, to hold a much larger Cerebellum, this organ in the latter would be regarded as necessarily very small. Now there is not only as much evidence of a strong development of the sexual propensity, in the characters and habits of the pyramidal-skulled Asiatics, as there is in regard to the elliptical-skulled Europeans, or the prognathous Negroes; but there is also anatomical evidence to show that *the size of the Cerebellum in the different races bears no relation whatever to the degree of projection of the occiput*; for the plane of this organ, being somewhat oblique in the elliptical skull, is horizontal in the prognathous, and nearly vertical in the pyramidal, while the size and anatomical relations of the organ are not in the least degree affected by this difference in its position.²—Hence it may be safely affirmed, that no evidence with regard to the relation asserted to exist between the size of the Cerebellum and the intensity of the Sexual propensity, has any value, save that which is drawn from the positive determination of the former by measure or weight.

¹ For a fuller examination of the indications afforded by Comparative Anatomy in regard to this question, see the "Brit. and For. Medical Review," Oct., 1846, pp. 534.

² The author's statements on this point are based on the very decided assertions of his friend, Prof. Retzius, of Stockholm, who has paid special attention to this inquiry.

769. Among the arguments adduced by Gall and his followers in proof of the connection between the Cerebellum and the sexual instinct, is one which would deserve great attention, if the facts stated could be relied on. It has been asserted, over and over again, that the Cerebellum, in animals which have been castrated when young, is much smaller than in those which have retained their virility—being, in fact, *atrophied* from want of power to act. Now it is unfortunate that vague assertion, founded on estimates formed by the eye from the cranium alone, is all on which this position rests; and it will be presently shown how very liable to error such an estimate must be. The following is the result of a series of observations on this subject, suggested by M. Leuret,¹ and carried into effect by M. Lassaigne: The *weight* of the Cerebellum, both absolutely, and as compared with that of the Cerebrum, was adopted as the standard of comparison. This was ascertained in ten Stallions, of the ages of from nine to seventeen years; in twelve Mares, aged from seven to sixteen years; and in twenty-one Geldings, aged from seven to seventeen years. The average weight of the Cerebrum in the *Stallions* was 433 grammes; the greatest being 485 gr., and the least (which was in a horse of ten years old) being 350 gr. The average weight of the Cerebellum was 61 gr.; the greatest being 65 gr., and the least 56 gr. The average proportion borne by the weight of the Cerebellum to that of the Cerebrum was, therefore, 1 to 7.07; the highest (resulting from a very small Cerebrum) being 1 to 6.25; and the lowest (resulting from an unusually large Cerebrum) being 1 to 7.46. Throughout it might be observed that the variation in the size of the Cerebellum was much less than in that of the Cerebrum.—In the twelve *Mares*, the average weight of the Cerebrum was 402 gr.; the highest being 432 gr., and the lowest 363 gr. That of the Cerebellum was 61 gr.; the highest being 66 gr. (which was in the individual with the smallest Cerebrum), and the lowest 58 gr. The average proportion of the weight of the Cerebellum to that of the Cerebrum was 1 to 6.59; the highest being 1 to 5.09, and the lowest 1 to 7. The proportion was, therefore, considerably higher in the perfect female than in the perfect male.—In the twenty-one *Geldings*, the average weight of the Cerebrum was 419 gr.; the highest being 566 gr., and the lowest 346 gr. The average of the Cerebellum was 70 gr.; the highest being 76 gr., and the lowest 64 gr. The average proportion was, therefore, 1 to 5.97; the highest being 1 to 5.16, and the lowest 1 to 7.44. It is curious that this last was in the individual which had the largest Cerebellum of the whole; but the proportional weight of the Cerebrum was still greater.—Bringing together the results of these observations, they are found to be quite opposed to the statement of Gall. The weight of the Cerebrum, reckoning the Cerebellum as 1, is thus expressed in each of the foregoing descriptions of animals:—

	Average.	Highest.	Lowest.
Stallions	7.07	7.46	6.25
Mares	6.59	7.00	5.09
Geldings	5.97	7.44	5.16

The average *proportional* size of the Cerebellum in Geldings, therefore, is so far from being *less* than that which it bears in entire Horses and Mares, that it is positively greater; and this depends not only on diminution in the relative size of the Cerebrum, but on its own larger dimension, as the following comparison of *absolute* weights will show:—

	Average.	Highest.	Lowest.
Stallions	61	65	56
Mares	61	66	58
Geldings	70	76	64

¹ "Anat. Comp. du Système Nerveux," tom. i. p. 427.

The difference is so remarkable, and appears, from examination of the individual results, to be so constant, that it cannot be attributed to any accidental circumstance arising out of the small number of animals experimented on. The average weight of the Cerebellum in the ten Stallions and twelve Mares is seen to be the same, and the extremes differ but little in the two; whilst the average in the Geldings is more than one-seventh higher, and the *lowest* is considerable above the *average* of the preceding, while the highest far exceeds the highest among the entire Horses. It is curious that Gall would have been much nearer the truth, if he had said that the dimensions of the *Cerebrum* are usually reduced by castration; for it appears from the following table that such is really the case:—

		Average.	Greatest.	Least.
Stallions		433	485	350
Mares		402	432	336
Geldings		419	566	346

The weight of the largest Cerebrum of the Gelding is far above the highest of the Stallions; but it seems to be an extraordinary case, as in no other was the weight above 490 gr. If this one be excluded, the *average* will be reduced still further, being then about 412; this may be seen, by looking over the whole table, to give a very fair idea of the usual weight in these animals, which is therefore *less*, by about one-twentieth, than the average in the Stallions.—The increased size of the Cerebellum in Geldings may perhaps be accounted for by remembering that this class of horses is solely employed for its muscular power, and that the constant exercise of the organ is not unlikely to develop its size; whilst Stallions, being kept especially for the purpose of propagation, are much less applied to occupations which call forth their motor faculties.

770. It is asserted, however, by the followers of Gall, that very strong evidence of the truth of his doctrine is afforded by Pathological phenomena; excitement of the genital organs, manifesting itself in priapism, turgescence of the testes, and seminal emissions, being an ordinary concomitant of some forms of apoplexy in which the Cerebellum is affected; whilst in other cases of disease or injury involving extensive destruction of the substance of the organ, there has been a complete abatement of sexual desire. The proportion of recorded cases of disease of the Cerebellum, however, in which any affection of the genital organs has been noticed, is extremely small; for out of 178 cases, which have been collected by Burdach,¹ only 10, or scarcely more than 1 in 18, presented any symptoms that tended to indicate a functional relation between the Cerebellum and the Genital organs. The same physiologist affirms that similar affections present themselves when the Cerebrum is the seat of the lesion; and there seems a strong probability that it is solely to the connection of these organs with the Spinal Cord that such affections of the genital apparatus are due. For erection of the penis has been noticed in a far larger proportion of cases in which the Spinal Cord itself has been the seat of the lesion; thus in 15 cases in which the cervical portion of the Cord was affected, erection of the penis was observed in 8; and in 13 cases of lesion of the dorso-lumbar portion of the cord, erection of the penis took place in 3.² It is well known that erection of the penis and emissio seminis are not infrequent phenomena of death by hanging; and this fact accords fully as well with the idea that the affection of the sexual organs is consequent upon lesion of the Cranio-Spinal axis, as with the doctrine that it is due to disordered function of the Cerebellum.—It has been suggested by Serres,³ who collected 7 cases in which excitement of the genital organs was

³ "Anatomie Comparée du Cerveau," tom. ii. p. 601, 717.

coincident with apoplexy of the median lobe of the Cerebellum, that, whilst the lateral lobes or hemispheres may be connected with the locomotive function, the median lobe may be the organ of the sexual instinct. Several cases have been recorded, in which some such relation appeared to be indicated; and the Author has been made acquainted with at least six,¹ in which an extraordinary salacity developed itself at an advanced period of life, whilst concurrently with this, or following upon it, there was that kind of unsteadiness of gait which may be held to indicate chronic disease of the Cerebellum; and in one of these cases, of which the history and post-mortem appearances have been carefully recorded by Mr. Dunn,² there was strong evidence that the excitement of the sexual propensity was coincident with the irritative stage of incipient disease in the central lobe of the Cerebellum, and that the abatement of the propensity was in like manner coincident with the subsequent destruction of its substance; whilst the advance of the disease into the lateral lobes was marked by impairment of the power of co-ordination of movement. But with regard to all such cases, and others that may be ranked in the same category,³ the objection of Petrequin⁴ holds good, that when disease or injury affects the median lobe of the Cerebellum, the Medulla Oblongata is almost certain to be implicated in it; so that, as the evidence already referred to clearly indicates the existence of a special relation between the genital organs and the upper part of the Spinal Axis, no positive proof is afforded by them that any portion of the Cerebellum has any special connection with the generative function.

771. The Author is far from denying *in toto*, that any peculiar connection exists between the Cerebellum and the Genital system; but if the evidence at present adduced in support of the Phrenological position be held sufficient to establish it, in defiance of so many opposing considerations, we must bid adieu to all safe reasoning in Physiology. The weight of testimony appears to him to be quite decided in regard to the connection of the Cerebellum with the regulation of the motor function; and as an additional argument in favor of this view, it may be stated, that the lobes of the Human Cerebellum undergo their most rapid development during the first few years of life, when a large number of complex voluntary movements are being learned by experience, and are being associated by means of the muscular sensations accompanying them; whilst in those animals which have, immediately after birth, the power of regulating their voluntary movements for definite objects, with the greatest precision, the Cerebellum is more fully developed at the time of birth. In both instances it is well formed and in active operation (so far as can be judged of by the amount of circulation through it), long before the sexual instinct manifests itself in any perceptible degree.—But neither doctrine need be maintained altogether to the exclusion of the other; and there are many among the Phrenologists of the present day who hold with Serres that whilst the hemispheres of the Cerebellum possess the endowments now generally assigned to them by Physiologists, the central lobe is connected with the genital function. It has been

¹ Four such cases have come under the notice of his friend Dr. Simpson of York.

² "Medico-Chirurgical Transactions," vol. xxxii.

³ Thus, a case has been communicated to the Author by Mr. Turley of Worcester, in which the sexual desire, which had been always strong through life, but which had been controlled within the limits of decency, manifested itself during a period of some months preceding death, in a most extraordinary degree; on *post-mortem* examination, a tumor was found on the Pons Varolii.—And he has been informed of another case by Dr. Evanson (formerly of Dublin), in which a young officer on the eve of marriage, having received a blow on the occiput by a fall from his horse, became impotent, without any other disorder of his bodily or mental powers; and in the distress consequent upon this discovery, committed suicide on the morning fixed for his wedding.

⁴ "Sur quelques points de la Physiologie du Cervelet et de la Moëlle Epinière," in "Gaz. Médicale," 1836, tom. iv. p. 546.

shown by Dr. N. S. Davis,¹ however, that there is no perceptible difference in the dimensions of this central lobe, any more than in those of the hemispheres, between Bulls and Oxen; and no proof has yet been offered, save that afforded by the pathological evidence just referred to, that any such endowment is possessed by it. That in some way or other, however, either the central portion of the Cerebellum, or some part of the Medulla Oblongata, has a special connection with the Generative function, appears to the Author to be indicated with tolerable clearness by several of the pathological phenomena already cited. The circumstance, too, of which he has frequently been assured, that great application to gymnastic exercises diminishes for a time the sexual vigor, and even totally suspends desire, seems worthy of consideration in reference to such a view; for if the Cerebellum be really connected with both kinds of function, it does not seem unreasonable that the excessive employment of it upon one should diminish its energy in regard to the other.—An analysis of the nature of the Sexual propensity, however, suggests the conclusion that we are not to look in this part of the Encephalon for anything else than a seat of the sexual *sensation*; the character of which seems to be sufficiently different from that of mere *tactile* sensation, to require a distinct ganglionic centre. Such a centre would be likely to be placed in the line of the other sensory ganglia, and in close connection with them.

772. As in the case of other sensations, the sexual, when moderately excited, may give rise to ideas, emotions, and desires, of which the Cerebrum is the seat; and these may react on the muscular system through the Intelligence and Will. But when inordinately excited, or when not kept in restraint by the Will, the sexual sensations will at once call into play respondent movements, which are then to be regarded as purely automatic; this is the case in Nymphomania and Satyriasis in the Human subject; and it is probably also the ordinary mode of operation of this sense in such of the lower animals as have not psychical power enough to form a conception of an absent object of gratification, and cannot, therefore, be said to have sexual *desires*. Thus, like other sensations, it may act either *intelligentially* or *automatically*; giving rise to *ideas*, by transmission to the Cerebrum, which ideas, associated with pleasurable feelings, originate *desires*, which stimulate the reasoning powers to devise means for their gratification, and excite the will to the necessary actions; or, by its immediate action upon the motor apparatus, producing respondent *movements*.—Of this double *modus operandi* we seem to have sufficient evidence. For, among many of the lower tribes of animals, at the time when the generative organs are in a state of functional activity, the presence of an individual of the opposite sex, indicated by the sight, smell, hearing, or touch, immediately excites the whole train of instinctive actions concerned in the reproductive operation; whilst we have no evidence in them of any voluntary exertion, resulting from the existence of a desire entertained in the absence of the object, and intended for the gratification of that desire. In Man, on the other hand, the principal operation of the sexual sensations is in awakening desires and affections, which serve as excitements to the intelligence and as motives to the will; and it is only, under ordinary circumstances, when the two sexes have been thus brought into close relation, that the direct reaction of the sexual sensation manifests itself in automatic movements. In cases, however, in which this sensation is excited in unusual strength, it may completely overmaster all motives to the repression of the propensity, and may even entirely remove the actions from the control of the will; and a state of a very similar kind exists in many idiots, in whom the sexual propensity exerts a dominant power, not because it is in itself peculiarly

¹ "Transactions of American Medical Association," vol. iii. p. 415.

strong, but because, the intelligence being undeveloped, it acts without control or direction from the will.

5.—*The Cerebrum, and its Functions.*

773. We come, in the last place, to consider the functions of that portion of the Nervous Centres, which is evidently, in Man, the predominant organ of his whole system; being not merely the instrument of his reasoning faculties, but also possessing a direct or indirect control over nearly all the actions of his corporeal frame, save those purely vegetative processes which are most completely isolated from his animal powers. We should be in great danger, however, of coming to an erroneous conclusion as to the real character of the Cerebrum and of its operations, if we confined ourselves to the study of the Human organism; and the history of Physiological science shows that every advance of knowledge respecting its functions has tended to *limit* them, whilst at the same time rendering them *more precise*. Thus the Brain (this term, in the older Anatomy, being chiefly appropriated to the Cerebrum) was accounted, not merely the centre of all motion and sensation, but also the source of all vitality; the different processes of nutrition, secretion, &c., being maintained, it was supposed, by a constant supply of "animal spirits," propagated from the brain, along the nerves, to each individual part. The more modern doctrine, that the Sympathetic System has for its special function to supply the nervous influence requisite for the maintenance of the functions of Organic life, was the first step in the process of limitation; still the Brain was regarded as the centre of all the Animal functions; and no other part was admitted to possess any power independently of it. By experiments and pathological observations, however, the powers of the Spinal Cord as an independent centre of action were next established; and it was thus shown that there is a large class of motions in which the Brain has no concern, and that the removal of the Cerebral hemispheres is not incompatible (even among the higher Vertebrata) with the prolonged maintenance of a sort of inert and scarcely conscious life. Still it has been usually maintained, and with great show of reason, that the Cerebrum is the instrument of all *psychical* operations, and the originator of *all* the movements which could not be assigned to the reflex action of the Spinal Cord. An attempt has been made, however, in the preceding pages, to show that this view is not correct; and that there is a class of actions, neither excito-motor nor voluntary, but directly consequent upon Sensations, and constituting (with the excito-motor) the truly *instinctive* actions which may be justly assigned to certain ganglionic centres, not less independent of the Cerebrum than is the Spinal Cord itself. It has been further advanced, that the Cerebrum must be considered in the light of an organ *superadded* for a particular purpose or set of purposes, and not as one which is essential to life; that it has no representative among the Invertebrata (except in a few of the highest forms, which evidently present a transition towards the Vertebrated series): and that, at its first introduction, in the class of Fishes, it evidently performs a subordinate part in the general actions of the Nervous System. Hence, whatever be the function, or set of functions, we assign to the Cerebrum, we must keep in view the *special* character of the organ; and must never lose sight of the fact that its predominance in Man does not deprive other parts of their independent powers, although it may keep the exercise of those powers in check, and may considerably modify their manifestations.

774. Before proceeding to inquire into the Physiology of the Cerebrum, we may advantageously take notice of some of the leading features of its structure.—In the first place, it forms an exception to the general plan on which the elements of ganglionic centres are arranged: in having its vesicular substance on the *exterior*, instead of in the *central* part of the mass. The purpose of this is

probably to allow the vesicular matter to be disposed in such a manner as to present a very large *surface*, instead of being aggregated together in a more compact mass; and by this means to admit, on the one side, the more ready access of the bloodvessels which are so essential to the functional operations of this tissue, as well as the more ready communication, on the other, with the vast number of fibres by which its influence is to be propagated. There is no reason whatever to believe that the relative functions of the vesicular and fibrous substances are in the least altered by this change in their relative position; indeed the results of observation upon the phenomena of disordered Cerebral action are such as to afford decided confirmation to the doctrine already propounded, that the action of the vesicular matter constitutes the source of nervous power, whilst the fibrous structure has for its office to conduct the influence generated in it towards the points at which this is to operate. The purpose of this arrangement is further evidenced by the fact that, in all the higher forms of Cerebral structure, we find a provision for a still greater extension of the surface at which the vesicular matter and the bloodvessels may come into relation; this being effected by the plication of the layer of vesicular matter into "convolutions," into the sulci between which the highly vascular membrane known as the "*pia mater*" dips down, sending multitudes of small vessels from its inner surface into the substance it invests.—In the fibrous or medullary substance of which the great mass of the Cerebrum is composed, three principal sets of fibres may be distinguished. These are—*first*, the radiating fibres, which connect the vesicular matter of the cortical substance of the Hemispheres with the *Thalami Optici*, and which, if our view of the function of the latter be correct, may be regarded as *ascending* or *sensory*;—*second*, the radiating fibres, which connect the vesicular matter of the cortical substance of the Hemispheres with the *Corpora Striata*, and which, on similar grounds, may be regarded as *descending* or *motor*;—and *third*, the Commissural fibres, which establish the connection between the opposite Hemispheres, and between the different parts of the vesicular substance of the same side, especially between that disposed on the surface of each hemisphere, and those isolated patches which are found in its interior. It is on the very large proportion which the Commissural fibres bear to the rest, that the bulk of the Cerebrum of Man and of the higher animals seems chiefly to depend; and it is easy to conceive that this condition has an important relation with the operations of the Mind, whatever be our view of the relative functions of different parts of the Cerebrum. It appears, from the late researches of M. Baillarger, that the *surface* and the *bulk* of the cerebral hemispheres are so far from bearing any constant proportion to each other, in different animals, that, notwithstanding the depth of the convolutions in the Human Cerebrum, its bulk is $2\frac{1}{2}$ times as great in proportion to its surface, as it is in the Rabbit, the surface of whose Cerebrum is smooth. The entire surface of the Human Cerebrum, when the convolutions are unfolded, is estimated by him at about 670 square inches.¹

775. With regard to the *Radiating* fibres, which connect the *Corpora Striata* and *Thalami Optici* with the vesicular surface of the Cerebral hemispheres, no positive proof has yet been obtained of their direct continuity with those which enter into the composition of the nerves proceeding from the Spinal Cord and Medulla Oblongata; and we have seen (§ 753) that there are certain phenomena,

¹ The inference drawn by M. Baillarger from the facts he has collected—namely, that the proportional surface of vesicular matter in different animals, whether considered absolutely, or relatively to the volume of the Cerebrum, has no correspondence with their intellectual capability—is far too sweeping an assumption; since, as above shown, the increase in the commissural fibres, causing an augmentation of the bulk of the Cerebrum, may be alike the cause of increased intelligence and of a diminished proportional amount of vesicular matter; though the latter still remains as the original source of power.

which are far better explained on the idea that these radiating fibres are of a *commissural* nature only, serving to connect the vesicular matter of the Cerebrum with that of the higher portions of the *Cranio-Spinal Axis*, through which alone they are brought into relation with the central terminations of the afferent nerves, and with the origins of the motor. On this view, the Cerebrum would receive all its sensory impressions by the commissural fibres that connect it with the ganglia, which are the real centres of these nerves; whilst it would call the motor trunks into action, by exciting, through another set of commissural fibres, the vesicular matter of the ganglionic centres from which they pass forth. The idea that there is no direct continuity between the radiating fibres of the Cerebrum and the fibres of the nerve-trunks derives support from the fact, in which the results of all experiments agree, that no irritation of the former produces either sensation or motion. These results are borne out by pathological observations in Man; for it has been frequently remarked, when it has been necessary to separate protruded portions of the Brain from the remainder, that this has given rise to no sensation, even in cases in which the mind has been perfectly clear at the time, nor has any convulsive action been produced. Such evidence, however, is by no means conclusive on the point; since the same is true of the *Thalami Optici* and *Corpora Striata*, in which there is more decided evidence of the absolute continuity of fibres from the nerve-roots to the vesicular substance of these parts respectively.

776. The *Commissural* fibres constitute two principal groups, the *transverse*, and the *longitudinal*; the former connecting the two Hemispheres with each

[Fig. 194†.

This figure is intended to show the course and connection of the fibres of the great transverse commissure of the hemispheres or corpus callosum. The dissection has only been carried into the right hemisphere. It will be seen that these fibres ascend to the convolutions above the mesial line. P P P. Fibres of the corpus callosum radiating into the hemispherical ganglion. B. Left hemispherical ganglion undissected. E. Cerebellum. Near the centre of the drawing, and a little to the right of the mesial line, is the representation of a broken fasciculus of fibres—the part torn off was traced most carefully into the convoluted surface of the brain.—Ep.]

other; the latter uniting the different parts of the same Hemisphere.—Of the transverse commissures, the *Corpus Callosum* is the most important. This consists of a mass of fibres very closely interlaced together; which may be traced into the substance of the hemispheres on each side, particularly at their lower part, where their connections are the closest with the *Thalami Optici* and *Corpora Striata*. It is difficult, if not impossible, to trace its fibres any further;

[Fig. 194†.

This figure represents longitudinal fibres placed above the great transverse commissure corresponding with those which we have just observed below it—the *superior longitudinal commissure*. The relations being more simple than those of the inferior commissure, are simply designated by the letters *s l*, *s l*. They are traced, ascending forwards, from the *locus quadratus*, which is anterior to the *fissura Sylvii*, and then, curving backwards and winding round the front of the great transverse commissure (*P*), receiving fibres from all the convolutions at the upper and sides of the hemispheres, winding round the posterior extremity of the same commissure, and terminating after crossing the *fissura Sylvii*, where it commenced in the *locus quadratus* at the base of the brain. *H*. Spinal cord. *J*. Pituitary gland, just above which is the divided optic nerve. *N*. Letter placed on the *crus cerebri*, and behind that root of the fornix which springs from the interior of the *thalamus*. *P*. Great transverse commissure. *S*. Olivary ganglion. *a*. Olfactory ganglion. *c d*. Optic ganglia. *c a*. *Corpus mammillare*, formed by the twist of the fornix. *c m*. *Commissura mollis* in the third ventricle. *k*. Optic thalamus. *o*. Peduncle of the pineal gland: if this line is traced backwards, it will be found connected with a dark rounded body, the pineal gland, which is lying on the anterior optic tubercle—nates; if this line is traced forwards, it will be seen joining the anterior pillar of the fornix, which has been turned down to show this connection. The divided end of the fornix is turned towards us. *p c*. Posterior commissure. *s*. *Tænia semicircularis* joining the fornix at the same point. This letter is placed in the anterior cornu of the lateral ventricle on the *corpus striatum*. This junction is very distinct in both the recent and hardened brain, though the connecting fibres are too delicate to be done justice to in a woodcut. *4*. Fourth ventricle. *P*. *Iter a tertio ad quartum ventriculum*. *u*. Posterior commissure.—Ed.]

but there can be little doubt that they radiate, with the fibres proceeding from the bodies just named, to different parts of the cortical substance of the Hemispheres. This commissure is altogether wanting in Fish, Reptiles, and Birds; and it is partially or completely wanting in those Mammals whose Cerebrum is formed upon the least complex plan—the Rodents and Marsupials. The *Anterior* commissure particularly unites the *Corpora Striata* of the two sides: but many of its fibres pass through those organs, and radiate towards the convo-

lutions of the Hemispheres, especially those of the middle lobe. [Fig. 189*, a, c.—ED.] This commissure is particularly large in those Marsupials in which the Corpus Callosum is deficient. The *Posterior* commissure is a band of fibres which connects together the *Thalami Optici*; crossing over from the posterior extremity of one to that of the other. [Fig. 194†, p. c.—ED.] Besides these, there are other groups of fibres, which appear to have similar commissural functions, but which are intermingled with vesicular substance. Such are the *soft* commissure, which also extends between the *Thalami*; the *Pons Tarini*, which extends between the *Crura Cerebri*; and the *Tuber Cinereum*, which seems to unite the optic tracts with the thalami, the corpus callosum, the fornix, &c., and to be a common point of meeting for several distinct groups of fibres.—Of the *longitudinal* commissures, some lie above, and others below, the *Corpus Callosum*. Upon the transverse fibres of that body, there is a longitudinal tract on each side of the median line, which serves to connect the convolutions of the anterior and posterior Cerebral lobes. Above this, again, is the *Superior longitudinal* commissure [Fig. 194†—ED.], which is formed by the fibrous matter of the greater convolutions nearest the median plane on the upper surface of the Cerebrum, and which connects the convolutions of the anterior and middle lobes with those of the

[Fig. 194‡.

This figure has been introduced with the view of assisting the student in his study of the relations of the inferior longitudinal commissure or *fornix*, which may be described as commencing in the centre of the thalamus nervi optici (L), proceeding from thence to the base of the brain, where it suddenly bends upwards and forwards, forming by this turn the knuckle (B), which is called corpus albicans or mammillare. This body receives a few fibres (A) from the locus niger (6) in the crus cerebri (5), running forward from thence towards the anterior commissure, receiving fibres from the convolutions at the base of the brain, crossing and as it were kneeling upon the anterior commissure (S), and, ascending towards the great transverse commissure, forms the anterior pillar of the fornix (C), receiving fibres in its course from the under and front part of the anterior lobes, and thus forming the septum lucidum (D); running back from thence, passing in its course backwards over the thalamus nervi optici (L), it spreads laterally, constituting that portion which is called the body of the fornix (E): descending again at the back part of the brain, it forms the descending or posterior pillar of the fornix *tænia hippocampi* (F), some of its fibres running back to be connected with the posterior lobes (I); others crossing the projection called hippocampus major (G), to be connected with the middle lobe, and others again passing over the pes hippocampi (H) to be connected with the anterior portion of the middle lobe. Thus does this commissure connect different portions of the convoluted surface of the brain together, which are inferior to the great transverse commissure, and on the same side of the mesial line. A. Fibres of the inferior longitudinal commissure, or fornix, from the locus niger. B. Corpus albicans. C. Anterior pillars of inferior longitudinal commissure, or fornix. D. Septum lucidum. E. Body of the fornix, or centre of the commissure. F. *Tænia hippocampi*, or descending fibres of the inferior longitudinal commissure. G. Fibres covering the hippocampus major. H. Fibres covering the pes hippocampi. I. Fibres covering the hippocampus minor. K. Great transverse commissure divided in the mesial line. L. Posterior cerebral ganglion, or thalamus. M. Anterior commissure. 5. Section of the crus cerebri. 6. Locus niger. 7. Anterior cerebral ganglion, or corpus striatum partially scraped away.—ED.]

posterior. Beneath the Corpus Callosum, we find the most extensive of all the longitudinal commissures, the *Fornix*. [Fig. 194§.—ED.] This is connected in front with the Thalami Optici, the Corpora Mammillaria, the Tuber Cinereum, &c.; and behind, it spreads its fibres over the Hippocampi (major and minor), which are nothing else than peculiar convolutions that project into the posterior and descending cornua of the lateral ventricles. The fourth longitudinal commissure is the *Tænia semicircularis*, which forms part of the same system of fibres with the fornix; connecting the corpus mamillare and thalamus opticus of each side with the middle lobe of the cerebral hemisphere. If, as Dr. Todd has remarked,¹ we could take away the corpus callosum, the gray matter of the internal convolution, and the ventricular prominence of the optic thalami, then all these commissures would fall together, and would become united in the same series of longitudinal fibres.—Experiment does not throw any light upon the particular functions of the Corpus Callosum and other Commissures; since they can scarcely be divided without severe general injury. It would appear, however, that the partial or entire absence of these parts, reducing the Cerebrum (in this respect at least) to the level of that of the Marsupial Quadruped, or of the Bird, is by no means an unfrequent cause of deficient intellectual power.²

777. The weight of the entire Encephalon in the adult Male usually ranges between 40 and 60 oz., the average being about 50 oz.; and in the Female, from 36 to 50 oz., the average being about 45 oz. The maximum of the healthy brain seems to be about 64 oz., and the minimum about 31 oz. But in cases of idiocy, the amount is sometimes much below this; as low a weight as 20 ounces having been recorded.—It appears, from the recent investigations of M. Bourguery, that the relative sizes of the different component elements of the Human Encephalon are somewhat as follows: Dividing the whole into 204 parts, the weight of the Cerebrum will be represented by about 170 of those parts, that of the Cerebellum by 21, and that of the Medulla Oblongata with the Optic Thalami and Corpora Striata at 13. The weight of the Spinal Cord would be, on the same scale, 7 parts. Hence the Cerebral Hemispheres of Man

¹ "Anatomy of the Brain, Spinal Cord," &c., p. 234.

² The following case of deficient commissures, recorded by Mr. Paget ("Medico-Chirurg. Transactions," vol. xxiv.), is of much interest. The middle portion of the Fornix, and the whole of the Septum Lucidum, were absent; and in place of the Corpus Callosum, there was only a thin fasciculated layer of fibrous matter, 1-4th inch in length, but of which the fibres extended to all the parts of the brain into which the fibres of the healthy corpus callosum can be traced. The Middle commissure was very large; and the lateral parts of the Fornix, with the rest of the Brain, were quite healthy. The patient was a servant-girl, who died of pericarditis. She had displayed, during her life, nothing very remarkable in her mental condition, beyond a peculiar want of forethought and power of judging of the probable event of things. Her memory was good; and she possessed as much ordinary knowledge as is commonly acquired by persons in her rank of life. She was of good moral character, trustworthy, and fully competent to all the duties of her station, though somewhat heedless; her temper was good, and disposition cheerful.—The mental deficiencies in most of the few other cases of which the details have been recorded seem to have been of the same order; and this is exactly what might have been anticipated; since the deprivation of these parts takes away that which is most characteristic of the Cerebrum of Man and of the higher Mammalia; their intellectual operations being peculiarly distinguished by that application of past experience to the prediction of the future, which constitutes one of the highest efforts of Intelligence.—Another case has been since put on record by Mr. Mitchell Henry (Op. cit., vol. xxxi.), in which the anterior portion of the Corpus Callosum was deficient, together with the middle and anterior portion of the Fornix, and the whole of the Septum Lucidum. There was in this case, also, a marked intellectual deficiency, but apparently of a different character from that which showed itself in the preceding case; for, instead of vivacity and habitual rapidity of action, there was here a disproportionate degree of slowness in action, amounting almost to stupidity. The difference in the two cases, however, is perhaps to be set down rather to the account of general temperament; since in both of them there seems to have been a deficiency in the power of carrying on a continuous train of thought.

include an amount of nervous matter, which is *four* times that of all the rest of the Cranio-Spinal mass, more than *eight* times that of the Cerebellum, *thirteen* times that of the Medulla Oblongata, &c., and *twenty-four* times that of the Spinal Cord.—The average weight of the whole Encephalon, in proportion to that of the body, in Man, taking the average of a great number of observations, is about 1 to 36. This is a much larger proportion than that which obtains in most other animals; thus the average of Mammalia is stated by M. Leuret to be 1 to 186, that of Birds 1 to 212, that of Reptiles 1 to 1321, and that of Fishes 1 to 5668. It is interesting to remark, in reference to these estimates, that the Encephalic prolongation of the Medulla Oblongata in Man (being about one-sixteenth of the weight of the whole Encephalon) is *alone* more than twice as heavy in proportion to his body, as the *entire* Encephalon of Reptiles, and ten times as heavy as that of Fish.—But there are some animals in which the weight of the Encephalon bears a higher proportion to that of the body than it does in Man; thus in the Blue-headed Tit, the proportion is as 1 to 12, in the Goldfinch as 1 to 24, and in the Field-Mouse as 1 to 31. It does not hence follow, however, that the *Cerebrum* is larger in proportion; in fact, it is probably not nearly so large; for in Birds and Rodent Mammals, the Sensory Ganglia form a very considerable proportion of the entire Encephalon. The importance of distinguishing between the several parts of this mass, which are marked out as distinct, alike by their structure and connections, as by the history of their development, has not been by any means sufficiently attended to.

778. The Encephalon altogether receives a supply of Blood, the amount of which is very remarkable, when its comparative bulk is considered; the proportion which goes to it being, according to the estimate of Haller, as much as one-fifth of the whole. The manner in which this blood is conveyed to the brain, and the conditions of its distribution, offer some peculiarities worthy of notice. The two Vertebral and two Carotid arteries, by which the blood enters the cavity of the cranium, have a more free communication by anastomosis than any similar set of arteries elsewhere; and this is obviously destined to prevent an obstruction in one trunk from interrupting the supply of blood to the parts through which its branches are chiefly distributed—the cessation of the circulation through the nervous matter being immediately productive (as formerly shown, § 355) of suspension of its functional activity.—Not only must there be a sufficient supply of blood, but it must make a regulated pressure on the walls of the vessels. Now the Encephalon is differently circumstanced from other vascular organs, in being inclosed within an unyielding bony case (§ 533); and we find a special provision for equalizing the bulk of the contents of this cavity, and for counterbalancing the results of differences in the functional activity of the brain and in its supply of blood, in the existence of a fluid which is found beneath the arachnoid, both on the surface of the brain and spinal cord, and in the ventricles of the former. The amount of this “cerebro-spinal fluid” seems to average about two ounces; but in cases of atrophy of the brain, as much as twelve ounces of fluid may sometimes be obtained from the cranio-spinal cavity; whilst in all instances in which the bulk of the brain has undergone an increase, whether from the production of additional nervous tissue, or from undue turgescence of the vessels, there is either a diminution or a total absence of this fluid. It appears from the experiments of Magendie (to whom our knowledge of the importance of this fluid is chiefly due), that its withdrawal in living animals causes great disturbance of the cerebral functions, probably by allowing undue distension of the bloodvessels; it is, however, capable of being very rapidly regenerated; and its reproduction restores the nervous centres to their natural state.—As the “cerebro-spinal fluid” can readily find its way from the subarachnoid spaces of the *cranial* cavity into those of the

spinal, and as it is no less readily absorbed than reproduced, it evidently serves as an equalizer of the amount of pressure within the cranial cavity; admitting the distension or contraction of the vessels to take place, within certain limits, without any considerable change in the degree of compression to which the nervous matter is subjected. That this uniformity is of the greatest importance to the functional exercise of the brain, is evident from a few well-known facts. If an aperture be made in the skull, and the protruding portion of the brain be subjected to pressure, the immediate suspension of the activity of the whole organ is the result; in this manner, a state resembling profound sleep can be induced in a moment, the normal activity being renewed *as* momentarily so soon as the pressure is withdrawn. This phenomenon has often been observed in the Human subject, in cases in which a portion of the cranial envelop has been lost by disease or injury. The various symptoms of Cerebral disturbance which are due to a state of general Plethora, are evidently owing to an *excess* of pressure within the vessels; but an undue diminution of pressure is no less injurious, as appears from the disturbance in the Cerebral functions which results from the very opposite cause, namely, a depression of the power of the heart, or a deficiency of blood in the vessels.—It is of peculiar importance to bear in mind the disturbance of the Cerebral functions, which is occasioned by internal *pressure*, when we are endeavoring to draw inferences from the phenomena presented by disease.

779. We shall now proceed with our physiological inquiry into the functions of the Cerebrum; and shall, as before, apply to Human and Comparative Anatomy, to Experiment, and to Pathology, for our chief data.—The anatomical relations of the Cerebrum to the other Encephalic centres clearly demonstrate that it is not one of the essential or fundamental portions of the Nervous system; but a superadded organ, receiving all its impulses to action from the parts below, and operating upon the body at large through them. And its great bulk, joined to its position at the summit of the whole apparatus—the vesicular substance of its convolutions affording a termination to the fibres in connection with it, and not being merely traversed by them, as is the case with the vesicular substance of all the lower centres—clearly mark it out as the highest in its functional relations, and as ministering, so far as any material instrument may do, to the exercise of those psychical powers which, in Man, exhibit so remarkable a predominance over the mere animal instincts. This conclusion is fully borne out, when we extend our inquiries from Human to Comparative Anatomy; for with some apparent exceptions, which there would probably be no great difficulty in explaining if we were in possession of all the requisite data, there is a very close correspondence between the relative development of the *Cerebrum* in the several tribes of Vertebrata, and the degree of *Intelligence* they respectively possess—using the latter term as a comprehensive expression of that series of mental actions, which consists in the *intentional* adaptation of means to ends, based on definite *ideas* as to the nature of both. It is the essential character of *Instinctive* actions, on the other hand, that they are performed automatically, in obedience to internal impulses, without even the perception of their adaptiveness on the part of the being who is the agent in them; these impulses being called into play by impressions on the nervous system, which are made either by external objects, or by changes in the individual organism. The justness of this distinction becomes obvious when we analyze our own consciousness, and distinguish our own Instinctive actions from those which involve Intelligence; for we are thus led to perceive that, in regard to those operations which are most closely concerned in the maintenance of our own lives and in the continuance of the race, provision has been made in the mechanism of the Automatic portion of our nervous system, so as to render them independent of the exercise of Intelligence or the exertion of Will on our own parts. Thus the infant seeks the

nipple, and puts its muscles into suctorial action, without any knowledge that by so doing it will relieve the uneasy feeling of hunger; and if we could imagine a man coming into the world with the full possession of all his faculties, we may feel tolerably certain that he would not wait to eat until he had learned by experience his dependence upon food. We have seen that adult animals, whose Cerebral hemispheres have been removed, will eat food that is put into their mouths although they will not go to seek it; and this is the case with many Human idiots. When the functions of the Brain are disturbed, or in partial abeyance, as in fever, we often see a remarkable return to the instinctive propensities in regard to food; and the Physician frequently derives important guidance as to the patient's diet and regimen (particularly as to the administration of wine) from the inclination or disinclination which he manifests. So, in regard to the intercourse of the sexes, the impulse which prompts to it does not arise from a knowledge of the ultimate purposes which it is designed to answer; and the higher powers of the mind are only so far concerned in it that, when the action of the instinctive impulse has led to the formation of a definite idea of the object of desire, the Intelligence is prompted to take means for its gratification.

780. It is not always easy to say, in the case of the lower animals, what parts of their actions are to be attributed to automatic impulses (*i. e.* to be considered as Instinctive), and what should be regarded as the results of Intelligence. Instinctive actions, however, may be generally distinguished from those which are directed by reason, by the following characters: (1) Their unvarying *constancy* in the different individuals of the same species, and the absence of any such change, during the progress of life or in the succession of generations, as indicates that the original plan of action has been intentionally departed from: (2) by their occurrence under circumstances which altogether forbid the idea that any past experience can have suggested the design, or that, in carrying it into effect, there has been a gradual perfectionizing of the means: these actions being performed as well when first attempted, as after the most frequent repetition: (3) by their occasional performance under circumstances in which the least Intelligence would indicate their absurdity as being nugatory for the ends they are originally destined to accomplish: as when a tame Beaver attempts to build its dam across a room, or when a community of Bees, having killed their Queen because she only lays drone-eggs, attempts to make a new queen from one of the drone-larvæ. The character of Intelligent actions, on the other hand, is shown (1) in the *variety* of means which may be adopted to compass the same ends, and this not merely by different individuals and by successive generations, but by the same individual at different times; (2) by the improvement in the mode of accomplishing the object, which results from the intelligent use of experience, and from the greater command of means which is progressively attained; and (3) by the conformity of the means to altered circumstances, so that the character of adaptiveness is still maintained, however widely the new conditions may depart from those which must be considered as natural to the species.

781. The difference between actions of a purely Instinctive character, and those which proceed from the Intellectual faculties prompted by the instinctive propensities, is well seen in comparing Birds with Insects. The Instinctive tendencies of the two classes are of nearly the same kind; and the usual arts which both exhibit in the construction of their habitations, in procuring their food, and in escaping from danger, must be regarded as intuitive, on account of the uniformity with which they are practised by different individuals of the same species, and the perfection with which they are exercised on the very first occasion. But in the adaptation of their operations to peculiar circumstances, Birds display a variety and fertility of resource far surpassing that which is

manifested by Insects; and it can scarcely be doubted by those who attentively observe their habits that in such adaptations they are often guided by real Intelligence. This must be the case, for example, when they make trial of several means, and select that one which best answers the purpose; or when they make an obvious improvement from year to year in the comforts of their dwelling; or when they are influenced in the choice of a situation by peculiar circumstances, which, in a state of nature, can scarcely be supposed to effect them. The complete domesticability of many Birds is in itself a proof of their possessing a certain degree of intelligence; but this alone does not indicate the possession of more than a very low amount of it; since many of the most domesticable animals are of the humblest intellectual capacity, and seem to become attached to Man, principally as the source on which they depend for the supply of their animal wants. But there are certain tribes of Birds, especially the Parrots and their allies, which possess an extraordinary degree of *educability*, and which manifest a power of performing simple acts of *reasoning*, that are quite comparable with those of a child when first learning to talk.—This development of the Intelligence under the influence of Man, and in accordance with *his* habits, rather than with the original habits of their species, is yet more remarkable in the case of those Mammals whose instincts lead them to attach themselves peculiarly to him, and whose powers of reasoning are called forth in adapting themselves to the new circumstances in which they are thus placed. The actions of a Dog, a Horse, or an Elephant are evidently the result, in many instances, of a complex train of reasoning, differing in no essential respect from that which Man would perform in similar circumstances; so that the epithet, “half-reasoning,” commonly applied to these animals, does not express the whole truth: for their mental processes are of the same *kind* with those of Man, and differ more in the *degree* of control which the animal possesses over them than they do in their own character. We have no evidence, however, that any of the lower animals have a voluntary power of guiding, restraining, or accelerating their mental operations, at all similar to that which Man possesses; these operations, indeed, seem to be of very much the same character as those which we perform in our dreams, different trains of thought commencing as they are suggested, and proceeding according to the usual laws, until some other disturb them.—Although it is customary to regard the Dog and the Elephant as the most intelligent among the lower animals, it is not certain that we do so with justice; for it is very possible that we are misled by that peculiar attachment to Man, which in them must be termed an instinct, and which enters as a motive into a large proportion of their actions; and that, if we were more acquainted with the psychical characters of the higher Quadrumana, we should find in *them* a greater degree of mental capability than we now attribute to them. One thing is certain, that the higher the degree of intelligence which we find characteristic of a particular race, the greater is the degree of variation which we meet with in the characters of individuals; thus everybody knows that there are stupid Dogs and clever Dogs, ill-tempered Dogs and good-tempered Dogs—as there are stupid Men and clever Men, ill-tempered Men and good-tempered Men. But no one could distinguish between a stupid Bee and a clever Bee, or between a good-tempered Wasp and an ill-tempered Wasp, simply because all *their* actions are prompted by an unvarying instinct.

782. In estimating the relative development of the Cerebrum in different tribes of Animals, and in comparing this with their relative Intelligence, it must be borne in mind that the *size* of the organ does not, considered alone, afford a means of accurate judgment as to its *power*. For the quantity of vesicular matter which it contains affords the only fair criterion of the latter; and of this we must judge, not merely by the superficial area, but by the number and depth of the convolutions, and by the thickness of the cortical layer. Again,

there are many reasons why it is not fair to estimate the relative development of the Cerebrum by the proportion which it bears to the whole bulk of the animal; and, on the whole, the most accurate basis of comparison would probably be afforded by the relation between the bulk of the Cerebrum and the diameter of the Spinal Cord. In making any such comparison, however, the Thalami Optici, Corpora Striata, and Corpora Quadrigemina should be excluded from the estimate, for reasons now sufficiently apparent; and the bulk of the Cerebrum *proper* should be alone determined, either by weight, or by the displacement of liquid.—But the Cerebrum varies in different classes and orders of Vertebrata, not merely in proportional size, but also in the relative development of its anterior, middle, and posterior lobes. This is a point of very great importance in determining the value to be assigned to the organological system of Gall and Spurzheim and their followers. The Cerebrum of the Oviparous Vertebrata is *not* a miniature representative of that of Man, as a whole, but only of his *anterior* lobes; as is sufficiently obvious from an examination of its connections with other parts, and from the absence of any other commissural connections between its two hemispheres, than those which are afforded by the Sensory Ganglia. It is in the Implacental Mammals that we find the first rudiment of the *middle* lobes of the Cerebrum, and of the proper intercerebral commissure, the Corpus Callosum; and even in the Rodents this is but very imperfectly developed. As we ascend the Mammalian series, we find the Cerebrum becoming more and more elongated posteriorly by the development of the middle lobes, and the intercerebral commissure becomes more complete; but we must ascend as high as the Carnivora before we find the least vestige of the *posterior* lobes; and the rudiment which these possess, and which is enlarged in the Quadrumana, only attains its full development in man, in whom alone the posterior lobes extend so far backwards as completely to cover in the Cerebellum.¹—The attention which has yet been given to this department of inquiry has not hitherto done more than confirm the statement already made with regard to the general correspondence between the development of the Cerebrum and the manifestations of Intelligence; very decided evidence of which is furnished by the great enlargement of the Cerebrum, and the corresponding alteration in the form of the Cranium, which present themselves in those races of Dogs most distinguished for their educability, when compared with those whose condition approximates most closely to what was probably their original state of wildness.

783. This general inference, drawn from Comparative Anatomy, is borne out by observation of the Human species. When the Cerebrum is fully developed, it offers innumerable diversities of form and size among various individuals; and there are as many diversities of character. It may be doubted if two individuals were ever exactly alike in this respect. That a Cerebrum which is greatly under the average size is incapable of performing its proper functions, and that the possessor of it must necessarily be more or less idiotic, there can be no reasonable doubt. On the other hand, that a large well-developed Cerebrum is found to exist in persons who have made themselves conspicuous in the world in

¹ It has been asserted by the followers of Gall that the development of the Cerebrum from behind forwards, as above described, is rather apparent than real; the whole organ being in fact pushed backwards by the excessive development of the anterior lobe. But the anatomical distinction between the anterior and middle lobes is sufficiently obvious externally; and that of the middle and posterior lobes is also clearly marked out by the development of the posterior cornua of the lateral ventricles, and the situation of the hippocampus major. Hence the facts above stated do not admit of any such interpretation; and they are fully borne out by the history of the Embryonic development of the Cerebrum in Man, which precisely follows the above plan.—It is not here denied that the anterior lobe of the Human Cerebrum is remarkable for its great extension *forwards*; but still, the difference between the Cerebrum of Man and that of the lower Mammalia consists much rather in the proportional development of the posterior lobes than in that of the anterior.

virtue of their intellectual achievements, may be stated as a proposition of equal generality. In these opposite cases, we witness most distinctly the antagonism between the Instinctive and Voluntary powers. Those unfortunate beings, in whom the Cerebrum is but little developed, are guided almost solely by their instinctive tendencies; which frequently manifest themselves with a degree of strength that would not have been supposed to exist: and occasionally new instincts present themselves, of which the Human being is ordinarily regarded as destitute.¹ On the other hand, those who have obtained most influence over the *understandings* of others have always been large-brained persons, of strong intellectual and volitional powers, whose emotional tendencies have been subordinated to the reason and will, and who have devoted their whole energy to the particular objects of their pursuit.—It is very different, however, with those who are actuated by what is ordinarily termed *genius*; and whose influence is rather upon the *feelings* and *intuitions*, than upon the *understandings* of others. Such persons are often very deficient in the power of even comprehending the ordinary affairs of life; and still more commonly, they show an extreme want of judgment in the management of them, being under the immediate influence of their passions and emotions, which they do not sufficiently endeavor to control by their intelligent will. The life of a “genius,” whether his bent be towards poetry, music, painting, or pursuits of a more material character, is seldom one which can be held up for imitation. In such persons, the *general* power of the mind being low, the Cerebrum is not usually found of any great size.—The *mere* comparative size of the Cerebrum, however, affords no accurate measure of the amount of mental power: we not unfrequently meet with men possessing large and well-formed heads; whilst their physical capability is not greater than that of others, the dimensions of whose crania have the same general proportion, but are of much less absolute size. Large brains, with deficient activity, are commonly found in persons of what has been termed the *phlegmatic* temperament, in whom the general processes of life seem in a torpid and indolent state; whilst small brains and great activity betoken what are known as the *sanguine* and *nervous* temperaments.

784. Having now inquired into the evidence of the *general* functions of the Cerebrum, which may be derived from examination of its Comparative development, we proceed to our other sources of information, Experiment and Pathological phenomena. From neither of these, however, is much positive information to be derived.—The results of partial mutilations are usually, in the first instance, a general disturbance of the Cerebral functions; which subsequently, however, more or less subsides, leaving but little apparent affection of the animal functions, except muscular weakness. The whole of *one* Hemisphere has been removed in this way without any evident consequence, save a temporary feebleness of the limbs on the opposite side of the body, and what was supposed to be a deficiency of sight through the opposite eye. The former was speedily recovered from, and the animal performed all its movements as well as before; the latter, however, was permanent, but the pupil remained active. When the upper part, only, of both Cerebral Hemispheres was removed by Hertwig, the animal was reduced, for fifteen days, to nearly the same condition with the one from which they had been altogether withdrawn; but, afterwards, sensibility evidently returned, and the muscular power did not appear to be much diminished.—The effects of the entire removal of the Cerebral Hemispheres have been already stated (§ 734). So far as any inferences can be safely drawn from

¹ A remarkable instance of this was published some years since.—A perfectly idiotic girl, in Paris, having been seduced by some miscreant, was delivered of a child without assistance; and it was found that she had *gnawed* the umbilical cord in two, in the same manner as is practised by the lower animals. It is scarcely to be supposed that she had any idea of the *object* of this separation.

them, these fully bear out the conclusion that the Cerebrum is the organ of Intelligence; since the animals which have suffered this mutilation appear to be constantly plunged in a profound sleep, from which no irritation ever seems able to arouse them into full activity, although they give manifestations of consciousness. It would be wrong hence to infer, however, as some have done, that such would be the natural condition of an animal without a Cerebrum; since it is obvious that much of the disturbance of the sensorial powers which is occasioned by this operation, is fairly attributable to the laying-open of the cranial cavity, to the disturbance of the normal vascular pressure, and to the injury necessarily done to the parts which are left, by their severance from the Cerebrum. Hence the persistence of consciousness, after the entire removal of the Cerebrum—which proves that the Cerebrum is *not* its seat, or at least *not its exclusive seat*—is a far more important fact than the positive destruction of psychical power which is consequent upon the operation. So far as they can be trusted, however, the results of such mutilations bear out the views already put forth as to the superadded and non-essential character of the Cerebrum; and justify us in applying to the higher animals the inferences to which we should be led by the contemplation of those forms of the nervous system in which no Cerebrum exists. There is nothing, therefore, to oppose the conclusion, that whilst *sensations* may be felt, and sensori-motor actions excited, independently of the Cerebrum, the presence of this organ is essential to the formation of *ideas* or notions respecting the objects of sense, and to the performance of those psychical operations to which ideas furnish at once the material and the stimulus to activity.¹

785. The information afforded by Pathological phenomena is equally far from being definite. Many instances are on record, in which extensive disease has occurred in *one* Hemisphere, so as almost entirely to destroy it, without either any obvious injury to the mental powers, or any interruption of the influence of the mind upon the body. But there is no case on record, of any such severe lesions of *both* hemispheres, in which morbid phenomena were not evident during life. It is true that, in Chronic Hydrocephalus, a very remarkable alteration in the condition of the Brain sometimes presents itself, which might *à priori* have been supposed destructive to its power of activity; the ventricles being so enormously distended with fluid, that the cerebral matter has seemed like a thin lamina, spread over the interior of the enlarged cranium. But there is no proof that absolute destruction of any part was thus occasioned; and it would seem that the very gradual nature of the change gives to the structure time for accommodating itself to it. This, in fact, is to be noticed in all diseases of the Encephalon. A *sudden* lesion, that may be so trifling as to escape observation, unless this be very carefully conducted, will occasion very severe symptoms; whilst a chronic disease may gradually extend itself, without any external manifestation. It will usually be found that sudden paralysis, of which the seat is in the Brain, results from some slight effusion of blood in the substance or in the neighborhood of the Corpora Striata; whilst, if it follow disorder of long standing, a much greater amount of lesion will usually present itself. In either case, the paralysis occurs in the opposite side of the *body*, as we should expect from the decussation of the Pyramids; but it may occur either on the same, or on the opposite side of the *face*—the cause of which is not very apparent. If convulsions accompany the paralysis, we may infer that the Corpora Quadrigemina, or the parts below, are involved in the injury; and in this

¹ It is worthy of remark, that M. Flourens, who in the first instance maintained that sensation is altogether destroyed by the removal of the Cerebrum, has substituted, in the Second Edition of his Researches, the word *perception* for *sensation*; apparently implying exactly what is maintained above.

case it is usually found that the convulsions are on the paralyzed side of the body—the effect of the lesion, both of the Cerebrum and of the Corpora Quadrigemina, being propagated to the opposite side, by the decussation of the Pyramids. Where, as not unfrequently happens, there is paralysis of one side, accompanying convulsions on the other, it is commonly the result of a lesion affecting the base of the Brain and Medulla Oblongata, on the side on which the convulsions take place; here the effect of the lesion has to *cross* from the Brain, whilst its influence on the Medulla Oblongata is shown on the *same* side. Many anomalies present themselves, however, which are by no means easy of explanation, in the present state of our knowledge.—The disturbance of the Cerebral functions, occasioned by those changes in its nutrition which are commonly included under the general term of Inflammation, presents a marked diversity of character, according to the part it affects. Thus it is well known that the delirium of excitement is usually a symptom of inflammation of the cortical substance, or of the membranes of the hemispheres. This is exactly what might be anticipated from the foregoing premises, since this condition is a perversion of the ordinary mental operations, which are dependent upon the instrumentality of the vesicular matter: and it is evidently impossible for the membranes to be affected with inflammation, without the nutrition of this substance being impaired, since it derives all its vessels directly from them. On the other hand, inflammation of the fibrous portion of the Cerebrum is usually attended rather with a state of torpor, than with excitement; and with diminished power of the will over the muscles. It is stated by Foville, that in acute cases of Insanity, he has usually found the cortical substance intensely red, but without adhesion to the membranes; whilst in chronic cases, it is indurated and adherent: but where the insanity has been complicated with Paralysis, he has usually found the medullary portion indurated and congested.

786. The general result of such investigations is, that the Cerebrum is the instrument of all those *psychical* operations, which we include under the general term *Intellectual*, whilst it also affords, in part at least, the instrumental conditions of *Emotional* states (using this term in its widest sense); and that all those muscular movements which result from *voluntary* determinations, or which are directly consequent upon *emotional* excitement, have their origin in its vesicular substance, though the motor impulse is immediately furnished by the Automatic apparatus, upon which the Cerebrum plays (§ 757).—All the operations of the Mind are *originally* dependent upon the reception of *Sensations*. If it were possible for a Human being to come into the world, with a Brain perfectly prepared to be the instrument of psychical operations, but with all the inlets to sensation closed, we have every reason to believe that the Mind would remain dormant, like a seed buried deep in the earth. The attentive study of cases, in which there is congenital deficiency of one or more sensations, makes it evident that the Mind is utterly incapable of forming any definite ideas in regard to those properties of objects of which those particular sensations are adapted to take cognizance. Thus the man who is born blind can form no conception of color; nor the congenitally deaf, of musical tones. And in those lamentable cases, in which the sense of touch is the only one through which ideas can be introduced, it is evident that the mental operations must remain of the simplest and most limited character, if the utmost attention be not given, by a judicious instructor, to the development of the intellectual faculties, and the cultivation of the moral feelings, through that restricted class of ideas which there is a possibility of exciting.—The activity of the Mind, then, is just as much the result of its consciousness of external impressions, by which its faculties are called into play, as the Life of the body is dependent upon the appropriation of nutrient materials, and the constant influence of external forces. But there is this difference between the two cases—that whilst the Body continually requires *new*

materials and a continued action of external agencies, the Mind, when it has been once called into activity, and has become stored with ideas, may remain active, and may develop new relations and combinations amongst these, after the complete closure of the sensorial inlets by which new ideas can be excited *ab externo*. Such is, in fact, what is continually going on in the state of Dreaming; but examples yet more remarkable are furnished in the vivid conceptions which may be formed of a landscape or a picture, from oral description, by those who have once enjoyed sight; or in the composition of music, even such as involves new combinations of sounds, by those who have become deaf—as in the well-known case of Beethoven. The mind thus feeds, as it were, upon the store which has been laid up during the activity of its sensory organs; but instead of diminishing, like material food, these ideas become more and more vivid, the oftener they are made the subjects of attention.

787. The seat of the *Sensational Consciousness*, as already shown, is indicated by a large mass of evidence to lie in the Sensory Ganglia, which are the real centres of the Nerves of Sense; and we may fairly conclude that, when not interrupted in the upward course already indicated, the changes which occur there give rise to a new excitement of nerve-force, which is propagated along the ascending nerve-fibres to the vesicular matter that forms the surface of the Cerebral Hemispheres; and that it is only when they arrive at the ultimate termination of these fibres in the latter, that these impressions give rise to those changes which are in the first instance instrumental in the formation of *Ideas*¹ and subsequently in the higher *Intellectual Operations*. These operations themselves become the source of new changes in the condition of the Nervous substance; and an excitation of nerve-force takes place as their result, which, transmitted downwards to the sensorial tract at the base of the Cerebrum, gives rise through it to respondent movements (§ 759).—Now it is an inquiry of considerable interest, both in its psychological and its physiological relations, whether the Cerebrum is itself endowed with consciousness; that is, whether we become conscious of changes which take place in the condition of its substance, so long as these changes are limited to itself. At first sight it would appear to be a very startling proposition, that the organ of the intellectual operations is not itself endowed with consciousness; but a careful consideration of its relations to the Sensory Ganglia will tend to show that there is no *à priori* absurdity in such a notion. For, if the relation of the vesicular matter of the Cerebral Hemispheres to the Sensorial Centres, be anatomically the same as that which is borne to these centres by the Retina, or by any other peripheral expansion of

¹ The Author cannot here enter into the discussion which has been the subject of so many abstruse and labored Metaphysical discussions, how far Ideas are to be considered as “transformed sensations,” or as “states or affections of the consciousness” which, though primarily *excited* by sensations, may have nothing in common with them. It will be sufficient for him to express his own conviction, that the latter is the only consistent mode of viewing the subject; and that the Idea can no more correctly be described as a “transformed sensation,” than sensation itself could be designated as a transformed impression. The one is antecedent, the other consequent; the one is the force which, acting on a certain prepared organization, evokes a further change, just as a mechanical or electrical stimulus applied to a muscle calls it into contraction.—The notion of Condillac and the Sensational School of Psychologists, that ideas are “transformed sensations,” appears to have been based upon the consideration of those ideas alone which are most nearly allied to Sensations in their nature, being the immediate psychical representations of objective or concrete realities. But it cannot be legitimately held of those *abstract* or *general* ideas, which have no objective representatives, and which are the products of mental operations that are by no means truly described by the term *transformation*. Thus the idea of the invariability of the *laws* of Nature arises out of a constant succession of new and diversified *phenomena*; as has been beautifully shown by Prof. Oersted, in his Essay on “The Spiritual in the Material,” which forms the first section of his Treatise on “The Soul in Nature,” recently given to the English public.

vesicular matter in an organ of sense, which we have seen that it is (§ 753),—and if the same kind of change may be excited in the Sensorial Centres by an impression from each source, which has been shown to be a matter of common occurrence (§ 758)—it can scarcely be deemed unlikely that the Sensorial Centres should be the seat of consciousness, not merely of the impressions transmitted

Fig. 195.

Diagram of the mutual relations of the principal Encephalic centres as shown in a vertical section: A, Cerebrum; B, Cerebellum; c, Sensori-motor tract, including the Olfactive ganglion *olf*, the Optic *opt*, and the Auditory *aud*, with the Thalami Optici *thal*, and the Corpora Striata *cs*; D, Medulla Oblongata; E, Spinal Cord: a, olfactive nerve; b, optic; c, auditory; d, pneumogastric; e, hypoglossal; f, spinal: fibres of the medullary substance of the cerebrum are shown, connecting its ganglionic surface with the sensori-motor tract.

to them by the nerves of the external senses, but also of the impressions brought to them by the “nerves of the internal senses;” as the sagacious Reil designated the radiating fibres of the Cerebral Hemispheres. And there is on the other hand an *a priori* improbability that there should be *two* seats of consciousness, so far removed from one another as the Sensory Ganglia and the vesicular surface of the Hemispheres (for to their medullary substance no such attribute can be assigned with the least probability); an idea which is quite at variance with that very simple and familiar class of phenomena which consists in the *recollection of sensations*. For the remembered sensation is so completely the repetition of the original, that we can hardly suppose the seat of the two to be different; yet the act of recollection is clearly Intellectual, and therefore Cerebral; consequently if we admit that the Sensory Ganglia are the seat of the original sensation, we can scarcely but admit that they are also the seat of that which is reproduced by a Cerebral act—a view which is fully confirmed by the

¹ It is interesting to observe how remarkably this view is confirmed by the history of Development. For the Retina, like the cortical substance of the Cerebrum, is a vesicular expansion originally detached from the Sensory Ganglia, and gradually carried to a greater and greater distance from them; but still remaining connected by the commissural tract of white fibres, which we call in the one case the Optic Nerve, and in the other the Medullary substance of the Hemispheres.

occurrence of automatic movements as consequences of its recall (§ 758). But further, we shall hereafter find evidence to the same effect, in our experience of the occasional evolution of results such as ordinarily proceed from intellectual action, without any consciousness on our own parts of the steps whereby these are attained (§§ 813, 819, 820).

788. Without presuming, then, to affirm positively what cannot be proved, it may be stated as a probable inference from the Physiological facts already referred to, and from the Psychological evidence hereafter to be adduced, that the Sensory Ganglia constitute the seat of consciousness, not merely for impressions on the Organs of Sense, but also for changes in the cortical substance of the Cerebrum; so that, until the latter have reacted downwards upon the Sensorium, we have no consciousness either of the formation of ideas, or of any intellectual process of which these may be the subjects. Ideas, emotions, intellectual operations, &c., have of late been frequently designated as "states of consciousness;" and this psychological description of them is in full harmony with the physiological account here given of the material conditions under which they respectively occur. For a Sensation being a state of consciousness excited through the intermediation of the Sensorium, by a certain change (*e. g.*) in the condition of the Retina, it is not difficult to understand how a change in the condition of the Cerebrum may excite, through the same instrumentality, that state of consciousness which may be termed Ideational,¹ or that another change may produce the Emotional Consciousness, another the Intuitional Consciousness, another the Logical Consciousness. And although it may be thought at first sight to be a departure from the simplicity of Nature, to suppose that the Cerebrum should require another organ to give us a consciousness of its operations, yet we have the knowledge that the Eye does not give us visual consciousness, nor the Ear auditory consciousness, unless they be connected with the Sensory Ganglia; and in the end (the Author feels a strong assurance) it will be found much simpler to accept the doctrine of a common centre for *sensational* and for what may be distinguished as *mental* consciousness, than to regard the two centres as distinct.²—We shall now proceed with a brief analysis of the operations of which the Cerebrum is the instrument; considering them in the ascending series, as founded upon Sensational changes.

789. Neither the operation of the Intellectual Powers, nor Emotional excitement is *immediately* called forth by the Sensational Consciousness; for if we do not advance beyond this, we merely recognize the fact that certain changes have occurred in our own "subjective" state, and do not refer these changes to any external or "objective" source. Of this we occasionally meet with examples among the phenomena of dreaming, and in some of the conditions resulting from the use of Anæsthetic agents; for if we fall asleep whilst suffering from bodily pain, we may entirely lose all perception of the cause of that pain as having its seat in our own bodily fabric, and yet remain conscious of a perturbed state of feeling; and when a surgical operation is performed in a state of incomplete Anæsthesia, it is obvious that pain is felt without any distinct

¹ The Author ventures to use this term, the meaning of which requires no explanation, on the authority of Mr. James Mill, who remarks: "As we say Sensation, we might also say Ideation; it would be a very useful word; and there is no objection to it, except the pedantic habit of decriing a new term. Sensation is the general name for one part of our constitution [or rather, for one state of our consciousness], Ideation for another." ("Analysis of the Human Mind," vol. i. p. 42.)—If the use of the substantive Ideation be admitted, there can be no reasonable objection to the adjective *ideational*.

² It may serve to give additional confidence in the views above propounded, if the Author mentions that he was led by them to *predict* the psychological phenomena referred to at the end of § 787, of which he was not at the time aware as facts, but of which he afterwards became assured by the analysis of his own consciousness, and by the communicated experience of others to whom he stated the question.

consciousness of its source, and the patient may subsequently describe his state as an uneasy dream. Such, it is probable, is the condition of the Infant at the commencement of its psychical life. "If," as has been well remarked by Mr. Morell,¹ "we could by any means transport ourselves into the mind of an infant before the perceptive consciousness is awakened, we should find it in a state of absolute isolation from everything else in the world around it. Whatever objects may be presented to the eye, the ear, or the touch, they are treated simply as subjective feelings, without the mind's possessing any consciousness of them *as objects* at all. To it, the inward world is *everything*, the outward world is *nothing*."—However difficult it may be, under the influence of our life-long experience, to dissociate any sensation which we experience from the idea of its external cause—since, the moment the feeling is experienced, and the mind is directed to it, the object from which it arises is immediately suggested—yet nothing is more certain than that all of which we are ourselves conscious, in any case whatever, is a certain internal or subjective state, a change in our previous consciousness; and that the formation of the idea of the object to which that change is due, is dependent upon a higher mental process, to which the name of *Perception* or *Perceptive Consciousness* is now generally accorded.² We may recognize the manifestation of this process in the child, as it advances beyond the first few months of its helplessness. "A sight or a sound," remarks Mr. Morell (Op. cit.), "which at first produced simply an involuntary start, now awakens a smile or a look of recognition. The mind is evidently struggling *out of itself*; it begins to throw itself into the objects around, and to live in the world of outward realities." We may recognize a similar transition, more rapidly effected, during the passage from sleep, or from the insensibility of a swoon, to the state of complete wakefulness; when we are at first conscious only of our own sensations, and gradually come to the knowledge of our condition as it relates to the world around, and of the position and circumstances, new and strange as they may be, in which we find ourselves.

790. Now the elementary notion of the *outness* or *externality*³ of the cause of sensational change is undoubtedly formed by a law of our mental nature; and must be regarded as a mental instinct or *intuition*. We do not *infer* the existence of objective realities by any act of the reason; in fact, the strict application of logical processes tends rather to shake than to confirm the belief in the external world; but the qualities of matter are directly and immediately recognized by our minds, and we then go on to shape the information we have thus acquired, into a definite notion of the object. Some of these notions are so simple, and so constantly excited by certain sensations, that we can scarcely do otherwise than attribute their formation to original and fundamental properties of the mind, called into activity by the sensations in question; thus, as we shall hereafter see (CHAP. XV. SECT. 5), the notion of the *projection* or *solidity* of an object is necessarily developed in our minds, when two pictures, having certain relations of *dissimilarity*, are projected on our two retinæ. But in other cases, the ideas are connected with the sensations by habit alone; and it is entirely due to the association which has been gradually formed between them, that the one calls up the other. Of this we have a valuable illustration in the process by which

¹ "Philosophy of Religion," p. 7.

² For the attachment of this definite meaning of the term *Perception*, as for many other services to Psychological Science, we are indebted to Sir William Hamilton.—See especially his note on the "Philosophy of Sensation and Perception," in his edition of the "Works of Dr. Reid."

³ This term is to be understood, in the present inquiry, as implying what is external to the *mind*. Viewed in that aspect, the bodily organism stands in the same kind of relation to it, as does the world beyond; and the changes in the former which give rise to sensations are as much *objective* as are those of the latter.

we acquire a language. A certain sound comes to be connected in the mind of the child with a certain object, its knowledge of which is derived through the visual or other sense; and by the habitual recurrence of this connection, the sensational consciousness of the sound comes to suggest the idea of the object, so that the notion of bread or of water is at once called up by the mention of their names; whilst, on the other hand, the idea of the object reproduces that sensational consciousness of the sound of its name, which is the necessary guide in the pronunciation of the word. And the adult, in learning a new language, goes through a process of a very similar kind; the association being first formed between *its* words and the words of the language already familiar to him, and the former at last directly suggesting the corresponding ideas, without any necessity for the intermediate process of translation. On the other hand, the sight or the sound of the words of a language altogether unknown to us, excites no other respondent idea in our minds than that which arises out of the simple act of perception; namely, the externality of the object which has impressed our sense of vision or of hearing. But the case is different with regard to those signs which are the *natural* expressions of ideas; for, in so far as they are so, they *intuitively* suggest those ideas to the mind of another. This, however, is much more noticeable with regard to the signs of *emotional* states—which are very early interpreted by children, and also by the lower animals—than with respect to those which express *simple ideas*.¹

791. We have seen that, for the production of a Sensation, a *conscious* state of mind is all that is required; whilst, on the other hand, for the exercise of the Perceptive power, a certain degree of *attention* is requisite; or, in other words, the Mind must be *directed towards* the Sensation. And thus it happens that, owing either to the inactivity of the Cerebrum, or to the complete engrossment of the mind by some other subject of thought, the sensation may neither be perceived nor remembered, notwithstanding that we have evidence, derived from the respondent movements of the body, that it has been felt. Thus a person in a state of imperfect sleep may start at a loud sound, or may turn away from a light shining on his face; being conscious of the sensation, and acting automatically upon it, but having no consciousness whatever of the object which gave rise to it. And, in like manner, a person in a state of profound abstraction may perform many automatic movements (§ 749), which cannot (so far as we know) be excited except through the medium of sensation; and yet the exciting sensations are neither perceived by him at the time, nor are they afterwards remembered; so that, when he is aroused from his reverie, he may be astonished to find himself in circumstances altogether different from those under which he passed into it. Sometimes, however, the sensorial impression may excite a sort of imperfect perception, which is subsequently remembered and completed. For example, the student who does not hear the repeated strokes of the clock when his mind is entirely given up to his object of pursuit, may have a sort of vague consciousness of them if his attention be less completely engrossed by his studies; and although the sounds may not suggest at the moment any distinct idea of the passage of time, yet, when he subsequently

¹ The deaf and dumb are trained to communicate with each other, not merely by the "finger-language," by which words are alphabetically spelled, but also by the "sign-language," by which ideas are conveyed through the much more direct medium of single signs. These signs, though partly conventional, are made to conform as nearly as possible to the *natural* expressions of ideas; and are usually acquired very quickly by the deaf and dumb, whose want of other modes of utterance forces into activity a mode of expressing their ideas and emotions, which is unnecessary to those who have the command of language, and is consequently but little exerted by them. Young children, however, who associate much with the deaf and dumb, very readily acquire this "sign-language," and will often prefer the continued use of it to the acquirement of *spoken* language.

gives his attention to the sensorial impression, he may remember to have heard the clock strike, and may even be able to retrace the number of strokes.¹ When the attention is directed, however, to the sonorous impressions (as when we are *listening* for the striking of the clock), or when it is not so closely fixed on any other object as that it may be attracted by the sensations, the sounds are not only recognized as proceeding from an external source, which is a simple act of Perception, but, by a mental act which depends upon previous associations, the sounds give rise to the complex idea of the striking of a clock, and are referred, it may be, to some particular clock. Hence, when we say (as we commonly do) that we have heard the clock strike, we affirm that which is not strictly correct; for that which we hear is simply the series of sounds, and it is by an intuitive perception that we are led to consider those sounds as originating in an external object; whilst the formation of a definite notion with regard to the nature of that object is an act of judgment and comparison, guided by past experience. When such an operation has been very frequently performed, however, the notion comes to be so directly excited by the sensation, that it is uniformly and necessarily called up when the attention is directed to the latter; the individual being quite forgetful of the mental process by which this connection was originally established.

792. Thus the formation of what have been designated as *acquired* perceptions, in contradistinction to those of the *intuitive* kind, bears a striking analogy to the process by which habitual movements come to be linked on to the sensations that prompt them, so as at last to be automatically performed although originally guided by the Will (§ 749). And it can scarcely be regarded as improbable, that, in the one case as in the other, the nervous mechanism *grows* to particular modes of activity (§ 726); so that successions of action are uniformly excited by particular stimuli, which were not provided for in its original construction. Such a view harmonizes well with the fact that such associations, both between sensations and respondent *movements*, and between sensations and respondent *ideas*, are formed much more readily during the period of childhood and adolescence, than they are after the full measure of development has been attained; and that they are much more durable in the former case than in the latter. For that which has been already pointed out with regard to the nutrition of other tissues (§ 591), may not unreasonably be applied to that of the Nervous system; that, when once a certain mode of nutrition has been fully established, it tends to perpetuate itself, provided that it be not altogether unconformable to the original type. Throughout the whole constitution of Man, physical and mental, we witness this capacity of adaptation to a great variety of circumstances; and it seems to be purposely left to Man to educate himself in accordance with those circumstances; so that he gradually *acquires* those modes of action which in other animals are directly prompted by instinctive or intuitive tendencies. The idea of the distance of an object, for example, is one derived in Man from many sources, and is the result of a long experience; the infant, or the adult seeing for the first time, has to bring the senses of sight and of touch to bear upon one another, in order to obtain it; but, when once the power of determining it is acquired, the steps of the process are lost sight of. In the lower tribes of animals, however, in which the young receive no assistance from their parents, there is an evident necessity for some *immediate* power

¹ It is curious that in so retracing a number, we are often assisted by mentally reproducing the succession of strokes, *imagining* their recurrence, until we feel that we have counted up to the impression that was left upon our sensorium. In the same way, if asked how many stairs there are in a staircase which we are in the habit of using, we may not be able to name the number; yet, when actually ascending or descending, we are conscious that we have arrived at the top or the bottom, by the completion of that series of sensorial changes which has become habitual to us.

of forming this determination; since they would not be able to obtain their food without it. Accordingly, they manifest in their actions a perception or governing idea of distances, which can only be gained by Man after long experience. A fly-catcher, for instance, just come out of its shell, has been seen to peck at an insect, with an aim as perfect as if it had been all its life engaged in learning the art.—In some cases, animals seem to learn that, by intuitive perception, at which Man could only arrive by the most refined processes of reasoning, or by the careful application of the most varied experience. Thus, a little fish, named the *Chaetodon rostratus*, is in the habit of ejecting from its prolonged snout, drops of fluid, which strike insects that happen to be near the surface of the water, and cause them to fall into it, so as to come within its own reach. Now by the laws of refraction of light, the place of the Insect in the air will not really be that at which it appears to the Fish in the water; but it will be a little below its apparent place, and to this point the aim must be directed. But the difference between the real and the apparent place will not be constant; for the more perpendicularly the rays enter the water, the less will be the variation; and, on the other hand, the more oblique the direction, the greater will be the difference. Now it is impossible to imagine but that, by an intuitive perception, the real place of the Insect is known to the Fish in every instance, as perfectly as it could be to the most sagacious Human mathematician who might determine it in each case by a process of calculation, or to a clever marksman who had learned it practically by a long experience.

793. Just as the simple feelings of pleasure or pain are associated with particular sensations (§ 759), the same feelings connect themselves with particular *Ideas*; and thus are produced those *Emotional* states of mind, which, directly or indirectly, determine a great part of our habits of thought, and are largely concerned in the government of our conduct. The formation of a true *desire*, even for the gratification of some bodily appetite, requires that an idea of the object of desire shall have been formed; and it is the expectation of the pleasure which will arise from the performance of the act in question, or of the pain which will be produced by abstinence from it, which makes the idea a *motive* to action. A careful analysis of the various Propensities, Moral Feelings, Sentiments, &c., which are ranked by Metaphysicians under the general term “active principles,” will show (the Author believes) that such is the essential nature of all. Thus, Benevolence is the pleasure in the happiness of others; and shows itself alike in the habitual entertainment of the abstract or general idea, and in the direction of the conduct in any particular instance. So there is a positive pleasure, in some ill-constituted minds, in the contemplation of the unhappiness of others; and this we designate as Malevolence. Again the Combativeness of Phrenologists is nothing else than the pleasurable idea of setting one’s self in antagonism with others; which may manifest itself either physically or psychically, according to the temperament of the individual.¹ So Pride (or self-esteem) consists in the pleasurable contemplation of our own superior excellencies; whilst the essence of Vanity (or love of approbation) lies in the pleasurable idea of the applause of others. Again, in Conscientiousness we have the

¹ There are individuals who never manifest the least degree of *physical* combativeness, who yet show a remarkable love of opposition in all their *psychical* relations with others. That objections will be raised by such persons to *any* plan that may be proposed, we can always feel sure, though we may not have the remotest idea as to what the objection may be in each particular case. Persons in whom this tendency exists in a less prominent degree are apt to see objections and difficulties *first*, although their good sense may subsequently lead them to consider these as of less account, or to be outweighed by the advantages of the scheme. Such was the case with the late Sir Robert Peel. On the other hand, those who are spoken of as of *sanguine* temperament are apt to lose sight of the intervening difficulties, in the pleasurable idea of the *result*.

love of right, that is, the association of pleasure with the idea of right; Veneration may be defined as the pleasurable contemplation of rank or perfections superior to our own; and the source of Ambition, which is in some degree the antagonistic tendency, lies in the pleasurable idea of self-exaltation. In like manner, Hope is the pleasurable contemplation of future enjoyment; Fear is the painful contemplation of future evil; and Cautiousness is the combination of the desire to avoid anticipated pain with the pleasurable contemplation (an extremely strong feeling in many individuals) of precautions adapted to ward it off.—The same view may be applied to the love of Truth, of Beauty, of Sublimity, of Goodness, of Order, of Possessions, of Country, &c.; and also to Cheerfulness, Wit, Humor, &c., and to many conditions usually considered as purely Intellectual. And in fact, the association of *sensorial pleasure* with *any idea*, or *class of ideas*, gives to it an Emotional character; so that the Emotional states are not by any means limited within the categories which most Psychologists have attempted to lay down; these being, for the most part, *generic terms*, which comprehend certain groups of ideas bearing more or less similarity to each other, but not by any means including all possible combinations.¹—By those who regard the Propensities, Moral Feelings, &c., as simple states of mind, it is usually said that their indulgence or exercise is attended with pleasure, and the restraint of them with pain. But, if the view here taken be correct, it is the very coexistence of pleasurable or painful feelings with the idea of a given object, that causes desire or aversion as regards that object; since the mind instinctively pursues what is pleasurable, and avoids what is painful. And thus, according to the readiness with which these different classes of ideas are excited in different minds (partly depending upon original constitution, and partly upon the habitual direction of the thoughts), and to the respective degrees in which they respectively call forth the sensorial feelings of pleasure or pain (as to which there is obviously an inherent difference amongst individuals, analogous to that which exists with regard to the feelings of pleasure or pain excited by external sensations, sights, sounds, tastes, odors, or contacts), will be the disposition of the mind to entertain them, the frequency with which they will be brought before the mental view, and the influence which they will exert in the determination of our conduct.²

¹ The truth of this statement must be apparent to all who are familiar with the manifestations of Eccentricity and Insanity; for we frequently see pleasurable feelings associating themselves with ideas, which to ordinary minds appear *indifferent* or are even regarded with pain; and thus are engendered motives, which exert a most powerful influence over the conduct, and which, if not kept in restraint by the Will, render the whole being their slave.—It may be also remarked, in this place, that the impossibility of classing all the Emotional states of mind under a limited number of categories, constitutes a most serious and fundamental objection to any system which professes to mark out in the Cerebrum distinct seats for the Animal Propensities, Moral Feelings, &c.

² The above view of the nature of Emotional states was first developed by the Author in an article on the "Physiology of the Brain," in the "British and Foreign Medical Review," October, 1846.—It was not until he had thought out the subject for himself, on the physiological basis which is here given to it, that his attention was directed to Mr. James Mill's masterly "Analysis of the Human Mind," as containing a very similar doctrine. It has been a great satisfaction to him to find that a Metaphysician of so high a rank had anticipated his conclusions, and this upon psychological grounds only; since it gives him the more confidence in the truth of the physiological doctrines with which he has connected them. His principal point of difference from Mr. Mill lies in the greater difference which he believes to exist between *ideas* and *sensations*; for he cannot, with Mr. Mill, regard an Idea as a mere "trace or copy of the sensation, which remains after the sensation ceases," but must consider it as a state of mind altogether different, excited or induced by sensations; and consequently, he does not consider the emotional state to consist in the anticipation of a future pleasurable *sensation*, since the pleasure is generally associated with *ideational states* which have no analogy whatever to the sensations which excited them. Thus the Love of Praise does not consist in the association of pleasure with the

794. The influence of Emotional conditions, when strongly excited, in directly producing involuntary movements, is readily explained on the idea that the Sensory Ganglia are the seat of all consciousness, and the Cranio-Spinal axis the real source of all movement. For there is no more difficulty in understanding that the excitement of peculiar states of consciousness in the Sensorial centres, through the instrumentality of the Cerebrum, should give rise to automatic movements, than that such movements should follow similar states of consciousness when excited by impressions made upon the organs of vision, hearing, &c. And the correspondence is seen to be very close, when the idea (as is doubtless the case in some instances) is very nearly akin to the sensation. Thus, the laughter excited by the act of tickling is a purely consensual movement (§ 748); but, in a very "ticklish" person, the mere *idea* of tickling, suggested by pointing a finger at him, is sufficient to provoke it. So, again, laughter may be excited by odd sights or sounds which do not in themselves excite any emotional state, and which we call "ludicrous" merely because they *do* excite laughter; and the vivid recollection of these, being attended with a state of the sensorium corresponding to that produced by the sensation, may give rise to the same involuntary cachinnation. But laughter may also be excited by ideas that are much more removed from actual sensations, as, for example, by those unexpected combinations of ideas of a purely intellectual nature, which we designate as "witty;" and here, too, we may recognize the very same *modus operandi*. For the mere sound or sight of the *words* excites no feeling of the ludicrous; the *sensation* must develop an *ideational* change; and it is the latter alone, which, reacting downwards upon the Sensorium, and there becoming associated with the feeling of pleasure, gives rise to the impulse to laugh. The same might be shown to be the case with regard to the act of Crying; which may be either purely consensual, being excited by painful sensations; or may be induced by the vivid recollection of past or the anticipation of future sensations; or may be excited by ideas which have no direct relation to sensational states. Again, the movements which take place under the violent excitement of the passions of Anger, Lust, &c., are of the same involuntary character; being directly prompted by feelings which may be either excited by external sensations, or by internal ideas more or less akin to them. Thus the passionate man who receives a blow instinctively makes another blow in the direction from which it seemed to him to come, without any thought of whether the blow was accidental or intentional; and the idea of an insult, which is a source of mental disturbance, may excite the very same movement, although no bodily suffering had been experienced. In states of excessive sexual excitement, again, the desire, which arises out of the idea of the object (§ 772), produces involuntary movements corresponding to those which are ordinarily linked on to the actual sensations alone. There are many of the movements of Expression, which are referable in like manner to states of consciousness, whether pleasurable or painful, which may arise either from sensational or from ideational conditions. Thus the cheerful aspect of some individuals is due to a sense of general *physical* well-being, and is altogether discomposed by anything which disturbs this; whilst, on the contrary, it proceeds in others from a happy frame of mind (which may be partly the result of original constitution, and partly of habitual self-direction), disposing them to take the cheerful view of everything that affects themselves or others, notwithstanding (it may be) great bodily discomfort. And the reverse aspect

auditory or visual sensations produced by spoken or written *words*; but in the association of pleasure with the *ideas* which these words call forth in the mind.—A view of the nature of the Emotional states which approaches more nearly to his own, though not developed with the analytical precision of Mr. Mill's, is contained in the Rev. Sydney Smith's "Lectures on Moral Philosophy;" which, although delivered early in the present century, were not published until the year 1850.

of Gloom may in like manner proceed alike from bodily or from mental uneasiness.—All these facts point, therefore, to the *singleness* of the centre from which the Emotional movements immediately proceed; and to its identity with the centre of the Sensori-motor actions.

795. That the Emotional and Volitional movements, however, differ as to their primal sources, is obvious, not merely from the fact that they are frequently in antagonism with each other—the Will endeavoring to restrain the Emotional impulse, and either succeeding in doing so, or being vanquished by the superior force of the latter—but also from the curious fact, which Pathological observation has brought to light, that muscles which will still act in obedience to emotional impulses may be paralyzed to the volitional, and *vice versâ*. Thus, for example, the arm of a man affected with hemiplegia, which no effort of his will could move, has been seen to be violently jerked under the influence of the mental agitation consequent upon the sight of a friend. And in the case of softening of the Spinal Cord already referred to (§ 704, *note*), the choreic movements, which were brought on by the mere approach of any one to the patient's bed, and still more strongly by putting a question to him, were most violent in the lower limbs, over which he had not the least voluntary power.—It is in the different forms of paralysis of the Facial nerve, however, which is the one most peculiarly subservient to the movements of Expression, that we have the best evidence of this distinctness. For it sometimes happens that the muscles supplied by this nerve are paralyzed so far as regards the Will, and yet are still affected by Emotional states of mind, and take their usual part in the automatic actions of Respiration, &c., retaining also their usual tension, so that no distortion is apparent unless Voluntary movements be attempted: thus, to select an action which may be performed either consensually, emotionally, or voluntarily, a patient affected with this form of paralysis cannot close the eyelid by an act of his will, although he winks when he feels the uneasy sensation that excites the action, and shuts the lids when the sudden approach of an object to the eye excites the fear of injury to that organ. On the other hand, the paralyzed condition may exist in regard to the automatic and emotional actions only, so that the muscles lose their tension, the mouth is drawn to one side, the movements of expression are not performed, and there is no involuntary winking: yet the Will may still exert its accustomed control, and may produce that closure of the lids which does not take place in responsiveness to any other impulse.¹—It has been inferred by Dr. M. Hall,² from cases of this kind, that the Emotional actions are among those which are performed by his “true spinal” system of nerves, as distinct from the sensori-volitional, and that they therefore fall under the general category of excito-motor actions. But it is obvious that they differ from these in their dependence, not merely upon sensations, but also upon higher states of mind; and there is no proof whatever that the same nerve-fibres do not serve for the conduction of the motor impulses proceeding from the two different mental sources, Volition and Emotion, as we have seen that they probably do for the volitional and automatic impulses (§ 753).³

¹ See the detailed accounts of such cases in Sir C. Bell's work on “The Nervous System of the Human Body;” also “Brit. and For. Med. Rev.,” vol. iv. p. 500, and vol. xiii. p. 553.

² “Memoirs on the Nervous System,” 1837, pp. 94, *et seq.*

³ In former editions of this Treatise, the author maintained, upon the principles advocated by Dr. M. Hall, that there must be distinct centres and conducting fibres for Volitional, Emotional, and Reflex movements. Having since arrived at what he believes to be a much simpler explanation of the phenomena, and one more in accordance with the facts of the case, he does not hesitate to make known the change in his convictions; and would hope that he may induce those who may have adopted his previous opinions, to reconsider the subject under the aspect in which he has now placed it.

796. The Emotions are concerned in Man, however, in many actions, which are in themselves strictly voluntary. Unless they be so strongly excited as to get the better of the Will, they do not operate downwards upon the Automatic centres, but upwards upon the Cerebral; supplying the *motives* by which the course of thought and of action is habitually determined. Thus, of two individuals, with differently constituted minds, one shall judge of everything through the medium of a gloomy morose temper, which, like a darkened glass, represents to his judgment the whole world in league to injure him; and his determinations being all based upon this erroneous view, its indications are exhibited in his actions, which are themselves, nevertheless, of an entirely voluntary character. On the other hand, a person of a cheerful, benevolent disposition looks at the world around as through a Claude Lorraine glass, seeing everything in its brightest and sunniest aspect; and, with intellectual faculties precisely similar to those of the former individual, he will come to opposite conclusions; because the materials which form the basis of his judgment are submitted to it in a very different condition. Various forms of Moral Insanity exhibit the same contrast in a yet more striking light. We not unfrequently meet with individuals, still holding their place in society, who are accustomed to act so much upon *impulse*, and to be so little guided by *reason*, as to be scarcely regarded as sane; and a very little exaggeration of such a tendency causes the actions to be so injurious to the individual himself, or to those around him, that restraint is required, although the intellect is in no way disordered, nor are any of the feelings perverted. Not unfrequently we may observe similar inconsistencies, resulting from the habitual indulgence of one particular feeling, or a morbid exaggeration of it. The mother who, through weakness of will, yields to her instinctive fondness for her offspring, in allowing it gratifications which she knows to be injurious to it, is placing herself below the level of many less gifted beings. The habit of yielding to a natural infirmity of temper often leads into paroxysms of ungovernable rage, which, in their turn, pass into a state of maniacal excitement. It is not unfrequently seen, that a delusion of the *intellect* (constituting what is commonly known as Monomania) has in reality resulted from a disordered state of the feelings, which have represented every occurrence in a wrong light to the mind of the individual. All such conditions are of extreme interest when compared with those which are met with amongst idiots, and animals enjoying a much lower degree of intelligence; for the result is much the same, in whatever way the balance between the feelings and the judgment (which is so beautifully adjusted in the well-ordered mind of Man) is disturbed; whether by a diminution of the Voluntary control or by an undue exaltation of the feelings and passions.

797. This double *modus operandi* of the Emotional consciousness—*downwards* through the nerve-trunks upon the muscular apparatus, and also upon many of the Organic functions (CHAP. XVIII.)—and *upwards* upon those Cerebral actions which give rise to the higher states of Mental consciousness—affords a satisfactory explanation of a fact which is practically familiar to most observers of Human nature, namely, that violent excitement of the feelings most speedily subsides, when these unrestrainedly expend themselves (so to speak) in their natural expressions. Thus it may be commonly noticed that those who are termed *demonstrative* persons are less firm and deep in their attachments, than those who manifest their feelings less; for, without any real insincerity or intentional fickleness, the strongly excited feelings of the former are rapidly calmed down by the expenditure of the impulse to action which they have generated; whilst in the latter the very same feelings acting internally acquire a permanent place in the psychical nature, and habitually operate as motives to the conduct. So, again, persons who are “quick-tempered,” manifesting great irascibility upon small provocations, real or supposed, are usually soon appeased,

and soon forget the affront; whilst those who make little or no display of anger, are very apt to brood over and cherish their feelings of indignation, and may visit them upon the unfortunate object of them when some favorable opportunity happens to occur, long after he had supposed that the occurrence which had given rise to them was forgotten. There is an instinctive restlessness, or tendency to general bodily movement, in some individuals, when they are suffering under emotional excitement; the indulgence of which appears to be a sort of safety-valve for the excess of nerve-force, whilst the attempt at its repression is attended with an increase in the excitement. Most persons are conscious of the difficulty of sitting still, when they are laboring under violent agitation, and of the relief which is afforded by active exercise; and this is particularly the case when the movements are such as naturally express the passion that is excited. Thus the combative propensities of the Irish peasant commonly evaporate speedily with the free play of the shillelagh; many irascible persons find great relief in a hearty explosion of oaths, others by a violent slamming of the door, and others (whose excitement is more moderate, but less transient) in a prolonged fit of grumbling.¹ So, again, if a ludicrous idea be suggested to our consciousness, occasioning an impulse to laugh, a hearty cachinnation generally works off the excitement, and we may be surprised a short time afterwards that such an absurdity should have provoked our risibility; but, if we restrain the explosion, the idea continues to "haunt" us, and is continually perturbing our trains of thought until we have given free vent to the expression of it. It is well known, again, that the depressing emotions are often worked off by a fit of crying and sobbing; and the "relief of tears" seems manifestly due to the expenditure of the pent-up nerve-force, in the production of an increased secretion. It is noticed in this case, too, that the absence of any such external manifestations of the depressing emotions gives them a much greater influence upon the course of thought, and upon the bodily state of the individual. Those who really "die of grief" are not those who are loud and vehement in their lamentations, for *their* sorrow is commonly transient, however vehement and sincere while it lasts; but they are those who have either designedly repressed any such manifestations, or who have experienced no tendency to their display; and their deep-seated sorrow seems to exert the same kind of anti-vital influence upon the organic functions that is exercised more violently by "shock;" producing their entire cessation without any structural lesion.²

¹ This view is most fully confirmed by certain phenomena of Insanity. It is a doctrine now generally received among practical men, that paroxysms of violent emotional excitement are much more likely to subside, when they are allowed to "work themselves off" freely, without any attempt at mechanical restraint; and maniacal patients are now placed, in all well-managed Asylums, in padded rooms, in which their movements can do no injury to themselves or others.—The following case was related to the Author by his friend Dr. Howe, of Boston, N. E., the instructor of Laura Bridgman. A half-idiotic youth in the Lunatic Asylum of that place was the subject (like many in his condition) of frequent and violent paroxysms of anger; and with the view of moderating these, it was suggested that he should be kept for some time every day in rather fatiguing exercise. Accordingly he was employed for two or three hours daily in sawing wood, to which task he made no objection; and the paroxysms of rage never displayed themselves except on Sundays, when his employment was intermitted. It having been considered, however, that it was better for him to spend part of that day in sawing wood than to be irascible during the whole of it, his occupation was continued through the whole week, when he became completely tamed down, and never gave any more trouble by his passionate displays.—This case appears to the author a most valuable confirmation of the doctrine laid down in the text; which is one whose practical bearings are most important.

² The Author once heard the following singular case of this kind.—One of two sisters, orphans, who were strongly attached to each other, became the subject of consumption; she was most tenderly nursed by her sister during a long illness; but on her death the other, instead of giving way to grief, in the manner that might have been anticipated, appeared perfectly unmoved, and acted almost as if nothing had happened. About a

798. Like the other sources of motor activity which have been already treated of, the Emotional tendencies may become morbidly excited, so as to produce a variety of movements which the Will vainly attempts to control. Of this abnormal condition there are several varieties. The most common is the *Hysterical* state (most frequent among females, though not peculiar to them) in which smiles and cries, laughter and sobbing, are strangely intermingled, and are brought on by the slightest emotional excitement. Now here the deficiency lies rather in the power of voluntary direction of the *thoughts*, than in the power of the will over the *muscles*; for such patients can be caused to restrain themselves, either by the presentation of some powerful motive (as the threat of severe discipline in the event of the return of the paroxysm), or by the more gradual exercise of the power of the Will in repressing the first access of emotional excitement by the withdrawal of the mind from the contemplation of all that induces it. For in such individuals the involuntary movements are but the expression of an unhealthy state of Mind; in which, either from an injudicious system of education, or from habitual want of self-control on the part of the individual, the emotions are allowed to exercise unchecked domination; and in which the Will is at last so weakened, that the subject of the disorder can scarcely be considered as a responsible being.—There are other Hysterical cases, again, in which there is less of mental disorder, but a greater physical excitability of the nervous system; so that most violent paroxysms of a tetanic or epileptic character are induced by very slight stimuli; and any emotional excitement may act as one among these stimuli, without, however, being at all excessive in its amount. Here, too, the Will may have a perfect control over the muscles at all other times than when they are thrown into violent action by the reflex excitability of the Automatic centres; and the treatment of such cases must be in great degree directed to the removal of such excitability, which frequently depends upon some morbid condition of the uterus or ovaries. At the same time, there is no doubt that an habitually perturbed state of the emotions, and especially of those relating to sexual love, has a most decided influence both in first inducing and in subsequently maintaining the automatic excitability; and that whilst mental tranquillity and self-regulation are almost essential to recovery, nothing promotes it so much as the supervention of a more favorable state of feeling, arising out of the prospective realization of desires repressed or of hopes deferred.—But there are other states in which Emotional excitement has a morbid power of inducing muscular movements; and this not through any deficiency of due control over the feelings, but often concurrently with a want of power to bring the Will to bear upon the muscles. This condition in its extreme form is known as *Chorea*, the nature of which will be hereafter examined more minutely; at present it will be sufficient to refer to some of those slighter forms of it which have received no definite appellation. Thus, there are individuals not at all remarkable for their emotional excitability, who cannot avoid making the most extraordinary grimaces whenever anything happens which in the least disturbs their usual equanimity, notwithstanding that they may make all the efforts in their power to prevent these.¹ The general muscular agitation of the

fortnight after her sister's death, however, she was found dead in her bed; yet neither had there been any symptoms during life, nor was there any post-mortem appearance, which in the least degree accounted for this event, of which no explanation seems admissible, except the depressing influence of her pent-up grief upon her frame generally, through the nervous system.

¹ The Author has a case at present under his observation, in which not merely the face, but the body and limbs, are thrown into the most extraordinary contortions, upon any agitation of the feelings, however trifling. This gentleman, a man of education and intelligence, of extreme benevolence of character, and a mind habitually well-regulated, can scarcely walk the streets without being liable to the induction of paroxysms of this kind, by causes that could scarcely have been supposed capable of thus operating. For example,

confirmed Stammerer is another case in point; here we have a deficiency in the power of the will over the Muscles, at first displayed only in regard to those of Voice; but when feelings of discomfort have been aroused by the failure of attempts to articulate, this want of voluntary control extends itself to the muscular system in general, which is thrown into a sort of paroxysmal effort, that usually subsides only with the explosion of the desiderated sound.

799. The influence of Emotional excitement may operate upon the muscles, however, not only in giving rise to movements which can be attributed to no other source, but also in affecting the power of the Will over the muscular system, by intensifying or weakening its action. For there can be no doubt that, under the strong influence of one class of feelings, the Will can effect results such as the individual would scarcely even attempt in his calmer moments; whilst the influence of another class of feelings is exercised in precisely the opposite direction, weakening or even paralyzing the force which was previously in full activity. But the same emotion does not always act in the same mode; thus, the fear of danger may nerve one man to the most daring and vigorous efforts to avert it, whilst another is rendered powerless, and gives way to unavailing lamentations; and the ardent anticipation of success may so unsettle the determinative energy of one aspirant, as to prevent him from attaining his object, whilst another may only be sustained by it in the toilsome struggle of which it is the final reward. Now in order that this variety may be explained, and the *modus operandi* of the Emotions on strictly Volitional¹ actions may be duly comprehended, we must here state two of the essential conditions of the latter; one of which is, that there should be not merely a distinct conception of the purpose *to be* attained, but also a belief that the purpose *will* or at least *may* be attained; whilst the other is, that the mental energy should be to a great extent withdrawn from other objects, and should be concentrated upon that towards which the Will is directed.—It is within the experience of every one, that there is nothing which tends so much to the success of a volitional effort, as a *confident expectation* of its success; whilst nothing is so likely to induce failure as the apprehension of it. Now, in so far as regards this mode of their operation alone, the tendency of the cheerful or joyous emotions being to suggest and keep alive the favorable anticipations, whilst that of the depressing emotions (of almost any kind) is to bring before the view all the chances of failure, the former will increase the power of the volitional effort, and the latter will diminish it. And they exert also a direct influence on the physical powers, through the organs of circulation and respiration; the heart's impulses being more vigorous and regular, and the aeration of the blood being more effectually performed, in the former condition than in the latter.—But an altogether contrary effect may be produced by the operation of these two classes of emotions through the second of the above channels. For the more completely the mental energy can be brought into one focus, and all distracting objects excluded, the more powerful will be the volitional effort; and the effect of

he was one day seized by one of these attacks, in consequence of seeing a man miss his footing (as he thought) in descending from the top of an omnibus; and the pleasurable excitement of meeting a friend usually induces the same result. The tendency varies very considerably in its degree according to the general condition of his health.

¹ The term *volitional* was some years since suggested by Dr. Symonds, in an excellent essay on the "Connection between Mind and Muscle," published in the "West of England Journal," 1835, as expressing more emphatically than *voluntary* the characters of an action proceeding from a distinct choice of the object, and from a determinative effort to attain it. The word *voluntary* may perhaps be applied to that wider class of actions, in which there is no very distinct choice or conscious effort, but in which the movement flows as it were spontaneously from the antecedent mental state; the consciousness, however, being fully awake to its performance, and the will being brought to bear determinately upon it, whenever an opposing motive tends to check the process or to alter its direction.

emotional excitement will thus in great degree depend upon the intellectual constitution which the individual may happen to possess. For if he have a considerable power of abstraction and concentration, and a full conviction that he has selected the best or the only means to accomplish his end, the intensest fear of the consequences of failure will only increase the force of the motive which prompts the effort; and the whole energy of which his nature is capable will display itself in the attempt. In a man of this temperament, the most joyous anticipation of success will produce no abatement of his efforts, no distraction of his attention; but will rather tend to keep him steady to his purpose until it shall have been accomplished; and then only does he dare to abandon himself to the current of ideas which rolls in upon his consciousness, so soon as his attention is free to entertain them. But the mind which is deficient in the power of concentrativeness is lamentably deranged by any kind of emotional excitement in the performance of any voluntary effort. For the fear of failure is constantly suggesting to him new distresses, weakens his confidence in any method suggested for his action, and makes him direct his attention, not to some fixed plan as the best or the only feasible one, but to any and every means that may present a chance of success, or may even serve to avert his thoughts from the dreaded catastrophe; whilst, on the other hand, the joyous anticipation of success leads him to allow his thoughts to direct themselves towards all its agreeable consequences, instead of fixing his intellectual and volitional energy upon the means by which success is to be attained.

800. If this be the true solution of the mode in which the Emotions chiefly affect the exercise of our Volitional powers, we should expect that similar effects might be induced, without any Emotional excitement, by means which affect the Intellectual consciousness alone; and that thus an action otherwise impossible to the individual may be performed by him, if (1) his mind be possessed with a full assurance of success, and (2) his entire motor energy be concentrated in the single exertion; whilst, on the other hand, an action which can be ordinarily performed with the greatest facility may become absolutely impossible to him, if (1) his mind be entirely possessed with the idea of its impossibility, or even (2) if, while his judgment entertains doubts of success, his attention be distracted by a variety of objects, so that he cannot bring it to bear upon the one effort which may alone be needed.—Now experience shows that such is really the case; but as this experience is the most remarkable in regard to certain states of the mind in which these two modes of operation may be worked in combination, it will be sufficient to refer to them for the demonstration (§§ 822, 825). And having now sufficiently considered the physiological conditions of the purely *Emotional* actions—which, in regard alike to the state of consciousness wherein they originate, and to the share which the Sensorial centres have in generating that state, may be considered as most nearly allied to the Consensual—we pass on to those *Psychical* operations, of which the Cerebrum must be regarded as the exclusive instrument.

801. Though it is now universally admitted among Psychologists that the mind does not come into existence with thoughts ready formed, or “innate ideas,” yet there are few who will deny that we are born with such *tendencies to thought*, that, when these are called into activity, certain results are sure to follow; and further, that whilst there is a certain fundamental similarity in these tendencies to thought, among all minds of ordinary constitution—so that, when excited to action in the same manner, the same results shall be evolved—yet that there is such a diversity in the relative degree of these tendencies in different individuals, as of itself becomes a source of different habits of thought. But the habits of thought are also determined in great degree by the influence of the emotions; for, whilst we are disposed to give ourselves up to the contemplation of subjects with which pleasurable feelings are connected, we are equally prone

to withdraw our attention from those that are accompanied with feelings of pain or discomfort; and, as the relative intensity of the different Emotional states varies greatly among different individuals, it becomes, as already noticed (§ 796), a source of extreme diversity in the formation of all those conclusions by which the conduct of life is directed, and tends to establish certain *uniformities of mental action for each individual*, which constitute what is termed his "character." But further, we are not to look merely at congenital peculiarities of psychical constitution, as the source of *original habitudes of thought*; for as the external conditions in which every individual is placed, differ to a certain extent from those which affect each one of his fellows, so does it happen that, as the development of every kind of capacity for mental action is augmented (like the nutrition of muscle and nerve) by its habitual exercise, the strength of that capacity, and its tendency to exert an active influence on the course of thought, will partly depend upon the degree in which circumstances call it into play, especially during the period when, in the natural progress of psychical evolution, it is first taking a prominent share in the operations of the mind. Hence there is a set of *acquired habitudes of thought*, which, no less than those dependent upon original constitution, determine the consequences of any particular impression upon the "ideational consciousness;" and which thus form part of the "character" of each individual, at any one period of his existence. But the psychical tendencies of every one undergo a consecutive change in the progress of life. Infancy, Childhood, Youth, Adolescence, Adult age, the period of Decline, and Senility, have all their characteristic phases of psychical as of physical development and decline; and this is shown, not merely in the general advance of the intellectual powers up to the period of middle life, and in their subsequent decay, but in a gradual change in the balance of the springs of action which are furnished by the emotional states, the pleasures and pains of each period being (to a certain extent) of a different order from those of every other. This diversity may be partly attributed to changes in the physical constitution; thus, the sexual feeling, which has a most powerful influence on the direction of the thoughts in adolescence, adult age, and middle life, has comparatively little effect at the earlier and later periods. So again, the thirst for novelty, and the pleasure in mental activity, which so remarkably characterize the young, when contrasted with the obtuseness to new impressions and the pleasure in tranquil occupations which mark the decline of life, may perhaps be attributed, in part at least, to the greater activity of the changes, both of disintegration and reparation, of which the nervous system (in common with the rest of the organized fabric) is the subject during the earlier part of life, and to its diminished activity as years advance. But there are other changes, which cannot be so distinctly traced to any physical source, but which yet are sufficiently constant in their occurrence, to justify their being regarded as a part of the developmental history of the psychical nature; so that each of the "Seven Ages of Man" has its own character, which may be with difficulty defined in words, but which is recognized by the apprehension, as it forces itself upon the experience, of every one.

802. It is universally admitted that, notwithstanding all the obvious diversities of Human character and Mental action, there are certain fundamental *uniformities* which may be traced throughout the whole of this series; and it is on the basis afforded by these, that the Science of Psychology is erected, to which may be applied, with a mere alteration of form, the definition given of Physiology in the first page of this treatise: "The object of the science of *Psychology* is to bring together, in a systematic form, the phenomena which normally present themselves during the existence of *thinking minds*; and to classify and compare these in such a manner as to deduce from them those general Laws or Principles which express the conditions of their occurrence, and to determine the causes to which they are attributable." As our present object,

however, is not to investigate the operations of the Mind itself, but only to consider their relations to those of the bodily Organism, we shall here enter into the examination of the nature and laws of psychical phenomena, only so far as may be requisite for the due explanation of those bodily changes which are related to them.—Of the nature of the connection between Nervous action and Mental action, we can form no distinct idea. Few Physiologists would be disposed to deny that the Cerebrum is the instrument of Psychical powers; and yet no one has been able to form a self-consistent theory of the mode in which it is so. Some who have attended exclusively to the close relationship which indubitably exists between corporeal and mental states have thought that *all* the operations of the Mind are but expressions or manifestations of material changes in the Brain; that thus Man is but a thinking machine, his conduct being entirely determined by his original constitution, modified by subsequent conditions over which he has no control, and his fancied power of self-direction being altogether a delusion; and that notions of “duty” or “responsibility” have no real foundation, Man’s character being formed *for* him and not *by* him, and his mode of action in each individual case being simply the consequence of the reaction of his Cerebrum upon the circumstances which called it into play.¹ On this view, what is commonly termed Criminality is but one form of Insanity, and ought to be treated as such; Insanity itself is nothing else than a disordered action of the Brain; and the highest elevation of Man’s Psychical nature is to be attained by due attention to all the conditions which favor his physical development. But again, there are others who have limited themselves to the cognizance of Mental phenomena, and who maintain the very opposite doctrine in regard to their nature and source. To them the Mind appears in the light of a separate immaterial existence, mysteriously connected, indeed, with a bodily instrument, but not dependent upon this in any other way for the conditions of its operation, than as deriving its knowledge of external things through its agency, and as making use of it to execute its determinations, so far as these relate to material objects. On this hypothesis, the operations of the Mind itself, having no relation whatever to those of Matter, are never themselves affected by conditions of the corporeal organism, whose irregularities or defects of activity only pervert or obscure the outward manifestations of the Mind, just as the light of the brightest lamp may be dimmed or distorted by passing through a bad medium; and, further, as the Mind is thus independent of its material tenement, and of the circumstances in which this may chance to be placed, but is endowed with a complete power of self-government, it is responsible for all its actions, which must be judged of by certain fixed standards. Those who most fully and legitimately carry out this doctrine are ready to maintain that even in the state of Intoxication, there is no truly mental perversion, and that, in spite of appearances, the *mind* of the Lunatic (*divinæ particula auræ*) is perfectly sound, its bodily instrument being alone disordered.

803. Now the first of these doctrines, legitimately designated the *Materialist*, recognizes certain great facts, on which the Physiologist can scarcely entertain a

¹ For the latest and most thorough-going expression of this doctrine, see the “Letters on the Laws of Man’s Nature and Development,” by Henry G. Atkinson and Harriet Martineau.—A few extracts will suffice to show the bearings of this system of philosophy. “Instinct, passion, thought, &c. are effects of organized substances.” “All causes are material causes.” “In material conditions, I find the origin of all religions, all philosophies, all opinions, all virtues, and ‘spiritual conditions and influences,’ in the same manner that I find the origin of all diseases and of all insanities in material conditions and causes.” “I am what I am; a creature of necessity; I claim neither merit nor demerit.” “I feel that I am as completely the result of my nature, and impelled to do what I do, as the needle to point to the north, or the puppet to move according as the string is pulled.” “I cannot alter my will, or be other than what I am, and cannot deserve either reward or punishment.”

doubt, notwithstanding the denial of their validity by those who have had comparatively little opportunity of observing them; we refer to the influence of the Body upon the Mind, of physical upon psychical states; an influence which no one will fail to recognize who studies its phenomena with freedom from preconceived theory. But, in reducing the Thinking Man to the level of "a puppet that moves according as its strings are pulled," it is so utterly antagonistic to our own consciousness of possessing a self-determining power—whilst, in putting aside, as mere delusions, what we feel to be the noblest conceptions of our nature, it is so thoroughly repugnant to the almost intuitive convictions which we draw from the simplest application of our Intelligence to our own Moral Sense—that we *feel* its essential fallacies with a certainty that renders logical proof quite irrelevant.—On the other hand, the purely *Spiritualist* doctrine is no less encumbered with difficulties, nor less opposed to facts of most familiar occurrence. For whilst it fully recognizes all that the other ignores, it ignores all that it recognizes; and in placing the Mind *outside* of the Body (so to speak), and in denying that the action of the Mind is ever disordered by corporeal conditions, it places us in the dilemma of either rejecting the plainest evidence, or of admitting that, after all, we know nothing whatever about the Mind itself, all that we *do* know being that lower part of our mental nature which operates on the body and is in its turn affected through it. For it must be admitted that, in the delirious ravings of Intoxication or of Fever, or in the perverted reasoning of the Lunatic, we have the same evidence of *mental* operation that we have in the sayings and doings of the same individuals in a state of sanity; and ample testimony to this effect is borne by those who have observed their own mental state during the access of these conditions, and who have described the alteration which takes place in the course of their thoughts, when as yet neither the sensorial nor the motor apparatus was in the least perturbed.¹ Nothing can be more plain to the unprejudiced observer, than that the introduction of Alcohol, or Opium, or other intoxicating agents, into the circulating system, perverts the action of the *mind*, disordering the usual sequence of phenomena most purely psychical, and occasioning new and strange results, which are altogether diverse from those of its normal operation. And when once this influence of physical conditions upon mental phenomena has been admitted, we can scarcely refrain from attributing to it a very wide range of action; seeing as we do how very much the due balance of the Emotions is dependent upon the purity of the blood and the general vigor of the system, and how strangely the normal succession of Intellectual operations may be interrupted or altered by local affections of the Cerebrum. No Physiologist could venture to deny, in the face of the crowd of facts which force themselves on his attention, that all Mental phenomena are inextricably linked with Vital changes in the Nervous system; and that the regular performance of the latter (which we have seen to be dependent on the due combination of physical and dynamical conditions) is essential to the normal sequence of the former. Nor can any one who duly examines the evidence which has been collected on the subject of Idiocy and Cretinism, feel any doubt that, in the original development of the Mental powers, the healthful activity of the Corporeal organism has just as important a share, as it has in their subsequent maintenance.

804. It may be fairly asked, then, whether there be any mode of combining the truths contained in the Materialist and Spiritualist doctrines, and of separating them from their associated errors; and whether any general expression can be framed, which may be in harmony alike with the result of scientific inquiry

¹ See especially the work of M. Moreau "Du Hachisch et de l'Aliénation Mentale, Etudes Psychologiques," Paris, 1845; and the well-known "Confessions of an English Opium-Eater."

into objective facts, and with those simple teachings of our own consciousness, which must, after all, be recognized as affording the ultimate test of the truth of all Psychological doctrines. The Author is not without hope that some approach to such a solution may be found in the views of which the following is an outline; and although far from regarding them as expressing the *whole* truth, or as solving *all* the difficulties of the subject, he considers that they express so much *more* than any scheme he has ever heard of, that he ventures to request for them a thoughtful consideration on the part of those who feel, with him, the importance of attaining some definite conceptions on this head.—In the first place, it may be remarked that the whole tendency of Philosophical Investigation at the present day is to show the utter futility of all the controversies which have been carried on with regard to the relation of *Mind* and *Matter*. The essential nature of these two entities is such, that no relation whatever *can* exist between them. Matter possesses extension, or occupies space; whilst Mind has no such property. On the other hand, we are cognizant of Matter only through its occupation of space, of which we are informed through our senses; we are cognizant of the existence of Mind by our direct consciousness of feelings and ideas, which are to us the most certain of all realities. But, what is perhaps a more important distinction, the existence of Matter is essentially *passive*; left to itself, it always impresses our consciousness in one and the same mode; and any change in its condition is the consequence of external agency. What have been termed the active states of matter, are really the manifestations of *forces*, of which we can conceive as having an existence independent of matter, and as having no other relation to it than that which consists in their capability of changing its state. Thus Water continues unchanged so long as its temperature remains the same; but the dynamical agency of Heat occasions that mutual repulsion between its particles, which transforms it from a non-elastic liquid into an elastic vapor; and all that heat is given forth from it again, when the aqueous vapor is transformed back to the liquid state. On the other hand, the existence of Mind is essentially *active*; all its states are states of change, and we know nothing whatever of it save by its changes. Sensations, Perceptions, Ideas, Emotions, Reasoning processes, &c., in fact every term which expresses a Mental state, is a designation of a phase of mental existence which intervenes between other phases, in the *continual succession* of which our idea of Mind consists.

805. But whilst between Matter and Mind it is utterly vain to attempt to establish a relation of identity or analogy, a very close relation may be shown to exist between *Mind* and *Force*. For in the first place, Force, like Mind, can be conceived of only as in a state of activity; and our idea of it essentially consists in the succession of different states, under which its manifestations present themselves to our consciousness. But, secondly, our consciousness of Force is almost as direct, as is that of our own mental states; our notion of it being based upon our internal sense of the exertion which we determinately make to develop one form of Force, which may be taken as the type of all the rest—that, namely, which produces or which resists motion. When we attempt to lift a weight, or to put a windlass in motion, or to stop a horse that is running away, we are directly conscious of a Mental exertion, as the immediate and invariable antecedent of the development of motor power through the contraction of our muscles; and the connection of the two is further established by that “sense of effort” which we intuitively refer to the muscles themselves, arising as it does from their own condition (§ 754); and thus we are led to feel that, in this particular case, Force must be regarded as the direct expression or manifestation of that Mental state which we call Will. The analogy becomes stronger, when we trace it into the relations which these two agencies respectively bear to Matter. For in the phenomenon of Voluntary movement, we can scarcely avoid seeing that Mind is *one* of the dynamical agencies which is capable of acting on Matter;

and that, like other such agencies, the mode of its manifestation is affected by the nature of the material *substratum* through which its influence is exerted. Thus, the Physiologist knows full well that the immediate operation of the Will is not upon the Muscles, but upon the Brain, wherein it excites that active state of Nervous matter, which he designates as the operation of Nerve-force; and that the propagation of this force along the Nerve-trunks is the determining cause of the Muscular contraction, which is the immediate source of the motor power. He knows, too, that this dynamical metamorphosis is effected (like every other analogous change) by the intermediation of a peculiar material *substratum*, which itself undergoes a change of condition; the components both of the Nervous and Muscular substances ceasing to exist under their previous forms, and entering into new combinations.—Thus, then, we have evidence, in what we know of the physiological conditions under which Mind produces Motion, that certain forms of Vital Forces constitute the connecting link between the two; and it is difficult to see that the dynamical agency which we term Will is more removed from Nerve-force, on the one hand, than Nerve-force is removed from Motor force on the other. Each, in giving origin to the next, is itself expended, or ceases to exist *as such*; and each bears, in its own intensity, a precise relation to that of its antecedent and its consequent.—But we have not only evidence of the excitement of Nerve-force by Mental agency; the converse is equally true, Mental activity being excited by Nerve-force. For this is the case in every act in which our Consciousness is excited through the instrumentality of the Sensorium, whether its condition be affected by impressions made upon Organs of Sense, or by changes in the state of the Cerebrum itself; a certain active condition of the nervous matter of the Sensorium, being (we have every reason to believe) the immediate antecedent of *all* consciousness, whether sensational or ideational. And thus we are led to perceive that, as the power of the Will can develop Nervous activity, and as Nerve-force can develop Mental activity, there must be a *Correlation* between these two modes of dynamical agency, which is not less intimate and complete than that which exists between Nerve-force on the one hand, and Electricity or Heat on the other (§ 365). This idea of Correlation of Forces will be found completely to harmonize with those phenomena already referred to, which unmistakably indicate the influence of physical conditions in the determination of mental states (§ 803); whilst, on the other hand, it explains that relation between Emotional excitement and bodily change, which is manifested in the subsidence of the former when it has expended itself in the production of the latter (§ 797). And further, it will be found no less applicable to the explanation of all that *automatic* action of the Mind, which consists in the succession of ideas, according to certain “laws of thought,” without the exercise of any control or direction on the part of the individual to whose consciousness they present themselves, and which manifests itself in the action of those ideas upon the centres of movement. For this succession must be regarded as the exponent of a series of changes taking place in the Cerebrum itself, in response to impressions made upon it; whilst the motions which proceed from these must be considered as being no less the results of its “reflex” operation, than are the “consensual” of the reflex action of the Sensory Ganglia, and the “excito-motor” of that of the Spinal Cord.¹ For all Physiological purposes, then,

¹ The application of the doctrine of “reflex action” to the Brain was fully developed by Dr. Laycock of York, in a paper “On the Reflex Function of the Brain,” read before the Medical Section of the British Association at its meeting in York, Sept. 1844, and afterwards published in the “Brit. and For. Med. Rev.,” vol. xix.—Not having recognized what appears to the Author the essential distinction, both in their anatomical and physiological relations, between the Sensory Ganglia and the Cerebrum or Hemispheric Ganglia, Dr. Laycock did not mark out the distinction between the “*sensory-motor*” or “consensual” actions, which are the manifestations of the reflex power of the former, and the “*ideo-*

we may consider the nervous matter of the Cerebrum as the *material substratum* through which the metamorphosis of Nerve-force into Mind-force, and of Mind-force into Nerve-force, is effected; and, as every such metamorphosis involves, like other analogous transformations, a change in the state of the matter through which it is effected, so should we expect that Mental activity would involve the disintegration of the Nervous substance which thus ministers to it: and such appears (§§ 358-362), from a variety of evidence, to be really the case.

806. It is obvious that the view here taken does not in the least militate against the idea that Mind may have an existence altogether independent of the Material body through which it here manifests itself. All which has been contended for is that the connection between the Mind and Body is such, that each has, in virtue of its constitution, a determinate relation to the other, in this present state of existence (which is all of which Science can legitimately take cognizance); and that the actions of our Minds, *in so far as they are carried on without any interference from our Will*, may be considered (in the limited sense formerly explained, § 395) as functions of the Cerebrum.—On the other hand, in the control and direction which the Will has the power of exerting over the course of the thoughts, we have the evidence of a new and independent power, which is entirely opposed in its very nature to all the automatic tendencies, and which, according as it is habitually exerted, tends to render the individual *a free agent*. And, truly, in the existence of this Power, which is capable of dominating over the very highest of those operations that we know of as connected with corporeal states, we find a better evidence than we gain from the study of any other part of our psychical nature, that *there is* an entity wherein Man's nobility essentially consists, which does not depend for its existence on any play of physical or vital forces, but makes these subservient to its determinations. It is, in fact, in virtue of the Will, that we are *not* mere thinking automata, mere puppets to be pulled by suggesting-strings, capable of being played upon by every one who shall have made himself master of our springs of action. It may be freely admitted that such thinking automata *do* exist: for there are many individuals whose Will has never been called into due exercise, and who gradually almost entirely lose the power of exerting it, becoming the mere creatures of habit and impulse; and there are others in whom (as we shall hereafter see) such states are of occasional occurrence; whilst in others, again, they may be artificially induced. And it is by the study of those states in which the Will is completely in abeyance—the course of thought being *entirely* determined by the influence of suggestions upon the Mind, whose mode of reaction upon them depends upon its original peculiarities and subsequently acquired habits—and by the comparison of such states with that in which an individual, in full possession of all his faculties, and accustomed to the habitual control and direction of his thoughts, determinately applies his judgment to the formation of a decision between various plans of action, involving the appreciation of opposing motives—that we shall obtain the most satisfactory ideas of what share the Will really takes in the operations of our minds and in the direction of our conduct, and of what must be set down to the Automatic operation of our psychical nature.

807. We shall now briefly pass in review the chief of those modes of Psychical activity, which constitute in the aggregate what we are accustomed to term the Intellectual Powers. And the first of these in order of development, and that which lies at the foundation of all the rest, is the *Association of Ideas*, that is,

motor" actions which depend upon the reflex action of the latter. But in adopting that part of it which is strictly applicable to the Cerebrum, and in applying it to those various states which agree in the common characteristic of the existence of Mental Activity without Volitional control, the Author considers that he is merely giving greater definiteness and a wider application to Dr. Laycock's doctrine.

the formation of such a connection between two or more ideas, that the consciousness of one tends to bring the other also before the consciousness; or, in other words, each tends to *suggest* the other. Certain laws of Association, expressive of the conditions under which this connection is formed, and the mode in which it acts, have been laid down by Psychologists; and these may be concisely stated as follows: 1. *Law of Contiguity*. Two or more states of consciousness, habitually existing together or in immediate succession, tend to cohere, so that the future occurrence of any one of them is sufficient to restore or revive the other. It is thus (to take a simple illustration) that the impressions made upon our sensational consciousness by natural objects, which are usually received through two or more senses at once, are compacted into those aggregate notions, which, however simple they may appear, are really the result of the intimate combination of many distinct states of ideation. Thus our notion of the *form* of an object is made up of separate notions derived from the visual and muscular senses respectively; our notion of the character of its surface, from the combination of impressions received through the visual and tactile senses; and with both of these our notion of color, as in the case of an orange, may be so blended, that we do not readily conceive of its characteristic form and surface, without also having before our minds the hue with which these have been always associated in our experience. So, again, the external aspect of a body suggests to our minds its internal arrangement and qualities, such as we have before found them invariably to be; thus, to use the preceding illustration, the shape and color of the orange bring before our consciousness its fragrant odor and agreeable taste, as well as the internal structure of the fruit. And our notion of an orange must be considered as the aggregate of all the preceding ideas.—Not only the different ideas excited by one object, but those called up by objects entirely dissimilar, may thus come to be associated, provided that the mind has been accustomed to the presentation of them in frequent contiguity one with the other. Such conjunctions may be natural, that is, they may arise out of the “order of nature;” or they may be artificial, being due to human arrangements; all that is requisite is, that they should have sufficient permanence and constancy to habituate our minds to the association.—Of this law of contiguity, moreover, we have a most important example in the association which the mind early learns to form between successive *events*, so that, when the first has been followed by the second a sufficient number of times to form the association, the occurrence of the first suggests the *idea* of the second; if that idea be verified by its occurrence, a definite *expectation* is formed; and if that expectation be unfailingly realized, the idea acquires the strength of a *belief*. And thus it is that we come to acquire that part of the notion of “cause and effect,” which consists in invariable and necessary sequence (see p. 34), and to form our fundamental conception of the invariability of Nature. It is by the same kind of operation, again, that we come to employ words as the symbols of ideas, for the convenience of intercommunication and reference (§ 790); a certain number of repetitions of the sound, concurrently with the sight of the object, or the suggestion of the notion of that object, being sufficient to establish the required relation in our minds. Of the large share which this kind of action takes in the operations of *Memory* and *Recollection*, evidence will be presently given.—The readiness with which these Associations are formed varies greatly in different individuals and at different periods of life. As a general rule, it is far greater during the period of growth and development, than after the system has come to its full maturity; and remembering that those new functional relations between other parts of the Nervous system, which give rise to the “secondarily-automatic” movements or acquired instincts, are formed during the same period, it seems fair to surmise that the substance of the Cerebrum *grows to* the conditions under which it is habitually exercised; and

as its subsequent nutrition (according to the general laws of assimilation, § 591) takes place on the same plan, we can understand the well-known force of early associations, and the obstinate persistence of early habits of thought.

808. But a not less important "tendency to thought," and one whose operation is more concerned in all the higher exercises of our reasoning faculties, is that which may be expressed under the designation of the *Law of Similarity*, and which consists in the general fact that any present state of consciousness tends to revive previous states that are similar to it. It is thus that we instinctively invest a new object with the attributes we have come to recognize in one that we have previously examined, to which the new object bears such a resemblance, that the sight of the latter suggests those ideas which our minds connect with the former. Thus, we will suppose a man to have once seen and eaten an orange; when he sees an orange a second time, although it may be somewhat larger or smaller, somewhat rougher or smoother, somewhat lighter or darker in hue, he recognizes it as an orange, and mentally assigns to it the fragrance and sweetish acidity of the one which he had previously eaten. But if, instead of being yellow, the fruit were green, he would doubt of its being an orange; and if assured that it still was, but had not come to maturity, he would no longer expect to find it sweet, the notion of intense acidity being suggested to his mind by his previous experience of other green and unripe fruit.—It is in virtue of this kind of action, that we extend those elementary notions which are primarily excited by sensation, to new objects. Thus, the idea of roundness (like other notions of form) is originally based on the combination of the muscular and visual sensations, and must be first acquired by a process of considerable complexity; but when once derived from the examination of a single object, it is readily extended to other objects of the same character.—So, again, it is by the operation of this mental tendency, that we recognize similarity where it exists in the midst of difference, and separate the points of agreement from those of discordance; and this, again, not merely as regards objects which are before our consciousness at the same time or in close succession, but also with regard to all past states of consciousness. It is thus that we *identify* and *compare*, that we lay the foundations of classification, and that we recover all past impressions which have anything in common with our present state of consciousness. The intensity of this tendency, and the habitual direction which it takes, vary extremely in different individuals. Some have so great an incapacity for recognizing similarity, that they can only perceive it when it is in marked prominence, their minds taking much stronger note of differences; whilst others have a strong bias for the detection of resemblances and analogies, and discover them where ordinary minds cannot recognize them. Some, again, address themselves to the discovery of similarity among objects of sense, whilst others study only those ideas which are the objects of our internal consciousness; and it is in the detection of what is essentially similar among the latter, that all the higher operations of the intellect essentially consist. Even here we find that some are contented with superficial analogies, whilst others are not satisfied until they have penetrated by analysis to the depths of the subject, and are able to compare its fundamental idea with others of like kind.—It is this habit of mind, which is of essential value in all the sciences of Classification and Induction. Thus, in the formation of generic definitions to include the characters which a number of objects have in common, their subordinate differences being for a time left out of view, we are entirely guided by the recognition of similarity between the objects we are arranging; and the same is the case in the formation of all the higher groups of families, orders, and classes, the points of similarity becoming fewer and fewer as we proceed to the more comprehensive groups, whilst those of difference increase in corresponding proportion. The sagacity of the Naturalist is shown in the selection of the *best* points of resemblance, as the

foundation of his classification; the value of characters being determined, on the one hand by their constancy, and on the other by their degree of coincidence with important features of general organization or of physiological history.¹ In the determination of Physical laws, the process is somewhat of the same kind; but the similarities with which we have here to do, are not, as in the preceding case, objective resemblances, but exist only among our subjective ideas of the nature and causes of the phenomena brought under our consideration. Thus, there is no obvious relation between the fall of a stone to the Earth, and the motion of the Moon in an elliptical orbit around it; but the penetrating mind of Newton detected a relation of *common causation* between these two phenomena, which enabled him to express them both under one law. It was by a like intellectual perception of similarity, that Franklin was led to determine the identity of lightning with the spark from an electrical machine. And it would be easy to show that it has been in their extraordinary development of this power of recognizing *causative* similarity, leading to a kind of intuitive perception of its existence where no adequate ground can be assigned by the reason for such a relationship, that those men have been eminent, who have done the most to advance science by the process of inductive generalization.—The same kind of mental action is also employed in the contrary direction; namely, in that extension of generic definitions to new objects, which takes place upon every discovery of a new species; and in that application of general laws to particular instances, which constitutes deductive reasoning. We may trace it, again, even in the extension of the meaning of words so as to become applicable to new orders of ideas, in consequence of the resemblance which the latter are felt to bear to those of which the words were previously the symbols: as in the application of the word “head,” which primarily designated the most elevated part of the human body, in such phrases as the “head of a house,” the “head of a state,” the “head of an army,” the “head of a mob,” in each of which the idea of superiority and command is involved; or in the phrases the “heads of a discourse,” or the “heads of an argument,” in which we still trace the idea of authority or direction; or in the phrases the “head of a table,” the “head of a river,” in which the idea of superiority or origin comes to be locally applied; or in the “head of a bed,” or “head of a coffin,” in which we have the more distinct local association with the position of the head of man. Of the foregoing applications, those first cited belong to the nature of a metaphor, which has been described to be “a simile comprised in a word;” and the judicious use of metaphors, which frequently adds force as well as ornamental variety to the diction, is most seen amongst men who possess a great power of bringing together the “like” in the midst of the “unlike.”—Every effort, in fact, to trace out unity, consistency, and harmony, in the midst of the wonderful and (at first sight) perplexing variety of objects and phenomena amidst which we are placed, is a manifestation of this tendency of the Human Mind; and, when conducted in accordance with the highest teachings of the Intellect, or guided by that Intuition which in some minds supersedes and anticipates all reasoning, it enables us to rise towards the comprehension of that great Idea of the Universe, which we believe to exist in the Divine Mind in a majestic simplicity of which we can here but faintly conceive, and of which all the phenomena of Nature are but the manifestations to our consciousness.—It may be remarked that this mode of action of the mind is in some degree opposed to the preceding; for whilst *contiguity* leads to the arranging of ideas as they happen to present themselves in

¹ Thus, for example, it is now generally admitted, amongst Zoologists, that the Implantental Mammalia should constitute a separate sub-class, in virtue of the peculiar conformation of their generative apparatus, instead of being distributed among other Orders, as they were left by Cuvier.

natural juxtaposition, and thus to induce a routine which is often most unmeaning (§ 836), *similarity* breaks through juxtaposition, and brings together like objects from all quarters. And it is further to be observed, that, with this purely intellectual operation, there is frequently associated a peculiar feeling of pleasure, which constitutes a true emotional state. All the discoveries of identification, where use and wont are suddenly broken through, and a common feature is made known among objects previously looked on as entirely different, produce a flash of agreeable surprise, and the kind of sparkling cheerfulness that arises from the sudden lightening of a burden. There are few who devote themselves to the pursuit of Science, who do not experience this pleasure, either from the detection of new relations of similarity by their own perception of them, or in the recognition of them as developed by others. It is, however, much more intense in some minds than in others; and according to its intensity, will it act as a motive in the prosecution of scientific inquiry amidst discouragements and difficulties. It is recorded of Newton, that when he was bringing his great idea of the causative relation between terrestrial gravity and the motions of the heavenly bodies to the test of calculation, his agitation became so great that he could not complete the computation, and was obliged to request a friend to do so.

809. Although the single relations established between ideas, either through contiguity or through similarity, may suffice for their mutual connection; yet that connection becomes much stronger when two or more such relations exist consentaneously. Thus, if there be present to our minds two states of consciousness, each of them associated, either by contiguity or similarity, with some third state that is past and "out of mind" at the time, the compound action is more effective than either action would be separately; that is, the separate suggestions might be too weak to revive the past state of consciousness, but reproduce it by acting together. Of this, which has been termed the *Law of Compound Association*, we have examples continually occurring to us in the phenomena of Memory; but it is especially brought into operation in the voluntary act of Recollection (§ 813).—Another mode in which the associative tendency operates, is in the formation of aggregate conceptions of things that have never been brought before our consciousness by sensory impressions. This faculty, which has been termed that of *Constructive Association*, is the foundation of Imagination; and it is exercised in every other mental operation in which we pass from the known to the unknown. When we attempt to form a conception, which shall differ from one that we have already experienced as a matter of objective reality, by the introduction of only a single new element—as when we imagine a brick building replaced by one of stone in every respect similar as to size and form—we substitute in our minds the idea of stone for that of brick, and associate it by the principle of contiguity with those other ideas, of which that of the whole building is an aggregate. So, again, if we conceive a known building transferred from its actual site to some other already known to us, we dissociate the existing combinations, and keep together the ideas which were previously separated, until their contiguity has so intimately united them, that the picture of the supposed combination may present itself to the mind exactly as if it had been a real scene which we had long and familiarly known. By a further extension of the same power, we may conceive the elements to be varied, as well as the mode of their combination; and thus we may bring before our consciousness a representation, in which no particular has ever been before our minds under any similar aspect, and which is, therefore, *as a whole*, entirely new to us, notwithstanding that, when we decompose it into its ultimate elements, we shall find that each of these has been previously before our consciousness. Such a representation, by being continually dwelt on, may come to have all the force and vividness of one derived from an actual sensory

impression; and we can scarcely conceive but that the actual state of the Sensorium itself must be the same in both cases, though this state is induced in the one case by an act of Mind, and in the other by Material conditions. A very common *modus operandi* of this "constructive association" is the realization of a landscape, a figure, or a countenance, from a pictorial representation of it. Every picture must be essentially defective in some of the attributes of the original, as, for example, in the representation of the *projection* of objects; and all, therefore, that the picture can do is to *suggest* to the mind an idea, which it completes for itself by this constructive process, so as to form an aggregate which may or may not bear a resemblance to the original, according to the fidelity of the picture, and the mode in which it acts upon the mind of the individual. Thus to one person a mere sketch shall convey a much more accurate notion of the object represented, than a more finished picture shall give to another; because, from practice in this kind of mental reconstruction, the former recognizes the true meaning of the sketch, and fills it up in his "mind's eye;" whilst the latter can see little but what is actually before his bodily vision, and interprets as a literal presentation that which was intended merely as a suggestion. And it is now generally admitted that in all the higher forms of representative Art, the aim should be, *not* to call into exercise the faculty of mere objective *realization*, but to address that higher power of *idealization*, which invests the conception suggested by the representation with attributes more exalted than those actually possessed by the original, yet not inconsistent with them. It depends, however, as much on the mind of the individual addressed, as on that of the Artist himself, whether such conceptions shall be formed; since by those who do not possess this power, the highest work of Art is only appreciated, in so far as it enables them to realize the object which it may represent.

810. Having thus pointed out what may be considered the most elementary forms of Mental Action,¹ we shall briefly pass in review those more complex operations, which may be regarded as in great part compounded of them. The capacity for performing these is known as the Intellect or the Reasoning Power; and the capacities for those various forms of Intellectual activity, which it is convenient to distinguish for the sake of making ourselves more fully acquainted with them, are termed Intellectual Faculties. It appears to the author, however, to be a fundamental error to suppose that the entire Intellect can be *split up* into a certain number of faculties; for each faculty that is distinguished by the Psychologist, expresses nothing else than a *mode of activity*, in which the whole power of the mind may be engaged at once—just as the whole power of the locomotive steam-engine may be employed in carrying it forwards or backwards, according to the direction given to its action. And if this be true, it must be fundamentally erroneous to attempt to parcel out the Cerebrum into distinct "organs" for these respective faculties; the whole of it (so far as we can form a judgment) being called into operation in every kind of mental activity.

811. That state in which the consciousness is actively directed to a Sensorial change—whether this change originate in impressions received through the external organs of sense, or in operations of the Cerebrum—is termed *Attention*. Like the other states of Mental Activity, which will come under our consideration, it may be either *voluntary* or *automatic*; that is, we may either "fix our attention" on an object of consciousness by an effort of the Will, or the atten-

¹ In the foregoing brief exposition of the laws and leading phenomena of Mental Association, the author has derived great aid from the excellent article on "The Human Mind," contributed to Messrs. Chambers's "Information for the People," by his friend Mr. Alexander Bain.—Though not agreeing with all the views expressed in that article, the author can cordially recommend the perusal of it to his readers.

tion may be drawn towards it by the attractive qualities of the object itself, and may be held to it until it is intentionally detached, or until the mind has become satisfied by the persistence of one kind of impression. The intentional direction of the attention to external objects is what is commonly known as *Observation*; those men being designated as "observant," who do not allow their attention to be so far engrossed by one object or occurrence, or (as very frequently happens) by their own trains of thought, as to exclude the cognizance of what may be taking place around them; whilst those are spoken of as "unobservant," who, by allowing their consciousness to remain fixed upon some one object or train of thought, prevent it from receiving a legitimate degree of influence from other impressions received and transmitted to the Sensorium by the organs of sense. We shall hereafter (CHAP. XV., Sect. 1) more particularly examine the remarkable influence of Attention in augmenting the acuteness of sensory impressions; but it may be here remarked, that the same influence extends itself to the perception of our own mental states; and that, as will be presently shown (§ 817), it is in the degree of Attention which we automatically or voluntarily bestow on certain ideas presented to us by suggestion, that those peculiar modes of thought, which are sometimes termed Intellectual Faculties, essentially consist.—The intentional direction of the consciousness to what is passing *within* us, is sometimes designated as Reflection, but is more appropriately termed *Introspection*.

§12. The reproduction of past states of consciousness by either of the forms of suggestive action already described, constitutes what is known as *Memory*.¹—There seems much ground for the belief, that *every* sensory impression which has been once recognized by the perceptive consciousness, is registered (so to speak) in the Cerebrum, and may be reproduced at some subsequent time, although there may be no consciousness of its existence in the mind during the whole intermediate period. Instances are of very frequent occurrence, in which ideas come up before the mind during delirium or dreaming, and are ex-

¹ It is commonly stated that Memory consists in the renewal of past sensations and of the ideas they have excited; but it may be questioned whether we primarily retain anything else than the impressions left by *ideas*, and whether the recall of *sensations* is not a secondary change, dependent upon the reaction of ideational (Cerebral) changes upon the Sensorium. For if we wish to reproduce any sensational state—whether visual, auditory, olfactive, gustative, or tactile—we first recall the notion of some object by which that state was formerly produced; and it is only by keeping that notion strongly before our consciousness, that we can bring ourselves to see, hear, smell, taste, or feel, that which we desire to experience. Indeed, it is not every one who can thus reproduce sensational states, the general notion being most commonly all that is arrived at; of this we have a good illustration in the conception we form of the face of an absent friend, it being only a comparatively small number of persons who are able to reproduce the visual image with sufficient distinctness to serve as a model for delineation, although a much larger number would be able to say how far such a delineation realized their own conception of the countenance, and to point out in what it might depart from this. It is a further confirmation of this view, that the *expression* of a countenance, which directly appeals to our ideational consciousness, is much more distinctly remembered by most persons than the *features*, the recognition of which is more dependent upon the recall of antecedent sensational states.—What is true of the act of Recollection in this particular is probably true also in a great degree of *spontaneous* Memory; but perhaps we should admit that the renewal of past states of sensational consciousness may be effected by fresh sensory impressions which are closely allied to them; as would seem probable from the fact that we find ourselves comparing the new sensations with the old, without having in the mean time formed any distinct conception of the object by which the old were produced.—It may, however, be pretty certainly affirmed that the Sensory Ganglia do not themselves register *sensory impressions*; and that these can only be reproduced afresh by external objects, or by the occurrence of ideational changes in the Cerebrum. On the other hand, the Cerebrum seems to act quite independently of the Sensory Ganglia, in reproducing *ideas*; save in so far as the results of its action must (on the theory advanced) be impressed on the Sensorium, before we can be rendered conscious of them.

pressed at the time or are subsequently remembered, although the individual cannot himself retrace them as having ever before been present to his consciousness; they being yet proved to have been so at some long antecedent period. A very extraordinary case of this kind has been recorded, in which a woman, during the delirium of fever, continually repeated sentences in languages unknown to those around her, which were found to be Hebrew and Chaldaic; of these she stated herself, on her recovery, to be perfectly ignorant; but on tracing her former history, it was ascertained that, in early life, she had lived as servant with a clergyman, who had been accustomed to walk up and down his passage, repeating or reading aloud sentences in these languages, which she must have retained in her memory unconsciously to herself.—Of the nature of the change by which sensory impressions are thus registered, it seems in vain to speculate; there can be little question, however, that it is in some way dependent upon the nutrition of the Cerebrum, since we see that alterations in that function have a marked effect upon the Memory. Thus, in the case just cited, we can scarcely doubt that some alteration either in the circulation of the blood through the cortical substance of the Cerebrum, or in the quality of the fluid, was the cause of changes, which, transmitted downwards to the Sensorium, reproduced the former sensations; just as a disturbance of the circulation in the retina produces the sensation of flashes of light or other visual phenomena. Again, it is certain that disease or injury of the Cerebrum may destroy the Memory generally, or may affect it in various remarkable modes. Thus we not unfrequently meet with cases, in which the brain has been weakened by attacks of epilepsy or apoplexy in such a manner as to prevent the reception of any *new* impressions; so that the patient does not remember anything that passes from day to day; whilst the impressions of events which happened *long before* the commencement of his malady, recur with greater vividness than ever. On the other hand, the memory of the long since past is sometimes entirely destroyed; whilst that of events which have happened subsequently to the malady, is but little weakened. The memory of particular classes of ideas is frequently destroyed; that of a certain language, or some branch of science, for example. The loss of the memory of words is another very curious form of this disorder, which not unfrequently presents itself: the patient understands perfectly well what is said, but is not able to reply in any other terms than *yes* or *no*—not from any paralysis of the muscles of articulation, but from the incapability of expressing the ideas in language. Sometimes the memory of a particular class of words only, such as nouns or verbs, is destroyed; or it may be impaired merely, so that the patient mistakes the proper terms, and speaks a most curious jargon. So, again, a person may remember the letters of which a word is composed, and may be able to *spell* his wants, though he cannot speak the *word* itself; asking for *bread* (for example) by the separate letters b, r, e, a, d. A very curious affection of the memory is that in which the *sound* of spoken words does not convey any idea to the mind; yet the individual may recognize in a written or printed list of words, those which have been used by the speaker; and the *sight* of them enables him to understand their meaning. Conversely, the sound of the word may be remembered, and the idea it conveys fully appreciated; but the visual memory of its written form may be altogether lost, although the component letters may be recognized. For this class of phenomena, in which there is rather a severance of the associative connections that have been formed between distinct states of consciousness, than an actual annihilation of the impression left by any of the latter, the term “dislocation of memory” has been proposed by Dr. Holland;¹ but, as he justly remarks, “no single term can express the various effects of accident, disease, or decay, upon

¹ See his “Chapters on Mental Physiology,” p. 146.

this faculty, so strangely partial in their aspect, and so abrupt in the changes they undergo, that the attempt to classify them is almost as vain as the research into their cause." It is, perhaps, in the sudden changes produced by blows or falls, that we have the most extraordinary examples of this kind of disturbance; and it is scarcely less extraordinary, that there should sometimes be a no less sudden recovery of the lost impression, which we can scarcely do wrong in attributing to the return of the Cerebral organization to that previous condition from which it had been perverted.—When we take all these phenomena into consideration, we can scarcely resist the conclusion that every act of perceptive consciousness produces a certain modification in the nutrition of the Cerebrum; that the new mode of nutrition is continued according to the laws of Assimilation already adverted to; and that thus the Cerebrum forms itself in accordance with the use that is made of it. And this unconscious storing up of impressions, which can only be brought before the consciousness (under ordinary circumstances at least) by the connecting link of associations, affords a powerful argument for the doctrine which has already been frequently referred to as probable—that the Cerebrum is not itself a centre of consciousness, but that we only become conscious of *its* states, in the same manner as we do of those of the Retina and of other surfaces for the reception of external impressions, by means of the communication of the changes which take place in it to the Sensorium.

813. Although the term Memory is very commonly used to designate the *intentional* recall of past states of consciousness, as well as their spontaneous or automatic recurrence, yet it is properly restricted to the latter operation; the term *recollection* being that which is appropriate to the former, whose peculiarity consists in the exertion of the will to bring that before the consciousness, which does not spontaneously present itself. (Now as this process affords a typical example of the mode in which the Will acts in directing the current of thought, we shall examine it a little more minutely.—In the first place it may be positively affirmed, that we cannot call up any idea by simply *willing* it; for it is a necessary condition of an act of will, that there should be in the mind an idea of *what* is willed; and if the idea of the thing willed be already in the mind, it is obviously impossible to use the will to bring it there. But every one is conscious of the state of mind, in which he *tries* to remember something which is not at the time present to his consciousness; and the question is, *how* he proceeds to bring the idea before his mind. The process really consists in the fixation of the attention upon one or more ideas already present to the mind, which may recall, by suggestion, that which is desiderated; the very act of thus *attending* to a particular idea not only serving to intensify the idea itself, but also to strengthen the associations by which it is connected with others. There are certain ideas so familiar to us, that they seem necessarily to recur upon the slightest prompting of suggestion; yet even with regard to these, the voluntary recollection at any particular time involves the process just described. Thus, if a man be asked his name, he usually finds no difficulty in giving the proper answer, because it only requires that his attention should be directed to the idea involved in the words "my name," to suggest the words of which that name may consist. But if the individual should be in that state of "absence of mind," which really consists in the fixation of the attention upon some internal train of thought, he may not be able on the sudden to transfer his attention to the new idea that is forced upon his consciousness *ab externo*; and may thus hesitate and bungle, before he is able to answer the question with positiveness. So, again, it sometimes happens in old age that men fail to recollect their own names, or the names of persons most familiar to them, in consequence of the weakening of the bond of direct association; and they then only recall it by the operation to be presently described. And there are states of mind, in which the power of voluntarily directing the thoughts is for a time suspended, and in

which the individual cannot make the slightest effort to recall the most familiar fact, especially if possessed with the conviction that such effort is impossible (§ 825).—But supposing the mind to be in full possession of its ordinary powers, and the desiderated idea to be one which does not at once recur on the direction of the attention to some idea already in the mind; we then apply the same process to other ideas which successively come before our consciousness, selecting those which we think most likely to suggest that which we require, and following out one train of thought after another, in the directions which we deem most probable, until we either succeed in finding the idea of which we are in search, or give up the pursuit as not worth further trouble. Thus a man who is making up his accounts, and finds that he has expended a sum in a mode which he cannot recollect, sets himself to remember what business he has done, where he has recently been, what shops he may have entered, and so on. Or when a man meets another whom he recognizes as an acquaintance without remembering his name, he runs over a number of names (one being suggested by another, when the attention is given to them), in hopes that some one of these may prove to be the one, which, when brought to his mind, is recognized as that of the object then before his consciousness; or he thinks of the place in which he may have previously seen him, this being recalled by fixing the attention on the associations suggested by the sight of his face and figure, or by the sound of his voice, or by his personality altogether; or he endeavors to retrace the time which has elapsed since he last met with him, the persons amongst whom he then was, or the actions in which he was engaged; that some one or other of these various associations may suggest the desiderated name.—But it is a most curious phenomenon, and one which, though most men are occasionally conscious of it, has been scarcely recognized by Metaphysical inquirers, that after all these expedients have been employed in vain, and the attempt to bring a particular idea to the mind has been abandoned as useless, it will often occur spontaneously a little while afterwards, suddenly flashing (as it were) before the consciousness; and this although the mind has been engrossed in the mean time by some entirely different subject of contemplation, and cannot detect any link of association whereby the result has been obtained, notwithstanding that the whole train of thought which has passed through the mind in the interval may be most distinctly remembered.¹ Now it is difficult, if not impossible, to account for this fact upon any other supposition, than that a certain train of action has been set going in the Cerebrum by the voluntary exertion which we at first made; and that this train continues in movement after our attention has been fixed upon some other object of thought, so that it goes on to the evolution of its result, not only without any continued exertion on our own parts, but also without our consciousness of any continued activity. This seems to be one of the instances of what may be termed *unconscious cerebration*, to which reference has been already made (§ 787), and of which other examples will be presently adduced (§§ 818, 819). But we may here remark, as bearing on the same subject, as well as upon that of a preceding paragraph, that it is well known that impressions to which the attention is

¹ So frequently has this occurred within the Author's experience, that he is now in the habit of trusting to this method of recollection, where he has reason to feel sure that the desired idea is not far off, if the mind can only find its track—as when it relates to some occurrence (such as a payment of money) which is known to have taken place within a few days previously; for he has found himself much more certain of recovering it, by withdrawing his mind from the search when it is not speedily successful, and by giving himself up to the occupation appropriate to the time, than by inducing fatigue by unsuccessful efforts. And this is not his own experience only, but that of many others. The fact has been noticed by Dr. Holland ("Chapters on Mental Physiology," p. 66); from whom he has learned that the above plan has been put into successful action by many to whom he has recommended it.

strongly directed a short time before sleep supervenes, are fixed upon the mind with remarkable force ;¹ a fact that seems to indicate that these impressions modify the nutrition of the Brain (which is taking place with peculiar activity during the state of mental repose), and that the peculiar readiness with which they may be recalled thus depends upon organic changes of which we are unconscious, rather than upon any intentional strengthening of the links of association.

814. By Attention to our own mental states and operations, a class of Ideas is generated, of a very different character from those which are called up by external objects ; and these, being entirely dependent upon the operation of the Intellectual powers, and having no relation to sensations except as the original springs of those operations, may be termed *intellectual* Ideas, in contradistinction to the *sensational* Ideas. The former, like the latter, become the subjects of the associating tendency ; and thus are combined in *Trains of Thought*. Some of these intellectual ideas appear to be so necessarily excited by mental operations, even of the simplest kind, and to be so little dependent on individual peculiarities, either inherent or acquired, that they take rank as *fundamental axioms* or principles of Human Thought. Such are—the belief in our own *present existence*, or the faith which we repose in the evidence of Consciousness : this idea being necessarily associated with every form and condition of mental activity : the belief in our *past existence*, and in our *personal identity* so far as our memory extends, which is necessarily connected with the act of Recollection ; with this, again, is connected the general idea of Time : the belief in the *external and independent existence* of the causes of our sensations, which results from the direction of the mind to the Perceptual ideas originating in them ; with this is connected the general idea of Space : the belief in the existence of an *efficient cause* for the changes which we witness around us, which springs from the perception of those changes ; whence is derived our idea of Power : the belief in the *stability of the order of nature*, or in the invariable sequence of similar effects to similar causes, which also springs directly from the perception of external changes, and seems prior to all reasoning upon the results of observation of them (being observed to operate most strongly in those whose experience is most scanty, and in relation to subjects that are perfectly new to them) ; but which is the foundation of all applications of our own experience or that of others, to the conduct of our lives or to the extension of our knowledge : lastly, the belief in *our own free will*, involving the general idea of Voluntary Power ; which is in like manner a direct result of our internal perception of those mental changes which are excited by sensations. Hence it is evident that “ the only foundation of much of our belief, and the only source of much of our knowledge, is to be found in the constitution of our own minds ;” but it must be steadily kept in view, that these fundamental axioms are nothing else than expressions of the general fact, that the ideas in question are uniformly excited (in all ordinarily constituted minds at least) by simple Attention to the changes in which they originate.—Among those elementary modes of thought, which arise out of the constitution of our own minds, we must also rank the ideas of Truth, Beauty, and Right, which intuitively present themselves to our consciousness, in connection with certain objects or occurrences respectively adapted to excite them ; the first connecting itself especially with the operations of the Reason, the second with the production of those states of feeling which are termed Sentiments, and the third with the determinations of the Will in the guidance of conduct. *Truth* may be defined to be an apprehension of the relations of things as they actually exist ; and the conception of truth,

¹ Thus it is well known to schoolboys who have a task to commit to memory, that if they can put it together correctly, however hesitatingly, over night, they can generally repeat it fluently in the morning.

which is originally based upon sensational ideas, comes to be also applied to those which are purely intellectual. The notion of *Beauty* is one that it is very difficult to define; but it seems to consist essentially in the conformity of an external object to a certain ideal standard, by which conformity a pleasurable feeling is produced. That ideal standard is a work of the Imagination, and is generated (by a kind of automatic process) by the elimination of all those elements which we recognize as inferior, and by the intensification and completion of all those which we regard as excellent. Hence according to the æsthetic judgment which every individual pronounces as to these particulars, will be his ideal of beauty. The notion of beauty extends itself, also, to the pure conceptions of the Intellect; and thus we may experience the sense of beauty in the recognition of a Truth. We experience the sense of beauty, too, in witnessing the conformity of conduct to a high standard of Moral excellence; which excites in our minds a pleasure of the same order, as that which we derive from the contemplation of a noble work of art. The idea of *Right* connects itself with voluntary action. We have no feeling of approval or disapproval with respect to actions that are necessarily connected with our physical well-being; but in regard to most of those which are left to our choice, it is impossible to feel indifferent; and the sphere of operation of this principle becomes widened, in proportion as the mind dwells upon the notion of Moral Obligation which arises out of it. Then, too, the idea of Right is brought to attach itself to thoughts, as well as to actions; and this, not merely because the right regulation of the thoughts is perceived to be essential to the right regulation of the conduct, but also because the mind intuitively perceived that whatever we can govern by the Will has also a moral aspect.

815. Closely connected with many of the foregoing, and arising in most minds from some or other of them by the very nature of our psychical constitution, are those ideas which relate to the Being and attributes of the Deity. The conception which each individual forms of the Divine Nature depends in great degree upon his own habits of thought; but there are two extremes, towards one or other of which most of the current notions on this subject may be said to tend, and between which they seem to have oscillated in all periods of the history of Monotheism. These are, *Pantheism*, and *Anthropomorphism*.—Towards the Pantheistic aspect of Deity, we are especially led by the philosophic contemplation of His agency in external Nature; for in proportion as we fix our attention exclusively upon the “laws” which express the orderly sequence of its phenomena, and upon the “forces” whose agency we recognize as their immediate causes, do we come to think of the Divine Being as the mere *First Principle* of the Universe, an all-comprehensive “Law” to which all other laws are subordinate, that most general “Cause” of which all the physical forces are but manifestations. This conception embodies a great truth, and a fundamental error. Its truth is the recognition of the universal and all-controlling agency of the Deity, and of His presence in Creation rather than on the outside of it. Its error lies in the absence of any distinct recognition of that *conscious volitional* agency which is the essential attribute of Personality; for without this, the Universe is nothing else than a great self-acting machine, its Laws are but the expressions of “surd necessity,” and all the higher tendencies and aspirations of the Human Soul are but “a mockery, a delusion, and a snare.”—The Anthropomorphic conception of Deity, on the other hand, arises from the too exclusive contemplation of *our own* nature as the type of the Divine; and although, in the highest form in which it may be held, it represents the Deity as a being in whom all the noblest attributes of Man’s spiritual essence are expanded to infinity, yet it is practically limited and degraded by the impossibility of *fully* realizing such an existence to our minds; the failings and imperfections incident to our Human nature being

attributed to the Divine, in proportion as the low standard of intellectual and moral development in each individual keeps down his idea of possible excellence. Even the lowest form of any such conception, however, embodies (like the Pantheistic) a great truth, though mingled with a large amount of error. It represents the Deity as a *Person*; that is, as having that Intelligent Volition, which we recognize in ourselves as the source of the power we determinately exert, through our bodily organism, upon the world around; and it invests Him, also, with those Moral attributes, which place him in sympathetic relation with his sentient creatures.—But this conception is erroneous, in so far as it represents the Divine nature as restrained in its operations by any of these limitations which are inherent in the very constitution of Man: and in particular, because it leads those who accept it to think of the Creator as “a remote and retired mechanism, inspecting from without the engine of creation to see how it performs,” and as either leaving it entirely to itself when once it has been brought into full activity, or as only interfering at intervals to change the mode of its operation.—Now the truths which these views separately contain, are in perfect harmony with each other: and the very act of bringing them into combination effects the elimination of the errors with which they were previously associated. For the idea of the universal and all-controlling agency of the Deity, and of his immediate presence throughout Creation, is not found to be in the least degree inconsistent with the idea of His personality, when that idea is detached from the limitations which cling to it in the minds of those who have not expanded their anthropomorphic conception by the scientific contemplation of Nature; on the contrary, when we have once arrived at that conception of *Force* as an expression of *Will*, which we derive from our own experience of its production, the universal and constantly-sustaining agency of the Deity is recognized in every phenomenon of the external Universe; and we are thus led to feel that in the Material Creation itself, we have the same distinct evidence of His personal existence and ceaseless activity, as we have of the agency of intelligent minds in the artistic creations of Genius, or in the elaborate contrivances of Mechanical skill, or in those written records of Thought which arouse our own psychical nature into kindred activity.

816. There is, in fact, no part of Man's psychical nature which does not speak to him of the Divine, when it is rightly questioned. The very perception of *finite* existence, whether in time or space, leads to the idea of the Infinite. The perception of *dependent* existence leads to the idea of the Self-existent. The perception of change in the external world leads to the idea of an Absolute Power as its source. The perception of the order and constancy underlying all those diversities which the surface of Nature presents, leads to the idea of the Unity of that power. The recognition of Intelligent Will as the source of the power we ourselves exert, leads to the idea of a like Will as operating in the Universe. And our own capacity for reasoning, which we know not to have been obtained by our individual exertions, is a direct testimony to the Intelligence of the Being who implanted it. So are we led from the very existence of our Moral Feelings, to the conception of the existence of attributes, the same in kind, however exalted in degree, in the Divine being. The sense of Truth implies its actual existence in a being who is himself its source and centre; and the longing for a yet higher measure of it, which is experienced in the greatest force by those who have already attained the truest and widest view, is the testimony of our own souls to the Truth of the Divine Nature. The perception of Right, in like manner, leads us to the Absolute lawgiver who implanted it in our constitution; and, as has been well remarked, “all the appeals of innocence against unrighteous force are appeals to eternal justice, and all the visions of moral purity are glimpses of the infinite excellence.” The aspirations of the most exalted moral natures after a yet higher state of

Holiness and Purity, can only be satisfied by the contemplation of such perfection as no merely Human being has ever attained; and it is only in the contemplation of the Divine Ideal, that they meet their appropriate object. And the sentiment of Beauty, especially as it rises from the material to the spiritual, passes beyond the noblest creations of art and the most perfect realization of it in the outward life, and soars into the region of the Unseen, where alone the imagination can freely expand itself in the contemplation of such Beauty as no objective representation can embody.—And it is by combining, so far as our capacity will admit, the ideas which we thus derive from reflection upon the facts of our own consciousness, with those which we draw from the contemplation of the Universe around us, that we form the justest conception of the Divine Nature, of which our finite minds are capable. We are led to conceive of Him as the Absolute, Unchangeable, Self-Existent—Infinite in duration—Ilimitable in space—the highest ideal of Truth, Right, and Beauty—the All-powerful source of that agency which we recognize in the phenomena of Nature—the All-Wise designer of that wondrous plan, whose original perfection is the real source of the uniformity and harmony which we recognize in its operation—the All-Benevolent contriver of the happiness of His sentient creatures—the All-Just disposer of events in the Moral world, for the evolution of the ultimate ends for which Man was called into existence. In proportion to the elevation of our own spiritual nature, and the harmonious development of its several tendencies, will be the elevation and harmoniousness of our conception of the Divine; and in proportion, more particularly, as we succeed in raising ourselves towards that ideal of perfection which has been graciously presented to us in the “well-beloved Son of God,” are the relations of the Divine Nature to our own *felt* to be more intimate. And it is from the consciousness of our relation to God, as His creatures, as His children, and as independent but responsible fellow-workers with Him in accomplishing His great purposes, that all those Ideas and Sentiments arise, which are designated as Religious, and which constitute that most exalted portion of our nature, of whose continued existence and yet higher elevation we have the fullest assurance, both in the depths of our own consciousness and in the promises of Revelation.

817. Upon the Sensational and Intellectual Ideas thus brought under the cognizance of the Mind, all acts of *Reasoning* are founded. These consist, for the most part, in the aggregation and collocation of ideas, the decomposition of complex ideas into more simple ones, and the combination of simple ideas into general expressions; in which are exercised the faculty of *Comparison*, by which the relations and connections of ideas are perceived—that of *Abstraction*, by which we fix our attention on any particular qualities of the object of our thought, and isolate it from the rest—and that of *Generalization*, by which we connect together those properties which have been thus discovered to be common to a number of objects. These operations, when carefully analyzed, seem capable of reduction to this one expression—namely, the fixation of our Attention on some particular *classes of ideas*, from among those which Suggestion brings before our consciousness; and this fixation may result, as already shown, either from the peculiar attractiveness which these classes of ideas have for us (the constitution of individual minds varying greatly in this respect), or on the determination of our own Will.—The foregoing are the purely intellectual processes chiefly concerned in the simple acquirement of knowledge, with which class of operations the Emotional part of our nature has very little participation; and there is strong reason to believe that they may be performed *automatically* to a very considerable extent, without any other than a permissive act of Will. It is clearly by such automatic action that the above-mentioned “fundamental axioms” or “intuitions” are evolved; and there is not one of the operations above described, which may not be performed quite involuntarily, especially by

an individual who is naturally disposed to it. Thus to some persons, the tendency to compare any new object of consciousness with objects that have been previously before the mind, is so strong as to be almost irresistible; and this, or any other original tendency, is strengthened by the habit of acting in conformity with it. So, again, the tendency to abstraction is equally strong in the minds of others, who instinctively seek to separate what is fundamental and essential in the properties of objects, from what is superficial and accidental; and their attention being most attracted by the former, they readily recognize the same characters elsewhere, and are thus as prone to combine and generalize, as others are to analyze and distinguish. It is only, in fact, when we *intentionally* divert the current of thought from the direction in which it was previously running—when we *determine* to put our minds in operation in some particular manner—and make a *choice of means* adapted to our end (as in the act of Recollection already described) by purposely fixing our attention upon one class of objects and excluding others—that we can be said to use the Will in the act of Reasoning; and this exercise of it is shown, by the analysis of our own consciousness, to be much rarer than is commonly supposed. Thus we may imagine a man sitting down at a fixed hour every day, to write a treatise upon a subject which he has previously thought out; after that first effort of Will by which his determination was made, the daily continuance of his task becomes so habitual to him, that no fresh exertion of it is required to bring him to his desk; and, unless he feel unfit for his work, or some other object of interest tempt him away from it, so that he is called upon to decide between contending motives, his Will cannot be fairly said to be brought into exercise. It may need, perhaps, some voluntary fixation of his attention upon the topics upon which he had been engaged when he last dropped the thread, to enable him to recover it so as to commence his new labors in continuity with the preceding; but when once his mind is fairly engrossed with his subject, this develops itself before his consciousness according to his previous habits of mental action; ideas follow one another in rapid and continuous succession, clothe themselves in words, and prompt the movements by which those words are expressed in writing; and this automatic action may continue uninterruptedly for hours, without any tendency of the mind to wander from its subject, the Will being only called into play when the feeling of fatigue or the distraction of other objects renders it difficult to keep the attention fixed upon that which has previously held it by its own attractive power.¹—The converse of this condition is experienced when some

¹ Two very remarkable instances may be noticed, in men distinguished, the one for intellectual, the other for artistic ability; in both of whom the mental action which evolved the result seems to have been in great degree of an automatic character.—All accounts of Coleridge's habits of thought, as manifested in his conversation (which was a sort of *thinking aloud*), agree in showing that his train of mental operations, once started, went on *of itself*, sometimes for a long distance in the original direction, sometimes with a divergence into some other track, according to the consecutive suggestions of his own mind, or to new suggestions introduced into it from without. His whole course of life was one continued proof of the weakness of his Will; for, with numerous gigantic projects continually in his mind, he could never bring himself even seriously to attempt to execute any one of them; and his utter deficiency in self-control rendered it necessary for his welfare that he should yield himself to the control of others. The composition of the poetical fragment "Kubla Khan" *in his sleep* is a typical example of automatic mental action; and almost his whole life might be regarded as a sort of waking dream, in regard to the deficiency of that self-determining power which is the pre-eminent characteristic of every really great mind. (The most striking portraiture of Coleridge's habits of conversation is to be found in Carlyle's "Life of John Sterling.")—The whole artistic life of Mozart, from his infancy to his death, save in so far as the earlier part of it was directed by his father, may be cited as an example of the spontaneous or automatic development of musical ideas, which expressed themselves in the language appropriate to them. When only four years old, he began to write music, which was found to be in strict accordance with the rules of composition, although he had received no instruction in these. And when engaged in adult life, in the

powerful interest tends to draw off the attention elsewhere, and the thoughts are found to wander continually from the subject in hand; or when, from the undue protraction of mental exertion, the state of the brain is such that the thoughts no longer develop themselves consecutively in the mind, nor shape themselves into appropriate forms of expression. In either of these cases, the intellectual powers can only be kept in action upon the pre-determined subject, by a strong effort of the Will; of this effort we are conscious at the time, and feel that we need to put forth even a greater power than that which would be required to generate a large amount of physical force through the muscular system; and we subsequently experience the results of it, in the feeling of excessive fatigue which always follows any exertion that calls the Cerebrum into extraordinary activity.

818. But we seem justified in proceeding further, and in affirming that the Cerebrum may act upon impressions transmitted to it, and may elaborate results such as we might have attained by the purposive direction of our minds to the subject, *without any consciousness* on our own parts; so that we only become aware of the operation which has taken place, when we compare the result, as it presents itself to our minds after it has been attained, with the materials submitted to the process. The ordinary experience of most persons will supply them with examples of this form of Cerebral activity. One of the simplest instances of it is to be found in the process by which we acquire a knowledge of the meaning of an author whose writings we are perusing. For, if the subject be one into which we readily enter, and if the writer's flow of thought be one which we easily follow, and his language be appropriate to express his ideas, we acquire the meaning of one *sentence* after another, without any conscious recognition of the meaning of each of the component *words*; and yet it is certain that a particular impression must have been made by each of these words upon the Cerebrum, before we can comprehend the notion which they were collectively intended to convey. It is only when the language is ill chosen, or when we do not readily follow the author's train of thought, that we direct our attention to the signification of the individual words, and become conscious of their separate meaning. In like manner, an expert calculator will cast his eye rapidly from the bottom to the top of a column of figures and will name the total, without any conscious appreciation of the value of each individual figure.—But in these instances, no higher act of mind is required than the production of one complex idea out of an aggregate of simpler elements; there are cases,

production of those works which have rendered his name immortal, it was enough for him once to fix his thoughts in the first instance upon the subject (the libretto of an opera, for example, or the words of a religious service), so as to give the requisite start and direction to his ideas, which then flowed onwards without any effort of his own; so that the whole of a symphony or an overture would develop itself in his mind, its separate instrumental parts taking (so to speak) their respective shapes, without any *intentional* elaboration. In fact, the only exercise of Will that seemed to be required on his part consisted in the noting down of the composition when complete; and this, under the temptations of social intercourse, and a dislike to anything like "work," he would sometimes postpone until the last moment. Thus it is well known that his overture to Don Giovanni was only written out (although it must have been previously composed) during the night previous to its performance, which took place without any rehearsal. It is recorded of him, that being once asked by an inferior musician how he set to work to compose a symphony, he replied—"If you once think of *how* you are to do it, you will never write anything worth hearing. I write because I cannot help it." Mozart, like Coleridge, was a man of extremely weak will; he could neither keep firm to a resolution, nor resist temptation; and when not under the guidance of his excellent wife, was the sport of almost every kind of impulse. But there was probably never a more remarkable example than his musical career presents, of the automatic operation of that *creative* power which specially constitutes Genius; and his life is altogether a most interesting study to the Psychologist, as well as to the Musician. (See especially the "Life of Mozart" by Edward Holmes.)

however, in which processes of a far more elaborate nature are carried on, without necessarily affecting our consciousness. Most persons who attend to their own mental operations are aware that when they have been occupied for some time about a particular subject, and have then transferred their attention to some other, the first when they return to the consideration of it, may be found to present an aspect very different from that which it possessed before it was put aside; notwithstanding that the mind has since been so completely engrossed with the second subject, as not to have been consciously directed towards the first in the interval. Now a part of this change may depend upon the altered condition of the mind itself, such as we experience when we take up a subject in the morning with all the vigor which we derive from the refreshment of sleep, and find no difficulty in overcoming difficulties and in disentangling perplexities which checked our further progress the night before, when we were too weary to give more than a languid attention to the points to be made out, and could use no exertion in the search for their solutions. But this by no means accounts for the *entirely new development* which the subject is frequently found to have undergone, when we return to it after a considerable interval; a development which cannot be reasonably explained in any other mode, than by attributing it to the intermediate activity of the Cerebrum, which has in this instance automatically evolved the result without our consciousness. Strange as this phenomenon may at first sight appear, it is found, when carefully considered, to be in complete harmony with all that has been affirmed in the preceding paragraphs, respecting the relation of the Cerebrum to the Sensorium, and the independent action of the former; and looking at all those automatic operations by which results are evolved without any intentional direction of the Mind to them, in the light of "reflex actions" of the Cerebrum, there is no more difficulty in comprehending that such reflex actions may proceed without our knowledge, so as to evolve *intellectual products* when their results are transmitted to the Sensorium and are thus impressed on our consciousness, than there is in understanding that impressions may excite muscular movements, through the "reflex" power of the Spinal Cord, without the necessary intervention of Sensation. In both cases, the condition of this form of independent activity is that the *receptivity* of the Sensorium shall be suspended *quoad* the changes in question, either by the severance of structural connection, or through its temporary engrossment by other objects.¹

819. It is difficult to find an appropriate term for this class of operations. They can scarcely be designated as Reasoning Processes, since "unconscious reasoning" is a contradiction in terms. The designation *Unconscious Cerebration* is perhaps less objectionable than any other.—But it must not be left out of view, that *emotional* states, or rather states which constitute emotions when we become conscious of them, may be developed by the same process; so that our feelings

¹ It may serve to give the readers of this Treatise more confidence than they might otherwise feel in the truth of the above doctrine, if the author mentions that, having been led to entertain it as *possible* on purely Physiological grounds, he then began to question not merely his own experience, but that of others, as to the Psychological evidence of unconscious Cerebral activity. Having found enough in the results of this inquiry to convert the possibility into a *probability*, he next took an opportunity of placing his views before two of the deepest thinkers of the present day, Sir W. Hamilton and Mr. John Stuart Mill. From the former he learned that the doctrine had been advanced by Leibnitz more than two centuries since; and that the first of the above illustrations had actually been adduced by that eminent philosopher in its support. By the latter he was assured that the fact of the unconscious development of a subject of thought was so familiar to him, that, when he found it difficult to pursue an inquiry further, not seeing his way clearly through its entanglements, he was accustomed to lay it aside for weeks or even months, and to devote himself to some other object, with the full expectation (derived from frequent experience) of being able to prosecute his first investigation with diminished difficulty, whenever he might feel disposed to resume it.

towards persons and objects may undergo most important changes, without our being in the least degree aware, until we have our attention directed to our own mental state, of the alteration which has taken place in them. A very common but very characteristic example of this kind of action is afforded by the powerful attachment which often grows up between individuals of opposite sexes, without either being aware of the fact; the full strength of this attachment being only revealed to the consciousness of each, when circumstances threaten a separation, and when each becomes cognizant of the feelings entertained by the other. The existence of a mutual attachment, indeed, is often recognized by a bystander (especially if the perceptions be sharpened by jealousy, which leads to an intuitive interpretation of many minute occurrences which would be without signification to an ordinary observer), before either of the parties has made the discovery whether as regards the individual *self*, or the beloved *object*; the Cerebral state manifesting itself in action, although no distinct consciousness of that state has been attained, chiefly because, the whole attention being attracted by the present enjoyment, there is little disposition to Introspection. The fact, indeed, is recognized in our ordinary language; for we continually speak of the feelings which we unconsciously entertain towards another, and of our not becoming aware of them until some circumstances call them into activity. Here, again, it would seem as if the material organ of these feelings tends to *form itself* in accordance with the impressions which are habitually made upon it; so that we are as completely unaware of the changes which may have taken place in it, as we are of those by which passing events are registered in our minds (§ 812), until some circumstance calls forth the conscious manifestation, which is the "reflex" of the new condition which the organ has acquired. And it may be remarked, in this connection, that the Emotional state seems often to be determined by circumstances of which the individual has no distinct consciousness, and especially by the emotional states of those by whom he is surrounded; a mode of influence which is exerted with peculiar potency on the minds of children, and which is a most important element in their Moral Education.¹

820. The faculty of *Imagination* is in some respects opposed in its character to that of Reason; being chiefly concerned about fictitious objects, instead of real ones. Still, it is in a great degree an exercise of the same powers, though in a different manner. Thus it is partly concerned in framing new combinations of ideas relating to external objects, and is thus an extended exercise of Conception; placing us, in idea, in scenes, circumstances, and relations in which actual experience never found us; and thus giving rise to a new set of objects of thought. In fact, every Conception of that which has not been itself an object of perception, may, strictly speaking, be regarded as the result of the exercise of Imagination. Now the new Conceptions or mental creations thus formed, take their character, in great degree, from the Emotional tendencies of the mind; so that the previous development of particular feelings and affections will influence, not merely the selection of the objects, but the mode in which they are thus idealized. In the higher efforts of the Imagination, the mind is not so much concerned with the class of sensational ideas, as with those of the intellectual character; and the collocation, analysis, and comparison of these, by which new forms and combinations are suggested to the mind, involve the exercise of the same powers as those concerned in acts of Reasoning; but they are exercised in a different way. Whilst the Imagination thus depends upon the Intellectual powers for all its higher operations, the understanding may be said to be equally indebted to the imagination; for the ideal combinations which

¹ See an admirable Discourse on "Unconscious Influences," by the Rev. Horace Bushnell, of Hartford (N. E.), published in the "Penny Pulpit," No. 1199.

are the results of the action of the latter, do not merely engage the attention of the Artist, who aims to develop them in material forms, but are the great sources of the improvement of the knowledge and happiness possessed by our race—operating alike in the common affairs of life, by suggesting those pictures of the future which are ever before our eyes, and are our animating springs of action; with their visions of enjoyment never perhaps to be fully realized, and their prospects of anticipated evil that often prove to be an exaggeration of the reality—prompting the investigations of Science, that are gradually unfolding the sublime plan on which the Universe is governed—and leading to a continual aspiration after those highest forms of Moral and Intellectual beauty which are inseparably connected with purity and love.

821. We have now, in the last place, to inquire into the mode in which *Volition* operates in determining the course of thought and the regulation of the conduct;—a problem of extreme difficulty, the entire solution of which may not lie within the limited sphere of Man's present capacity. The chief subject of embarrassment is rather the nature and source of the Will itself, than the conditions of its operation; for whilst a careful analysis of our own consciousness throws much light on the latter, the scientific investigation of the former tends to results which are inconsistent with our intuitive conviction of freedom, as well as with our scarcely less intuitive notion of moral responsibility. Dismissing the former question, therefore, as one which requires a much more labored discussion than could here be appropriately bestowed upon it, we may apply ourselves to the consideration of the mode in which *Volition* acts (1) upon the Corporeal organism, and (2) upon our Psychical nature.

822. It is a fact of universal experience, that, although certain states of Mind have a remarkable influence on the Organic functions, no change in their usual course can be determined by the direct influence of the Will.¹ The only sensible effect which the strongest effort of *Volition* can produce on the bodily frame, is the excitation of *muscular contraction*. Now if we examine into the *cause* of a Volitional movement, we find it to lie, as in other instances, in a certain combination of *material conditions* with *dynamical agency* (p. 3). The aggregate of the material conditions is a state of integrity of the muscular and nervous apparatus through which the Will operates; the dynamical agency is the *effort* which we are conscious of putting forth, and which we feel to be *the power* by which the work is done, the degree of volitional exertion required being strictly proportional to the amount of *resistance* to be overcome, and being followed by a corresponding sense of *fatigue*, which is the indication of the expenditure of force. As already pointed out (§ 799), it is an essential condition of every Volitional action, that a distinct idea should exist of the object to be attained, and that there should be also a belief in the possibility of attaining it by the means employed; and further, the amount of power which can be put forth on any occasion, is dependent, *cæteris paribus*, upon the degree in which the attention is concentrated upon the effort, and the mind withdrawn from the contemplation of other objects. Hence it is (we have seen) that Emotional excitement may either intensify or paralyze the Volitional power, according as it determines or interferes with the special direction of the mental energy to the object with which it is connected. But the same influence is capable of being exerted by the simple dominance of *ideas*, in certain states of mind in which the directing power of the Will over the current of thought is altogether suspended, without the destruction of the capacity for voluntary exertion of the nervo-muscular apparatus. Thus the Author has seen a man remarkable for the poverty of his muscular development, who shrank from the least exertion in

¹ "Which of you, by taking thought, can add one cubit to his stature?" "Thou canst not make one hair white or black."

his ordinary state, lift a 28-lb. upon his little finger alone, and swing it round his head with the greatest facility, when in that state of artificial somnambulism termed Hypnotism by Mr. Braid (§ 827); his extraordinary command of muscular power in this condition being simply due to the complete concentration of his mental energy upon the one object, and to the dominance of the idea (with which his mind was possessed by the confident assurances of Mr. Braid) that he *could* attain it with the greatest facility—that idea not being negated by his ordinary experience, for reasons hereafter to be stated (§ 824). On the other hand, the same individual (whilst in the hypnotic state) declared himself altogether unable to raise a handkerchief from the table, after many apparently strenuous efforts; his mind having been previously possessed by the assurance that its weight was too great for him to move.¹ In that curious state of artificial Reverie, which has recently attracted much attention under the inappropriate name of “Electro-Biology” (§ 825), precisely the same phenomena may be observed; the subjects of it being prevented from performing the commonest voluntary movements, by the assurance that they *cannot* execute them, which assurance takes full possession of their minds, in virtue of their want of power to bring their ordinary experience to bear upon the idea thus introduced; whilst they may be compelled by the dominance of ideas, introduced in like manner by external suggestion, to perform actions, which, if not physically impossible to them in their ordinary state, they could not be induced to execute by any conceivable motives.—These facts are not so far removed from our ordinary experience as might at first sight appear. For it must be within the knowledge of every one, that, when *first* attempting to perform some new kind of action, the power we feel capable of exerting depends in great measure upon the degree of our assurance of success. Of this we have a good example in the process of learning to swim; which is greatly facilitated, as Dr. Franklin pointed out, by our first taking means to satisfy ourselves of the buoyancy of our bodies in the water, by attempting to pick up an object from the bottom. And every one is aware of the assistance derived from the encouragement of others, when we are ourselves doubtful of our powers; and of the detrimental influence of discouragement or suggested doubt, even when we previously felt a considerable confidence of success.² These familiar facts show us, therefore, that the pheno-

¹ The Author has every reason to believe that the personal character of this individual placed him above the suspicion of deceit; and it is obvious that, if he had *practised* the first of the above performances (which very few, even of the strongest men, could accomplish without practice), the effect would have been visible in his muscular development. Of course, there was not an equal proof of the absence of deception in the second case as in the first; but if the reality of the first, and the validity of the explanation above given, be admitted, there need be no difficulty in the reception of the second, since it is only another manifestation of the same mental condition.

² The Author well remembers, several years ago, being among those who tested the validity of the statement put forth in Sir D. Brewster’s “Natural Magic,” that four persons can lift a full-sized individual from the ground, high into the air, with the greatest facility, if they all take in a full breath previously to the effort, the person lifted doing the same. He could readily understand, upon physiological principles, that a full inspiration on the part of the *lifters* would have a certain degree of efficacy in augmenting their nervo-muscular power; but he could not perceive how the performance of the same act by the *person lifted* could have any appreciable effect; and while many of his acquaintances assured him that, when all the conditions were duly observed, the body went up “like a feather,” and that they felt satisfied of being able to support it upon the points of their fingers, he found his own experience quite different; and came to the conclusion, after much observation, that the facility afforded by this method entirely depended upon the degree in which it fulfilled the above-mentioned conditions, namely, the fixation of the attention upon the effort, and the conviction of the success of the method. Whenever the attention was distracted and confidence weakened by skepticism as to the result, the promised assistance was not experienced.—The Author may also mention, as a very characteristic illustration of the same principles, the following little circumstance

mena just described as occurring in abnormal states are in no respect contrary to our knowledge of the conditions under which the Will operates in producing muscular movement; but afford, when rightly interpreted, a strong confirmation of the statements already made respecting the nature of those conditions.

823. The Will is exerted, however, not merely in determining the actions of the body, but also in regulating the operations of the Mind; and here again we find that its action is limited by certain conditions, the knowledge of which is of great importance. It may be said, generally, that we have no direct power of calling before our consciousness, by a volitional effort, ideas which are not already present there; thus, in the act of Recollection, we can do no more than fix our minds upon those ideas which seem most likely to recall, by an act of suggestion, the one which we desiderate (§ 813). But what we do possess, is the power of excluding some ideas, and of bringing others prominently before our mental vision; and this by the power of *Voluntary Attention*, which is the chief if not the sole means by which the sequence of our thoughts is directed by the Will. It has been already pointed out that the Attention may be involuntarily fixed upon certain subjects of consciousness, through the attraction they exert upon the individual mind, in virtue either of its original constitution or of its acquired habitudes; it being this attraction which determines the automatic action of our faculties (§ 811). When most strongly exerted, it causes the consciousness to be so completely engrossed by one train of ideas, that the mind is, for the time, incapable of any other ideational change: sensory impressions, if felt not being perceived; and, where the consciousness is most completely concentrated upon the internal operations, the individual being as insensible to external impressions as if he were in a profound sleep. But these automatic tendencies of the mind may be to a certain extent antagonized by the Will, which keeps them in check (just as it restrains many of the automatic impulses to bodily movement) by the special power which it exerts over the Attention. This it can detach from subjects which have at the time the greatest attractiveness to it, and can forcibly direct it to others from which the former would otherwise divert it. And in its most complete and powerful exercise (which is not within the capacity of every one), it can so completely limit the mind to one train of thought, that the state of Abstraction induced by the Will may be as complete as that which in some individuals is of spontaneous occurrence. In proportion as we are able thus to concentrate our attention on the subject proper to the time, and to exclude all distracting considerations whilst pursuing the trains of thought which the contemplation of it suggests, will be our power of advantageously employing our Intellectual Faculties in the acquirement of knowledge and in the pursuit of truth; and all men who have been distinguished by their intellectual achievements have possessed this faculty in a considerable degree. It is one which is "eminently capable of cultivation by steady intention of mind and habitual exercise;" and the more frequently it is put in practice, the easier the exercise becomes. In fact, when a man has once brought his Intellectual faculties under the mastery of his Will, to such an extent as to induce the state of Abstraction whenever he pleases, this state becomes (as it were) "secondarily automatic;" and the fixed direction of the thoughts, which at first required a *constant* volitional effort for its maintenance, comes to be continued without any consciousness of exertion, so long as the Will may permit.—We have, in our own consciousness of effort, and in our

communicated to him by a friend. This gentleman relates that having been accustomed in his boyhood to play at bagatelle with other juniors of his family, the party was occasionally joined by a relative who was noted for her success at the game, and who was consequently much dreaded as an opponent; and that, on one occasion, when she was about to take her turn against him, he roguishly exclaimed, "Now, aunty, you will not be able to make a hit;" the effect of which suggestion was that she missed every stroke—and not only at that turn, but through the remainder of the evening.

experience of subsequent fatigue, a very strong indication that the power which thus controls and directs the current of thought, is of the same *kind* with that which calls forth Volitional movements of the body, though exerted in a different mode. And just as the strongest exertion of Will is required to produce or sustain Muscular contraction, when the sense of muscular fatigue is already strongly experienced, or when we are antagonizing a powerful automatic impulse, so, in the determination of Mental effort in a particular direction, we find ourselves necessitated to make the greatest Volitional effort when we are already laboring under the sense of cerebral fatigue, or when the attention is powerfully solicited by some other attractive object. And it is after any such contest with our natural tendencies, that we experience the greatest degree of exhaustion; the merely automatic action of the Mind, which is attended with no effort, being followed by comparatively little fatigue.¹

824. But this determining power of Volition is employed, in however slight a degree, whenever the succession of thought is not *perfectly spontaneous*; ² whenever, in fact, we *wish* our consciousness to take a particular direction, even for the apprehension of ideas most familiar to our minds. Of this we derive the best evidence from those curious states in which the directing power of the Will is entirely suspended, whilst yet the mind remains freely open to external impressions; a condition which shows us what we should be, if we really *were* what some writers assure us that we actually *are*, mere thinking automata, puppets moved in any direction by the pulling of suggesting strings (§ 802, *note*). This condition presents itself spontaneously in some individuals, and may be induced in others; and it is not a little remarkable that it may occur as a modification both of the *waking* and the *sleeping* states. Of the former we have an example

¹ The author is satisfied, from his own experience, that a most valuable indication may be hence drawn, in regard to the regulation of the habits of Intellectual labor. To individuals of ordinary mental activity, who have been trained in the habit of methodical and connected thinking, a very considerable amount of *work* is quite natural; and when such persons are in good bodily health, and the subject of their labor is congenial to them—especially if it be one that has been chosen by themselves because it furnishes a centre of attraction around which their thoughts spontaneously tend to range themselves—their intellectual operations require but little of the controlling or directing power of the Will, and may be continued for long periods together without fatigue. But from the moment when an indisposition is experienced to keep the attention fixed upon the subject, and the thoughts wander from it unless coerced by the Will, the mental activity loses its spontaneous or automatic character; and more exertion is required to maintain it volitionally during a brief period, and more fatigue is subsequently experienced from such an effort, than would be involved in the continuance of an automatic operation through a period many times as long. Hence he has found it practically the greatest economy of mental labor, to work vigorously when he feels disposed to do so, and to refrain from exertion, so far as possible, *when it is felt to be an exertion*.—Of course this rule is not applicable to all individuals, for there are some who would pass their whole time in listless inactivity if not actually spurred on by the feeling of necessity; but it holds good for those who are sufficiently attracted by objects of interest before them, or who have in their worldly circumstances a sufficiently strong motive to exertion, to make them feel that they *must* work, the question with them being *how* they can attain their desired results with the least expenditure of mental labor.

² It is hoped that the reader will have been made sufficiently aware, by the preceding explanations, that by the terms “spontaneous” or “automatic” succession of thought, it is intended to designate that sequence of states of consciousness, in which every one is the immediate resultant of that which preceded it, whether that were ideational or sensational. Thus the current of thought is alike “spontaneous,” when it flows onwards in one continuous channel, being directed by a single dominant idea which absorbs the whole attention; and when the mind is freely accessible to external impressions, and may be entirely guided by them. The phenomena of Reverie, Abstraction, and Somnambulism (as will be presently seen) afford illustrations of *both* these states; which, though apparently opposite in their nature, are really characterized by the same essential feature, namely, the absence of the directing power of the Will.

in ordinary *Reverie*, a state to which some persons are peculiarly prone; the characteristic of which is, that whilst, as in Dreaming, the succession of thought is entirely automatic, it is in no small degree influenced by external impressions, especially such as arise from the various phenomena of Nature. It is in minds in which the emotional and imaginative elements predominate, that we usually find the greatest tendency to reverie; and the sequence of thought, if subsequently analyzed, will be found to have been chiefly determined by these tendencies. Now this sequence may conduct us to notions altogether inconsistent with our most familiar experience; and yet we accept them as realities, notwithstanding this incongruity, because the ideas to which they are opposed are not present to our minds at the time, and the dormant state of our Will prevents us from making the slightest effort to bring them before the consciousness. The state of *Abstraction*, or "absence of mind," is essentially the same with that of reverie; the chief difference being, that in true Abstraction the mind is at work ratiocinatively, a certain train of thought being followed out by the intellectual operations to its logical conclusion; it being the Philosopher who is most prone to abstraction, as the Poet is to reverie. Now it is one of the most curious phenomena of this state, that external impressions, if received by the consciousness at all, are very often *wrongly* perceived, being interpreted in accordance with the ideas which happen to be dominant in the mind at the time, instead of giving rise to those new ideas which ordinarily connect themselves with them, in virtue of the individual's habitual experience. The records of "absence of mind" are full of amusing instances of such misinterpretation. Nothing seems too strange for the individual to believe, nothing too absurd for him to do under the influence of that belief. Thus of Dr. Robert Hamilton, a well-known Professor at Aberdeen, who was the author of many productions distinguished for their profound and accurate science, their beautiful arrangement, and their clear expression, we are informed that, "In public, the man was a shadow; pulled off his hat to his own wife in the streets, and apologized for not having the pleasure of her acquaintance; went to his classes in the college on the dark mornings with one of her white stockings on the one leg, and one of his own black ones on the other; often spent the whole time of the meeting in moving from the table the hats of the students, which they as constantly returned; sometimes invited them to call on him, and then fined them for coming to insult him. He would run against a cow in the road, turn round, beg her pardon, call her 'Madam,' and hope she was not hurt. At other times, he would run against posts, and chide them for not getting out of his way."¹

825. A state may be artificially induced in many individuals, by a continued fixed gaze at an object at a moderate distance, which is the same as that of Reverie and Abstraction in regard to the complete suspension of the directing power of the Will over the current of thought, but which differs from these in the readiness with which the mind may be possessed with ideas suggested to it through the medium of language. This state has been commonly known by the name *Electro-Biological*, from the mode in which its induction was originally practised;² but it is now more frequently designated by the very inappropriate

¹ See "New Monthly Magazine," vol. xxviii. p. 510.—The Author has heard from an old pupil of Dr. Hamilton an anecdote so singularly illustrative of this peculiar condition, that he cannot refrain from here introducing it. The Professor, walking one day along the High Street with the front of his breeches open (no very unusual occurrence with him), chanced to encounter a woman in a white apron; and apparently mistaking this apron for his own shirt, he laid hold of it, and began to push it into the situation which his shirt should occupy!

² The "Electro-Biologists," as they term themselves, at first maintained that a wonderful virtue resided in the little disk of copper with a zinc centre, to which they directed the gaze of their "subjects." It is now universally admitted, however, that *any* object which

term *Biological*. The subject of it may be truly characterized as a *thinking automaton*, the whole course of whose ideas may be determined by suggestions operating from without; and his mind, having in itself no power of altering the course of these in even the slightest degree, is cut off from all recourse to previous experience for the examination of their correctness or the determination of their fallacy. The senses of the biologized subject are freely accessible to external impressions; but, as in the case of the "absent" man, his perception of these is governed by the ideas which may be dominant in his mind at the time; and he may be consequently led to any kind of absurd misinterpretation of them. Yet his state of mind is not so far removed from his ordinary condition as to prevent his usual habits of thought and feeling from displaying themselves; and he has in most cases a perfect recollection of what has taken place, when he returns to his usual condition of mental activity, though sometimes the recollection does not extend to particulars. All the phenomena of the "biologized" state, when attentively examined, will be found to consist in the occupation of the mind by the *ideas* which have been suggested to it, and in the influence which these ideas exert upon the actions of the body. Thus the operator asserts that the "subject" cannot rise from his chair, or open his eyes, or continue to hold a stick; and the "subject" thereby becomes so completely possessed with the fixed belief of the impossibility of the act, that he is incapacitated from executing it, *not* because his will is controlled by that of another, but because his will is in abeyance, and his muscles are entirely under the guidance of the conviction which for the time possesses his mind. So, again, when he is made to drink a glass of water, and is assured that it is coffee, or wine, or milk, that assurance, delivered in a decided tone, makes a stronger impression on his mind than that which he receives through his taste, smell, or sight; and not being able to judge and compare, he yields himself up to the "dominant idea."¹ Here, again, we perceive that it is not really the *will* of the operator which controls the *sensations* of the subject; but the *suggestion* of the operator which excites a corresponding *idea*, the falsity of which is not corrected, simply because the mind of the subject, being completely engrossed by it, cannot apprehend the truth less forcibly impressed on it through his own senses. The same general statement applies to what has been designated as "control over the memory." The subject is assured that he cannot remember the most familiar thing, his own name for example; and he is prevented from doing so, not by the will of the operator, but by the conviction of the impossibility of the mental act, which engrosses his own mind, and by the want of that

serves as a *point d'appui* for the fixed gaze, is equally efficacious.—The Author has no hesitation in avowing his belief in the *reality* of the phenomena, which are described as occurring in this state; these having been presented to himself and to other scientific inquirers, by numerous individuals, on whose honesty and freedom from all disposition to deceive themselves or others, implicit reliance could be placed. All *public* exhibitions, the performers in which are of questionable character, are of course open to the obvious fallacy of intentional deceit. With regard to the *interpretation* of these phenomena, however, he entirely dissents from the statements commonly made, to the effect that the Will of the "biologized" subject is entirely under the control of that of the operator; since he regards the latter as having no other influence over the former than through the *suggestions* which his language and manner convey.

¹ It is very curious to observe, in some instances, the perplexity arising from the contrariety between the opposing sensory impressions. The mind seems unable to reconcile this contrariety, and yields itself up to the impression which is most strongly felt. Sometimes it is convinced by the repeated assurances of the operator, so long as the *taste* alone is opposed to them, but attaches a superior importance to the indications of *sight*; in other individuals, again, the indications of sight may be put aside, and yet the "subject" cannot be made to believe what is in opposition to his sense of taste. There are some individuals who can never be thus played upon, notwithstanding that their muscular movements and their purely mental conceptions are completely amenable to this kind of direction.

voluntary control over the direction of his thoughts which alone can enable him to *recall* the desiderated impression. And the abolition of the sense of personal identity—Mr. A. believing himself to be Mrs. B., or Mrs. C. believing herself to be Mr. D., and acting in conformity with that belief—is induced in the same mode; the assurance being continually repeated, until it has taken full possession of the mind of the “subject,” who cannot so direct his thoughts as to bring his familiar experience to antagonize and dispel the illusive idea thus forced upon him. The phenomena presented by different “biologized subjects” are by no means the same; for in some individuals it is the relation of the mind to bodily action which is most remarkably affected, in others it is the relation of the perceptive consciousness to sensations, and in others (especially those who are naturally of an imaginative and excitable disposition) it is the course of thought and of emotion which is most completely under external guidance. It is frequently to be observed, moreover, that some capability of volitional effort still remains, so that the “subject” endeavors to resist the commands of the operator; but this may usually be subdued by the emphatic reiteration of the assurance “You *must* do this,” or “You *cannot* do that,” which, when it takes complete possession of the mind of the subject, reduces the will to a state of entire powerlessness.¹

826. It is obvious that, if the account here given of the condition of the Mind and of the mode of its operation on the Body, in the state of natural and artificial Reverie and Abstraction, be correct, all the actions performed in these states must be regarded as essentially *automatic* in their nature; the course of thought being entirely determined by the associations previously formed, and all the bodily movements being the direct manifestations of the *ideas* which possess the mind at the time, just as the ordinary movements of “expression” are of its *emotions*. And it is, therefore, in these remarkable phases of psychical existence, that we have the clearest manifestation of the power which Cerebral changes possess, to produce muscular movement independently either of Volition or of Emotion; an action which may be distinguished as *ideo-motor*, since it only takes place when these changes are of a kind to awaken the ideational consciousness; and which is a true “reflex” action of the Cerebrum. The same designation may be fairly applied, also, to all those actions performed by us in our ordinary waking state, which are rather the automatic expressions of the ideas which are dominant in our minds at the time, than prompted by distinct volitional effort (§ 817). Of this kind, the act of expressing the thoughts in language, whether by speech or writing, may be considered as a good example; for the attention may be so completely given up to the choice of words and to the composition of the sentences, that the movements by which these words are uttered by the voice or traced on paper no more partake of the truly volitional character, than do those of our limbs when we walk through the streets in a state of Abstraction. And it is a curious evidence of the influence of Ideas, rather than of the agency of the Will, in producing them, that, as our conceptions are a little in advance of our speech or writing, it occasionally

¹ It is worthy of particular notice in this connection, that this want, not really of power to move, but of belief in the possession of the power, is a frequent characteristic of that state of the nervous system which is commonly designated as “Hysterical;” and that here, also, the most efficacious treatment consists in the encouragement of volitional efforts on the part of the patient to put the paralyzed limbs in action, and in the repetition of assurances that she *will* recover the use of them, if she only take the appropriate means. The expectation of recovery excited in other ways produces the same effect; and thus it has been that many pseudo-miracles have been wrought on this class of patients by religious enthusiasts, and that many wonderful cures have been effected by the supposed influence of Mesmerism. All that is wanted is that state of confident anticipation which is commonly designated as Faith.

happens that we mispronounce or misspell a word, by introducing into it a portion of some other whose turn is shortly to come, its place in the sentence which is in process of formation being a little further on; or it may be that the whole of the anticipated word is substituted for the one which ought to have been expressed. Now it is obvious that there could be neither any consciously formed intention of breaking the regular sequence, nor any volitional effort to do so; and the result is evidently due to the superior vividness with which the idea of the anticipated word is present to the mind, as compared with that of the word which the course of construction requires. It is the *dominant idea*, then, which determines the movement, the Will simply permitting it; and the more completely the Volitional power is directed to other objects, the more completely automatic are the actions of this class. They may, indeed, come to be performed even without the consciousness, or at least without the remembered consciousness, of the agent; as we see in the case of those who have the habit of "thinking aloud," and who are subsequently quite surprised on learning what they have uttered. The one-sided conversation of some persons, who are far more attentive to their own trains of thought, than they are to what may be expressed by others, and who are allowed to proceed with little or no interruption, is often a sort of "thinking aloud."¹—All that is here stated is in perfect accordance with the general principle already laid down (§ 683), that in proportion as the higher channels of activity are obstructed, will the excitation of nerve-force manifest itself through the lower. For, whilst the ordinary sequence is for external impressions to excite sensations, for sensations to excite ideas, and for ideas (after becoming the subject of reasoning processes of greater or less complexity) to issue in volitional determinations, the direct action of *ideational* changes in the Cerebrum on the motor system, when either the Will is in abeyance or is entirely directed to mental operations, seems quite as natural as the immediate reaction of *sensational* changes through the Sensory ganglia, or of *impressional* changes through the Spinal Cord.

827. The phenomena of *Somnambulism* are no less important in a scientific point of view, when they are regarded under the same aspect. They differ from those already described, in that they occur in a state of consciousness so far distinct from the ordinary waking condition, as not to be connected with it by the ordinary link of Memory; and although the course of thought in Somnambulism usually manifests the directing influence of previous habits, and the knowledge of persons and things possessed during the waking state may be readily brought before the mind, yet nothing which occurs during the state of Somnambulism is ever retraced spontaneously, or can be brought back by an act of recollection. Impressions upon the nervous system, however, are sometimes left by strong emotional excitement, which give rise to subsequent feelings of discomfort, of whose origin the individual is entirely unconscious.² The phenomena of Somnambulism are so various, that it is difficult to give any general definition that shall include the whole; but it is a condition which is common to all forms of this state, that the controlling power of the Will over the current of thought is entirely suspended, and that all the actions are directly prompted by the ideas which possess the mind; and the differences chiefly arise out of the mode in which the succession of ideas is directed, this being in some cases a coherent sequence through the whole of which some one dominant impression may be traced, whilst in other instances it is more or less completely determinable by ex-

¹ This was pre-eminently the case with Coleridge, whose peculiar habits have been already noticed, § 817, *note*.

² See a very curious example of this kind, which fell under the author's own observation, narrated in the Article "Sleep," in the "Cyclop. of Anat. and Phys.," vol. iv. p. 693.

ternal suggestions.—The first of these phases, which is nearly akin to the state of Abstraction, is frequently seen in *natural* Somnambulism; in which a train of reasoning is often carried out with remarkable clearness and correctness, and its results expressed in appropriate language, or otherwise acted on. Thus, a mathematician may work out a difficult problem, an orator make a speech appropriate to the occasion on which he supposes himself to be called up, or an author may compose and commit to writing poetry or prose, upon the subject which occupies his thoughts. But it is a frequent defect of the intellectual operations carried on in this condition, that, through the complete absorption of the attention by one set of considerations, no account is taken of others which ought to modify the conclusion; and this, although it may be palpably inconsistent with the teachings of ordinary experience, is not felt to be so, unless the latter should happen to present themselves unbidden to the thoughts.—The second of the phases above mentioned, which is especially seen in the *artificial* Somnambulism induced by the (so called) Mesmeric process, or by the fixed gaze at a near object (as practised by Mr. Braid under the name of Hypnotism), is essentially the same as that of the “biological” condition, save in the different relation which they respectively bear to the waking state; for there is the same readiness to receive new impressions through the senses (the visual sense, however, being generally in abeyance), and the same want of persistence in any one train of ideas, the direction of the thoughts being entirely determined by the suggestions which are introduced from without. In either of these extreme forms of Somnambulism, and in the numerous intermediate phases which connect the two, the consciousness seems entirely given up to the one impression which is operating upon it at the time; so that whilst the attention is exclusively directed upon any object, whether actually perceived through the senses, or brought suggestively before the mind by previous ideas, nothing else is felt. Thus there may be complete insensibility to bodily pain, the somnambulist’s whole attention being given to what is passing in his mind; yet in an instant, by directing the attention to the organs of sense, the anæsthesia may be replaced by ordinary sensibility; or, by the fixation of the attention on any one class of sensations, these shall be perceived with most extraordinary acuteness, whilst there may be a state of complete insensibility as regards the rest. So, again, when the attention of the somnambulist is fixed upon a certain train of thought, whatever may be spoken in harmony with this is heard and appreciated, but what has no relation to it, or is in discordance with it, is entirely disregarded. It is among the most curious of the numerous facts which Mr. Braid’s investigations upon artificial Somnambulism have brought to light, that the suggestions derived from the “muscular sense” have a peculiar potency in determining the current of thought. For if the face, body, or limbs be brought into an attitude that is expressive of any particular emotion, or that corresponds with that in which it would be placed for the performance of any voluntary action, the corresponding mental state—that is, either an emotional condition affecting the general direction of the thoughts, or the idea of a particular action—is called up in response to it. Thus, if the hand be placed upon the vertex, the Somnambulist will frequently of his own accord, draw his body up to its fullest height, and throw his head slightly back; his countenance then assumes an expression of the most lofty pride, and the whole train of thought is obviously under the domination of this feeling, as is manifested by the replies which the individual makes to interrogatories, and by the tone and manner in which these are delivered. Where the first action does not of itself call forth the rest, it is sufficient to straighten the legs and spine, and to throw the head somewhat back, to arouse the emotion, with its corresponding manifestation, in its full intensity. If, during the most complete domination of this emotion, the head be bent forwards and the body and limbs be gently flexed, the most

profound humility then takes its place. So, again, if the angles of the mouth be gently separated from one another, as in laughter, a hilarious disposition is immediately generated; and this may be made to give place to moroseness, by drawing the eyebrows towards each other and downwards upon the nose, as in frowning.¹ So, again, if the hand be raised above the head, and the fingers be flexed upon the palm, the idea of climbing, swinging, or pulling at a rope is called up in such as have been used to this kind of exertion; if, on the other hand, the fingers be flexed when the arm is hanging down at the side, the idea suggested is that of lifting a weight; and if the same flexure be made when the arm is advanced forwards in the position of striking a blow, the idea of fighting is at once aroused, and the Somnambulist is very apt to put it into immediate execution.²

828. The state of *Dreaming* presents us with another series of phenomena, which fall under the same general category with the preceding. In fact, between Dreaming and Somnambulism there is every stage of gradation; for that form of Somnambulism in which the actions are expressive of ideas that arise spontaneously within the mind, instead of being prompted by external suggestions, may be designated as an acted dream; whilst, on the other hand, there are states of Dreaming, in which the bystander is able in greater or less degree to trace the current of thought and feeling, by the words occasionally uttered, or by the play of the countenance of the sleeper. Instances might be cited, which it would be very difficult to assign to either one of these conditions, so completely do they partake of the character of both; as for example, the well-known case of the officer who amused his friends by acting his dreams during the expedition to Louisburgh, the course of these dreams being capable of direction by whispering into the sleeper's ear, especially if this was done by a friend with whose voice he was familiar.³ It is usually considered to be a distinction between Dreaming and Somnambulism, that the senses are in complete abeyance in the former state, while they are more or less capable of action in the latter. But we have seen that the sensibility to external impressions may be partially or even completely suspended in Somnambulism; whilst, on the other hand, it may exist to a slight extent in Dreaming, as in the instance just quoted. And it is quite certain that even where sensations are not recognized by the mind as proceeding from external objects, they may affect the course of its own thoughts; so that the character of the dreams may be in some degree predetermined by such an arrangement of sensory impressions as is likely to modify them. This is especially the case in regard to the dreamy state induced

¹ The author has not only repeatedly witnessed all these effects, as produced by Mr. Braid upon "hypnotized" subjects, of whom several had never been previously in that condition, and had no idea whatever of what was expected from them; but he has been assured by a most intelligent medical friend, who has paid special attention to the psychological part of this inquiry, that, having subjected himself to Mr. Braid's practice, and having been only partially thrown into the "hypnotic" state, he distinctly remembers everything that was done, and can retrace the uncontrollable effect upon his emotional state, which was produced by this management of his muscular apparatus.

² On one occasion on which the author witnessed this result, a violent blow was struck, which chanced to alight upon a second somnambulist within reach; his combativeness being thereby excited, the two closed, and began to belabor one another with such energy, that they were with difficulty separated. Although their passions were at the moment so strongly excited, that even when separated they continued to utter furious denunciations against each other, yet a little discreet manipulation of their muscles soon calmed them and restored them to perfect good-humor.

³ This case is detailed by Dr. Abercrombie ("Inquiries concerning the Intellectual Powers," 5th ed., p. 277), on the authority of Dr. Gregory, to whom it was related by a gentleman who witnessed it. A case of a very similar nature, the subject of which was a medical student at Edinburgh, is related in Smellie's "Philosophy of Natural History."

by certain narcotics, such as the Hachisch (a preparation of *Cannabis Indica*) employed for this purpose in the East; for the emotional condition of the individual under its influence is entirely under the control of external impressions; so that those who give themselves up to the intoxication of the *fantasia*, take care to withdraw themselves from everything which could give their delirium a tendency to melancholy, or excite in them anything else than feelings of pleasurable enjoyment.¹—The difference between the state of mind in ordinary Dreaming and that which is characteristic of Somnambulism is most remarkable in regard to the rapidity and incoherence of the trains of thought in the former state, as compared with the slowness and steadiness of the mental action usually observed in the latter. It is true that in ordinary dreaming there is sometimes a remarkable degree of consistency in the mental operations; for reasoning processes may be carried on correctly, and even (through that freedom from distraction which is consequent upon the suspension of external disturbing agencies) with remarkable vigor and completeness, especially when they are the continuation of a train of thought on which the mind had been previously engaged during the waking hours; and music, poetry, &c., may be composed, which, if afterwards remembered and written down, is found to be in accordance with the rules of taste. Such, however, is not the usual character of the state of dreaming; for more commonly there is an entire want of any ostensible coherence between the ideas which successively present themselves to the consciousness; and we are completely unaware of the incongruousness of the combinations which are thus formed. It has been well remarked that “nothing surprises us in dreams.” All probabilities of “time, place, and circumstance” are violated; the dead pass before us as if alive and well; even the sages of antiquity hold personal converse with us; our friends upon the antipodes are brought upon the scene, or we ourselves are conveyed thither, without the least perception of the intervening distance; and occurrences, such as in our waking state would excite the strongest emotions, may be contemplated without the slightest feeling of a painful or pleasurable nature. Facts and events long since forgotten in the waking state, present themselves to the mind of the dreamer; and many instances have occurred, in which the subsequent retention of the knowledge thus re-acquired has led to most important results.² But one of the most remarkable of all the peculiarities in the state of dreaming, is the *rapidity* with which trains of thought pass through the mind; for a dream in which a long series of events has seemed to occur, and a multitude of images has been successively raised up, has been often certainly known to have occupied only a few minutes, or even seconds, although whole years may seem to the dreamer to have elapsed. There would not appear, in truth, to be any limit to the amount of thought which may thus pass through the mind of the dreamer, in an interval so brief as to be scarcely capable of measurement; as is obvious from the fact, that a dream involving a long succession of supposed events, has often distinctly originated in a sound which has also awoken the sleeper, so that the whole must have passed during the almost inappreciable period of transition between the previous state of sleep and the full waking consciousness.³ Hence

¹ See the Author's article “Sleep,” in the “Cyclop. of Anat. and Phys.,” vol. iv. pp. 688—690; and Moreau “Du Hachisch et de l'Aliénation Mentale, Etudes Psychologiques,” p. 67.

² See a number of such cases in Dr. Abercrombie's “Inquiries concerning the Intellectual Powers.”

³ The only phase of the waking state, in which any such intensely rapid succession of thoughts presents itself, is that which is now well attested as a frequent occurrence, under circumstances in which there is imminent danger of death, especially by drowning; the whole previous life of the individual seeming to be presented instantaneously to his view, with its every important incident vividly impressed on his consciousness, just as if all were combined in a picture, the whole of which could be taken in at a glance.

it has been argued by some, that *all* our dreams really take place in the momentary passage between the states of sleeping and waking; but such an idea is not consistent with the fact already referred to, that the course of a dream may often be traced by observing the successive changes of expression in the countenance of the dreamer. It seems, however, that those dreams are most distinctly remembered in the waking state, which have passed through the mind during the transitional phase just alluded to; while those which occur in a state more allied to Somnambulism, are more completely isolated from the ordinary consciousness.—There is a phase of the dreaming state which is worthy of notice, as marking another gradation between this and the vigilant state; that, namely, in which the dreamer has a consciousness that he is dreaming, being aware of the unreality of the images which present themselves before his mind. He may even make a voluntary and successful effort to prolong them if agreeable, or to dissipate them if unpleasing; thus evincing the possession of a certain degree of that directing power, the entire want of which is the characteristic of the true state of Dreaming.

829. Very nearly allied to the states of Somnambulism and Dreaming, are those of *Delirium* and of *Mania*, which graduate almost imperceptibly into one another; being chiefly distinguished by the degree and kind of excitement which they respectively exhibit, and by the nature of the bodily states with which they are connected. The loss of voluntary control over the current of thought is the primary element of both these conditions; and the gradual weakening of this may be frequently traced, when the transition from the normal state is not so rapid as to prevent its various steps from being watched. The *artificial delirium* produced by intoxicating agents affords peculiar facilities for this kind of observation; and among these agents, there is none whose operation is so interesting in this respect as the Hachisch. The first effect of a dose of this substance, as described by M. Moreau (Op. cit.), is commonly to produce a moderate exhilaration of the feelings, and an unusual activity of the intellectual powers; but this activity gradually frees itself from the control of the Will. The individual feels himself incapable of fixing his attention upon any subject; his thoughts being continually drawn off by a succession of ideas which force themselves (as it were) into his mind, without his being in the least able to trace their origin. These speedily occupy his attention, and present themselves in strange combinations, so as to produce the most fantastic and impossible creations. By a strong effort of volition, however, the original thread of the ideas may be recovered, and the interlopers driven away. These "lucid intervals" successively become of shorter and shorter duration, and can be less frequently procured by a voluntary effort; for the internal tempest becomes more and more violent, the torrent of (apparently) disconnected ideas increases in vehemence, so as completely to arrest the attention, and the mind is at last entirely given up to it, and at the same time withdrawn from the perceptive consciousness of external things, although, as already pointed out (§ 828), it is by no means removed from the influence of sensory impressions. The succession of ideas has at first less of incoherence than in ordinary dreaming, the ideal events not departing so widely from possible realities; and the disorder of the mind is at first manifested in errors of perception, in false convictions, or in the predominance of one or more extravagant notions. These false ideas are generally not altogether of an imaginary character, but are originally called into existence by external impressions, these being erroneously interpreted through the disordered action of the perceptive faculty; thus, for example, among the most common perversions are those relating to time and space, minutes seeming hours, hours being prolonged into years, and all idea of time being at last obliterated, so that past and present are confounded together as in ordinary dreaming: whilst in like manner streets may appear of an interminable length, the people at the other end seeming to be at a vast distance; the mind having a tendency to

exaggerate every impression made upon the consciousness, especially those which affect the emotional state. The effect of a full dose, however, is at last to produce the complete withdrawal of the mind from the contemplation of external things, and entirely to suspend the action of the will over the current of thought; and the condition then comes to be nearly the same as that of ordinary Dreaming, the chief difference consisting in the readiness with which the emotions may be excited in those who are under the influence of the Hachisch, and in the degree in which these are amenable to external influences.—The following concise and faithful description of the ordinary Delirium of disease will show how completely it corresponds in all its essential characters with that which is induced by the introduction of intoxicating agents into the blood. "In its highest degree, it is a complete disturbance of the intellectual actions; the thoughts are not inactive, but rather far more active than in health; they are uncontrolled, and wander from one subject to another with extraordinary rapidity; or, taking up one single subject, they twist and turn it in every way and shape, with endless and innumerable repetitions. The thinking faculty seems to have escaped from all control and restraint, and thought after thought is engendered without any power of the patient to direct and regulate them. Sometimes they succeed each other with such velocity, that all power of perception is destroyed, and the mind, wholly engrossed with this rapid development of thoughts, is unable to perceive impressions made upon the senses; the patient goes on unceasingly raving, apparently unconscious of what is taking place around him; or it may be, that his senses have become more acute, and that every word from a bystander, or every object presented to his vision, will become the nucleus of a new train of thought; and, moreover, such may be the exaltation of his sensual perception, that subjective phenomena will arise in connection with each sense, and the patient fancies he hears voices or other sounds, whilst ocular spectra in various forms and shapes appear before his eyes and excite further rhapsodies of thought."¹ It must be remarked that there is usually a greater disorder of the perceptive faculty in Delirium than in ordinary Dreaming; for, in the former condition, the erroneous images are more vividly conceived of as having an existence external to the mind, than they are in the latter, the illusory visual and auditory perceptions having all the force of reality, and being the original *sources* of ideas, instead of (as seems to be rather the case in dreaming) their *products*.²

¹ See Dr. Todd's "Lumleian Lectures, on the Pathology and Treatment of Delirium and Coma," in the "Medical Gazette," 1850, vol. xlv. p. 703.—A circumstance was mentioned to the Author, whilst he was a student at Edinburgh, which remarkably illustrates the influence of suggestions derived from external sources, in determining the current of thought. During an epidemic of Fever, which had occurred some time previously, and in which an active delirium had been a common symptom, it was observed that many of the patients of one particular physician were possessed by a strong tendency to throw themselves out of the window, whilst no such tendency presented itself in unusual frequency in the practice of others. The Author's informant, himself a distinguished Professor in the University, explained this tendency by what had occurred within his own knowledge, as follows: His friend and colleague, Dr. A., was attending a patient, Mr. B., who seems to have been the first to make the attempt in question; impressed with the necessity of taking due precautions, Dr. A. then visited Dr. C., in whose *hearing* he gave directions to have the windows properly secured, as Mr. B. had attempted to throw himself out. Now Dr. C. distinctly remembers that, although he had not previously experienced any such desire, it came upon him with great urgency as soon as ever the idea was thus suggested to him; his mind being just in that state of incipient delirium, which is marked by the temporary dominance of some one idea, and by the want of voluntary power to withdraw the attention from it. And he deemed it probable that, as Dr. A. went on to Mr. D., Dr. E., &c., and gave similar directions, a like desire would be excited in the minds of all those who happened to be in the same impressible condition.

² In true Dreaming, the sensational consciousness is entirely closed to the outward world; and all the images which we may believe we see, or the sounds that we fancy our-

830. Those more violent forms of Delirium in which there is considerable emotional disturbance, pass by almost imperceptible gradations into the state of *Mania*, which is usually characterized by the combination of complete derangement of the intellectual powers, with passionate excitement upon every point which in the least degree affects the feelings. There is, however, a considerable amount of variety in the phases of *Mania*, depending upon differences in the relative degree of *intellectual* and of *emotional* disturbance. For there may be such a derangement of the former, as gives rise to complete incoherence in the succession of ideas, so that the reasoning power is altogether suspended; and yet there may be at the same time an entire absence of emotional excitement, so that the condition of the mind is closely allied to that of dreaming or of rambling delirium. On the other hand, the intellectual powers may be themselves but little disturbed, the trains of thought being coherent, and the reasoning processes correctly performed; but there may be such a state of general emotional excitability, that nothing is *felt* as it should be, and the most violent passion may be aroused and sustained by the most trivial incidents, or by the wrong ideas which are formed by the mind as a consequence of their misinterpretation (§ 796). Between these two opposite states, and that in which the disturbance affects at the same time the intellectual and the emotional part of the Mental nature, there is a complete succession of transitional links; but, under all phases of this condition (these often passing into each other in the same individual), there is one constant element, namely, the deficiency of Volitional control over the succession of ideas. This deficiency appears to be a primary element in those forms which essentially consist in Intellectual disturbance; whilst in those of which Emotional excitement is the prominent feature, it seems rather to result from the overpowering mastery that is exercised over the Will, by the states of uncontrollable passion which succeed each other with little or no interval. It seems probable, however, from the phenomena of Intoxication (§ 829), that the very same agency which is the cause of the undue Emotional excitability, also tends to produce an absolute diminution in the power of Volitional control.

831. From the state of *Mania*, we naturally pass to those more persistent forms of *Insanity*, in which there is some settled disorder in the action of the Mind. Although this may arise from a perversion of any part of the psychical nature, yet a partial or complete deficiency in the Volitional control over the current of thought, and consequently over the actions which are the expressions of it, seems to be a characteristic feature of every form of *Insanity*; and it is this, which, in so far as it exists, ought to be considered as rendering the individual irresponsible for his actions.—It is chiefly (but not solely) in those cases in which the Cerebral power has been weakened by a succession of attacks of *Mania*, *Epilepsy*, or some other disorder which consists in a perverted action of the whole organ, that we find the *Intellectual* powers specially and permanently disordered; the succession of thought becoming incoherent, and the perception of those relations of ideas on which all reasoning processes depend, being more or less completely obscured. The failure usually shows itself *first* in the power of Volitional direction, and especially in the faculty of Recollection; in proportion as the mind is unable to bring the results of past experience to bear on its present operations, do these lose their connectedness and consistency; and at last all the ordinary links of association appear to be severed, and (as in the most incoherent kinds of Dreaming) the succession of thoughts cannot be ac-

cesses to hear, seem to result from changes in the Sensorium excited by Cerebral influence; but in Delirium there is an evidently disordered action of the sensorium itself, of which spectral illusions and other “subjective sensations” are the manifestation. This is particularly obvious in that form of Delirium which is known as *delirium tremens*.

counted for on any known principles of psychical action. All this may occur with or without emotional excitement; not unfrequently the latter occurs in paroxysms, which interrupt the otherwise tranquil life of the subjects of this form of Insanity, and it is not at all incompatible with this condition, that there should be a special excitability upon some one point, which, owing to the annihilation of the Volitional controlling power, acquires a temporary predominance whenever it is called into play. It is the general characteristic, however, of this form of Insanity, that there are no *settled* delusions; the mind not being disposed to dwell long upon any one topic, but wandering off in a rambling manner, so as speedily to lose all trace of the starting-point. Such patients are unable to recollect what passed through their thoughts but a few minutes previously; if any object of desire be placed before them, which it requires a consistent reasoning process to attain, they are utterly unable to carry this through; and the direction of their desires is perpetually varying, and may be readily altered by external suggestion. Cases of Intellectual Insanity, depending (as this form of the disease usually does) upon structural disorder of the Cerebrum, are less amenable to treatment than are those of the other forms presently to be described; and their tendency is usually towards complete fatuity.

832. There may, however, be no primary disorder of the Intellectual faculties; and the Insanity may essentially consist in a tendency to disordered Emotional excitement; which affects the course of thought, and consequently of action, without disordering the reasoning processes in any other way than by supplying wrong materials to them. Now the emotional disturbance may be either *general* or *special*; that is, there may be a derangement of feeling upon almost every subject, matters previously indifferent becoming invested with strong pleasurable or painful interest, things which were previously repulsive being greedily sought, and those which were previously the most attractive being in like manner repelled; or, on the other hand, there may be a peculiar intensification of some one class of feelings or impulses, which thus acquire a settled domination over the whole character, and cause every idea with which they connect themselves to be presented to the mind under an erroneous aspect. The first of these forms, now generally termed *Moral Insanity*, may and frequently *does* exist without any disorder of the Intellectual powers, or any delusion whatever; it being (as we shall presently see) a result of the generality of the affection of the Emotional tendencies, that no one of them maintains any constant hold upon the mind, one excitement being (as it were) driven out by another. Such patients are among those whose treatment requires the nicest care, but who may be most benefited by judicious influences. Nothing else is requisite, than that they should exercise an adequate amount of self-control; but the best directed moral treatment cannot enforce this, if the patient do not himself (or herself¹) co-operate. Much may be effected, however, as in the education of children, by presenting adequate *motives* to self-control; and the more frequently this is exerted, the more easy does the exertion become. —The more limited and settled disorder of any one portion of the Emotional nature, however, gives an entirely different aspect to the character, and produces an altogether dissimilar effect upon the conduct. It is the essential feature of this state, that some one particular tendency acquires a dominance over the rest; and this may happen, it would seem, either from an extraordinary exaggeration of the tendency, whereby it comes to overmaster even a strongly-exercised Volitional control; or, on the other hand, from a primary weakening of the Volitional control, which leaves the predominant bias of the individual

¹ This form of Insanity is particularly common among females of naturally "quick temper," who, by not placing an habitual restraint upon themselves, gradually cease to retain any command over it.

free to exercise itself. Again, the exaggerated tendency may operate (like an ordinary Emotion) either in directly prompting to some kind of action which is the expression of it; or in modifying the course of thought, by habitually presenting erroneous notions upon the subjects to which the disordered feeling relates, as the basis of Intellectual operations. The first of these forms of Monomania is that which is known as *impulsive* Insanity; and the recognition of its existence is of peculiar importance in a juridical point of view. For whilst the Law of England only recognizes as *irresponsible*, on the ground of Insanity, those who are incapable of distinguishing right from wrong, or of recognizing the consequences of their acts, it is unquestionable that many criminal actions are committed under the irresistible dominance of some insane impulse, the individual being at the time perfectly aware of their evil nature and of his amenableness to punishment.¹ Such an impulse may lead the subject of it to kill, to commit a rape, to steal, to burn, and so on, and this without the least intention of doing injury to another; and many instances have occurred, in which the individuals thus affected have voluntarily withdrawn themselves from the circumstances of whose exciting influence they were conscious, and have even begged to be put under restraint.—It is a remarkable fact, moreover, and one that strikingly confirms the view of the nature of Emotional states which has been here advocated, that the insane impulse appears to be not unfrequently the expression of a dominant *idea*, with which there is no such association of pleasurable feeling as makes the action prompted by it an object of *desire*, but which operates by taking full possession of the mind, and by forcing (so to speak) the body into the movements which express it. The individual thus affected regards himself as the victim of a *necessity* which he cannot resist, and may be perfectly conscious (as when the impulse proceeds from a strong desire) that what he is doing will be injurious to others

¹ The following very characteristic example of the Homicidal form of impulsive Insanity is given in one of the recent Reports of the Morningside (Edinburgh) Lunatic Asylum.—The case was that of a female, who was not affected with any disorder of her intellectual powers, and who labored under no delusions or hallucinations, but who was tormented by “a simple abstract desire to kill, or rather, for it took a specific form, to strangle. She made repeated attempts to effect her purpose, attacking all and sundry, even her own nieces and other relatives; indeed, it seemed to be a matter of indifference to her *whom* she strangled, so that she succeeded in killing some one. She recovered, under strict discipline, so much self-control as to be permitted to work in the washing-house and laundry, but she still continued to assert that she ‘must do it,’ that she was ‘certain she would do it some day,’ that she ‘could not help it,’ that ‘surely no one had ever suffered as she had done’—was not hers ‘an awful case;’ and, approaching any one, she would gently bring her hand near their throat, and say mildly and persuasively, ‘I would just like to do it.’ She frequently expressed a wish that all the men and women in the world had only one neck, that she might strangle it. Yet this female had kind and amiable dispositions, was beloved by her fellow-patients, so much so that one of them insisted on sleeping with her, although she herself declared that she was afraid she would not be able to resist the impulse to get up during the night and strangle her. She had been a very pious woman, exemplary in her conduct, very fond of attending prayer-meetings, and of visiting the sick, praying with them, and reading the Scriptures, or repeating to them the sermons she had heard. It was the second attack of insanity. During the former, she had attempted suicide. The disease was hereditary, and it may be believed that she was strongly predisposed to morbid impulses of this character, when it is stated that her sister and mother both committed suicide. There could be no doubt as to the sincerity of her morbid desires. She was brought to the Institution under very severe restraint, and the parties who brought her were under great alarm upon the restraint being removed. After its removal, she made repeated and very determined attacks upon the other patients, the attendants, and the officers of the Asylum, and was only brought to exercise sufficient self-control by a system of rigid discipline. This female was perfectly aware that her impulses were wrong, and that if she had committed any act of violence under their influence, she would have been exposed to punishment. She deplored, in piteous terms, the horrible propensity under which she labored.”

or to himself. This state bears a close resemblance to that of the "biologized" subject, who is peremptorily told: "You *must* do this," and does it accordingly (§ 825); and it is one that is particularly liable to be induced in persons who habitually exercise but little Volitional control over the direction of their thoughts, by the influence of suggestions from without, and especially by occurrences which fix themselves strongly upon their attention.¹

833. Now although the existence of any morbidly exaggerated impulse, leading to the commission of acts which must be regarded as truly Insane, may be fairly considered as constituting *Monomania*, yet that term is usually restricted to those forms of Insanity in which there are positive *delusions* or *hallucinations*, that is to say, fixed beliefs which are palpably inconsistent with reality. These delusions are not attributable to perversions of the reasoning process, but arise out of the perverted Emotional state. This gives rise, in the first place, to a misinterpretation of actual occurrences in accordance with the prevalent state of the feelings (§ 796); but, when the disorder has lasted some time, ideas which the imagination at first presents under a very transient aspect, are habitually dwelt upon in consequence of the interest with which they are invested, and at last become realities to the consciousness of the individual, simply because he has not brought them to the test of actual experience. When the mind has once yielded itself up to the dominance of these erroneous ideas, they can seldom be dispelled by any process of reasoning; for it results from the very nature of the previous habits of thought that the reasoning powers are weakened, and that the volitional control, through want of exercise, can no longer be exerted. And consequently, although a vigorous determination to get rid of the ideas which are felt to be erroneous, and to keep down the emotional tendency whose exaggeration is the essence of the disorder—in other words, a strong effort of self-control—may be effective in an early stage of this condition,² yet, when the wrong habits of thought have become settled, little

¹ To this condition are to be referred many of the insane actions which are commonly set down to the account of *Imitation*. This term would be best restricted to that state of mind, in which there is an *intention* to imitate; for what is called "involuntary imitation" is merely the expression of the fact that the consciousness of the performance of a certain act by one individual gives rise to a tendency to its performance by the other. Thus the excitement of the act of yawning by the sight or the sound of it in another, is a simple phenomenon of consensual movement proceeding from an *exciting sensation*. And in like manner, the commission of suicide or homicide, after an occurrence of the same kind which has previously fixed itself strongly upon the attention, is an *ideo-motor* action, prompted by a *suggesting idea*. Thus, it is well known that after the suicide of Lord Castlereagh, a large number of persons destroyed themselves in a similar mode. Within a week after the "Pentonville Tragedy," in which a man cut the throats of his four children and then his own, there were two similar occurrences elsewhere. After the trial of Henriette Cornier for child-murder, which excited a considerable amount of public discussion on the question of homicidal insanity, Esquirol was consulted by numerous mothers, who were haunted by a propensity to destroy their offspring.—The following is a remarkable example of the *sudden* domination of a morbid impulse, to which no tendency seems to have been previously experienced, and which appears to have been altogether devoid of any emotional character. Dr. Oppenheim, of Hamburg, having received for dissection the body of a man who had committed suicide by cutting his throat, but who had done this in such a manner that his death did not take place until after an interval of great suffering, jokingly remarked to his attendant: "If you have any fancy to cut your throat, don't do it in such a bungling way as this; a little more to the left here, and you will cut the carotid artery." The individual to whom this dangerous observation was addressed was a sober, steady man, with a family and a comfortable subsistence; he had never manifested the slightest tendency to suicide, and had no motive to commit it. Yet, strange to say, the sight of the corpse, and the observation made by Dr. O. suggested to his mind the idea of self-destruction; and this took such firm hold of him that he carried it into execution, fortunately, however, without duly profiting by the anatomical instructions he had received; for he did not cut the carotid, and recovered.

² See an excellent little essay by the Rev. J. Barlow, on "Man's Power over himself to

can usually be done by way of direct attack upon them ; and the most efficacious treatment consists in the encouragement of the general habit of self-control, and in the withdrawal of the mind, so far as may be possible, from the morbid state of action, by presenting to it other sources of interesting occupation.

834. Returning now from the consideration of these Pathological conditions of Mind (as they may be not unfairly designated) to the examination of the Psychological constitution of Man in the state of normal activity of all his faculties, we shall find that very important data may be drawn from these sources, with regard to the *modus operandi* of the Will, and the manner in which our conduct is determined. For we have seen that, in so far as the directing influence of the Will over the current of thought is suspended, the individual becomes a thinking automaton, destitute of the power to withdraw his attention from any idea or feeling by which his mind may be possessed, and as irresistibly impelled, therefore, to act in accordance with this, as the lower animals are to act in accordance with their instincts. In so far, therefore, as this directing influence is not exercised, the succession of trains of thought which occupy the consciousness (associated, or not, with feelings that give them an *emotive* character) must be considered as dependent on the "reflex action" of the Cerebrum ; the nature of this action being determined, not merely by the original constitution of the organ, but by the mode in which it has been subsequently exercised ; its nutrition taking place in such conformity to the impressions made upon it, and to the modes in which it is habitually directed by the Will, that it *grows to* these, so that a new organization thus comes to be established, by which habits of thought are determined, such as would not have arisen from its original constitution.¹

prevent or control insanity."—It may be well for the Author to state, that he was led, several years since, to the formation of the view above enunciated with regard to the emotional source of most if not all the delusions of the Insane, by the careful observation of a case in which the gradual formation of such delusions could be traced, and in which the varying tenacity of their hold over the belief (which sometimes appeared disposed to get rid of them) corresponded exactly with varying degrees of intensity of the dominant emotion. Having been led, by his interest in this case, to make particular inquiries as to the point in question, among those whose experience of Insanity has been far more extensive than his own, he has obtained from them full confirmation of the view above expressed.—It is not a little interesting, in this connection, as well as in the additional relation which it indicates between Insanity and the various phases of Dreaming, Delirium, &c., that the *particular delusion* seems often to be suggested by accidental circumstances, the mind being previously under the influence of the morbid tendency which gave the peculiar *direction* to the thoughts. Thus we find it mentioned in the "Morningside Report," from which we have already quoted, that the Queen's public visit to Scotland seemed to give a special direction to the ideas of several individuals who became insane at that period, the attack of insanity being itself in some instances traceable to the excitement induced by that event. One of the patients, who was affected with puerperal mania, believed that in consequence of her confinement having taken place on such a remarkable occasion, she must have given birth to a person of royal or divine dignity. During the religious excitement which prevailed at the time of the "disruption" of the Scotch Church, an unusually large number of patients were admitted into the various asylums of Scotland, laboring under delusions connected with religion ; the disorder having here also doubtless commenced in an exaggeration of this class of *feelings*, and the erroneous *beliefs* having been formed under their influence. Again, in the Report of the same Institution for 1851, it is stated that, as in former instances, "the current topics of the day gave coloring and form to the delusions of the disordered fancy. We have thus had no less than five individuals admitted during the year, who believe themselves the victims of Mesmeric agency"—a sort of "Mesmeric mania" having been prevalent in Edinburgh during that period—"three of the inmates talked much of California, and of the bags full of gold which they had obtained from the diggings ; and one of them arrived at the persuasion that his body was transmuted into gold."

¹ See Dr. Farcock's Essay "On the Reflex Function of the Brain," in the "Brit. and For. Med. Review," vol. xix. p. 298.—If it be thought that, in the above expressions, there is too much of a *Materialistic* character, the author would beg to refer back to the

The variety of phases which these different states present is chiefly dependent upon the following elements : (1) the relative degree in which the Mind is in a state of receptivity for external impressions, or is attending only to what passes within itself ; (2) the degree in which the coherence of the successive states is maintained by the continuance and right operation of the preformed associations, so that trains of thought are consistently carried out, and reasoning processes correctly performed ; and (3) the degree in which the normal operation of the intellectual faculties is disturbed by emotional excitement, either general, or limited to one class of feelings. The influence of the *first* of these elements is remarkably seen in the contrast between natural and artificial Reverie (§§ 824, 825) ; also between some forms of natural and artificial Somnambulism (§ 827) ; and not less between different forms of Insanity, since in this last condition we find some patients constantly brooding over particular trains of thought, and almost incapable of being turned from the contemplation of these by external suggestions, whilst others are no less remarkable for the instability of their mental states, and for the readiness with which a new direction may be given to the thoughts by sensory impressions. The influence of the *second* element is strikingly manifested in the difference between the various phases of the state of Dreaming, and in the contrast between the incoherence of the commoner forms of this, and that consistency in the trains of thought which generally characterizes the state of Somnambulism ; but it is yet more remarkably displayed in those forms of Delirium and Insanity which are especially characterized by the complete *confusion* of the Intellectual powers, all previous states of consciousness being (as it were) jumbled together, and the order of their recurrence, and the nature of the new combinations which may arise out of them, being irreducible to any principle of orderly sequence. The influence of the *third* element is well seen in those forms of artificial Reverie and Somnambulism, in which the *feelings* as well as the *ideas* admit of being played upon by external influences ; for it is easy to bring the mind of the subject under the domination of any particular emotion, by taking the appropriate means to excite it ;¹ and, so long as this may continue, the language and actions most obviously display its impress. But it is in Insanity that we best see the influence of Emotional states upon the course of thought and of action ; for here we find them supplying impulses to bodily action, which the weakened Will cannot resist, although the intellect distinctly apprehends the evil consequences of such actions ; or, on the other hand, we find them directing the whole course of mental activity, giving a wrong color to all the ideas which are related to them, and so fixing the attention upon the trains of thought founded upon these, that they come to attain a complete domination over the mind, and hence over the conduct, to which they supply *motives* of such potency that the Will can neither resist them nor withdraw the mind from attending to them.

835. Thus, then, we see that in all those states in which the directing power of the Will over the current of *thought* is suspended, the course of *action* is determined by some *dominant idea*, which for the time has full possession of the mind, and from which the individual has no power of withdrawing his consciousness ; the *motive power* of this idea being such as either impels to action

antecedent portions of this inquiry, and especially to §§ 804—6, as showing to what extent he regards the *organization* of the Cerebrum as determining its mode of *psychical activity*.

¹ We have seen how remarkably the emotions may be played upon, in the “hypnotic” state, by muscular associations (827) ; in the “biologized” state, it is often sufficient to ask the “subject”—“Why are you so angry,” “Why are you so sad,” &c.—to induce these conditions respectively, the suggestions being here conveyed verbally, instead of through the muscular sense.

by a feeling of internal necessity (analogous to that which prompts the reflex actions of the Cranio-Spinal axis), or solicits it by the anticipation of pleasure in its result, or of pain in abstinence from it. On the other hand, the man in full possession of his psychical capacity, whilst equally amenable with those in the foregoing states to the influence of the motive power of ideas, differs from them all in this most important particular—that he has the power of refraining from action under the immediate pressure of motives, and of so far *modifying their relative force* by the mode in which he contemplates them, that their original balance may be completely altered; and hence his ultimate determination, whilst still governed by the predominance of motives, may be entirely different from that on which he would have acted, if he had given way to his first impulse. For, just as we may direct our Intellectual operations by an exercise of Volition, so as to fix upon certain ideas only, out of the many which present themselves to our consciousness, and to limit our attention to certain peculiar aspects of these (§ 823), so may we fix our attention upon any one or more among the motives which tend to determine our action, and keep these (as it were) in a strong light before the mind's eye, whilst by withdrawing our attention from others, we virtually throw them into the background, just as we can do with regard to objects of sensation. And further, by calling the Reasoning powers into operation, and bringing them to bear upon the questions at issue, so as to follow out each of the modes of action that are before the mind to its probable consequences, the Will indirectly brings a set of new motives, arising out of these consequences, before the judgment; and these, at first overlooked, may become important elements in the decision. On the other hand, it may be that in thus reasoning out the probable consequences of an action, motives which at first presented themselves in great strength, lose more or less of their force, and even become altogether futile.—It is in these modes that “second thoughts” generally prove to be best, save where selfish considerations are brought to take the place of primary generous impulses; whilst a hasty determination often leads to wrong action, because all the motives that should be taken into account have not been duly weighed.¹

836. Now, if we examine into the different kinds of *Motive Powers*, which, under the permission or the intentional direction of the Will, are the sources of Human action, we shall find that they may be ranged under the following heads: (1) *Previously-acquired Habits*, which automatically incite us to do as we have been previously accustomed to do under the like circumstances, without the idea of prospective pleasure or pain, or of right or wrong, being at all present to our minds. The formation of Habits, both of thought and action, seems referable to the psychical principle of Contiguous Association (§ 807) and to the physiological principle of Nutritive Assimilation (§ 591), which, in regard to the operations of the Cerebrum, seem to be only different expressions of the same fact; namely, that whatever mode of activity has been once strongly impressed on the organ, this has a tendency to perpetuate itself. In so far as the Will yields to this tendency, instead of controlling it, the individual becomes the slave of *routine*; and this condition is often very remarkably presented by

¹ It has been held by some, that when a man is struggling with a temptation, and the motives to good and the motives to evil are nearly in equilibrium, like weights in the two scales of the balance, the Will acts as an independent preponderating power, like a hand pushing down the scale-beam on one side. It appears to the author, however, to be much more conformable to the results of a careful examination of our own conduct, to regard the will as imparting an augmented gravity (as it were) to the weights on one side, by directing attention to their value, and by indirectly making additions to them, in the manner stated above; whilst it diminishes the force of those on the other side, by preventing the mind from giving its attention to them, and also (it may be) by virtually abstracting some of them from the scale.

persons who are deficient in Volitional power, as it is also among the lower animals, from whose actions we may derive our best illustrations of what Habit will do, when it is not under the direction of any higher principle.¹ The tendency to habitual action is so universally recognized as an important part of our psychical nature, that Man has been said to be "a bundle of habits." Where the habits have been judiciously formed in the first instance the tendency is an extremely useful one, prompting us to do that spontaneously which might otherwise require a powerful effort of the Will:² but, on the other hand, if a bad set of habits have grown up with the growth of the individual, or if a single bad tendency be allowed to become an habitual spring of action, a far stronger effort of Volition will be required to determine the conduct in opposition to them. This is especially the case, when the habitual idea possesses an Emotional character, and becomes the source of *desires*; for the more frequently these are yielded to, the more powerful is the solicitation they exert.—(2). *Emotional states*, which incite us to particular actions, either by the expectation of gratification in the act itself or in some consequence which our reason leads us to anticipate from it, or by the expectation of pain if the act be not performed. All those *desires* and *aversions* which have so large a share in determining our conduct, come under this category; and to it must likewise be referred all those

¹ It is not uncommon to meet with Idiots, in whom the tendency to the automatic recurrence of modes of action once impressed on the consciousness is extremely remarkable. The following is stated by Miss Martineau in regard to a youth under her own observation, who, in consequence of early injury to the brain, never acquired the power of speech, or of understanding the language of others, or of in any way recognizing other minds; but was at the same time strongly affected by sensory impressions. "He could endure nothing out of its position in space or its order in time. *If any new thing was done to him at any minute of the day, the same thing must be done at the same minute every day thenceforward.*" Thus, although he disliked personal interference, his hair and nails having been one day cut at ten minutes past eleven, the next day, and every day after, at ten minutes past eleven, he, "as if by a fate," brought comb, scissors, and towel; and it was necessary to cut a snip of hair before he would release himself. Yet he had no knowledge whatever of the measurement of time by clocks and watches, and was no less minutely punctual in his observances when placed beyond the reach of these aids. So in regard to form, number, and quantity, his actions were equally methodical. He occupied himself much in making paper-cuttings, which were remarkable for their symmetry. If, when he was out of the room, a brick were taken from the heap with which he amused himself, he would pass his hand over them, spread them a little, and then lament and wander about till the missing one was restored. If seven comfits had once been put into his hand, he would not rest with six; and if nine were given, he would not touch any until he had returned two. ("Letters on the Laws of Man's Nature and Development," p. 71.)—It would be easy to adduce multitudes of analogous instances from the actions of animals, especially such as are purposely *trained* to particular habits, by taking advantage of the principle of "contiguous association," which seems to be peculiarly strong in Dogs, Horses, &c. And the recurrence of particular actions at particular intervals of time, without any means of consciously estimating its passage, or any incidents that can suggest the return of the period, is a very curious indication of the degree in which organic changes in the nervous system, once determined by a certain number of repetitions, tend to perpetuate themselves. Thus, a dog that has been accustomed to receive food at a certain hour and place every day will come in search of it with extraordinary punctuality; and the horse of a commercial traveller, after going the same journey a few times, will stop at the houses of all his master's customers; and when he has been pulled up at a new point on one journey, will spontaneously stop at the same point on the next—a fact of which the author has personal knowledge.

² This is especially the case with regard to habits of intellectual exertion, which are in themselves peculiarly free from any emotional complication. The author can speak from long and varied experience, of the immense saving of exertion which arises from the formation of *methodical habits* of mental labor; which cause the ordinary routine to be performed with a far less amount of fatigue than would be required on a more desultory system. Even here, however, care should be taken to avoid allowing one's-self to be as much the slave of habits, that all mental labor, save that which is undertaken at a particular time, or in a particular place, becomes difficult and wearisome.

considerations which are simply *prudential*, these usually having reference to the *remoter* effects which our actions are likely to have upon our own welfare or upon that of others, and thus bringing before the mind, as elements in its determination, certain additional objects of desire or aversion.—(3) *Notions of Right and of Duty*, which, so far as they attach themselves to our actions, give them a *moral* and *religious* character. These may act simply as *ideas*, whose coercive power depends upon the intensity with which they are brought before the mind; but they obtain a much stronger influence, when they acquire an Emotional character from the association of the feeling of *desire* with the idea of *obligation*; that is, when we feel a *wish* to do that which we are conscious we *ought* to do. This association is one which it is peculiarly within the capability of the Will to cherish and strengthen. And still more powerful is the operation of these combined motives, when a constant *habit* of acting upon them has been formed; for the strongest desires are then immediately repressed, the strongest aversions cease to exert an influence, when once the question is looked at in its moral aspect, and a clear perception has been attained of its right and its wrong side.¹

837. It has been usually considered by Moralists and Theologians that *Conscience*, or the *Sense of Duty*, is an autocratic faculty, which unmistakably dictates what is right in each individual case, and which should consequently be unhesitatingly obeyed as the supreme and unerring guide. Now this view of the case is attended with practical difficulties, which make it surprising that it can ever have been entertained. For it must be obvious to every one who carefully considers the matter, that, whilst a *notion of right and wrong*, attaching itself to certain actions, is as much a part of the moral nature of every individual, as the feeling of *pleasure* or *pain* attaching itself to certain states of consciousness is of his sensational nature, yet the determination of *what* is right and *what* is wrong is a matter in great degree dependent upon education, habits of thought, conventional associations, &c.; so that the moral standard of no two men shall be precisely alike, and the moral standards of men brought up under entirely different circumstances shall be of the most opposite nature.² So, whilst

¹ The difference between the *habitual*, the *prudential*, and the *moral* aspects of the very same action, may be made apparent by a very simple illustration.—We will suppose that a man has been accustomed to take a ride every day at a particular hour; his whole nature so accommodates itself to the *habit*, that he feels both mentally and physically uncomfortable at any interruption to the usual rhythm. But suppose that, just as the appointed hour comes round, the sky becomes overcast, threatening the rider with a drenching if he perseveres in his attention, his decision will then be founded on a *prudential* consideration of the relative probabilities of his escaping or of his being exposed to the shower, and of how far the enjoyment he may derive from his ride is likely to be replaced by the discomfort of a thorough wetting. But suppose, further, that, instead of taking a mere pleasure ride, a medical man is about to set forth on a professional visit to a patient whose condition requires his aid; a new motive is thus introduced, which alters the condition of the whole question, making it no longer one of prudence only, but one of *morality*. Another motive which should give the question a moral aspect, would be consideration for himself, and the risk of life or health he might run; this should be decisive where the motive which impels him to the act in question is merely that of self-gratification; but if it bring into antagonism his duty to his patient and his desire to benefit him, and on the other hand his duty to himself and his regard for the ulterior welfare of those who may be immediately dependent upon him, the question has its right and its wrong aspect on both sides, and the right may only be determined after a careful balance of probabilities. Such moral conflicts are continually occurring amongst medical practitioners in regard to exposure to the severity of the weather, to dangerous infection, or to risks of other kinds; and the decision will mainly depend upon the previously formed habits, on the one hand of disregarding all considerations connected with self, on the other of attaching special weight to them.

² Without having recourse to the strange estimates of right and wrong which prevail amongst Savage nations, for an illustration of this position, it may be sufficient to compare the different views *conscientiously* entertained on the question of Slavery, by high-minded, estimable, and Christian men and women in different parts of the American Union.

the notion of a God sustaining any direct relation to us, involves the notion of *Duty*, which attaches itself to all actions with which he can be considered as having any concern, the dictates of this sense will vary with the ideas entertained respecting the character and requirements of the Deity; and actions may be sincerely regarded as an acceptable sacrifice by one class of religionists, which are loathed as barbarous and detestable by another. Moreover, in what have been designated as "cases of conscience," the most enlightened Moralist may have a difficulty in deciding what is the right course of action, simply because the moral sense finds so much to approve on both sides that it cannot assign a preponderance to either. And the same difficulty attends the determination of *Duty*, in many peculiar contingencies; each of two or more possible modes of action being recommended by its conformity to the divine law on certain points whilst it seems opposed to it on others. Thus, individuals in whose characters the love of *truth* and of *justice* and the *benevolent* affections are the prominent features, and who would shrink with horror from any violation of these principles of action for any selfish purpose whatever, are sorely perplexed when they are brought into collision with each other; a strong motive to tell a falsehood being presented by the desire to protect a defenceless fellow-creature from unmerited oppression or death.¹—If, then, neither the Moral Sense nor the Sense of Religious Duty affords a clear and unvarying rule of action in each individual case, it is evident that the determination of what is *right* and *wrong* must be a matter of *judgment*; the rule of Moral action being based on a comparison of the relative nobility of the motives which impel us to either course, and being decided by the preference which is accorded to one motive or combination of motives above another.² If it be asked how are the relative values of these

¹ Thus, if a man, who might be urged to conceal a fugitive slave near the Canadian frontier, were to refuse to do so merely on the fear of unpleasant consequences to himself, he would be justly branded with the character of a cold-hearted coward; but if his refusal should proceed from the conviction that the divine law requires the preference of rigid truthfulness over every other motive, and that, by concealing the suppliant he should be forced into a violation of that law, he cannot be blamed even by those who believe that the law of compassion written upon our hearts is at least equally imperative.—Similar difficulties beset the upholders of the non-resistance creed, which teaches that *love* is the all-powerful principle in the moral world, and that it should entirely supersede all those impulses of our nature which lead us to oppose force to force, and to resist an unjust and unprovoked assault. Here, again, we might readily understand and sympathize with those who consider that the fear of personal suffering does not warrant our doing a severe injury to another in warding off a threatened attack; but when the question comes to be, not of *self-defence*, but of protection to others who are helpless dependents upon our succor, and who are bound to us by the closest ties of natural affection, we feel that the comparative nobility of the latter motive warrants actions which our individual peril might scarcely justify.

² This view of the nature of Conscience will be found more fully developed in the "Prospective Review" for November 1845, pp. 587-9.—"Every moral judgment," it is well remarked by the reviewer, "is *relative*; and involves a comparison of (at least) two terms. When we praise what *has been* done, it is with the coexistent conception of *something else that might have been* done; and when we resolved on a course as *right*, it is to the exclusion of some other that is *wrong*." This is why we cannot attach any moral character to the actions of animals that are performed under the direction of a blind undesigning instinct, leaving them no choice between one course and another; nor to those which are executed by human beings, even when possessed of their full intelligence, under the domination of impulses which they have it not in their power to restrain; nor, again, to those performed by individuals whose moral sense has either never been awakened, or has been so completely misdirected by early education, that their standard of right and wrong is altogether opposite to that which the enlightened conscience of mankind agrees in adopting. But, although there are doubtless many cases in which criminal actions are committed under the impulse of passions (such as anger, lust, &c.) which the individual has not at the moment the power to control, and although he must be absolved from moral responsibility *quoad* the immediate motives of those particular actions, yet these motives

motives to be decided, the answer must be sought in the general consciousness of Mankind, which is found to be more and more accordant in this respect, the more faithfully it is interpreted, the more habitually it is acted on, and the more the whole intelligence is expanded and enlightened. It is this tendency towards universal agreement which shows that there is really as good a foundation for Moral science in the psychical nature of Man, as there is for that of Music in the pleasure which he derives from certain combinations and successions of sounds. So, again, the more elevated are the religious ideas of Mankind in regard to the character and will of the Deity, the more will they approach to a general accordance in regard to what constitutes Religious Duty; and the complete coincidence which exists between the dictates of the Christian law and the highest principles of pure Morality prevents one set of motives from ever coming into antagonism with the other. The *Conscience* of the religious man, indeed, may be said to be the *resultant* of his Moral sense, combined with the idea of Duty which arises out of his sense of relation to the Deity. With the former are closely associated all those emotions and propensities which render him considerate of the welfare of his fellow-men as of his own; and with the notion of duty to God are closely united the desire of His favor, the fear of his displeasure, the aspiration after His perfection, all which act like other motives in deciding the Will. Their relative force on any occasion, as compared with that of the lower propensities and sensual desires, greatly depends on the degree in which they are *habitually* brought to influence the mind; and it is in its power of fixing the contemplation on those higher considerations which ought to be paramount to all others, and of withdrawing it from the lower, that the Will has the chief influence in the direction of the conduct according to the dictates of Virtue.

838. From the general survey which we have now taken of the phenomena of Mind, it seems to be the obvious conclusion that these phenomena essentially consist in a *succession of states of consciousness*; and that this succession takes place, like the phenomena of the Material Universe, under certain determinate conditions. We have seen that, in those actions of the Nervous system (as of other parts of the body) in which the Will is not concerned, we have simply to consider the two elements of which we take account in all scientific inquiry; namely, the force that operates, and the organized structure on and through which it operates—in other words, the dynamical agency, and the material conditions. And if we could imagine a being to grow up from infancy to maturity, with a mind in the state of that of a “biologized” subject (§ 825), we should see that it would be strictly correct to speak of his character as formed *for* him and not *by* him; all his thoughts, feelings, and actions being but the reflex of his own nature upon the impressions made upon it; and that nature being determined in part by original constitution, and in part by the mode in which it is habitually called into action.—This last condition is one that is peculiar to a living and growing organism; and it is one which cannot be too strongly or too constantly kept in mind. A mere inorganic substance reacts in precisely the same mode to mechanical, chemical, electrical, or other agencies, however frequently these are brought to bear upon it, provided it has been restored to its original condition; thus water may be turned into steam, the steam condensed into water, and the water raised into steam again, any number of times, without the slightest variation in the effects of the heat and cold which are the efficient causes of the change. But every kind of activity peculiar to a living body,

too frequently derive all their force from the habit of yielding to their promptings in lesser matters, which gradually gives them a dominance, such as the Will (weakened by want of exercise in the habit of self-restraint) is unable to resist. Hence the criminal *action* is to be regarded as but the expression of a long previous course of criminal *thought*, for which, in so far as he could have otherwise directed it, the individual may legitimately be held responsible.

involves (as has been repeatedly shown) a change of structure; and the formation of the newly generated tissue receives such an influence from the conditions under which it originates, that all its subsequent activity displays their impress.—This view, indeed, must be extended to that remarkable *hereditary transmission* of psychical character, which presents itself under circumstances that entirely forbid our attributing it to any agency that can operate subsequently to birth, and which it would seem impossible to account for on any other hypothesis than that the formative capacity of the germ determines the subsequent development of the Brain, as of other parts of the body, and (through this) its mode of activity, in accordance with the influences under which that germ was first impregnated. And thus what we speak of as the “original constitution” of each individual, is in great part (if not entirely) determined by the conditions, dynamical and material, of the parent-organisms; a convincing proof of which general fact is afforded by a careful examination of the parental constitution and habits, in a large proportion of cases of Idiocy.¹ Whatever may be the congenital constitution, however, there can be no question that this is liable to great modification from external influences, both such as directly affect its physical conditions, and such as operate through the consciousness, in determining the course of thought and feeling, before the individual has acquired any self-determining power. Of this influence of physical agencies, we have a typical example in the phenomena of Cretinism; since, although the conditions under which that state is developed have not yet been precisely determined, no one can reasonably doubt that they are such as act in the first instance in modifying the nutrition and activity of the bodily organism in general, and of the Nervous system in particular.

839. From the time when the Human being first becomes conscious that he has a power within himself of *determining the succession* of his mental states, from that time does he begin to be a free agent; and in proportion as he exerts that power, does he emancipate himself from the domination of his constitutional or automatic tendencies. It is a principle now recognized by all the most enlightened educators, that the development of this power of self-control ought to be the object of all nursery discipline; and the process of its acquirement is very gradual. When an infant is excited to a fit of passion by some unpleasant sensation, its nurse attempts to restore its equanimity by presenting some new object to its attention, so that the more recent and vivid pleasurable impression may efface the sense of past uneasiness. As the infant grows into childhood, the judicious parent no longer trusts to mere sensory impressions for the diversion of the passionate excitement, but calls up in its mind such ideas and feelings as it is capable of appreciating, and endeavors to keep the attention fixed upon these, until the violence of the emotion has subsided; and recourse is had to the same process, whenever it is desired to check any tendency to action which depends upon the selfish propensities—appeal being always made to the highest motives which the child is capable of recognizing, and punishment being only had recourse to for the purpose of supplying an additional set of motives when all others fail. For a time, this process of external suggestion may need to be continually repeated, where there are strong impulses whose unworthy character calls for repression; but if it be judiciously adapted and consistently persevered in, a very slight suggestion serves to recall the superior motives to the conflict. And in further space, the child comes to feel that he has *himself* the power of recalling them, and of controlling his urgent impulses to immediate action. The power of self-control, thus usually acquired in the first instance

¹ A most valuable collection of data on this subject is afforded by Dr. Howe's admirable “Report on Idiocy” made to the Legislature of Massachusetts, of which an abstract is contained in the “American Journal of the Medical Sciences,” April, 1849.

in regard to those impulses which directly determine the conduct, gradually extends itself to the habitual succession of the thoughts ; and in proportion as this is brought under the direction of the Will, does the individual become capable of forming his own character, and therefore truly responsible for his actions.—It must not be forgotten, however, that the power of self-control may be turned to a bad as well as to a good account ; and that the value of its results will entirely depend upon the *direction* in which it is employed. The thoughts may be so determinately drawn away from the higher class of motives, the suggestions of conscience so habitually disregarded, and the whole attention so completely fixed upon the gratification of selfish or malevolent propensities, that the Human nature acquires far more of the Satanic than of the Divine character ; the highest development of this type (if the term may be permitted) being displayed by those who use their power of self-control for the purposes of hypocrisy and dissimulation, and cover the most malignant designs under the veil of friendship. Such men (whose portraiture is presented by our great Dramatist in the character of Iago) show us to what evil account the highest intellect and the most powerful will may be turned, when directed by the baser class of motives ; and we cannot but feel that they are far more degraded in the moral scale, than those who, having never learned to control their animal propensities, and being unconscious of the very existence of a higher nature within themselves, simply obey the promptings of their automatic impulses, and are rather to be considered as ill-conditioned automata, than as vicious men. Of this latter class, some, from original constitution and early influences of the most degrading kind, seem altogether destitute of anything but a *brutal* nature ; such ought to be treated as irresponsible beings, and, as such, restrained by external coercion from doing injury to society. But this class is small in proportion to that of individuals who *act* viciously, simply because they have never been led to *know* that any other course is open to them, or to *feel* any motives that might give them a different impulse. With these, the object should rather be to awaken the higher parts of the moral nature, “to find out the holy spot in every child’s heart,” and to develop habits of self-control in the manner just described, than to subjugate by external restraint ; and the success which has attended this method, in the hands of those who have judiciously applied it, is sufficient evidence of its superiority ; many of the most apparently debased natures having been thus elevated to a grade which it seemed at first impossible they could ever attain. From the *Satanic*, or positively and wilfully evil type of Human nature, in which the highest powers are turned to the worst account, we are thus conducted through the *brutal* or negatively evil type, towards that higher aspect of Humanity, which is presented by those who habitually keep before them the *Divine* ideal, and who steadily endeavor to bring their *whole nature* into conformity with it. This is *not* to be effected by dwelling *exclusively* on *any one* set of the motives already referred to, as those which the truly religious man keeps before his mind. Even the idea of Duty, *operating alone*, tends to reduce the individual to the subservience of a slave, rather than to induce in him that true mastery over himself which consists in such a regulation of his emotions and propensities that his course of duty becomes the spontaneous expression of his own higher nature ; but it is a most powerful aid in the acquirement of that regulation, by the fixation of the thoughts and affections on “things on high,” which is the best means of detaching them from all that is earthly and debasing. It is by the *assimilation*, rather than by the *subjugation* of the Human Will to the Divine, that Man is really lifted towards God ; and in proportion as this assimilation has been effected, does it manifest itself in the life and conduct ; so that even the lowliest actions become holy ministrations in a temple consecrated by the felt presence of the Divinity. Such was the

life of the Saviour; towards that standard it is for the Christian disciple to aspire.¹

840. *Of Sleep.*—It is a peculiar feature in the physiology of the Cerebral and Sensory Ganglia, that their activity undergoes a periodical suspension, more or less complete; the necessity for this suspension arising out of the fact that the exercise of their functions is in itself destructive to their substance, so that, if this be not replaced by nutritive regeneration, they speedily become incapacitated for further use. In ordinary profound sleep, there is a state of complete unconsciousness, so far as *external* phenomena are concerned; no ordinary impressions upon the organs of sense being either felt or perceived; although an extraordinary impression, or even an habitual one upon which the attention has been previously fixed as that at which the slumberer is to awake himself (§ 843), occasions a renewal of sensorial activity. It is in this capability of being aroused by external impressions, that the chief difference lies between Sleep and the abnormal condition of Coma, whether this arise from the influence of pressure or effusion within the cranium, or be consequent upon the poisoning of the blood by narcotic substances, or follow a previous state of abnormal activity of the brain, such as delirium. Between these two conditions, however, every gradation may be seen; as in the gradually increasing torpor which results from slow effusion within the cranium, the gradual loss of susceptibility to external impressions which is observed after an over-dose of a narcotic, and the intensification of ordinary sleep which is consequent upon extreme previous fatigue. It is a matter of doubt, however, whether the suspension of sensorial consciousness is equally complete as regards *internal* or Cerebral changes; for some are of opinion that, even in the most profound sleep, we still dream, although we may not remember our dreams; whilst others (and among these the Author would rank himself) consider that dreaming is a mark of imperfect sleep, and that, in profound ordinary sleep, the Cerebrum, as well as the Sensory Ganglia, is in a state of complete functional inactivity. When dreaming takes place, there is usually a less complete exclusion of sensory impressions, although the perceptive consciousness may be entirely suspended; so that the course of the dream may be influenced by them, although the mind is not conscious of them as such (§ 828). If this be the true account of the case, we may consider that, in profound Sleep, the functional activity of the Cerebrum and of the Sensory Ganglia is alike suspended; that in Dreaming, the Cerebrum is partially active, and that the Sensorium is in such a condition of recieience for Cerebral impressions that the mind becomes directly conscious of them, whilst it only becomes conscious of impressions made upon the Organs of Sense, after their influence has been transmitted through it to the Cerebrum, and has been, as it were, reflected back by that organ. It is, in fact, by their influence upon the current of *ideas*, and not by their power of exciting *sensations*, that we recognize their operation under such circumstances.

841. The state of Sleep is one to which there is beyond doubt a *periodical* tendency; for, when the waking activity has continued for a considerable proportion of the twenty-four hours, a sense of fatigue is usually experienced, which indicates that the brain requires repose; and it is only under some very strong physical or moral stimulus, that the mental energy can be sustained through the whole cycle. In fact, unless some decidedly abnormal condition of the Cere-

¹ The careful study of the Epistles of St. Paul will show this to be the *dominant idea* of this Apostle's teachings. Under the name of "the law," he refers to the spirit of bondage or external coercion, which "was the schoolmaster to bring us to Christ;" whilst under the designation of "the Gospel" he obviously desires to express that spirit of freedom or internal spontaneity which is the source of all that is truly noble in the Christian character.

brum be induced by the protraction of its functional activity, Sleep will at last supervene, from the absolute inability of the organ to sustain any further demands upon its energy, even in the midst of opposing influences of the most powerful nature.¹ That the strongest voluntary determination to remain awake is forced to give way to Sleep, when this is required by the exhaustion of nervous power, must be within the experience of every one; and the only way in which the Will can even retard its access, is by determinately fixing the consciousness upon some definite object, and resisting every tendency in the thoughts to wander from this. It does not appear to be of any consequence, whether this exhaustion be produced by the active exercise of volition, reflection, emotion, or simple sensation; still we find that the *volitional* direction of the thoughts, in a course different from that in which they tend spontaneously to flow, is attended with far more *effort* than the automatic activity of the mind (§ 823); whilst, on the other hand, the excess of *automatic* activity, whether as regards the intellectual operations or emotional excitement, tends to prevent sleep. This is particularly the case when the feelings are strongly interested; thus, the strong desire to work out a result, or to complete the survey of a subject, is often sufficient to keep up the intellectual activity as long as may be requisite (a state of restlessness, however, being often induced, which prevents the access of sleep for some time longer); so, again, anxiety or distress is a most frequent cause of wakefulness; and it is generally to be observed that the state of *suspense* is more opposed to the access of sleep than the greatest joy or the direst calamity when certainty has been attained.² But although an excess of automatic activity is opposed, so long as it continues, to the access of sleep, yet it cannot be long protracted without occasioning an extreme exhaustion of nervous power, which necessitates a long period of tranquillity for its complete restoration.—But whilst the necessity for sleep arises out of the state of the nervous system itself, there are certain external conditions which favor its access; and these, in common parlance, are termed its predisposing causes. Among the most powerful of these is the *absence* of sensorial impressions; thus, darkness and silence usually promote repose; and the cessation of the sense of muscular effort, which takes place when we assume a position that is sustained without it, is no less conducive to slumber. There are cases, however, in which the *continuance* of an accustomed sound is necessary, instead of positive silence, the cessation of the sound being a complete preventive of sleep; thus it happens that persons living in the neighborhood of the noisiest mills or forges cannot readily sleep elsewhere. Such cases are referable, either to the influence of *habit*, which causes the attention of the

¹ Thus it is on record, that during the heat of the battle of the Nile, some of the over-fatigued boys fell asleep upon the deck; and during the recent attack upon Rangoon, the Captain of one of the war-steamers most actively engaged, worn out by the excess of continued mental tension, fell asleep and remained perfectly unconscious for two hours, within a yard of one of his largest guns, which was being worked energetically during the whole period. So even the severest bodily pain yields before the imperative demand occasioned by the continued exhaustion of the powers of the sensorial centres; thus Damiens slept upon the rack, during the intervals of his cruel sufferings; the North American Indian at the stake of torture will go to sleep on the least remission of agony, and will slumber until the fire is applied to awaken him; and the medical practitioner has frequent illustrations of the same fact. That the continued demand for muscular activity is not incompatible with the access of sleep, is obvious from what has been already said of the persistence of the automatic movements in that condition (§ 726): it is well known that, previously to the shortening of the hours of work, factory children frequently fell asleep whilst attending to their machines, although well aware that they should incur severe punishment by doing so.

² Thus it is a common observation that criminals under sentence of death sleep badly so long as they entertain any hopes of a reprieve; but as soon as they are satisfied that their death is inevitable, they usually sleep more soundly, and this even on the very last night of their lives.

individual to be more attracted by the suspension of the sound than by its continuance; or to the fact that the *monotonous repetition* of sensorial impressions is often more favorable to sleep than their complete absence. Thus it is within the experience of every one that the droning voice of a heavy reader on a dull subject is often a most effectual hypnotic; in like manner, the ripple of the calm ocean on the shore, the sound of a distant waterfall, the rustling of foliage, the hum of bees, and similar impressions upon the auditory sense, are usually favorable to sleep; and the muscular and tactile senses may be in like manner affected by a uniform succession of gentle movements, as we see in the mode in which the nurses "hush-off" infants, or in the practice of gently rubbing some part of the body, which has been successfully employed by many who could not otherwise compose themselves to sleep. The reading of a dull book acts in the same mode through the visual sense; for the eyes wander on from line to line and from page to page, receiving a series of sensorial impressions which are themselves of a very monotonous kind, and which only tend to keep the attention alive in proportion as they excite interesting ideas.—In these and similar cases, the influence of external impressions would seem to be exerted in withdrawing the mind from the distinct consciousness of its own operations (the loss of which is the transition-state into that of complete unconsciousness), and in suspending the directing power of the Will. And this is the case even where the attention is in the first instance *voluntarily* directed to them; as in some of the plans which have been recommended for the induction of sleep, when there exists no spontaneous disposition to it. In other methods, the attention is fixed upon some internal train of thought, which, when once set going, may be carried on automatically; such as counting, or repeating a French, Latin, or Greek verb. In either case, when the sensorial consciousness has been once steadily fixed, the monotony of the impression (whether received from the Organs of Sense or from the Cerebrum) tends to retain it there; so that the Will abandons, as it were, all control over the operations of the mind, and allows it to yield itself up to the soporific influence. This last method is peculiarly effectual, when the restlessness is dependent upon some mental agitation, provided that the Will has power to withdraw the thoughts from the exciting subject, and to reduce them to the tranquillizing state of a mere mechanical repetition.

842. The access of Sleep is sometimes quite sudden; the individual passing at once from a state of complete mental activity to one of entire torpor. More generally, however, it is gradual; and various intermediate phases may be detected, some of which bear a close resemblance to the state of Reverie, whose peculiar nature has been already described (§ 824). The same may be said with regard to the transition from the state of Sleep to that of wakeful activity; for this also may be sudden and complete, although it usually consists of a succession of stages—the complete consciousness of the individual's relation to the external world, and the power of directing his thoughts and actions to any subject about which he may be required to exert himself, being the last to be acquired. There may be a rapid alternation of these different states; the loss and recovery of the waking consciousness being many times repeated in the course of a few minutes, when the circumstances are such as to prevent the access of profound sleep by the recurrence of sensory impressions; as when a man on horseback, wearied from want of rest, lapses at every moment into a dozing state, from which the loss of the balance of his body as frequently and suddenly arouses him; or when a man going to sleep in a sitting posture, gradually loses the support of the muscles which keep his head erect, his head droops by degrees and at last falls forwards on his chest, and the slight shock thence ensuing partially arouses and restores his voluntary power, which again raises the head. Similar fluctuations occur in the sensory perceptions; and these may be often artificially induced by very simple means. "We find, for example, one condi-

tion of sleep so light, that a question asked restores consciousness enough for momentary understanding and reply; and it is an old trick to bring sleepers into this state, by putting the hand into cold water, or producing some other sensation, not so active as to awaken, but sufficient to draw the mind from a more profound to a lighter slumber. This may be often repeated, sleep still going on; but make the sound louder and more sudden, and complete waking at once ensues. The same with other sensations. Let the sleeper be gently touched, and he shows sensibility, if at all, by some slight muscular movement. A ruder touch excites more disturbance and motion, and probably changes the current of dreaming; yet sleep will go on; and it often requires a rough shaking, particularly in young persons, before full wakefulness can be obtained." * * * "It is certain that the faculties of sensibility and volition are often unequally awakened from sleep. The case may be stated, familiar to many, of a person sleeping in an upright posture, with the head falling over the breast; in whom sensibility is suddenly aroused by some external impression, but who is unable, for a certain time, to raise his head, though the sensation produced by this delay of voluntary action is singularly distressing." These various cases, it is justly remarked by Dr. Holland,¹ depending severally on the intensity of sleep, and on the kind and degree of the external exciting causes, will be found to explain many of those so-called Mesmeric phenomena which are offered to us under a widely different interpretation. And it may be here remarked, that among those intermediate states between sleep and waking, which either occur spontaneously, or can be induced in numerous individuals by very simple processes (§§ 825, 827), there are several which exhibit peculiarities that are not in themselves in the least degree less remarkable than are those which are regarded with so much wonder by the uninformed observer, when induced by the asserted Mesmeric influence, and paraded as specimens of its powers (see § 845, *note*).

843. It is unquestionable that the supervision of Sleep may be promoted by the strong previous expectation of it; and this is true, not merely of ordinary sleep, but of the states of artificial Reverie and Somnambulism formerly described. Every one knows the influence of habit, not only in regard to "time," but also as to "place and circumstance," in predisposing to Sleep. Thus, the celebrated pedestrian Capt. Barclay, when accomplishing his extraordinary feat of walking 1000 miles in as many successive hours, obtained at last such a mastery over himself that he fell asleep the instant he lay down. And the sleep of soldiers, sailors, and others, who may be prevented from obtaining regular periods of repose, but are obliged to take their rest at short intervals, may be almost said to come at command; nothing more being necessary to induce it than the placing the body in an easy position, and the closure of the eyes. It is related that the Abbé Faria, who acquired notoriety through his power of inducing somnambulism, was accustomed merely to place his patient in an arm-chair, and then, after telling him to shut his eyes and collect himself, to pronounce in a strong voice and imperative tone the word "*dormez*," which was usually successful. The Author has had frequent opportunities of satisfying himself that the greater success which attends the "hypnotic" mode of inducing somnambulism (§ 827) in the hands of Mr. Braid, its discoverer, than in that of others, partly lies in the mental condition of his subjects, who come to him for the most part under the confident expectation of its production, and are further assured by a man of very determined will that it *cannot* be resisted.² And it is one of the most curious phenomena of the "biological" state (§ 825), that, in many sub-

¹ See his excellent Chapter on "Sleep," from which the above extracts are taken, in his "Medical Notes and Reflections," and his "Chapters on Mental Physiology."

² A very amusing instance in which Sleep, having been previously induced by the ordinary "mesmeric" and then by the "hypnotic" processes, was brought on by the simple

jects at least, sleep may be induced in a minute or less, by the positive assurance, with which the mind of the individual becomes possessed, that it *will* and *must* supervene.—The influence of previous mental states is yet more remarkable, in determining the effects produced upon the sleeper by different sensory impressions. The general rule is, that *habitual* impressions of any kind have much less effect in arousing the slumberer than those of a new and unaccustomed character. An amusing instance of this kind has been related to the Author, which, even if not literally true, serves extremely well as an illustration of what is unquestionably the ordinary fact. A gentleman who had taken his passage on board a ship-of-war was aroused on the first morning by the report of the morning gun, which chanced to be fired just above his berth; the shock was so violent as to cause him to jump out of bed. On the second morning he was again awake, but this time he merely started and sat up in bed; on the third morning the report had simply the effect of causing him to open his eyes for a moment, and turn in his bed; on the fourth morning it ceased to affect him at all, and his slumbers continued to be undisturbed by the report, so long as he remained on board. It often happens that sleep is terminated by the *cessation* of an accustomed sound, especially if this be one whose monotony or continuous repetition had been the original inducement to repose. Thus, a person who has been read or preached to sleep, will awake, if his slumber be not very profound, on the cessation of the voice; and a naval officer, sleeping beneath the measured tread of the watch on deck, will awake if that tread be suspended.—In this latter case, the influence of the simple cessation of the impression will be augmented by the circumstance next to be alluded to, which has received too little attention from writers on this subject, but which is of peculiar interest both in a physiological and psychological point of view, and is practically familiar to almost every one. This is, that the awakening power of sensory impressions is greatly modified by our *habitual state of mind* in regard to them. Thus, if we are accustomed to *attend* to these impressions, and our perception of them is thus *increased* in acuteness, we are much more easily aroused by them, than we are by others which are in themselves much stronger, but which we have been accustomed to disregard. Thus, most sleepers are aroused by the sound of their own names uttered in a low tone, when it requires a much louder sound of a different description to produce any manifestation of consciousness. The same thing is seen in comatose states; a patient being often capable of being momentarily aroused by shouting his name into his ear, when no other sound produces the least effect. The following circumstance, communicated to the Author by the late Sir Edward Codrington, is a most apposite illustration of this principle. When a young man, he was serving as signal-lieutenant under Lord Hood, at the time when the French fleet was confined in Toulon harbor; and being desirous of obtaining the favorable notice of his commander, he devoted himself to his duty—that of watching for signals made by the look-out frigates—with the greatest energy and perseverance, often remaining on deck nineteen hours out of the twenty-four, with his attention constantly directed towards this one object. During the few hours which he spent in repose, his sleep was so profound, that no noise of an ordinary kind, however loud, would awake him; and it used to be a favorite amusement with his comrades, to try various experiments devised to test the soundness of his sleep. But if the word “signal” was even whispered in his ear, he was instantly aroused, and fit for immediate duty.—The influence of habitual attention is shown as much in the effect produced by the cessation, as in that of the occurrence, of sensory impressions. Thus in the case of the naval officer aroused by

belief that a new process was being put in practice, will be found in the “Brit. and For. Med. Rev.,” vol. xix. p. 477.

the suspension of the measured tread of the watch over his head, the knowledge possessed, during the waking state, that this suspension is either an act of negligence which requires notice, or indicates some unusual occurrence, doubtless augments the effect which the discontinuance of the sound would of itself produce. It is not requisite, however, that the sound should be one habitually attended to during the hours of watchfulness; for it is sufficient if it be one on which the *attention has been fixed* as that at which the slumberer is to arouse himself. Thus the medical man, even in his first profound sleep after a fatiguing day's work, is aroused by the first stroke of the clapper of his night-bell; and to those who are accustomed to rise every morning at the sound of an alarm-clock, the frequency and regularity of the occurrence do not diminish, but rather increase the readiness with which it produces its effect, provided that the warning be promptly obeyed. On this usually depends the efficiency of the awakening sound; if it be disregarded as a thing to which there is no occasion to give heed, it very soon ceases to produce any effect, the entire peal not being sufficient to awake the sleeper; whilst, on the other hand, the first stroke is enough to break the repose of him who is impressed with the effectual desire of profiting by the warning. And thus it may happen that, of two persons in the same room, either shall be at once aroused by a sound which produces no disturbance in the slumbers of the other. To this influence of previous impressions, whether habitual, or but once forcibly made, we are also to refer the spontaneous termination of the state of sleep at particular times, without any sensorial excitement from external impressions. Thus, many persons who are accustomed to rise at a particular hour, wake regularly at that hour, whether they have gone to rest early or late; so that the act of spontaneously awakening is no proof that the desirable amount of repose has been obtained. But what is more remarkable is, that many individuals have the power of determining, at the time of going to rest, the hour at which they shall rise, so as to awake from a profound sleep at the precise time fixed upon. In others, however, the desire to rise at a particular hour only induces a state of restlessness throughout the night, destroying the soundness of the slumbers: the individual awakes many times in the night, with the belief that the hour is past, and very possibly oversleeps it after all, the system being worn out by the need of repose.

844. The *Amount of Sleep* required by Man is affected by so many conditions, especially *age, temperament, habit, and previous exhaustion*, that no general rule can be laid down on the subject.—The condition of the *fœtus in utero* may be regarded as one of continual slumber; the apparatus of animal life being completely secluded from all stimuli which could arouse it into activity, whilst the energy of the organic functions is entirely directed to the building up of the fabric. On its first entrance into the world, the infant continues to pass the greater part of its time in slumber; and this is particularly to be noticed in cases of premature birth, the seven months' child seeming to awake only for the purpose of receiving food, and giving but little heed to external objects, whilst even the eight months' child is considerably less alive to sensory impressions than one born at the full time. The excess of activity of the *constructive* over the *destructive* operations, which characterizes the whole period of infancy, childhood, and adolescence (§§ 129—131), requires that a larger proportion of the diurnal cycle shall be passed in sleep (during which the former may be carried on without hinderance), than is requisite when adult age has been attained, the two sets of changes being then balanced (§ 132); and the amount of sleep to which the system shows itself disposed, gradually diminishes from three-fourths to one-half, and from one-half to one-third, or even to one-quarter, of the twenty-four hours. It is to be noticed that the sleep of children or young persons is not only longer than that of adults, but is also more profound. On the other hand, as age advances, and the bodily and mental activity of the

waking state decrease, a smaller amount of sleep suffices; or, if the slumber be protracted, it is usually less deep and refreshing. It may be noticed, however, that very old persons usually pass a large proportion of their time in sleep, or rather in a sort of heavy doze, especially after meals; as if, in consequence of the want of energy of their nutritive operations, a very long period of repose is necessary to repair the waste which takes place during their short period of activity.—In regard to the influence of *temperament*, it may be remarked that a plethoric habit of body, sustained by full diet, usually predisposes to sleep, provided that the digestive powers be in a vigorous condition; persons of this constitution frequently pass nine or ten hours in slumber, and maintain that they cannot be adequately refreshed by less. On the other hand, thin wiry people, in whom the “nervous” temperament predominates, usually take comparatively little sleep, notwithstanding the greater activity of their nervous system when they are awake; but their slumber, while it lasts, is generally very deep. Persons of “lymphatic” temperament, heavy passionless people, who may be said to live very slowly, are usually great sleepers; but this rather because, through the dulness of their perceptions, they are less easily kept awake by sensorial or mental excitement, than because they really require a prolonged cessation of activity. As they are half asleep during the waking state, so would it appear that the constructive operations must be far from active while they are asleep, so little do they seem restored by the repose.—The amount of sleep, *cæteris paribus*, required by individuals, is very greatly influenced by *habit*; and, contrary to what we might anticipate, we find that the briefest sleepers have usually been men of the greatest mental activity. Thus Frederick the Great and John Hunter are said to have only required five hours’ sleep out of the twenty-four. General Elliot, celebrated for his defence of Gibraltar, is recorded not to have slept more than four hours out of the twenty-four. It may be doubted whether it would be possible for any one to sustain a life of vigorous exertion upon a smaller allowance than this; and the general fact is, that from six to eight hours of repose, out of every twenty-four, are required to keep the system of an adult in a state of healthful activity. The influence of habit may be brought to bear on the protraction, as well as on the abbreviation, of the usual period. Thus Quin, the celebrated actor, could slumber for twenty-four hours successively; and Dr. Reid, the metaphysician, could take as much food, and afterwards as much sleep, as were sufficient for two days.—It is needless to dwell upon the obvious fact, that, other things being equal, the amount of sleep required by man is proportional to the *amount of mental exertion* put forth during the waking hours; since this is an obvious result of what has been laid down as the cause of the demand for sleep. It may be remarked, however, that we must not measure the *amount* of sleep by its *duration* alone; since its *intensity* is a matter of equal importance. The light slumber which is disturbed by the slightest sounds cannot be as renovating as the profound sopor of those whom no ordinary noise will awake.

845. There are certain states of the encephalic centres, in which there is an *entire absence of sleep*; and this may continue for many days, or even weeks or months. Insomnia is, for instance, one of the characteristics of acute mania, and may also exist in various forms of monomania; it is usually, also, one of the symptoms of incipient meningeal inflammation; and it may constitute a specific disease in itself. In all these cases, however, the preponderance of the *destructive* processes over the *constructive* manifests itself, sooner or later, in the exhaustion of the mental and bodily powers. Thus mania, when prolonged or frequently occurring, subsides into dementia; and, if it continue for any length of time, is sure to be followed by a great sense of wretchedness and prostration, frequently accompanied by continual restlessness. Such effects, too, in a less aggravated degree, result from habitual *deficiency* of sleep; whether

this result from emotional excitement, which keeps repose at bay, or from a voluntary determination to keep the intellect in activity. This is a very common occurrence among industrious students, who, with a laudable desire for distinction, allow themselves less than the needed quantum of repose. Headache, tension, heat, throbbing, and various other unpleasant sensations in the head, give warning that the brain is being overtasked; and if this warning be not taken, sleep, which it was at first difficult to resist, becomes even more difficult to obtain; a state of general restlessness and feverish excitement are induced; and if, in spite of this, the effort be continued, serious consequences, in the form of cerebral inflammation, apoplexy, paralysis, fever, insanity, or loss of mental power, more or less complete, are nearly certain to be induced. Some individuals can sustain such an effort much longer than others, but it is a great mistake to suppose that they are not equally injured by it; in fact, being possessed with the belief that they are not suffering from the exertion, they frequently protract it until a sudden and complete prostration gives a fearful demonstration of the cumulative effects of the injurious course in which they have been persevering. Those, consequently, who are earlier forced to give way, are frequently capable of accomplishing more in the end.—In regard to the degree of *protraction* of sleep which is consistent with a healthy state of the system in other respects, it is difficult to speak with certainty. Of the numerous well-authenticated instances on record,¹ in which sleep has been continuously prolonged for many days or even weeks, it is enough here to state that they cannot be regarded as examples of natural sleep; the state of such persons being more closely allied to hysteric coma. An unusual tendency to ordinary sleep generally indicates a congested state of the brain, tending to apoplexy; and it has been stated that apoplexy has been actually induced by the experimental attempt to ascertain how large a proportion of the diurnal cycle might be spent in sleep. Thus, on either side, inattention to the dictates of Nature, in respect to the amount of sleep required for the renovation of the system, becomes a source of disease, and should therefore be carefully avoided.²

¹ Such, for example, as that of Samuel Chilton ("Phil. Trans.," 1694), and that of Mary Lyall ("Trans. of Roy. Soc. of Edinb.," 1818).

² *On Mesmerism.*—It appears to the Author that the time has now come, when a tolerably definite opinion may be formed regarding a large number of the phenomena commonly included under the term "Mesmerism." Notwithstanding the exposures of various pretenders, which have taken place from time to time, there remains a considerable mass of phenomena, which cannot be so readily disposed of, and which appear to him to have as just a title to the attention of the scientific Physiologist as that which is possessed by any other class of well ascertained facts.

Passing over, for the present, the inquiry into the manner in which these effects may be induced, the Author may briefly enumerate the principal phenomena which he regards as having been veritably presented in a sufficient number of instances to entitle them to be considered as genuine and regular manifestations of the peculiar bodily and mental condition under discussion:—

1. A state of complete *Coma* or perfect insensibility, analogous in its mode of access and departure to that which is known as the "Hysteric Coma," and (like it) usually distinguishable from the Coma of Cerebral oppression by a constant twinkling movement of the eyelids. In this condition, severe surgical operations may be performed, without any consciousness on the part of the patient; and it is not unfrequently found that the state of torpor extends from the Cerebrum and Sensory Ganglia to the Medulla Oblongata, so that the respiratory movements become seriously interfered with, and a state of partial asphyxia supervenes.

2. A state of *Somnambulism* or Sleep-waking, which may present all the varieties of the natural Somnambulism, from a very limited awakening of the mental powers, to the state of complete Double Consciousness, in which the individual manifests all the ordinary powers of his mind, but remembers nothing of what has passed when restored to his natural waking state. This state of Somnambulism, in the form which it commonly takes, is characterized by the facility with which the thoughts are directed into any channel which the observer may desire, by the principle of "suggestion;" and by the want of power, on

the part of the Somnambulist, to apply the teachings of ordinary experience to the correction of the erroneous ideas which are thus made to occupy the mind. In these particulars, this condition closely corresponds with that of the Artificial Somnambulism or "hypnotism" of Mr. Braid (§ 827); and the only peculiarity in its phenomena which can be regarded as at all essential, consists in the special relation which is affirmed to exist between the mesmerizer and his "subject." Now in regard to the existence of this *rapport*, it is especially noteworthy that it was not discovered until long after the practice of Mesmerism had come into vogue, having been unknown to Mesmer himself and his immediate disciples; and that its phenomena have only acquired constancy and fixity, in proportion as its (supposed) laws have been announced and received as established. The history of Mesmerism, candidly and philosophically analyzed, affords abundant evidence in proof of this position; but the best guarantee of its truth is drawn from the results obtained by the numerous Mesmerizers, who have begun to experiment for themselves without any knowledge of what they were to expect, and who have produced a great variety of remarkable phenomena, without having ever discovered this *rapport*; and yet have obtained immediate evidence of it, when once the idea has been put into their own minds, and thence into those of their "subjects." It is quite easy to understand, that if the mind of the "subject" be so yielded up to that of the mesmerizer, as to receive and act upon any impression which the latter forces upon or even suggests to it, the notion of this peculiar relation is as easily communicable as any other, and may exert a complete domination over the "subject," through the whole of the sleep-waking state. Thus the commands or suggestions of the mesmerizer meet with a response which those of no other individual may produce; in fact, the latter usually seem to be unheard by the somnambule, simply because they are not related to the dominant impression—a phenomenon of which the experience of natural somnambulism is continually presenting examples. And further, it being a fact that individuals of what may be termed the susceptible constitution, have brought themselves, by the habit of obedience, into complete subjection to the expressed or understood will of some other party, even in the waking state, without any mesmeric influence whatever, it is not at all difficult to understand how such a habit of attending to the operator, and to him alone, should be peculiarly developed in the state of Somnambulism, in which the mind seems to have lost its self-acting power, and to be the passive recipient of external impressions. And the same explanation applies to the other phenomena of this *rapport*; such as its establishment with any bystander, by his joining hands with the mesmerizer and the somnambule; for, as already shown (§ 827), it is quite sufficient that the somnambule should be previously possessed with the idea that this new voice will thus be audible to her, and that she must obey its behests, for it to produce all the same effects upon her as that of the mesmerizer had previously done. In all the *successful* experiments of this kind which the Author has seen, this previous idea *was* entertained, both by mesmerizer and somnambule; but in by far the larger proportion of cases which have fallen under his notice, and especially when the subjects of them were not *habitués* of the mesmeric *séances*, the phenomena of this class could not be made to show themselves, the consciousness of the somnambule not being limited to the mesmerizer or to those *en rapport* with him, but being equally extended to all around her.

3. A frequent phenomenon of this condition, and one which has its parallel in Natural Somnambulism, is a remarkable *Exaltation of one or more of the Senses*, so that the individual becomes susceptible of influences, which, in his natural condition, would not be in the least perceived. The Author has witnessed a case in which such an exaltation of the sense of Smell was manifested; and in the same case, as in many others, there was a similar exaltation of the sense of Temperature. The exaltation of the muscular Sense, by which various actions that ordinarily require the guidance of vision, are directed independently of it, is a common phenomenon of the "mesmeric" with various other forms of artificial as well as of natural Somnambulism. The Author has repeatedly seen Mr. Braid's "hypnotized" subjects write with the most perfect regularity, when an opaque screen was interposed between their eyes and the paper, the lines being equidistant and parallel; and it is not uncommon for the writer to carry back his pen or pencil to dot an *i* or cross a *t*, or make some other correction in a letter or word. Mr. B. had one patient who would thus go back and correct with accuracy the writing on a whole page of note-paper; but if the paper was moved from the position it had previously occupied on the table, all the corrections were on the *wrong* points of the paper as regarded the *actual* place of the writing, though on the *right* points as regarded its *previous* place; sometimes, however, he would take a fresh departure, by feeling for the upper left hand corner of the paper, and all his corrections were then made in their right positions, notwithstanding the displacement of the paper.—To the extraordinary exaltation of one or more of the senses, which is a characteristic of this state, may fairly be attributed a great number of the phenomena which have been supposed to indicate a peculiar and mysterious influence exerted by the mesmerizer over his subject; since the latter will be far more receptive of "suggesting" impressions,

than an ordinary bystander would suppose possible. And it is to be borne in mind that the concentration of the attention upon these may often give them a far greater significance to the individual, than they possess for others; this, it seems likely, is especially the case in regard to tones of voice, emphasis of manner, &c., when questions are propounded.

4. The Muscular system may also be excited to action in unusual modes, and with unusual energy. Notwithstanding the fallacy of many of the cases of Cataleptic rigidity which have been publicly exhibited, the Author is satisfied, from investigations privately made, of the possibility of artificially inducing this condition. A slight irritation of the muscles themselves, or of the skin which covers them—as by drawing the points of the fingers over them, or even wafting currents of air over the surface—is sufficient to excite the tonic muscular contraction, which may continue in sufficient force to suspend a considerable weight, for a longer period than it could be kept up by any conceivable effort of voluntary power. But these are phenomena which are quite as well displayed in Artificial Somnambulism induced in other ways, as they are in the “mesmeric” state; and do not afford, therefore, any more than the preceding, the slightest indication of the speciality of the latter, or the least proof of any extraneous influence exerted over the “subject.”

5. Various effects, it is asserted, may be produced upon the *Organic Functions* by “Mesmeric” influence; and it is on account of this agency, that it claims to be admitted as a directly curative agent. It will be hereafter shown, however, that effects of a precisely similar kind may be produced in other forms of Artificial Somnambulism, by simply fixing the attention on the part; and that the same may be done, even in the ordinary waking state, in certain subjects who can be worked up to the requisite pitch of confident expectation. (See CHAP. XVIII.)

The foregoing are the principal phenomena of the “Mesmeric” state, in regard to which the Author feels his mind made up. He does not see why any discredit should be attached to them, since they correspond in all essential particulars with those of states which naturally or spontaneously occur in many individuals, and which he has had opportunities of personally observing, in cases in which the well-known characters of the parties placed them above suspicion. When the facility with which the mind of the Somnambulist is played on by suggestions (conveyed either in language, or through other sensations which excite associated ideas), and the absence of the corrective power ordinarily supplied by past experience, are duly kept in view, many of the supposed “higher phenomena” of Mesmerism may be accounted for, without regarding the patient on the one hand as possessed of extraordinary powers of divination, or on the other as practising a deception. Thus, bearing in mind that Somnambulism is an acted dream, the course of which is governed by external impressions, it is easy to understand how the subject of it may be directed by leading questions to enter buildings which he has never seen, and to describe scenes which he has never witnessed, without any intentional deceit. The love of the marvellous, so strongly possessed by many of the witnesses of such exhibitions, prompts them to grasp at and to exaggerate the coincidences in all such performances, and to neglect the failures; and hence reports are given to the public, which, when the real truth of them is known, prove to have been the results of a series of guesses, the correctness of which is in direct relation to the amount of guidance afforded by the questions themselves. In like manner, the manifestations of the excitement of the “phrenological organs” seem to depend upon the conveyance of a suggestion to the patient, either through his knowledge of their supposed seat, or through the anticipations expressed by the bystanders. Many instances are recorded, in which the intention has been stated of exciting one organ, whilst the finger has been placed upon or pointed at another; and the resulting manifestation has always been that which would flow from the former. It does not hence follow that intentional deception is being practised by the Somnambulist; since the condition of mind already referred to causes it to respond to the suggestion which is most strongly conveyed to it.

In regard to the alleged powers, which are said to be possessed by many Somnambulists, of reading with the eyes completely covered, or of discerning words inclosed in opaque boxes, or of giving an account of what is taking place at a distance, all coming under the general term *Clairvoyance*, the Author need only here express his conviction that no case of this description has ever stood the test of a searching investigation.

With respect to the modes in which the “Mesmeric” Somnambulism is induced, it appears to him that they are all referable to those states of *monotony of sensory impressions*, and of *expectation*, to which reference has been already made as among the most potent of the predisposing causes of conditions allied to Sleep (§ 843). It is asserted by Mesmerizers, that they can induce the “Mesmeric” state from a distance, without the least consciousness on the part of their “subjects” that any influence is being exerted on them—an assertion, which, if true, would go far to establish the existence of a force altogether *sui generis*, capable of being transmitted from one individual to another. Here, however, as in regard to the “higher phenomena” last adverted to, the Author feels compelled to

6.—Of the Sympathetic System, and its Functions.

846. That collection of scattered but mutually-connected ganglia and nerves, which altogether constitute what is now generally designated the *Sympathetic System*, may be ranged under the following groups: 1. The isolated ganglia and nerves in immediate connection with the viscera, which seem to be the chief centres of the system; these form three principal plexuses, the *cardiac*, the *solar*, and the *hypogastric*. 2. The double chain of *prevertebral* ganglia, with connecting cords, which lies in front of the Vertebral column, and communicates on the one hand with the spinal nerves, and on the other with the before-named plexuses. Under this head we should probably rank the minute cranial ganglia, which are situated in the neighborhood of the Organs of Sense, and in immediate connection with the branches of the 5th Pair that proceed to them; these are the *ophthalmic*, *otic*, *spheno-palatine*, and *submaxillary* ganglia. 3. The ganglia on the posterior roots of the Spinal nerves; under which head we are probably to rank not only the Gasserian ganglion of the 5th Pair, but also the ganglia near the roots of the Pneumogastric and Glosso-pharyngeal nerves.—The trunks of the Sympathetic are made up of different orders of fibres; some of these being derived from the Cerebro-Spinal system, whilst others have their central termination in the vesicular matter of the Sympathetic ganglia themselves.—These last, which are all of the “gelatinous” kind (§ 339),¹ are most abundant in the great visceral plexuses; but they may be traced from the prevertebral ganglia into the spinal nerves, where they are reinforced by the fibres which have their centres in the ganglia of the posterior roots. Thus it appears that the Cerebro-Spinal and Sympathetic systems interpenetrate one another; each having its own series of ganglionic centres and of trunks con-

state that no evidence of an affirmative kind has yet been adduced, which can be in the least degree satisfactory to a scientific inquirer, who duly appreciates all the sources of fallacy to which these occurrences are open. Among these, the state of expectation on the part of the “subject” is the most important; since this has been shown, by repeated experiments, to be of itself quite sufficient to induce the state, when the “subject” has been led to entertain it; whilst, if it be *altogether* wanting, the most powerful mesmeric influence, so far as the Author’s personal knowledge extends (and on this subject, he must be excused for trusting rather to the results of his own investigations, than to the statements of other individuals, however trustworthy on ordinary matters), has always failed. A very striking instance of this kind is contained in the “Brit. and For. Med. Rev.,” vol. xix. p. 478, in an Article to which the Author may refer as on the whole expressing (although not written by himself) his own opinions on this curious and interesting subject; strengthened as these are by much subsequent inquiry into the phenomena of “Hypnotism” and “Electro-Biology,” the attentive and scientific study of which will tend, he feels assured, to eliminate the true from the false in Mesmerism, more effectually than any other method of procedure. Much has been done by the inquiries of Mr. Braid, of Manchester, who discovered the “hypnotic” mode of inducing Artificial Somnambulism, and who has carefully studied the phenomena of the hypnotic state; and the Author feels it due to that gentleman further to mention, that very soon after the publication of the first edition of Baron Reichenbach’s researches on Odyle, Mr. Braid discovered their true explanation, and exhibited to the Author many of the “odyle” phenomena, as the results of *suggestion* in certain individuals, whom he had discovered to have the power of voluntarily inducing a state of Abstraction or artificial reverie, closely corresponding to what is now termed the Electro-Biological condition.

On the whole subject of Sleep and its allied states, as well as on that of Cerebral Physiology generally, the Author would strongly recommend his readers to study Dr. Holland’s “Chapters on Mental Physiology;” in which they will find a most valuable and suggestive collection of facts and doctrines, based upon an extended practical experience, and brought to bear particularly upon the more difficult and recondite portions of the inquiry.

¹ It must be carefully borne in mind, that, although the proper Sympathetic fibres are all gelatinous, yet that the Cerebro-Spinal system contains gelatinous fibres of its own, which are very abundant in some parts.

nected with them; but each system transmitting its own fibres into the trunks of the other, and even ganglia of the Sympathetic being dispersed among the Cerebro-spinal tubules.

847. It is in virtue of the connections of the Sympathetic with the Cerebro-spinal system, that the parts which are solely supplied with nerves from the former are capable of transmitting sensory impressions to the Sensorium, and of receiving motor impulses from the Encephalic centres. It is true that, under ordinary circumstances, these parts are insensible, that is, impressions made upon them do not travel onwards through the Spinal Cord to the Encephalon; but their sensibility is acutely manifested in morbid states, in which the impressions seem to be propagated further than usual, in virtue of their greater potency. That it is the office of the ganglia on the roots of the Spinal nerves to "cut off sensation," that is, to prevent the further transmission of sensory impressions, is an old doctrine; and there seems much reason to believe that this may be effected by the free communication between one fibre and another, which is established through the vesicular substance of a ganglion, so that the whole force of ordinary impressions on the nerve-fibres is lost in diffusion among the rest of their contents. The same principle seems to apply to the motor fibres; for there are cases which show that when fibres obviously belonging to Cerebro-spinal nerves pass through Sympathetic ganglia, they do not so rapidly or so surely transmit motor impulses, as when they have no such relation to ganglia.¹—Although it is not easy to obtain definite evidence of the influence of the Sympathetic system on Muscular Contraction, since this influence is extinguished within a short time after death, yet it has been established by the elaborate researches of Prof. Valentin² that contractions of the various muscular parts supplied by the three great visceral plexuses may be excited by irritation applied to their nerves and ganglia. But he has further shown that the same effects may be produced by irritating the Prevertebral ganglia, the cords of communication with the Spinal nerves which have been sometimes termed the *roots* of the Sympathetic, and the roots of the Spinal nerves themselves. It results from his inquiries, that, although any particular division of the Sympathetic nerve must be regarded as extremely complex in its relations, deriving its motor fibres from many different sources, the ultimate distribution of these fibres is sufficiently simple, so that each organ is definitely supplied from a certain part of the cerebro-spinal axis. But the fibres proceeding from the roots of the cerebro-spinal nerves do not pass into the nearest organs, being transmitted through three or more of the prevertebral ganglia of the Sympathetic before reaching their ultimate destination; thus the motor fibres of the cardiac plexus are principally derived from the cervical portion of the Spinal Cord, those of the solar plexus from the thoracic region, and those of the hypogastric plexus from the dorsal region. No experimental evidence has yet been afforded, that the *proper fibres of the Sympathetic System* have any power of exciting muscular contraction, or that its ganglia can serve as centres of reflex action to the organs which they supply; on the contrary, it is quite certain that the ganglia in the posterior roots of the Spinal nerves have no such endowment. And as all the facts which have been supposed to indicate the existence of such a power may be otherwise explained in accordance with our fundamental doctrine (§§ 432-3, 497-8), it seems fair to conclude that the motor power of the Sympathetic system—which is chiefly exercised on the muscular substance of the heart and the walls of the bloodvessels, on the muscular coat of the alimentary canal and of the larger gland-ducts that open into it, and on the muscular walls of the

¹ See Messrs. Kirkes and Paget's "Handbook of Physiology," p. 361, *Am. Ed.*

² "De Functionibus Nervorum Cerebraliū et Nervi Sympathici," Bernæ, 1839; lib. ii. cap. 2.

genito-urinary organs—is entirely derived from the Cerebro-Spinal system. In no instance, however, can the Will exert any influence over the movements of these parts; they are strongly affected by emotional states of mind; and they frequently seem to respond to impressions made on remote organs. One of the most remarkable cases of a definite motion uniformly excited through the Sympathetic system is the *dilatation of the pupil*, which, after many imperfect attempts to determine its source, has now been shown by the experiments of MM. Budge and Waller to be effected through the cervical portion of the Sympathetic. For whilst irritation of the trunk of the cervical Sympathetic by means of the magneto-electric machine produces dilatation of the pupil with just as much certainty as irritation of the 3d pair determines its contraction, section of that trunk occasions permanent contraction of the pupil, the action of the 3d pair being no longer antagonized. But this, like the other motor powers of the Sympathetic, is dependent upon the Spinal Cord; for magneto-electric irritation of any part of it between the first cervical and the sixth dorsal vertebra produces the same effect, which is most decided when the irritation is applied to the central part of this region. It appears from other experiments, that the fibres by which this movement is effected pass through the Gasserian ganglion, and are distributed to the eye by the ophthalmic branch of the 5th Pair.¹

848. If, then, the sensori-motor endowments of the Sympathetic trunks be restricted to those fibres which are really Cerebro-Spinal in their origin or termination, it remains to inquire what are the functions of the *true* Sympathetic fibres, whose vesicular centres lie in the ganglia of the Sympathetic System. Upon this point we can only surmise; but there appears strong ground for the conclusion, that the office of these fibres is to produce a direct influence upon the chemico-vital processes concerned in the Organic Functions of nutrition, secretion, &c.; an influence which, although not essential to the performance of each separate act, may yet be required to harmonize them all together, and to bring them into connection with mental states. That the Nervous System does exert such an agency will be hereafter shown (CHAP. XVIII.); and reasons will there be assigned for regarding the Sympathetic fibres as its principal, if not as its sole channel.

7.—General Recapitulation, and Pathological Applications.

849. In summing up the views which have been propounded in this Chapter, with regard to the functions of the Nervous System, it will be advantageous to follow the reverse order to that which has been previously adopted, and to proceed from above downwards, instead of from below upwards.

I. The entire *Nervous System*, like other organs of the body, possesses vital endowments peculiar to itself, in virtue of which it tends to respond in a determinate manner to impressions made upon it; its several parts being distinguished by the results of impressions acting upon each respectively. In so far, then, as any part of the Nervous System merely reacts upon impressions which are made upon it, we must regard its operations as *automatic*; and this as much when they give rise to Psychological changes, as when they manifest themselves in evoking Muscular movements, or in modifying the processes of Nutrition and Secretion.

II. But the automatic actions of most parts of the Nervous System are subject, more or less completely, to the domination of the *Will*, a power which is purely Psychological, and of which we know nothing but what we learn from our own direct consciousness of its exercise. The power of the Will is the *greatest* over the automatic actions of the *highest* portions of the Nervous Centres, which

¹ See "Gazette Médicale," 1851, Nos. 41, 44.

are concerned in psychical changes; whilst it has the *least* influence over the automatic actions of those lower centres which minister solely to the functions of the bodily organism.

III. The *Cerebrum* is the material organ, through whose instrumentality all the processes of Thought are carried on. These processes are first called into activity by impressions conveyed to the vesicular matter of the Cerebral surface, by *ascending* nerve fibres which proceed to it from the Sensory Ganglia; and the influence of that activity is retransmitted to the Sensory Ganglia by a converse set of *descending* fibres.¹ There is much reason to consider that, until such retransmission has taken place, the consciousness is not so affected by Cerebral changes as to give to the results of these changes a *psychical* character; for the central Sensorium appears to stand in precisely the same anatomical and physiological relation to the vesicular matter of the Cerebral surface that it does to the vesicular matter of the Retina or other peripheral expansions of the Sensory nerves; and there is strong analogical ground for the belief that the process by which the Mind is rendered conscious of changes in the Cerebrum, is performed by the same instrumentality as that by which it is made acquainted with impressions on the Organs of Sense. And this view is confirmed by the fact that automatic changes may take place in the Cerebrum, without any consciousness on our own parts, the results of which, when we are at last made conscious of them, correspond with those that we ordinarily attain by processes whose successive steps excite as many successive states of consciousness.

IV. These Cerebral changes, then, acting downwards upon the Sensorium, give rise to those changes in our consciousness which we designate as *Mental Processes*. These processes—called into activity by Sensorial changes—ranging from the simple act of Perception to the highest operations of intellectual power—consisting also in the play of Fancy and Imagination, and including those active states known as Passions, Emotions, Moral Feelings, Sentiments, &c.—must be regarded as essentially *automatic* in their nature, and as the manifestations of the “reflex” activity of the Cerebrum; since we have abundant evidence that they can take place without any self-direction on the part of the individual, who, whilst his Will is in abeyance, is in the condition of an animal entirely governed by Instinct. There is, however, far less of uniformity in these “reflex actions” of the Cerebrum, than we observe in those reflex actions of other parts of the Nervous System, which give rise to the movements ordinarily designated as instinctive; this diversity seems partly attributable to differences in the *original* constitution of different individuals; but it is certainly due in great part to differences in the *acquired* constitution of the organ, arising out of the mode in which it has been habitually exercised—this being dependent, on the one hand, on the circumstances in which the individual has been placed; and, on the other, on the use he has made of his Will.

v. When the power of the *Will* has been duly cultivated, it acquires so complete a domination over the automatic actions of the Cerebrum, that it can regulate the course of thought and the degree of emotional excitement; intensifying some of these actions, and repressing others, by determinate efforts directed with a special purpose. Its power is so far limited, however, that it can only *select* from the objects which spontaneously present themselves to the consciousness, those which it desires to retain and employ; and has no direct power of bringing before the mind any object not actually present to it. Hence it is that,

¹ The structural distinctness of these two sets of fibres must be admitted to be hypothetical, and it is improbable that any anatomical evidence can ever be attained, by which the hypothesis may be established. But all the analogy of the afferent and efferent fibres throughout the body is opposed to the idea that the same fibres can serve both purposes. Whatever may be thought of their structural distinctness, however, there can be no reasonable doubt of the transmission of nerve-force in the two directions above indicated.

whilst we have an almost unlimited power of turning to the best account the endowments we possess, by strengthening our intellectual powers, expanding our higher emotional tendencies, and bringing the lower under wholesome restraint, we cannot, by any effort of the Will, introduce *new* elements into our psychical nature.¹

VI. The power of the Cerebrum to call forth muscular movements is entirely exerted through the intermediation of the Cranio-Spinal Axis upon which it is superimposed; no motor fibres directly issuing from the Cerebrum itself. These movements, when directly determined by the Will, may be designated as *Volitional*; when they are involuntarily excited by states of passion, feeling, &c., of which they are the external expressions, they are distinguished as *Emotional*; and when they are prompted, in the absence of any volitional exertion, by dominant ideas, they may be termed *Ideational*. In each case the nerve-force transmitted downwards from the Cerebrum appears to produce the very same state of activity in the Sensori-motor apparatus as that which may be directly excited in it by impressions transmitted from the Organs of Sense; and thus the same instrumentality serves for all classes of movements, voluntary and involuntary; the difference in their character being solely referable to the diversity of their primal source.

VII. The Cerebrum being the instrument of all psychical activity, we must regard its action as disordered in every state in which that activity is perverted. The first degree of departure from the normal state is usually shown in the want of Volitional control over the sequence of thought; and this may exist merely to the extent of giving the reflex power of the organ too great a predominance, so that trains of thought and states of feeling succeed each other automatically, and all the actions of the individual are simply the expressions of these. Such is the mental state which exists in *Reverie* and in *Somnambulism*, natural or induced; the principal varieties in these states being traceable to the relative degree of influence of ideas already fixed in the mind, and of external suggestions, in determining the course of thought. It is to be remarked, in regard to these conditions, however, that they are generally characterized by a somewhat inactive state of the Cerebrum, so that the changes in the state of consciousness are not rapid, but such as do occur are coherent.² In *Dreaming*, *Delirium*, and the artificial Delirium of *Intoxication*, on the other hand, with a like absence of the directing and restraining power of the Will, there is a greater and more irregular activity in the Cerebral operations, the ideas pre-

¹ No one has ever *acquired* the creative power of genius, or *made himself* a great artist or a great poet, or *gained by practice* that peculiar insight which characterizes the original discoverer; for these gifts are mental instincts or intuitions, which may be developed and strengthened by due cultivation, but which can never be generated *de novo*. It not unfrequently happens, however, that the gift lies dormant, until some appropriate impression excites it into activity. Such is especially the case with regard to the higher Moral Feelings, which are too often so completely repressed by the degrading influences under which the youthful mind expands itself, that they might be considered as altogether wanting. Though dormant, however, they are rarely extinct, and may be called into activity by appropriate management. It has been by faith in this principle, and by skill in its application, that those have achieved the greatest success who have recently devoted themselves to the much-needed work of Juvenile Reformation. (See "Reformatory School," by Mary Carpenter.)

² In most forms of induced Somnambulism, it appears as if the mental activity is only sustained by external prompting, all *spontaneous* activity being suspended; for the "subject" continually relapses into a state of unconsciousness, and does not pass from one subject to another unless induced to do so by "leading questions." In some cases of this kind, however, as well as in all those forms of natural Somnambulism in which the individual acts on the spontaneous promptings of his own thoughts, the mental state is one of continuous activity; but it is obvious that its operations are slow, and are very limited in their nature.

senting themselves in far more rapid succession, and possessing a less perfect mutual coherence.

VIII. The foregoing states are closely allied to *Insanity*; many forms of which may be almost exactly paralleled by transient states of Somnambulism, whilst others are but a modification of Delirium. A deficiency or entire absence of the controlling power of the Will is the common feature of all forms of this disorder, and is frequently its first manifestation. But Insanity is essentially constituted by excessive, deficient, or perverted activity of some one or more of the automatic tendencies, and must thus be regarded as consisting in a disordered action of the Cerebrum. This may be traced to a great variety of causes, which may be classified in different ways, according as we take their *own nature* or their *modus operandi* as the basis of our arrangement. Thus it is unquestionable that in a large proportion of cases of settled Insanity, there is an impairment of the due *Nutrition* of the Cerebrum; and this, which is often an hereditary defect, may arise *de novo*, like abnormal changes in the nutrition of other parts (CHAP. XI.), from deficiency or perversion in the formative power of the tissue, or from an imperfect supply, or from an altered character of its pabulum. Of the influence of deficient or perverted formative power in the tissue, we have examples in the Insanity resulting from mechanical injuries of the brain, and from excessive "wear" of the organ by forced activity. Of the effects of deterioration in the character of the blood, we have illustrations in the Insanity that is often linked on with constitutional diseases of which such deterioration is a marked feature, and in that which is so frequent a consequence of habitual excess in the use of Alcoholic liquors. These conditions may exist in combination;¹ and it is, probably, by such a combination that many of the "moral causes" of Insanity operate. For there can be little doubt that Emotional excitement, from its immediate relation to Nerve-force (§ 805), has a direct influence on the formative capacity of the Cerebrum; whilst, on the other hand, we know that it has so great an influence over the Organic functions, that it can produce very serious alterations in the condition of the Blood (CHAP. XVIII). But without any serious perversion of the *nutrition* of the Cerebrum, its *action* may be disturbed, either by the presence of some toxic agent in the Blood, or by functional disturbance in other parts of the Nervous system. The delirium of Intoxication is, whilst it lasts, a true Insanity; and it ceases because the poison is eliminated from the system. But there are many cases in which there is a continual production of a poison within the system, which deranges the normal train of mental action so long as the blood is tainted by it; the indication of treatment is here obviously to check this production, and to depurate the blood; and when this has been effectually accomplished, the healthy action of the Brain is immediately restored, which would not have been the case if its nutrition had been seriously impaired. Most persons have experienced the extreme depression of spirits and incapacity for mental exertion, which are consequent upon certain derangements of the digestive function, and especially upon disorder of the biliary apparatus; and it is unquestionable that many forms of Insanity, in which extreme dejection is a prominent symptom, but which may also include intellectual delusions,

¹ Thus *Delirium tremens*, which may be regarded as a form of temporary Insanity, essentially consisting in perverted and imperfect nutrition of the Cerebrum, seems ordinarily dependent conjointly upon the excessive and irregular activity to which the organ has been previously forced, and on the alteration of the normal character of the Blood produced by the habitual presence of Alcohol in its current; but it is well known that *Delirium tremens* may occur as the result of other agencies that primarily depress the nutritive power without perverting the blood; such as excessive depletion, the shock of severe injuries, or extreme cold. In either case, however, the indications of treatment are the same; namely, to induce sleep, whereby the irregular activity of the organ may be completely suspended, and its due nutrition restored: and to correct what may be faulty in the condition of the blood.

are solely dependent upon this cause. The functional disturbance of the Cerebrum induced by the irregular action of other parts of the Nervous System, is a part of the Etiology of Insanity which has been as yet but very little attended to, but which deserves a careful study. Numerous examples of it are furnished by certain peculiar forms of disordered Mental action, which are connected with "hysterical" states of the female system, especially mutability and irritability of temper and disposition to deceit;¹ but we are probably also to refer to this cause, in part at least, those very distressing states of mind which arise out of disorders in the sexual apparatus of the male, or even from irritation of neighboring parts.²—It frequently happens that agencies of both classes contribute to the result; some long-continued defect of nutrition (very often arising from hereditary constitution) serving as the "predisposing cause," whilst some violent mental emotion, or depravation of the blood by some noxious matter, acts as the "exciting cause;" the two conjointly producing that effect, which neither would singly have brought about.

IX. Without any Mental perversion, however, indicative of structural or functional disorder of the Cerebrum, there may exist a partial severance of its connection with the Sensori-motor apparatus; so that it cannot receive sensory impressions from particular organs or parts of the body, or call forth muscular movement in response to volitional determinations or to emotional excitement. Or, again, there may be a weakening of Voluntary power over the muscles in general, whilst they still remain amenable to the stimulus of Emotion; and in such cases, as might be expected, the influence of sensory impressions in directly exciting muscular movements is obviously manifested.³ Of the precise pathological alterations which give rise to these peculiar conditions (which frequently manifest themselves in regard to particular groups of muscles, such as those of vocalization), nothing whatever is known.—Nearly allied to this state is that which gives rise to the "jactitating convulsion," interfering with volitional movement, which is known as *Chorea*. On the physiological views here advo-

¹ See Dr. Laycock's "Treatise on the Nervous Diseases of Women," in which these *sympathies* are fully dwelt on.

² See M. Lallemand's "Treatise on Spermatorrhoea," translated by Mr. McDougal.—In some of the cases recorded by M. Lallemand, the most extreme mental depression was engendered by the presence of ascarides in the rectum!

³ Of this curious state, the following example was communicated to the Author, about four years since, by his friend Mr. Noble.—"Mr. R., æt. 41, of a sanguine nervous temperament, a married man, and father of several children, the youngest being but two months old, exhibited the following symptoms, first experienced in a slight degree about five years ago, and since then having become much aggravated, the climax having apparently been attained about two years ago.—There was partial paralysis of voluntary motion upon the left side, exhibiting under ordinary circumstances the customary phenomena; but with this peculiarity—that although Volition was comparatively powerless, any incident excitator impression of an unusual character, by exciting, as it were, Consensual action, would give effect to the voluntary intention; thus when the affected arm was raised by another to a certain height, the patient was unable by mere volition to elevate it still more; but if the hand were smartly struck or blown upon either by himself or by another, movement of a rapid character would at once ensue, and that too in conformity with the Volitional effort. Upon inquiry, moreover, it appeared that any unwonted impression upon the internal as well as the external senses was capable of leading to a realization of the effort vainly attempted by the mere will; hence, by accomplishing the commencement of a *run* or *trot* by aid of some undue impression, he could go on; he stated, on the case being proposed, that if, in utter paralysis of voluntary power over the muscles, a hundred-pound note were suddenly placed before his vision, and he were told that on seizing it the same should be his, he should at once be equal to the requisite effort.—When in health, Mr. R. stated that he had excellent controlling power over the Emotions, but that now the pleasure and the pain attendant upon their excitation were exalted, and the consensual phenomena quite irresistible; and on further inquiry it appeared that, in the matter of laughing and crying, he exhibited very much of the hysterical condition. In early life, Mr. R. had been what is called a free liver; both in regard to women, and to alcoholic stimulants."

cated, this disease must be regarded as consisting essentially in a diminution of the power of the Will (exerted through the Cerebrum) over the muscular apparatus, concurrently with an augmented and perverted activity of the Sensori-motor centres. That its special seat is at the summit of the Cranio-Spinal axis, where it comes into connection with the Cerebrum, would appear from several considerations, particularly from the interruption of voluntary power, the aggravation of the movements by emotion, and their cessation during sleep; the two latter facts being inconsistent with the idea that the proper Spinal centres are essentially involved, although they are frequently affected coincidently or subsequently. The choreic convulsion is occasionally hemiplegic; and it sometimes gives place to paralysis, which is seldom complete, however, and may usually be cured by appropriate treatment. This disorder appears generally traceable to a state of imperfect nutrition, dependent upon a depraved and perhaps a poisoned state of the blood, rather than on any organic lesion.¹ Not unfrequently the defect of nutrition seems to act as the "predisposing cause" of the disease; the attack being immediately traceable to mental emotion.²—*Stammering* may be regarded as a sort of Chorea, affecting the muscles of Voice.

x. The *Sensory Ganglia*, collectively constituting the *Sensorium*, may be regarded as the most essential part of the Encephalon; since we find them fully developed in animals which scarcely possess a rudiment of a Cerebrum, and presenting the same relative condition to the latter in the early embryo of Man. They directly receive the nerves proceeding from the organs of Special Sense, each pair of which has its own distinct ganglionic centre; and they receive, also, through the (so-called) *Crura Cerebri*, the nerves of "common sensation," whose ganglionic centre appears to lie in the *Thalami Optici*. They give off a large number of motor fibres, which, descending through the *Crura Cerebri*, are distributed, with the fibres proceeding from the Spinal ganglia, through the various motor trunks, to the muscular system generally.³ On the other hand, by one set of the radiating fibres of the Cerebral substance, they transmit sensorial impressions upwards to the vesicular surface of the Hemispheres; whilst conversely, by its descending fibres, they receive the impressions transmitted downwards from the Cerebral ganglia; and they thus constitute the medium by which alone the Cerebrum communicates with the Organs of Sense on the one hand, and with the muscular apparatus on the other.—The Sensory Ganglia must be collectively regarded as forming the organ through whose instrumentality the Mind is rendered conscious of impressions made on the Organs of Sense; and reasons have been advanced for the belief, that it also serves as the instrument whereby the Consciousness is affected by Cerebral changes, which, in so far as they take place independently of the Will, are the cause and not the consequence of Mental activity. There is no reason to think that the Sensorium has in itself any higher function than that of impressing the consciousness of the individual; this impression on the consciousness, when made by an external agency operating through the sensory nerves, is that which is known as *Sensation*; but, when produced by Cerebral changes, it constitutes *Ideation*. With the states

¹ See Dr. Todd's Lumleian Lectures "On the Pathology and Treatment of Convulsive Diseases" in the "Medical Gazette," April 20 and 27, 1849.

² A remarkable number of cases of Chorea were admitted into the Bristol Infirmary within a few weeks after the memorable Riots of 1833.

³ The doctrine previously advocated (§ 701), that there is an actual continuity of fibres between the Sensorial centres and the roots of the Spinal Nerves, has lately received very important confirmation from the elaborate researches of Dr. Turck on the alterations produced in the Spinal Cord by Hemiplegia originating in intra-cranial lesion. See his Memoir "Über secundäre Erkrankung einzelner Rückenmarksstränge und ihrer Fortsetzungen zum Gehirn," in "Denkschriften der kaiserlichen Academie der Wissenschaften," Wein, 1851.

of consciousness termed Sensations are associated the simple *feelings* of pleasure and pain, the seat of which is obviously sensorial; and similar feelings, associating themselves with those states of consciousness termed Ideas, give to them an Emotional character, and become the sources of those *motives* by which the determination of conduct made by the Reason is in great part guided.

XI. The "reflex action" of the Sensory Ganglia, which proceeds from their own independent activity, is manifested in all those instinctive or automatic movements, which are excited through sensations, and which may hence be designated as *consensual* or *sensori-motor*. These actions are but little noticed, in Man, in the active state of his Cerebrum; for the automatic movements on which the maintenance of his organic functions is immediately dependent are provided for by the Spinal centres; and the purposes which are answered in the lower animals by the higher order of Instinctive actions are worked out in him by the Intelligence. There is, however, a large group of *secondarily-automatic* movements, which, though originally determined by the Will, are brought by habit so far under the direct influence of sensations, that they continue, whilst prompted and guided by the latter, after the Will has ceased to act.—The operation of the Sensory Ganglia in Man is usually subservient to that of the Cerebrum; for the influence of Sensational changes, being propagated upwards to that organ, excites further changes in it; these, reflected downwards to the Sensori-motor centres, become the sources of ideational or of emotional movements; and the determining power of the Will, in producing volitional movements, is exercised through the same channel. It is a remarkable indication of the participation of the Sensorial centres even in volitional movements that these cannot be executed save with the concurrence of *guiding sensations*. The extent to which the Sensory Ganglia may act as independent centres of action is seen in cases in which the functions of the Cerebrum are entirely in abeyance. This may happen through congenital defect, as in some cases of complete Idiocy, especially among the Cretins of the first degree, who spend their whole time in basking in the sun or sitting by the fire (experiencing merely sensorial pleasure), and who show no higher traces of intelligence than is evinced by their going, when excited by hunger, to the places where they have been accustomed to receive food. It may occur, too, as a consequence of disease or injury. Of this we have an example in a case mentioned by Dr. Rush, of a man who was so violently affected by some losses in trade, that he was deprived almost instantly of his mental faculties; he did not take the slightest notice of anything, not even expressing a desire for food, but merely receiving it when it was put into his mouth; a servant dressed him in the morning, and conducted him to a seat in his parlor, where he remained the whole day, with his body bent forwards and his eyes fixed on the floor; in this state he continued for five years, and then recovered completely and rather suddenly. The well-known case of the sailor who suffered for more than a year from depressed fracture of the skull, and was at last restored to his normal condition by the elevation of the depressed bone (which was effected by Mr. Cline), affords another illustration of the same suspension of cerebral activity, without the loss of sensorial power; this man passed the period between the accident and the operation in a condition very similar to that of the subject of the preceding case; and after his recovery, the whole intervening space was a perfect blank to his recollection. The most remarkable example of this condition, however, yet put on record, is a case which occurred a few years ago under the observation of Mr. Dunn,¹ of whose excellent account an abridgment is here given, for the sake of illustrating the nature of a purely *sensorial* and *instinctive*, as distinguished from an *intelligent* existence, and the gradual nature of the

¹ "Lancet," Nov. 15 and 29, 1845.

transition from the one to the other.¹ A very similar condition presents itself, as the result of the complete exhaustion of Cerebral power, in those extreme forms of Dementia, or rather Amentia, which are frequently consequent upon

¹ The subject of this case was a young woman of robust constitution and good health, who accidentally fell into a river and was nearly drowned. She remained insensible for six hours after the immersion; but recovered so far as to be able to give some account of the accident and of her subsequent feelings, though she continued far from well. Ten days subsequently, however, she was seized with a fit of complete stupor, which lasted for four hours; at the end of which time she opened her eyes, but did not seem to recognize any of her friends around her; and she appeared to be utterly deprived of the senses of hearing, taste, and smell, as well as of the power of speech. Her mental faculties seemed to be entirely suspended; her only medium of communication with the external world being through the senses of sight and touch, neither of which appeared to arouse *ideas* in her mind, though respondent *movements* of various kinds were excited through them. Her vision at short distances was quick; and so great was the exaltation of the general sensibility upon the surface of the body, that the slightest touch would startle her; still, unless she was touched, or an object or a person was so placed that she could not help seeing the one or the other, she appeared to be quite lost to everything that was passing around her. She had no notion that she was at home, nor the least knowledge of anything about her; she did not even know her own mother, who attended upon her with the most unwearied assiduity and kindness. Wherever she was placed, there she remained during the day. . . . Her appetite was good; but having neither taste nor smell, she ate alike indifferently whatever she was fed with, and took nauseous medicines as readily as delicious viands. All the automatic movements unconnected with sensation, of which the spinal cord is the instrument, seemed to go on without interference; as did also those dependent upon the sensations of sight and touch; whilst the functions of the other ganglia, together with those of the cerebral hemispheres, appeared to be in complete abeyance. The analysis of the facts stated regarding her ingestion of food seems to make this clear. She swallowed food when it was put into her mouth; this was a purely automatic action, the reception by the lips being probably excited by sensation, whilst the act of deglutition, when the food is carried within reach of the pharyngeal muscles, is excited without the necessary concurrence of sensation. She made no spontaneous effort, however, to feed herself with the spoon; showing that she had not even that simple idea of helping herself, which infants so early acquire. But after her mother had conveyed the spoon a few times to her mouth, and had thus caused the muscular action to become associated with the sensorial stimulus, the patient continued the operation. It appears, however, to have been necessary to repeat this lesson on every occasion; showing the complete absence of memory for any idea, even one so simple and so immediately connected with the supply of the bodily wants. The difference between an *instinct* and a *desire* or *propensity*, heretofore dwelt on (§ 772), is here most strikingly manifested. This patient had an instinctive tendency to ingest food; as is shown by her performance of the actions already alluded to; but these actions required the stimulus of the present sensation, and do not seem to have been connected with any notion of the character of the object *as food*; at any rate, there was no manifestation of the existence of any such notion or idea, for she displayed no *desire for food* or drink in the absence of the objects, even when she must have been conscious of the uneasy sensations of hunger and thirst. The very limited nature of her faculties, and the *automatic* life she was leading, appear further evident from the following particulars. One of her first acts on recovering from the fit had been to busy herself in picking the bedclothes; and as soon as she was able to sit up and be dressed, she continued the habit by incessantly picking some portion of her dress. She seemed to want an occupation for her fingers, and accordingly part of an old straw bonnet was given to her, which she pulled to pieces of great minuteness; she was afterwards bountifully supplied with roses; she picked off the leaves, and then tore them into the smallest particles imaginable. A few days subsequently, she began forming upon the table, out of these minute particles, rude figures of roses and other common garden flowers; she had never received any instructions in drawing.—Roses not being so plentiful in London, waste paper and a pair of scissors were put into her hands; and for some days she found an occupation in cutting the paper into shreds; after a time these cuttings assumed rude figures and shapes, and more particularly the shapes used in patchwork. At length she was supplied with proper materials for patchwork; and after some initiatory instruction, she took to her needle and to this employment in good earnest. She now labored incessantly at patchwork from morning to night, and on Sundays and week-days, for she knew no difference of days; nor could she be made to comprehend the difference. She had no remembrance from day to day of what she had been doing on the previous day, and so every morning commenced

repeated attacks of Mania, or a long succession of Epileptic seizures. And it is also worth notice that the "picking at the bedclothes," which is so frequently seen towards the close of life, is a purely consensual movement, the

de novo. Whatever she began, that she continued to work at while daylight lasted; manifesting no uneasiness for anything to eat or drink, taking not the slightest heed of anything which was going on around her, but intent only on her patchwork. She gradually began, like a child, to register ideas and acquire experience. This was first shown in connection with her manual occupation. From patchwork, after having exhausted all the materials within her reach, she was led to the higher art of worsted-work, by which her attention was soon engrossed as constantly as it had before been by her humbler employment. She was delighted with the colors and the flowers upon the patterns that were brought to her, and seemed to derive special enjoyment from the harmony of colors; nor did she conceal her want of respect towards any specimen of work that was placed before her, but immediately threw it aside if the arrangement displeased her. She still had no recollection from day to day what she had done, and every morning began something new, unless her unfinished work was placed before her; and after imitating the patterns of others, she began devising some of her own. The first *ideas* derived from her former experience, that seemed to be awakened within her, were connected with two subjects which had naturally made a strong impression upon her; namely, her fall into the river, and a love affair. It will be obvious that her pleasure in the symmetrical arrangement of patterns, the harmony of colors, &c., was at first simply *sensorial*; but she gradually took an interest in looking at pictures or prints, more especially of flowers, trees and animals. When, however, she was shown a landscape in which there was a river, or the view of a troubled sea, she became intensely excited and violently agitated, and one of her fits of spasmodic rigidity and insensibility immediately followed. If the picture were removed before the paroxysm had subsided, she manifested no recollection of what had taken place; but so great was the feeling of dread or fright associated with water, that the mere sight of it in motion, its mere running from one vessel to another, made her shudder and tremble; and in the act of washing her hands they were merely placed in water. From this it may be inferred that simple *ideas* were now being formed; for whilst the actual sight or contact of moving water excited them by the direct sensorial channel, the sight of a picture containing a river or water in movement could only do so by giving rise to the notion of water. From an early stage of her illness she had derived evident pleasure from the proximity of a young man, to whom she had been attached; he was evidently an object of interest when nothing else would rouse her; and nothing seemed to give her so much pleasure as his presence. He came regularly every evening to see her, and she as regularly looked for his coming. At a time when she did not remember from one hour to another what she was doing, she would look anxiously for the opening of the door about the time he was accustomed to pay her a visit; and if he came not, she was fidgety and fretful throughout the evening. When by her removal into the country she lost sight of him for some time, she became unhappy and irritable, manifested no pleasure in anything, and suffered very frequently from fits of spasmodic rigidity and insensibility. When, on the other hand, he remained constantly near her, she improved in bodily health, early associations were gradually awakened, and her intellectual powers and memory of words progressively returned. We here see very clearly, as it appears to us, the composite nature of the emotion of affection. At first there was simple pleasure in the presence of her lover, excited by the gratification which former association had connected with the *sensation*. Afterwards, however, it was evident that the pleasure became connected with the *idea*; she *thought* of him when absent, expected his return (even showing a power of measuring time when she had no memory for anything else), and manifested discomfort if he did not make his appearance. Here we see the true *emotion*, namely, the association of pleasure with the *idea*; and the manner in which the *desire* would spring out of it. The desire in her then condition would be inoperative in causing voluntary movement for its gratification; simply because there was no intellect for it to act upon. Her mental powers, however, were gradually returning. She took greater heed of the objects by which she was surrounded; and on one occasion, seeing her mother in a state of excessive agitation and grief, she became excited herself, and in the emotional excitement of the moment suddenly ejaculated, with some hesitation, "What's the matter?" From this time she began to articulate a few words; but she neither called persons nor things by their right names. The pronoun "this" was her favorite word; and it was applied alike to every individual object, animate and inanimate. The first objects which she called by their right names were wild flowers, for which she had shown quite a passion when a child; and it is remarkable that her interest in these and her recollection of their names should have manifested itself at a time when she exhibited not the least recollection of the "old familiar friends and

performance of which is an indication of the torpor that has supervened upon the functional activity of the Cerebrum.

XII. It is the *Sensorium* that is primarily, and (it may be) solely affected, in the state of *Coma*; which differs from ordinary sleep only in the completeness of the suspension of the functional activity of the Sensory Ganglia. This suspension not merely prevents impressions transmitted from the organs of sense, from affecting the consciousness as Sensations; but it also interposes the same obstacle to that mental recognition of Cerebral changes which, when the *Sensorium* is closed to the outer world, constitutes the state of Dreaming; and thus the comatose subject is not merely insensible to external impressions, but is cut off from all perception of self-existence. There seems reason to believe that, in the simpler forms of *Coma*, such as we frequently meet with in hysterical subjects, there is no perversion of the functions of the Cerebrum; for we observe that, if the insensibility suddenly supervene in the midst of a sentence which is being uttered by the patient (a circumstance of no uncommon occurrence), the series of words is taken up and completed the moment that the *coma* passes off, the patient being unconscious of the interruption; showing that there is none of that *confusion* of the Intellect which marks Cerebral disorder. In a large proportion of cases, however, it is obvious from the order in which the symptoms manifest themselves, that the Cerebrum is affected as well as the Sensorial centres; of this the best evidence is afforded by the phenomena of alcoholic intoxication, and the agency of narcotic poisons; and where *Coma* results from pressure within the cranium, this must act alike upon the Cerebrum and the *Sensorium*. Of the causes which induce the state of *Coma*, there are many which, when operating in smaller quantity, or in less intensity, produce delirium. This is particularly the case with the whole group of truly narcotic poisons; and is not merely true of those which are introduced as such from external sources, but also with regard to those which are generated within the

places" of her childhood. As her intellect gradually expanded, and her *ideas* became more numerous and definite, they manifested themselves chiefly in the form of *emotions*; that is, the chief indications of them were through the signs of pleasure and pain. The last were frequently exhibited in the attacks of insensibility and spasmodic rigidity, which came on at the slightest alarm. It is worth remarking that these attacks throughout this remarkable period, were apt to recur three or four times a day, when her eyes had been long directed intently upon her work; which affords another proof how closely the emotional cause of them must have been akin to the influence of sensory impressions, the effects of the two being precisely the same.—The mode of recovery of this patient was quite as remarkable as anything in her history. Her health and bodily strength seemed completely re-established, her vocabulary was being extended, and her mental capacity was improving, when she became aware that her lover was paying attention to another woman. This idea immediately and very naturally excited the emotion of jealousy; which, if we analyze it, will appear to be nothing else than a painful *feeling* connected with the *idea* of the faithlessness of the object beloved. On one occasion this feeling was so strongly excited, that she fell down in a fit of insensibility, which resembled her first attack in duration and severity. This, however, proved sanitary. When the insensibility passed off, she was no longer spellbound. The veil of oblivion was withdrawn; and, as if awakening from a sleep of twelve months' duration, she found herself surrounded by her grandfather, grandmother, and their familiar friends and acquaintances, in the old house at Shoreham. She awoke in the possession of her natural faculties and former knowledge; but without the slightest remembrance of anything which had taken place in the interval from the invasion of the first fit up to the present time. She spoke, but she heard not; she was still deaf, but, as she could read and write as formerly, she was no longer cut off from communication with others. From this time she rapidly improved, but for some time continued deaf. She soon perfectly understood by the motion of the lips what her mother said; they conversed with facility and quickness together, but she did not understand the language of the lips of a stranger. She was completely unaware of the change in her lover's affections which had taken place in her state of second consciousness; and a painful explanation was necessary. This, however, she bore very well, and has since recovered her previous bodily and mental health.

body. We have another illustration of it in the Coma of mere exhaustion, which is frequently preceded by delirium that is clearly attributable to nothing else than a deficient supply of blood. Still we must not regard Coma as always indicating a more advanced state of morbid change than that which occasions Delirium; for it stands to some forms of delirium in the same light in which ordinary sleep stands to the waking state, being the repose which is required for reparation after a state of excessive mental activity. In fact, the profound sleep which succeeds a protracted period of severe bodily or mental exertion, is often almost comatose, as regards the degree in which the subject of it is insensible to external stimuli. The same may be stated with great probability of the coma which is consequent upon "concussion" of the brain; for this may be regarded as a period of slow regeneration, during which the effects of the injury are being repaired by the nutritive processes; and any attempt to arouse the patient prematurely is far more likely to be injurious than beneficial, tending especially to increase the violence of the subsequent reaction.

XIII. It is, as we have seen, in the Sensorial centres, that those lesions are most commonly found, which give rise to hemiplegic *Paralysis*. There can be little doubt that this form of paralysis is usually attributable to some structural disorganization of the nervous substance, produced by hemorrhage, softening, &c. Still this, like other forms of partial paralysis, may be *toxic*, depending rather upon the condition of the blood than upon that of the nervous tissue. Of such toxic influence, we have a remarkable example in the peculiar local paralysis induced by the presence of Lead in the system; and there seems much reason to believe that some of the Hysterical forms of paralysis (as well as of convulsive disorders) are of toxic origin. There are many instances, too, in which paralysis, like convulsion, seems to depend upon some injurious influence propagated from the nerves of some other part.—Although it is in Hemiplegia that we have the most distinct evidence of disorder of the Encephalic centres, yet paralysis of any one part of the body may proceed from Encephalic lesion; and even some forms of Paraplegia seem traceable to disorders of the Cerebrum and Sensory Ganglia.¹

XIV. We seem entitled to consider the Sensory Ganglia as the primary seat of that combination of loss of sensibility, with spasmodic movements, which essentially constitutes *Epilepsy*. This is marked by the peculiar sensorial phenomena which usually precede the paroxysm; by the obliteration of consciousness, which is its prominent symptom; and by the peculiarity of the spasmodic contractions, which are *clonic* (or alternating with relaxation) instead of being *tonic* (or persistent), and which correspond with those that may be induced by artificial stimulation of this portion of the Encephalic centres (§ 738). The disordered action, however, manifestly extends itself to the Cerebrum; for a maniacal paroxysm frequently occurs in connection with the epileptic attacks; the attacks themselves are sometimes preceded, and very commonly followed, by considerable confusion of the intellect; the disease is seldom long persistent without impairing the memory and the control of the will over the mental operations; and in cases of long standing, the power of the Cerebrum appears to be almost entirely destroyed. There is very considerable diversity, on the other hand, in regard to the nature and intensity of the muscular convulsion; and there seems reason to think that when the morbid influence is determined downwards into the Motor apparatus, the Cerebrum escapes with a less serious impairment of its powers, since the destruction of the intellectual power occurs more surely where the fits are accompanied by much mental disturbance or stupor, than where the convulsive character predominates.—One of the most remarkable

¹ For much valuable information on the different forms of Paralysis, see Dr. Gull's Gulstonian Lectures "On the Nervous System" in the "Medical Times," 1849.

phenomena of Epilepsy is its tendency to periodic recurrence, with a more or less complete return to the normal state in the interval. This fact of itself seems to indicate that the disease cannot be fairly attributed to those obvious lesions of structure which are sometimes coincident with it, and which, as Dr. Todd has justly remarked, are rather the signs of the altered nutrition brought on by any cause which creates frequent disturbance of the actions of the brain, than the causes of that disturbance; for the influence of such lesions, if manifested at all (and it is remarkable what an extent of disorganization *may* take place without any obvious indication), would be rather continuous than intermittent. It is quite certain, on the other hand, that death *may* occur from Epilepsy, without any appreciable lesion. It may be considered, also, as a well-established fact, that the epileptic paroxysm may be induced either by an insufficient supply, or by depravation of blood; of this we have examples in the epileptiform convulsions brought on by excessive hemorrhage in parturient women, in the epileptiform paroxysm induced by asphyxia (especially by strangulation), and in poisoning by hydrocyanic acid, the phenomena of which, in the lower animals especially, so closely simulate those of the genuine disease, that they may be designated as an artificial epilepsy. These and many other facts in the etiology of the disease very strongly point to a disordered condition of the blood as its primal source; this acting either by altering the nutrition of the Encephalic centres, or by perverting their action, or in both modes conjointly, as in the case of Insanity (VIII.). According to the theory advocated by Dr. Todd, a continual mal-nutrition of certain parts of the Encephalon occasions a gradually increasing disturbance of their polar state; and this, when it has attained a certain measure of intensity, manifests itself in the epileptic paroxysm, just as a Leyden jar, when charged with electricity to a certain state of tension, gets rid of the disturbance of equilibrium by the "disruptive discharge."¹ The fact must not be disregarded, however, that when a state of mal-nutrition of the Nervous System has been established by causes which affect the condition of the Blood, the Epileptic paroxysm may be induced by some excentric or peripheral irritation, such as worms in the intestinal canal, the pressure of teeth in the eruptive stage of development against the capsule or the gum, &c.; neither cause being sufficient when acting alone. Hence, although the paroxysms may be suspended and the disease apparently cured, by the removal of the peripheral source of irritation (as by the expulsion of the worms, or the complete eruption of the teeth), the liability to it still remains, as is shown by the renewal of the paroxysms whenever any fresh irritation may arise. It is very important, therefore, not to rest satisfied with local treatment in such cases; but to have recourse to measures adapted to produce a general invigoration of the system.²

xv. The *Spinal Axis* (including the *Medulla Oblongata*) forms a continuous series of ganglionic centres, which are connected by afferent and efferent nerve-trunks with the several segments of the body; but these centres are enveloped in white or fibrous strands, which not only connect the various segmental divisions with each other, but also, there seems good reason to believe, establish a continuous connection between the Nerve-roots and the Sensorial centres. The independent activity of the Spinal centres is seen in the various reflex movements which are performed after they have been cut off from all connection with

¹ See Dr. Todd's "Lumleian Lectures" in the "Medical Gazette," May 18, 1849; and the "Brit. and For. Med. Chir. Rev.," Jan. 1850, pp. 24—33.

² The Author does not think it necessary here to devote any space to the examination of Dr. M. Hall's pathological theory of Epilepsy, which makes it depend upon spasmodic compression of certain muscles of the neck, producing compression of the veins and congestion of the cerebrum; since he considers that the fallacies of this theory have been already sufficiently pointed out by Dr. Todd (loc. cit.).

the Encephalon; and of these reflex movements, there are certain definite groups, which are subservient to the functions of Respiration, Deglutition, Defecation, &c. In so far as these are performed by the Spinal Cord alone, without the participation of the Sensorium, they do not involve any affection of the consciousness; and, as the separation of the Spinal Cord from the Sensorium effectually prevents the impression which excites the reflex movement from exciting sensation at the same time, we know that sensation cannot be necessary to the movement; hence this class of actions is best distinguished as *excito-motor*, in contradistinction to the *sensori-motor*, in which Sensation necessarily participates. Putting aside, however, those actions which are subservient to the Organic functions, and which are performed in the state of full integrity and activity of the nervous system, we find that the reflex power of the Spinal Cord is only distinctly manifested when that organ is detached from the Encephalon; for in its normal state it serves as little else than the channel through which impressions are transmitted upwards to the Sensorium, and thence to the Cerebrum, and through which motor impulses are propagated downwards from these centres to the muscles. For the actions of the Spinal Cord are placed in subordination to the control of the Cerebrum, in every particular as to which they can be, without detriment to the welfare of the system generally; so that we find excitor impressions, which are quite competent to evoke reflex actions if they are prevented from travelling beyond the Cord, losing their power to do so when they are discharged (so to speak) into the Sensorium; whilst even the movements of Respiration, Defecation, &c., which do not require the participation of the Cerebrum, in their ordinary performance, can be to a certain extent controlled by the Will.

XVI. In the various classes of *Convulsive* diseases in which the consciousness is *not* affected, we have manifestations of the perverted activity of the Spinal Cord as a whole, or of certain of its segments.—Of the distinct forms or combinations of which this class of disorders is composed, *Tetanus* is one of the most interesting and instructive. This disease essentially consists in an undue excitability of the whole series of Spinal Ganglia; so that very slight impressions produce violent and extensive reflex actions, the disturbance of nervous polarity induced by the impression, radiating (as it were) through the whole Cord, and affecting nerve-fibres that proceed from each of its different segments; and when this state is fully established, convulsive actions may proceed from purely *centric* irritation, no excitor impression being required to originate them. Such a state may be induced by various causes, among the most prominent of which are, on the one hand, those which affect the nutrition of the Cord, and, on the other, those which call it into disordered action, by altering the relations which the blood bears to it as the exciting fluid of the nervous battery. That which is termed the idiopathic form of the disease seems traceable to mal-nutrition of the Cord, consequent upon impoverishment or depravation of the blood; that, on the other hand, which is produced by the introduction of Strychnia into the blood, is dependent upon the peculiar potency of this substance in determining a wrong action of the Spinal centres, for which it seems to have an elective affinity, in the same way that alcohol and opium have for the encephalic. With regard to the traumatic form of Tetanus, it is impossible to say with certainty whether the peculiar condition of the Spinal Cord be determined, as in the preceding case, by the introduction of a poison into the blood, through some morbid action taking place in the wound; or whether the disturbance of the usual equilibrium be consequent upon the propagation of a morbid influence directly from the injured nerve-trunk to the Spinal centres, without any participation of the Circulating System in this extension of the mischief. Whichever be the true account of it, this much is certain, that when the Tetanic state of the Spinal Cord is once fully established, nothing is gained

by removal of the injured part; and powerful sedative remedies alone possess any influence in restraining the paroxysms. The Cerebral apparatus is entirely unaffected in this disorder; but the nerves of deglutition are usually those first influenced by it; those of respiration, however, being soon affected, as also those of the trunk in general.—The condition termed *Hydrophobia* is nearly allied to that of traumatic Tetanus, differing chiefly in the mode in which the cranio-spinal axis is affected. The irritable state of the nervous centres obviously results from the introduction of a poison into the blood; and here the early removal of the wounded part is very desirable as a means of prevention; although, when the poison has once begun to operate on the centres, it is of no use. The muscles of respiration and deglutition are, as in Tetanus, those spasmodically affected in the first instance; but there is this curious difference in the mode in which they are excited to action—that, whilst in Tetanus the stimulus operates through the Spinal Cord (either centrally, or by being conveyed from the periphery), in *Hydrophobia* it is often transmitted from the ganglia of Special Sense, or even from the Cerebrum; so that the sight or sound of fluids, or even the idea of them, occasions—equally with their contact, or with that of a current of air—the most distressing convulsions.—Many forms of that protean malady, *Hysteria*, are attended with a similar irritability of the Nervous Centres; but there is this remarkable difference in the two cases, that the morbid phenomena of *Hysteria*, whilst they often simulate those of Chorea, Tetanus, *Hydrophobia*, *Epilepsy*, &c., are evidently dependent upon a state of the system of a much less abnormal character. The absence of any structural lesion, and even of any serious impairment of the nutrition, of the parts of the Nervous System which are the sources of the actions in question, is proved by the length of time during which the severest forms of them may exist without permanently serious consequences, and by the suddenness with which the several forms of them give place one to another, or pass off altogether. The strange combinations, moreover, which they occasionally present, remarkably distinguish them from the more settled forms of the diseases which they simulate.¹ The clinical history of *Hysteria*, then, would lead us to sup-

¹ Thus, the Author has known an obstinate case of *Hysteric disorder*, in which at one period attacks of the most complete *Opisthotonos* coexisted with perfect *Coma*; at another period, the *Coma* recurred alone; then again, there was *Trismus*, lasting for five consecutive days, without any other spasmodic action or loss of sensibility; this sometimes alternated with fits of *Yawning*, in which the jaw was held open for half an hour together; at another period, the convulsions had more of the *Epileptic* character, the face being distorted, and the limbs agitated, concurrently with a state of *Coma*, but without *laryngismus*; with this alternated fits of *Laryngismus*, without insensibility, and occurring during the expiratory movement; whilst during the whole of this succession, there was *Paralysis* of the extensor muscles of both lower extremities, with paroxysms of the most violent and prolonged *Cramp* in one of them. (See § 325, note.) The mental phenomena were almost equally strange; for a state of almost *Maniacal* excitement often came on suddenly, and ceased no less abruptly; and every form of double consciousness, from simple sleep-waking to an alternation of two very similar states of mental existence, presented itself during one long period of the disorder.—It is worth noting that in this case the exciting cause of the disorder lay in the disappointment of affections long cherished in secret; but the nutrition of the nervous system had been previously impaired by anxiety and excessive mental exertion. The first access of the disorder was kept off by the influence of a very determined will; but when the malady had fully developed itself, it resisted every kind of treatment for four years. The catamenial discharge remained very scanty during the whole of that time, and was sometimes absent altogether; and the recurrence of the period was almost invariably marked by an aggravation of the spasmodic attacks, and frequently by pains resembling those of the first stage of labor. A slow and almost imperceptible improvement was taking place, when circumstances occurred, which gave a new turn to the feelings; a fresh attachment was formed, which was happily reciprocated; and from that time the cure rapidly advanced, the convulsive and paraplegic affections being speedily recovered from, and nothing being left but *dysmenorrhœa*, which still con-

pose that the convulsive action depends rather upon some state of the blood which alters its relation to the nervous tissue as its exciting fluid, than upon any such change in the nutritive supply which it affords as would induce a more permanent disorder in the system. Taking all the phenomena, however, into account, there seems much reason to think that a general excitability of the nervous system, such as is only an exaggeration of that which is characteristic of the female sex, is induced by some defect of Nutrition, comparatively permanent in its nature; whilst the particular forms of perverted action are determined either by some toxic agent in the blood, slight variations in which may give it a selective power for one part or another of the Nervous Centres, or by irritation of the peripheral nerves. Among the sources of imperfect nutrition, leading to undue excitability of the nervous system, and thus acting as a "predisposing cause," it seems probable that a gouty diathesis is one of the most frequent;¹ whilst among the exciting causes, some irregular action of the sexual apparatus is among the most common, though it would not be correct to affirm, that disorder of the nutritive or secretory functions of the sexual system is essential to the production of the hysteric condition. The influence of Emotional states upon this condition is among the most remarkable features in the history of the disorder. There can be little doubt that habitual indulgence of the feelings, especially when these are of a painful kind, has a direct tendency to affect the nutrition of the nervous system; but when these feelings have special reference to sexual subjects, they will exert a powerful indirect influence, by fixing the mind on the genital system, and thereby modifying its condition (CHAP. XVIII.). In either of these modes, the habitual emotional state acts as a "predisposing cause;" but we constantly observe that, when the hysteric diathesis is established, any particular access of emotional excitement, even though it be of a pleasurable nature, induces the hysteric paroxysm; and it is by making a powerful effort to restrain the feelings that the Will, if the patient can be led to exert it, has so much control over the hysterical tendency. It is generally, however, a part of the complaint, that the Will *cannot* be effectually exerted; and this either on account of the vehemence of the Emotional disturbance, or through an absolute impairment of voluntary power; the state of mind then approximating closely to some forms of Insanity. It is in such circumstances that the influence of powerful motives, adapted to work upon the Will through the feelings, may be brought to bear most effectually in checking the paroxysm; thus it is well known that when the sight of an "hysteric fit" in one individual tends to induce it in another, a determined threat of severe treatment is the most certain means of keeping it off.—Hence the treatment of Hysteria may be considered as requiring three classes of remedial means;—those, namely, which operate by improving the general state of nutrition of the Nervous System and by diminishing its excitability, these for the most part acting through the blood, and being directed to the increase of its nutritive components and to the elimination of any morbid matter which it may be suspected to contain; those which operate by removing the exciting causes of the

tinued to be occasionally accompanied by severe cramps, and sometimes by general convulsion, coma, &c. This was not altogether corrected, although improved by marriage; and any emotional excitement of an unpleasant kind was sure to produce an additional aggravation. The state of the os uteri was then examined; and as it was found to be unduly contracted, cautious dilatation by sponge-tents was practised. This had the best results; the dysmenorrhœa soon abated; pregnancy supervened, and after a miscarriage (which seemed traceable to emotional excitement, coinciding with the monthly nîsus) a second pregnancy, which went on to the full term; and no return of the spasmodic attacks has since occurred.—It is worthy of note that in this case there was an hereditary predisposition to Gout, which seemed once to manifest itself in a peculiar affection of the tissues about the wrist-joint, of a character rather gouty than rheumatic.

¹ See Dr. Laycock "On the Nervous Diseases of Women," pp. 161 *et seq.*

paroxysm, among which may be specially reckoned all such as promote the healthful performance of the menstrual function; and, lastly, all those which act beneficially on the Mind, diverting or repressing painful emotions, or substituting pleasurable feelings in their place, and strengthening the general control of the Will.

XVII. The foregoing are the chief Convulsive diseases in which the Spinal centres generally are involved; but there are many spasmodic affections of a more limited character, which are traceable to a morbid affection of some particular division of the Spinal Axis. Thus in the various forms of *Spasmodic Asthma*, the Medulla Oblongata would seem to be alone involved; the attacks of this disorder usually resulting from some internal irritation, either in the air-passages themselves, or in the digestive system, producing a reflex contraction of the muscular fibres of the bronchial tubes. In the purely spasmodic stage of *Whooping-Cough*, again, which frequently persists long after all inflammatory symptoms have subsided, we have another example of spasmodic action limited to the respiratory centres; and here we have distinct evidence that the morbid condition originates in the introduction of a poison into the blood. The same may be said of the *Croup-like Convulsion* or *Crowing Inspiration* of Infants, which is an obstruction to the passage of air through the Glottis, produced by a spasmodic contraction of the constrictors of the larynx; for, although the spasmodic action may be immediately brought on by various kinds of local irritation, such as that occasioned by teething, by the presence of undigested food, or by intestinal disorder, yet there is no doubt that the excitable condition of the Nervous Centres, without which these influences would be inoperative, is dependent upon a defect of nutrition arising from unwholesome food, bad air, or some other cause affecting the system generally.¹—Spasmodic closure of the Larynx may occur from other causes. When the *rima glottidis* is narrowed, by effusion of fluid into the substance of its walls, it is very liable to be completely closed by spasmodic action, to which the unduly irritable condition of the mucous membrane will furnish many sources of excitement. Choking, again, does not result so much from the pressure of the food on the air-passages themselves, as from the spasmodic action of the larynx excited by this; and the dislodgment of the morsel by an act of vomiting is the most effectual means of obtaining relief.—*Tenesmus* and *Strangury* are well-known forms of spasmodic muscular contraction, excited by local irritation acting through the Spinal centres. The abnormal action which leads to Abortion (CHAP. XIX.) is frequently excited in the same manner.—There is a form of *Incontinence of Urine*, which is very analogous to the morbid action just described; the sphincter has its due power; but the stimulus to the evacuation of the bladder is excessive in strength and degree, owing to the acridity of the urine or other causes. The part of the bladder upon which this appears chiefly to act is the trigonum (which is well known to be more sensitive to the irritation of calculi than the rest of the internal surface); and Sir C. Bell advises young persons who suffer during the night from this very disagreeable complaint, to lie upon the belly instead of the back, so that the contact of the urine with the trigonum may be delayed as long as possible.

XVIII. As convulsive diseases are dependent upon excessive activity of the Spinal centres, so do various forms of *Paralysis* arise from disease of the Cord, affecting its proper ganglionic substance, or the connections of its nerve-roots with the Encephalon. If the latter only be impaired, we have an interruption of sensibility and voluntary motion, the reflex actions of the Spinal ganglia being

¹ The influence of "change of air" is often as marked in this disease, as it is in the chronic stage of whooping-cough. That an impure atmosphere is of itself sufficient to induce fatal convulsive disorders in infants, has been sufficiently proved on a former occasion (§ 583).

still manifested; but if the former be involved, these reflex actions are suspended no less completely than are the sensori-volitional. There are many peculiar phenomena of Paralysis depending on Spinal lesion, however, which have not yet been explained on any physiological basis. Among these is the fact, to which Dr. Gull has prominently directed attention,¹ that in Paraplegia dependent upon lesion of the Cord, there is usually greater loss of motion than of sensation; whilst in Paraplegia dependent upon Encephalic disorder, or upon toxic agencies rather affecting the peripheral than the central portions of the nervous system (as seems to be generally the case, for example, in poisoning by lead), affections of the sensibility sometimes beginning with hyperæsthesia and then proceeding to more or less complete anæsthesia, usually constitute the prominent symptoms.

XIX. Our present knowledge of the Physiology and Pathology of the *Cerebellum* seems to justify the inference, that its special function consists in the co-ordination of voluntary movements; and the effects of lesions whose influence is limited to this organ display themselves most constantly in the impairment of this power.—But there are pathological phenomena which seem to indicate that a centre of sexual sensation has its place in or near the central lobe of the Cerebellum, and that, according to the degree of excitement or of depression of its functional activity, will be the strength or weakness of the sexual desire prompted by the sensation.

XX. Of the morbid affections of the *Sympathetic System*, it is impossible to state anything with precision, in our present state of almost complete ignorance of its physiological actions. It may be stated, however, as an indubitable fact, that, in virtue of the afferent Cerebro-spinal fibres which it contains, it may receive impressions from morbid states of the organs which it supplies, and may transmit these to the Spinal cord; through which, general convulsive movements, or irregular actions of the Sensorial or even of the Cerebral centres, may be excited. Of this we have an example in the erratic phenomena of Hysteria already referred to.

[In the foregoing view of the Functions of the Nervous System, the Author has endeavored to exhibit this most difficult and in many parts obscure subject, under the aspect in which it now presents itself to his own mind: believing that he could thus best explain it to his readers. As his views have been arrived at by his own careful study of the subject, he has not thought it necessary to be continually referring to other Physiologists, with whose doctrines his own may have more or less of coincidence. He would here state, once for all, that of the older writers on this branch of Physiology, he regards Unzer and Prochaska (whose treatises have been lately republished by the Sydenham Society) as having displayed the deepest insight into the truth; their doctrines requiring little more than the correction and extension which subsequent anatomical discoveries have afforded, to form part of the present fabric of the science. And he considers it as no unimportant confirmation of his own views that, although arrived at in complete ignorance of what Unzer had long previously put forth, they have proved to be in harmony, on all essential points, with those of so philosophic and penetrating a thinker.—Of modern Neurologists, the foremost rank is justly to be assigned to Sir C. Bell, for his discovery of the anatomical distinctness of the sensory and motor nerves, and for the inferences to which this discovery led. And the author is quite of opinion that the rediscovery of the Reflex Function of the Spinal Cord by Dr. M. Hall (which he believes to have been entirely original on that gentleman's part) has constituted an era of no less importance; although his limitation of the doctrine of reflex action to the Spinal ganglia has subsequently tended, in the Author's opinion, rather to retard than to promote the progress of Neurology. In extending this view to the Sensory Ganglia, and in showing that they minister to a class of "reflex" actions peculiarly their own, the Author believes that he may claim to have made the first definite attempt to free it from this limitation; and for its further extension to the Cerebrum, Science is indebted to Dr. Laycock, to whose Essay on the Reflex Action of the Brain, the Author has already expressed his obligations. To these he would add the names of Dr. Holland and Dr. Todd, as those of writers from whom he has derived many valuable suggestions, which have not, he trusts, been without fruit in his own mind.—It is a circumstance not devoid of

¹ "Gulstonian Lectures on the Nervous System," in "Medical Times," 1849, No. 495.

interest, that, during the present century, notwithstanding the large amount of anatomical and experimental inquiry which has been directed to the Nervous System both in France and Germany, and the vast addition to our knowledge of *details* which has hence arisen, the great advances in the *general doctrines* of this department of the science should have been made by British Physiologists.]

CHAPTER XV.

OF SENSATIONS, AND THE ORGANS OF THE SENSES.

1.—Of Sensation in General.

850. By the term *Sensation* is rightly understood that change in the condition of the Mind by which we become aware of an *impression* made upon some part of the Body; or, in a briefer form of expression, it may be defined to be the *consciousness of an impression*. Some Physiologists have, it is true, spoken of a *sensation without consciousness*; but it seems very desirable to limit the term to the mental change; since the word *impression* serves to designate the change produced in the afferent nerves by an external cause, up to the point at which the mind becomes conscious of it. We have seen reason to believe that the impressions communicated to the Spinal Cord may there excite motor actions, without occasioning true sensation; and it would seem to be with a certain part of the Encephalon only, that the Mind possesses the relation necessary for the production of such a change in it. Hence this organ is spoken of as the *Sensorium*. For the reasons already given (§§ 732-4), it seems probable that the ganglia of Special Sensation are the essential instruments of this function, rather than the Cerebral Hemispheres. The afferent nervous fibres, which connect the various parts of the body with the Sensorium, are termed *sensory*; and these are distributed in very different proportions to different parts. Those parts of the body which are endowed with sensory fibres, and impressions on which, therefore, give rise to sensation, are ordinarily spoken of as *sensible*; and different parts are spoken of as sensible in different degrees, according to the strength of the sensation which is produced by a corresponding impression on each. In accordance with what was formerly stated (§ 355) of the dependence of all Nervous action on the continuance of the Circulation of blood, it is found that the sensory nerves are distributed pretty much in the same proportion as the bloodvessels; that is to say, in the non-vascular tissues—such as the epidermis, hair, nails, cartilage, and bony substance of the teeth—no nerves exist, and there is an entire absence of sensibility; and in those whose vascularity is trifling, the sensibility is dull, as is the case with bones, tendons, ligaments, fibrous membranes, and other parts whose functions are simply mechanical, and even with serous and areolar membranes. Many of these textures are acutely sensible, however, under certain circumstances; thus, although tendons and ligaments may be wounded, burned, &c., without giving rise to much consciousness of the injury, they cannot be stretched without the production of considerable pain; and the fibrous, serous, and areolar tissues, when their vascularity is increased by inflammation, also become extremely susceptible of painful impressions. All very vascular parts, however, do not possess acute sensibility; the muscles, for instance, are furnished with a large supply of blood, to enable them to perform their peculiar function; but they are not sensible in by any means the same proportion. Even the substance of the brain, and of the nerves of special sensation, appears to be destitute of this endowment; and the same may be said of the mucous membranes lining the interior of the

several viscera, which, in the ordinary condition, are much less sensible than the membranes that cover those viscera, although so plentifully supplied with blood for their especial purposes. The most sensible of all parts of the body is the Skin, in which the sensory nerves spread themselves out into a minute network; and even of this tissue, the sensibility differs greatly in different parts. The organs of *special* sensation become, by the peculiar character of the nerves with which they are supplied, the recipients of impressions of a particular kind: thus the eye is sensible to light, the ear to sound, &c.; and whatever amount of *ordinary* sensibility they possess, is dependent upon other sensory nerves. The eye, for example, contrary to the usual notions, is a very insensible part of the body, unless affected with inflammation; for, though the mucous membrane which covers its surface, and which is prolonged from the skin, is acutely sensible to tactile impressions, the interior is by no means so, as is well known to those who have operated much on this organ. And there are many parts of the body that are supplied with the common sensory nerves, which receive and convey to the mind impressions of particular kinds, with much greater readiness than they communicate those of a different description.

851. An active Capillary Circulation being essential to the Sensibility of every part supplied with nerves, any cause which retards this deadens the sensibility, as is well seen with regard to Cold; and, on the other hand, an increase in its energy produces a corresponding increase in the sensibility, as is peculiarly evident in the "active congestion" which usually precedes and accompanies Inflammation. A diminution or increase of sensibility to external impressions may arise, however, not only from an abnormal state of the circulation in the organ or part itself, but from the similar conditions affecting that part of the sensorium in which the impressions are received. Thus, in those various conditions of the Encephalon, in which either a stagnation of the circulation, or an abnormal state of the blood, occasions a diminished functional activity in the Sensorial centres, this is marked by obtuseness to sensory impressions; on the other hand, in active congestion of the brain, the most ordinary external impressions produce sensations of an unbearable violence; and there are some peculiar conditions of the nervous system, known under the name of hysterical, in which the patients manifest the same discomfort, even when the circulation is in a feeble rather than in an excited state.¹ It is remarkable that the sensibility of the mucous membranes lining the internal organs is less exalted by the state of inflammation, than is that of most other parts; and in this arrangement we may trace a wise and beneficent provision; since, were it otherwise, the functions necessary to life could not be performed without extreme distress, with a very moderate amount of disorder in the viscera. If a joint is inflamed, we can give it rest; but to the actions of the alimentary canal we can give little voluntary respite.

852. The feelings of Pain or Pleasure which are connected with particular sensations, cannot (for the most part at least) be explained upon any other principle than that of the necessary association of these feelings, by an original law of our nature, with the sensations in question. As a general rule, it may be stated that the *violent* excitement of *any* sensation is disagreeable, even when the same sensation in a moderate degree may be a source of extreme pleasure. This is the case alike with those impressions which are communicated through the organs of sight, hearing, smell, and taste, as with those that are received through the nerves of common sensation; and there can be no doubt that the final cause, or purpose, of the association of painful feelings with such violent

¹ The influence of toxic agents introduced into the blood, in producing Anæsthesia and Hyperæsthesia, constitutes a very wide field of inquiry, which is well deserving of careful cultivation. It is remarkable that *Lead* should be capable of inducing either of these states.

excitement, is to stimulate the individual to remove himself from what would be injurious in its effects upon the system. Thus, the pain resulting from violent pressure on the cutaneous surface, or from the proximity of a heated body, gives warning of the danger of injury, and excites mental operations destined to remove the part from the influence of the injurious cause: and this is shown by the fact that loss of sensibility is frequently the indirect occasion of severe lesions—the individual not receiving the customary intimation that an injurious process is taking place.¹ Instances have occurred, in which severe inflammation of the membrane lining the passages has resulted from the effects of ammoniacal vapors, introduced into them during a state of syncope—the patient not receiving that notice of the irritation which, in an active condition of his nervous system, would have prevented him from inhaling the noxious agent.

853. It is a general rule, with regard to all sensations, that their intensity is much affected by *Habit*; being greatly diminished by frequent and continual repetition. This is not the case, however, with regard to those sensations to which the *attention* is peculiarly directed; for these lose none of their acuteness by frequent repetition; on the contrary, they become much more readily cognizable by the mind. We have a good example of both facts in the effects of sounds upon sleeping persons (§ 843). The general law, then, seems to be, that Sensations, *not attended to*, are blunted by frequent repetition; and this may perhaps be connected with certain other general facts, which lie under the observation of every one.—It is well known that the vividness of sensations depends rather on the degree of *change* which they produce in the system, than on the *absolute amount* of the impressing force; and this is alike the case with regard to the special and the ordinary sensations. Thus, our sensations of heat and cold are entirely governed by the previous condition of the parts affected; as is shown by the well-known experiment of putting one hand into hot water, the other into cold, and then transferring both to tepid water, which will seem cool to one hand, and warm to the other. Every one knows, too, how much more we are affected by a warm day at the commencement of summer, than by an equally hot day later in the season. The same is the case in regard to light and sound, smell and taste. A person going out of a totally dark room into one moderately bright, is for the time painfully impressed by the light, but soon becomes habituated to it; whilst another, who enters it from a room brilliantly illuminated, will consider it dark and gloomy. Those who are constantly exposed to very loud noises become almost unconscious of them, and are even undisturbed by them in illness; and the medical student well knows that even

¹ The following case, recorded in the "Journal of a Naturalist," affords a remarkable instance of this general fact. The correctness of the statement having been called in question, it was fully confirmed by Mr. Richard Smith, the late senior surgeon of the Bristol Infirmary, under whose care the sufferer had been. "A travelling man, one winter's evening, laid himself down upon the platform of a lime-kiln, placing his feet, probably numbed with cold, upon the heap of stones, newly put on to burn through the night. Sleep overcame him in this situation; the fire gradually rising and increasing, until it ignited the stones upon which his feet were placed. Lulled by the warmth, the man slept on; the fire increased until it burned one foot (which probably was extended over a vent-hole) and part of the leg above the ankle entirely off, consuming that part so effectually, that a cinder-like fragment was alone remaining—and still the wretch slept on! and in this state was found by the kiln-man in the morning. Insensible to any pain, and ignorant of his misfortune, he attempted to rise and pursue his journey, but missing his shoe, requested to have it found; and when he was raised, putting his burnt limb to the ground to support his body, the extremity of his leg-bone, the tibia, crumbled into fragments, having been calcined into lime. Still he expressed no sense of pain, and probably experienced none; from the gradual operation of the fire, and his own torpidity during the hours his foot was consuming. This poor drover survived his misfortunes in the hospital about a fortnight; but the fire having extended to other parts of his body, recovery was hopeless."—See also § 349, *note*.

the effluvia of the dissecting-room are not perceived when the organ of smell is habituated to them; although an intermission of sufficient length would, in either instance, occasion a renewal of the first unpleasant feelings, when the individual is again subjected to the impression.—Again, it is a well-known fact that impressions made upon the organs of sense continue to affect the consciousness for a time after the cause of the impression has ceased: it is in this manner that a musical tone, which seems perfectly continuous, results from a series of consecutive vibrations, following each other with a certain rapidity; and that a line or circle of light is produced by a luminous body moving with a certain velocity. And there seems reason to believe that sensorial changes of frequent recurrence produce a modification in the nutrition of the Sensorium itself, which *grows to them*, as it were, just as the Cerebrum may be considered as growing to the mode in which it is habitually exercised (§ 807); for not only would the production of such a modification be quite in accordance with the general phenomena of Nutrition,¹ but we can scarcely otherwise explain the progressive formation of that connection between sensorial changes and motor actions which gives rise to the “secondarily automatic” movements (§ 749).—Hence it seems reasonable to attribute that diminution in the force of Sensations which is the consequence of their habitual recurrence, to the want of such a *change* in the condition of the Sensorium as is needful to produce an impression on the consciousness; the effects which they at first induced being no longer experienced in the same degree, when the structure of the part has accommodated itself to them.

854. It is curious, also, that the feelings of Pain or Pleasure, which unaccustomed sensations excite, are often exchanged for each other, when the system is habituated to them; this is especially the case, in regard to impressions communicated through the organs of Smell and Taste. There are many articles in common use among mankind—such as tobacco, fermented liquors, &c., the use of which cannot be said to produce a natural enjoyment, since they are at first unpleasant to most persons; and yet they first become tolerable, then agreeable, and at last the want of them is felt as a painful privation, and the stimulus must be applied in an increasing degree, in order to produce the usual effect.

855. It is through the medium of Sensation, that we acquire a knowledge of the material world around us, by the psychological operations which its changes excite in ourselves. The various kinds or modes of Sensation excite in us various ideas regarding the properties of matter; and these properties are known to us only through the changes which they produce in the several organs (§ 786). It is well known that instances exist, in which, from some imperfection of the organization, there is an incapacity for distinguishing colors or musical tones, whilst there is no want of sensibility to light or sound; and that some persons are naturally endowed with a much greater range of the sensory faculties than others possess. Hence it does not seem at all improbable that there are properties of matter, of which none of *our* senses can take immediate cognizance; and which other beings might be formed to perceive, in the same manner as *we* are sensible to light, sound, &c. Thus many animals are affected by atmospheric changes in such a manner that their actions are regarded by Man as indications of the probable state of the weather; and the same is the case in a less degree with some of our own species, who are peculiarly susceptible of the same influences.—Now the most universal of all the qualities or properties of

¹ We have a remarkable exemplification of this in the *tolerance* which may be gradually established in the system for various toxic agents, especially for such as particularly affect the Nervous substance, such as Opium or Alcohol. It seems impossible to explain this tolerance on any other hypothesis than that of the alteration of the nutrition of the tissue by repeated doses, so that no further change can be produced by the quantity originally taken.

Matter, on which, in fact, our notion of it is chiefly founded (§ 804), is its occupation of space, producing a more or less complete *resistance* to displacement; and this quality is that through which alone any knowledge of the external world can be obtained by a large proportion of the lower Animals; *contact* between their own surface and some material body being required to produce sensation. We shall presently see, however, that the idea of the *shape* of a body which we form from the touch; results from a very complex process, such as animals of the lower grades can scarcely be supposed to exercise. There can be little doubt that, next to the mere sense of resistance, sensibility to *temperature* is the most universally diffused through the Animal kingdom; and probably the consciousness of *luminosity* is the next in the extent of its diffusion.¹ It is probable that the sense of *taste* (which has a close affinity to that of touch) exists very low down in the animal scale, being obviously of great importance in the selection of food; but the Anatomist has no means of ascertaining where this refinement exists, and where it does not; since the organs of taste and touch are very similar. The sense of *hearing* does not seem to be distinctly present among the Invertebrate animals, except in such as approach most nearly to the Vertebrata; it is not improbable, however, that sonorous vibrations may produce an effect upon the system of those animals, which do not receive them as *sound*. The sense of *smell*, which is concerned with one of the least general properties of matter, appears to be the least widely diffused among the whole; being only possessed in any high degree by Vertebrated animals, and being but feebly present in a large proportion of these.

856. Besides the various kinds of sensibility which have been just enumerated, there are others which are ordinarily associated together, along with the sense of material resistance (and its several modifications), and the sense of temperature, under the head of Common Sensation; but several of them, especially those which originate in the body itself, can scarcely be regarded in this light. Such are the feelings of hunger and thirst; that of nausea; that of distress resulting from suspended aeration of the blood; that of "sinking at the stomach," as it is vulgarly but expressively described, which results from strong mental emotion; the sexual sense, and perhaps some others.—Now in regard to all these, it is impossible in the present state of our knowledge to say, whether their peculiarity results from the particular constitution of the nerves that receive and convey them, or only from a modification in the impressing causes, from the particular endowments of their ganglionic centres, and from the mode in which they operate. Thus we have no evidence whether the nervous fibrils, which convey from the lungs the sense of distress resulting from deficient aeration, are of the same or of a different character from those which convey from the surface of the air-passages the sense of the contact of a foreign body. But as we know that all the trunks, along which these peculiar impressions travel, do minister to ordinary sensation, whilst the nerves of truly special sensation are not sensible to common impressions, it is evident that the probability seems in favor of the identity of the fibres, which minister to these sensations, with those of the usual sensory character. We shall see that, with regard to the sense of Temperature, there is strong evidence that its peculiarity depends on the speciality of the apparatus by which impressions are received at the peri-

¹ There is good reason to believe, from observation of their habits, that many animals are susceptible of the influence, and are directed by the guidance of light; whilst their organs are not adapted to receive true visual impressions, or to form optical images: and such would seem to be the function of the red spots frequently seen on prominent parts of the lower Articulata and Mollusca, and even of some Radiata. Wherever these are of sufficient size to allow their structure to be examined, they are found to be largely supplied with nerves, but to be destitute of the peculiar organization which alone constitutes a true eye.

pheral extremities of the tactile nerves, rather than upon any peculiarity in the transmitting fibres (§ 866).

857. There are certain external causes which can excite changes in the Sensorium through several different channels; the sensation being in each case characteristic of the particular nerve on which the impression is made. Thus pressure, which produces through the nerves of common sensation the feeling of resistance, is well known to occasion, when exerted on the eye, the sensation of light and colors; and, when made with some violence on the ear, to produce tinnitus aurium. It is not so easy to excite sensations of taste and smell, by mechanical irritation; and yet, as Dr. Baly¹ has shown, this may readily be accomplished in regard to the former. The sense of nausea may be easily produced, as is familiarly known, by mechanical irritation of the fauces. Electricity still more completely possesses the power of affecting all the sensory nerves with the changes which are peculiar to them; for, by proper management, an individual may be made conscious at the same time of flashes of light, of distinct sounds, of a phosphoric odor, of a peculiar taste, and of pricking sensations, all excited by the same cause, the effects of which are modified by the respective peculiarities of the instruments through which it operates.—But although there are some stimuli which can produce sensory impressions on all the nerves of sensation, it will be found that those to which any one organ is *peculiarly* fitted to respond, produce little or no effect upon the rest. Thus the ear cannot distinguish the slightest difference between a luminous and a dark object. A tuning-fork, which, when laid upon the ear whilst vibrating, produces a distinct musical tone, excites no other sensation, when placed upon the eye, than a slight jarring feeling. The most delicate touch cannot distinguish a substance which is sweet to the taste, from one which is bitter; nor can the taste (if the communication between the mouth and the nose be cut off) perceive anything peculiar in the most strongly-odoriferous bodies.—It may hence be inferred that no nerve of *special* sensation can, by any possibility, take on the function of another.

858. But whilst there is evidence of the peculiar aptitudes of the different Sensory nerves, to receive and convey impressions of particular kinds, yet there can be no doubt that their special endowments are in great degree dependent upon those of the *central* organs in which they terminate. For with regard to all kinds of Sensation, it is to be remembered that the change of which the Mind is informed is *not* the change at the peripheral extremities of the nerves, but the change communicated to the Sensorium; hence it results that external agencies can give rise to no kind of sensation which cannot also be produced by internal causes, exciting changes in the condition of the nerves in their course. This very frequently happens in regard to the senses of sight and hearing; flashes of light being seen, and ringing sounds in the ears being heard, when no external stimulus has produced such impressions. The production of odorous and gustative sensations from internal causes is perhaps less common; but the sense of nausea is more frequently excited in this manner, than by the direct contact of the nauseating substance with the tongue or fauces. The various phases of common sensibility often originate thus; and the sense of temperature is frequently affected without any corresponding affection of the tactile sensations, a person being sensible of heat or of chilliness in some part of his body, without any real alteration of its temperature. The most common of the internal causes of these *subjective* sensations (as they have been termed, in contradistinction to the *objective*, which result from a real material object) is congestion or inflammation; and it is interesting to remark that this cause, operating through each nerve, produces in the sensorium the changes to which

¹ Translation of Müller's "Elements of Physiology," p. 1062, *note*.

that nerve is usually subservient. Thus, congestion in the nerves of common sensation gives rise to feelings of pain or uneasiness; but when occurring in the retina and optic nerve it produces flashes of light; and in the auditory nerve it occasions "a noise in the ears."—But further, the phenomena of *subjective* sensation often originate in peculiar conditions of the Encephalon itself, and not in the organs of sense or the nervous trunks; thus, in dreaming, we have frequently very vivid pictures of external objects presented to our minds; and we sometimes distinctly hear voices and musical tones, or have perceptions (though this is less common) of tastes and odors. The phenomena of spectral illusions are very nearly connected with those of dreaming; both may be in some degree influenced by external causes, acting upon the organs of sensation, which are misinterpreted (as it were) by the mind, owing to its state of imperfect operation; but both also may entirely originate in the central organs. There seems to be no difference, in the feelings of the individual, between the sensations thus originating, and those which are produced in the usual manner; for we find that, unless otherwise convinced by their own reason, persons who witness spectral illusions believe as firmly in the reality of the objects that come before their minds, as if the images of those objects were actually formed on their retinae. This is another proof, if any were wanting, that the organ of sense, and the nerve belonging to it, are but the instruments by which certain changes are produced in the Sensorium; by which changes, and not by the immediate impressions of the objects, our Consciousness is really affected. There is yet another mode, however, in which subjective sensations may be excited; namely, by sensations originating in objective impressions on *other* parts. Thus the irritation of a calculus in the bladder gives rise to pain at the end of the penis; disease of the hip-joint is often first indicated by pain in the knee; irritation of the ovary will cause pain under the mamma; various disorders of the liver occasion pain under the left scapula; attention is often drawn to diseases of the heart by shooting pains along the arms; stimulation of the nipple, whether in the male or female, gives rise to peculiar sensations referred to the genital organs; the sudden introduction of ice into the stomach will cause intense pain in the supraorbital region, and the same pain is frequently occasioned by the presence of acid in the stomach, and may be very quickly relieved by its neutralization with an alkali. It will be seen that in most of these cases it is impossible to refer the sensations to any direct nervous connection with the parts on which the impressions are made; and they can scarcely be otherwise accounted for than by supposing that these impressions produce sensorial changes, which are referred to other parts, in virtue of some central track of communication with them, analogous to that through which reflex movements are excited. There are circumstances, indeed, which seem to render it not improbable that, just as the impression brought by the afferent nerves to the central organs, excites a reflex movement by disturbing the polarity of a motor nerve, it may excite a "reflex sensation" by disturbing the polarity of a sensory nerve. Certain it is that, after the long continuance of some of these reflex sensations, the organs to which they are referred themselves become diseased, although previously quite healthy; thus, pain in the testicle is frequently induced by irritation having its seat in the lower part of the spine, but, if this continue, some morbid affection of the testicle itself is likely to supervene; and Sir B. Brodie¹ has recorded several cases, in which "nervous" pains in various parts, apparently of a purely subjective character, have been followed by pain and swelling of the integuments. These phenomena are perhaps due to that habitual direction of the consciousness to the part which is prompted by the habitual sensation; this condition, as we shall see hereafter (CHAP. XVIII.),

¹ "On Local Nervous Affections," 1837.

being itself adequate to the production of changes in its ordinary nutritive action.

859. It seems to be by an innate law of our constitution, that these subjective sensations, whether originating at the central terminations of nerves, or in the course of their trunks, should be referred by the mind to the ordinary situations of their peripheral terminations; even though these should not exist, or should be destitute of the power of receiving impressions. Thus after amputations, the patients are for some time affected with sensations (originating probably in the cut extremities of the nerves), which they refer to the removed extremities; the same has been noticed in regard to the eye, as well when it has been completely extirpated, as when its powers have been destroyed by disease. The effects of the Taliacotian operation also exhibit the operation of this law in a curious manner; for until the flap of skin from which the new nose is formed obtains vascular and nervous connections in its new situation, the sensation produced by touching it is referred to the forehead. Another interesting illustration of it may be obtained by the following very simple experiment: If the middle finger of either hand be crossed behind the forefinger, so that its extremity is on the radial side of the latter, and the ends of the two fingers thus disposed be rolled over a marble, pea, or other round body, a sensation will be produced, which, if uncorrected by reason, would cause the mind to believe in the existence of two distinct bodies; this is due to the impression being made at the same time upon the radial side of the forefinger, and the ulnar side of the middle finger—two joints which, in the natural position, are at a considerable distance.

860. Sensations of a purely subjective nature may excite precisely the same muscular movements, or other changes in the bodily system, as do similar sensations produced by objective realities. Of this we have abundant evidence in the effects of sensations called up by ideas (§§ 758, 863); the following example, however, is peculiarly valuable, as showing that the sensation still operates in directing movement, even though there be an intellectual consciousness that there is no objective cause for it, and that the movement is consequently inappropriate. A lady nearly connected with the Author, having been frightened in childhood by a black cat, which sprang up from beneath her pillow just as she was laying her head upon it, was accustomed for many years afterwards, whenever she was at all indisposed, to see a black cat on the ground before her; and although perfectly aware of the spectral character of the appearance, yet she could never avoid lifting her foot as if to step over the cat, when it seemed to be lying in her path.

861. The acuteness with which particular Sensations are felt is influenced in a remarkable degree by the *attention* they receive from the mind. If the mind be entirely inactive, as in profound sleep, no sensation whatever is produced by ordinary impressions; and the same is the case when the attention is so completely concentrated upon some object of thought or contemplation that sensations altogether unconnected with it fail to make any impression on the perceptive consciousness. On the other hand, when the attention is from any cause strongly directed upon them, impressions very feeble in themselves produce sensations of even painful acuteness; thus, every one knows how much a slight itching of some part of the surface may be magnified by the direction of the thoughts to it, whilst, as soon as they are forced by some stronger impression into another channel, the irritation is no longer felt; so, too, it must be within the experience of most persons, how vividly sounds are perceived when they break in upon the stillness of the night, being increased in strength, not only by the contrast, but by absorbing the whole attention. An interesting experiment is mentioned by Müller, which shows how completely the mind may be unconscious of impressions communicated to it by one organ of sense, when

occupied, even without a distinct effort of the will, by those received through another. If we look at a sheet of white paper through two differently-colored glasses at the same time—one being placed before each eye—the resulting sensation is seldom that of a mixture of the colors : if the experiment be tried with blue and yellow glasses, for example, we do not see the paper of a uniform green ; but the blue is predominant at one moment, and the yellow at another ; or blue nebulous spots may present themselves on a yellow field, or yellow spots on a blue field. We perceive, from this experiment, that the attention may not only be directed to the impressions made on either retina, to the complete exclusion of those of the other, but it may be directed to those made on particular spots of either. This may be noticed, again, in the process by which we make ourselves acquainted with a landscape or a picture ; if our attention be directed to the whole field of vision at once, we see nothing distinctly ; and it is only by abstracting ourselves from the contemplation of the greater part of it, and by directing our attention to smaller portions in succession that we can obtain a definite conception of the details. The same is the case in regard to auditory impressions ; and here the power of attention, in causing one sensation or series of sensations to predominate over others which are really more intense, is often most remarkably manifested. When we are listening to a piece of music played by a large orchestra, for example, we may either attend to the combined effect of all the instruments, or we may single out any one part in the harmony, and follow this through all its mazes ; and a person with a practised ear (as it is commonly but erroneously termed, it being not the ear, but the mind, that is practised), can even distinguish the sound of the weakest instrument in the whole band, and can follow its strain through the whole performance. This attention to a single element can only be given, however, by withdrawing the mind from the perception of the remainder ; and a musician who thus listens, will have very little idea of the rest of the harmonic parts, or of the general effect. In fact, when the mind is thus directed, by a strong effort of the will, into a particular channel, it may be almost considered as unconscious *quoad* any other impressions.

862. The effects of attention are not only manifested in regard to the sensations which are excited by external impressions, but also in respect to those which originate within the system. Every one is aware how difficult it is to keep the body perfectly quiescent,¹ especially when there is a particular motive for doing so, and when the attention is strongly directed to the object. This is experienced even whilst a photogenic likeness is being taken, when the position is chosen by the individual, and a support is adapted to assist him in retaining it ; and it is still more strongly felt by the performers in the “*tableau vivans*,” who cannot keep up the effort for more than three or four minutes. Now it is well known that, when the attention is strongly directed to an entirely different object (when we are listening, for example, to an eloquent sermon, or an interesting lecture), the body may remain perfectly motionless for a much longer period ; the uneasy sensations, which would otherwise have induced the individual to change his position, not being perceived : but no sooner is the discourse ended, than a simultaneous movement of the whole audience takes place, every one then becoming conscious of some discomfort, which he seeks to relieve. This is the case also in regard to the respiratory sensation ; for it may generally be observed that the usual reflex movements do not suffice for the perfect aeration of the blood, and that a more prolonged inspiration, prompted by an uneasy feeling, takes place at intervals ; but under such circumstances as those just alluded to, this feeling is not experienced until the attention ceases to be engaged by a more powerful stimulus, and then it manifests itself by the

¹ Of course the movements of respiration and winking are left out of the question.

deep inspirations which accompany, in almost every individual, the general movement of the body.

863. It is remarkable that not merely are subjective sensations, like all others, rendered more intense by the direction of the attention to them, but they may be actually called into existence by the fixation of the attention on certain parts of the body; still more, by the belief in the existence of objective causes for such sensations. The "effects of mental attention on bodily organs" have been specially pointed out by Dr. Holland;¹ from whose examples the following may be cited in proof of the foregoing position. "The attention concentrated, for so by an effort of will it may be, on the head or sensorium, gives certain feelings of tension and uneasiness, caused possibly by some change in the circulation of the part; though it may be an effect, however difficult to be conceived, on the nervous system itself. Persistence in this effort, which is seldom indeed possible beyond a short time without confusion, produces results of much more complex nature, and scarcely to be defined by any common terms of language." "Stimulated attention will frequently give a local sense of arterial pulsation where not frequently felt, and create or augment those singing noises in the ears, which probably depend on the circulation through the capillary vessels." "A similar direction of consciousness to the region of the stomach creates in this part a sense of weight, oppression, or other less definite uneasiness; and, when the stomach is full, appears greatly to disturb the due digestion of the food. The state and action of the bowels are much influenced by the same cause." A peculiar sense of weight and restlessness approaching to cramp, is felt in a limb, to which the attention is particularly directed. So, again, if the attention be steadily directed to almost any part of the surface of the body, some feeling of itching, creeping, or tickling will soon be experienced. The fact that sensations may be *modified* by previous beliefs, which must be within the experience of every one, is remarkably illustrated by the well-known exclamation of Dr. Pearson, "Bless me! how heavy it is," when he first poised upon his finger the globule of potassium produced by the battery of Davy; his preconception of the coincidence between metallic lustre and high specific gravity causing him to feel *that* as ponderous which the unerring test of the balance determined to be lighter than water. Of the absolute creation of subjective sensations by the belief in the existence of their objective causes, the two following cases, related by Prof. Bennett,² are very satisfactory examples; the effect of the idea not being limited to the production of the sensations, but extending itself to the consequences which would have followed those sensations if their supposed cause had been real. "A clergyman told me that some time ago suspicions were entertained, in his parish, of a woman who was supposed to have poisoned her newly-born infant. The coffin was exhumed, and the procurator-fiscal, who attended with the medical men to examine the body, declared that he already perceived the odor of decomposition, which made him feel faint, and in consequence he withdrew. But, on opening the coffin, it was found to be empty; and it was afterwards ascertained that no child had been born, and consequently no murder committed." The second case is yet more remarkable. "A butcher was brought into the shop of Mr. Macfarlan, the druggist, from the market-place opposite, laboring under a terrible accident. The man on trying to hook up a heavy piece of meat above his head, slipped, and the sharp hook penetrated his arm, so that he himself was suspended. On being examined, he was pale, almost pulseless, and expressed himself as suffering acute agony. The arm could not be moved without causing excessive

¹ See his valuable Essay on that subject in his "Medical Notes and Reflections," and in his "Chapters on Mental Physiology."

² "The Mesmeric Mania of 1851," Edinburgh, 1851.

pain; and in cutting off the sleeve, he frequently cried out; yet when the arm was exposed, it was found to be quite uninjured, the hook having only traversed the sleeve of his coat!" In this and similar cases, the sensation was perfectly *real* to the individual who experienced it; but it originated in a Cerebral (ideational) change which produced its impression through the nerves of *internal* sensation (§ 758), instead of in an impression upon the nerves of the *external* senses to which it was referred. Of this kind of action we have seen other examples, in the production of sensations by "suggestion" in the state of artificial reverie (§ 825). And the excitement of the peculiar sensation of tickling in a ticklish person by any movement that suggests the idea, and of that of creeping or itching by the mention of bed-infesting insects to those who are peculiarly liable to their attacks, are familiar instances of the same fact; which strongly confirms the general doctrines heretofore advanced, respecting the analogy between the peripheral surface of the Cerebrum and the peripheral expansions of the Sensory nerves, as regards their mutual relations to the Sensorium (§ 753).

2.—Sense of Touch.

864. By the sense of Touch, as commonly understood, is meant that modification of the common sensibility of the body, of which the cutaneous surface is the especial seat. The Skin is peculiarly adapted for this purpose, not merely by the large amount of sensory nervous fibres which are distributed in its substance, but also by its possession of a papillary apparatus in which these nerves terminate, or rather commence. The *papillæ* are little elevations of the surface of the cutis, easily perceptible by the aid of a lens; each is chiefly composed of a vascular loop (Fig. 196), in close relation with a similar loop formed by the nervous fibril; and also incloses (as appears from the recent researches of Professors Wagner and Kölliker) an "axile body," composed of a mass of homogeneous areolar tissue with an external layer of imperfectly developed elastic tissue, and essentially similar to the bundles of fibrous tissue encircled by elastic fibres which are to be found in the cutis. These "axile bodies" are only to be found in the papillæ of those parts which are distinguished for acuteness of tactile sensibility; and hence we cannot regard them as *essential* to the exercise of the sense of touch, their function probably being to *intensify* tactile impressions, where delicacy of touch is peculiarly required.¹ The number of these papillæ within any given area pretty closely corresponds with the degree of sensibility of that part of the surface; thus we find them most abundant on the hands, especially towards the points of the fingers, and on the lips and tongue. Some interesting observations have been made by Prof. Weber on the sensibility of different parts of the skin. His mode of ascertaining this was to touch the surface with the legs of a pair of compasses, the points of which were guarded with pieces of cork; the eyes being closed at the time, the legs were approximated to each other, until they were brought within the smallest distance at which they could be felt to be distinct from one another, which has been

Fig. 196.

Capillary network at margin of lips.

¹ The accounts of the structure of the tactile papillæ given by Prof. Kölliker in his "Mikroskopische Anatomie," band ii. p. 24, and in the "Zeitschrift für Wissenschaften Zoologie," band iv. heft 1, 1852, are here followed. For a notice of the peculiar views of Prof. Wagner, see the "Brit. and For. Med.-Chir. Rev.," vol. x. p. 251 [or § 343—Ed.].

termed by Dr. Graves "the limit of confusion." The following are some of the results of his experiments:—

Point of tongue	$\frac{1}{2}$ of a line.	Mucous membrane of gums	9 lines.
Palmar surface of third phalanx	1 line.	Lower part of forehead	10 "
Red surface of lips	2 lines.	Lower part of occiput	12 "
Palmar surface of second phalanx	2 "	Back of hand	14 "
Dorsal surface of third phalanx	3 "	Neck, under lower jaw	15 "
Palmar surface of metacarpus	3 "	Vertex	15 "
Tip of the nose	3 "	Skin over patella	16 "
Dorsum and edge of tongue	4 "	— sacrum	18 "
Part of lips covered by skin	4 "	— acromion	18 "
Palm of hand	5 "	Dorsum of foot	18 "
Skin of cheek	5 "	Skin over sternum	20 "
Extremity of great toe	5 "	Skin beneath occiput	24 "
Hard palate	6 "	Skin over spine, in back	30 "
Dorsal surface of first phalanx	7 "	Middle of the arm	30 "
Dorsum of hand	8 "	— thigh	30 "

It is curious that the distance between the legs of the compasses seemed to be greater (although really so much less), when it was felt by the more sensitive parts, than when it was estimated by parts of less distinct sensibility. With the extremities of the fingers and the point of the tongue, the distance could be distinguished most easily in the longitudinal direction; on the dorsum of the tongue, the face, neck, and extremities, the distance could be recognized best when the points were placed transversely. As a general fact, it seems that the sensibility of the trunk is greater on the median line, both before and behind, and less at the sides. Differences in the temperature and weight of bodies were, according to Prof. Weber's observations, most accurately recognized at the parts which were determined to be most sensible by the foregoing method of inquiry.¹

865. As already stated (§ 855), the only idea communicated to our minds by the sense of Touch, when exercised in its simplest form, is that of *Resistance*; and it is by the various degrees of resistance which the sensory surface encounters, of which we partly judge by the muscular sense (§ 750), that we estimate the hardness or softness of the body against which we press. It is only when either the sensory surface or the substance touched is made to change its place in regard to the other, that we obtain the additional notion of *extension* or *space*; this also being derived from the combination of the muscular with the tactile sense. By the impressions made upon the papillæ, during the movement of the tactile organ over the body which is being examined, the roughness, smoothness, or other peculiar characters of the surface of the latter are estimated. Our knowledge of *form*, however, is a very complex process, requiring not merely the exercise of the sense of touch, but also great attention to the muscular sensations.—It is chiefly, as formerly remarked, in the variety of movements of which the hand of Man is capable, that it is superior to that of any other animal; and it cannot be doubted that the sense of Touch, thus employed, affords us a very important means of acquiring information in regard to the external world, and especially of correcting many vague and fallacious

¹ See his Memoir "De Pulsu, Respiratione, Auditu, et Tactu," Lipsiæ, 1834. This method of inquiry has been since pursued by M. H. Belfield-Lefèvre ("Recherches sur la Nature, la Distribution, et l'Organ du Sens Tactile," Paris, 1837), and by Prof. Valentin ("Lehrbuch der Physiologie des Menschen," band ii. § 566), with the same general results. It was found by Prof. Valentin, however, that a considerable amount of individual variation exists in regard to the "limit of confusion;" some persons being able to distinguish the points at one-half or even one-third of the distances required by others.—In the Author's article "Touch" in the "Cyclopædia of Anatomy and Physiology," vol. iv. p. 1169, will be found a Table including the whole series of observations made by Profrs. Weber and Valentin, the *maxima* and *minima* of the latter being stated, as well as the means.

notions which we should derive from the sense of Sight, if used alone. On the other hand, it must be confessed that our knowledge would have a very limited range, if this sense were the only medium through which we could acquire ideas. It is probably on the sensations communicated through the Touch, that the idea of the material world, as something external to ourselves, chiefly rests; but this idea is by no means a logical deduction from our experience of these sensations, being rather an instinctive or intuitive perception directly excited by them (§ 790).

866. That the conditions under which certain of the modifications of common sensation operate, are in some respects different from those of ordinary Touch, is very easily shown. Thus, the feeling of tickling is excited most readily in parts which have but a low tactile sensibility, namely, the armpits, flanks, and soles of the feet; whilst in the points of the fingers, whose tactile sensibility is most acute, it cannot be excited. Moreover, the nipple is very moderately endowed with ordinary sensibility; yet by a particular kind of irritation, a very strong feeling may be excited through it.—Again, in regard to Temperature, it is remarked by Weber that the left hand is more sensitive than the right: although the sense of touch is undoubtedly the more acute in the latter. He states that, if the two hands, previously of the same temperature, be plunged into separate basins of warm water, that in which the left hand is immersed will be felt as the warmer, even though its temperature is somewhat lower than that of the other. In regard to the sensations of heat and cold, he points out another curious fact—that a weaker impression made on a large surface, seems more powerful than a stronger impression made on a small surface; thus, if the forefinger of one hand be immersed in water at 104° , and the whole of the other hand be plunged in water at 102° , the cooler water will be thought the warmer; whence the well-known fact that water in which a finger can be held will scald the whole hand. Hence it also follows that minute differences in temperature, which are imperceptible to a single finger, are appreciated by plunging the whole hand into the water; in this manner, a difference of one-third of a degree may readily be detected, when the same hand is placed successively in two vessels. The judgment is more accurate, when the temperature is not much above or below the usual heat of the body; just as sounds are best discriminated when neither very acute nor very grave.—Some further experiments have recently been made by Professor Weber, to determine whether the sense of temperature is received through any other channel than the sensory apparatus contained in the integuments.¹ The first means of which he availed himself for deciding this question, was that afforded by the results of accident or surgical operations, in which a portion of skin had been left deficient. Thus, in three cases in which a large portion of the skin had been destroyed by a burn, and in which healing had not advanced so far as to renew the organ of touch, it was found that no correct discrimination could be made between two spatulas, one of them at a temperature of from 48° to 54° , the other of from 113° to 122° , which were brought into contact with the denuded surface; so that one of these patients thrice affirmed that he was being touched with the cold body, when it was the warm, and the reverse. But when the spatula was in one instance made somewhat warmer, and was brought into contact with the unskinned surface, the patient felt, not *heat*, but *pain*. Another means of gaining information on this point is afforded by the ingestion or injection of a large quantity of warm or cold fluid into the stomach or intestinal canal. Thus Professor Weber states that, after drinking a tumbler of water at 32° , he felt the cold water in the mouth, in the palate, and in the pharynx, as far as the limits of the sense of touch; but that the gradual passage of the cold water into the stomach could not be

¹ "Müller's Archiv.," 1849, heft iv. s. 273–283.

perceived. There was, it is true, a slight sensation of cold in the gastric region; but, as it only occupied the situation of the anterior wall of the stomach, it was attributable to the abstraction of heat from the abdominal integuments in contact with this. In an opposite experiment, the author drank quickly three glasses of milk, the temperature of the first of which was 158° , that of the second 145° , whilst that of the third was intermediate between the two. The sensation of heat could not be traced lower down than that of the cold in the previous experiment. At the moment when the fluid entered the stomach, there was a feeling which remained for some time, but which could not be distinguished as heat, being mistakable for cold. In order to ascertain the sensation produced in the large intestine by cold water, an injection of 14 ounces of water of the temperature of 65° was thrown up the rectum; but scarcely any sensation of cold could be perceived from it. In another instance, 21 ounces of water at the same temperature were thrown up, without any resulting sensation of cold. In both these cases, on the return of the enema a few minutes afterwards, a distinct feeling of cold was experienced at the anus. When water of so low a temperature as $45\frac{1}{2}^{\circ}$ was injected, the first feeling excited was a sensation of cold in the immediate neighborhood of the anus, and then a feeble movement in the bowels; but a little time afterwards, there was a faint sensation of cold, especially in the anterior wall of the abdomen. This sensation, however, remained after the return of the water; and may hence be attributed to the abstraction of warmth from the abdominal integuments, which was proved to take place, the temperature of the surface being lowered 3° . So, again, if the cavity of the nose be filled with cold water, the coldness is only perceived in the parts of the cavity which are most endowed with the proper tactile sense, namely, the neighborhood of the nostrils and of the pharynx; and it is not all discernible in the higher part of the cavity, which is especially subservient to the olfactory sense. But when the water injected is very cold (*e. g.* 41°), a peculiar pain is felt in the upper part of the nasal fossæ, extending to the regions of the forehead and the lachrymal canals; this pain, however, is altogether different from the sense of coldness.—From the foregoing experiments, it appears fair to conclude that the sensory nerves have no power of receiving impressions indicative of difference of temperature, unless those impressions are communicated through a special organ; but they afford no adequate ground for the supposition that a set of nerve-fibres is provided for their transmission, distinct from those which minister to common sensation. This conclusion is confirmed by the fact that we cannot excite impressions of heat or cold by direct application to the trunks of nerves which we know must conduct such impressions; for the parts of the skin, immediately beneath which lie large nerve-trunks, are not more sensitive to moderate heat or cold than are any others; whilst a greater degree of either is felt as pain, not as a change of temperature. Thus, a mixture of ice and water, applied over the ulnar nerve, affects it in fifteen seconds, and produces severe pain, having no resemblance to cold, such as cannot be excited by the same cold applied to any other region. So the nerve of the tooth-pulp is equally and similarly affected by water of 43° and of 112° ; either application causing a pain exactly similar to that excited by the other, or to that produced by pressure. The same is true of the impressions received through the skin itself, when they pass beyond certain limits of intensity; thus, the sensation produced by touching frozen mercury is said to be not distinguishable from that which results from touching a red-hot iron.

867. The improvement in the sense of Touch, in those persons whose dependence upon it is increased by the loss of other senses, is well known; this is doubtless to be in part attributed (as already remarked) to the increased attention which is given to the sensations, and in part, it may be surmised, to an increased development of the tactile organs themselves, resulting from the

frequent use of them. The process of the acquirement of the power of recognizing elevated characters by the touch, is a remarkable example of this improbability. When a blind person first commences learning to read in this manner, it is necessary to use a large type: and every individual letter must be felt for some time, before a distinct idea of its form is acquired. After a short period of diligent application, the individual becomes able to recognize the combination of letters in words without forming a separate idea of each letter; and can read line after line, by passing the finger over each, with considerable rapidity. When this power is once thoroughly acquired, the size of the type may be gradually diminished; and thus blind persons may bring themselves, by sufficient practice, to read a type not much larger than that of an ordinary large-print Bible. The case of Saunderson, who, although he lost his sight at two years old, became Professor of Mathematics at Cambridge, is well known; amongst his most remarkable faculties, was that of distinguishing genuine medals from imitations, which he could do more accurately than many connoisseurs in full possession of their senses. Several instances are recorded of men who became eminent as Sculptors after the loss of their sight, and who were particularly successful in modelling portrait-busts: here, it is obvious, not merely the *tactile*, but the *muscular* sensibility must be greatly augmented in acuteness by the habit of attention to it. The power of immediate recognition of individuals by the slightest contact of the hands, even after long periods of time, which most blind and deaf persons have displayed, is one of the most curious examples of the mode in which tactual perceptions will impress themselves on the memory, when they are habitually attended to. As an example of the correct notions which may be conveyed to the mind, of the forms and surfaces of a great variety of objects, and of the sufficiency of these notions for accurate comparison, the Author may mention the case of a blind friend of his own, who has acquired a very complete knowledge of Conchology, both recent and fossil; and who is not only able to recognize every one of the numerous specimens in his own cabinet, but to mention the nearest alliances of a shell previously unknown to him, when he has thoroughly examined it by his touch. Many similar instances might be cited, one of the most remarkable being that of John Gough, who, though blind, was a noted botanical collector, and earned his livelihood as a land-surveyor. Several cases are on record,¹ of the acquirement, by the blind, of the power of distinguishing the colors of surfaces, which were similar in other respects; and, however wonderful this may seem, it is by no means incredible. For it is to be remembered that the difference of color depends upon the position and arrangement of the particles composing the surface, which render it capable of reflecting one ray whilst it absorbs all the rest; and it is quite consistent with what we know from other sources, to believe that the sense of Touch may become so refined as to communicate a perception of such differences.²

3.—Sense of Taste.

868. The sense of Taste is that by which we distinguish the *sapid* properties of bodies. The term, as commonly understood, includes much more than this; being usually employed to designate the whole of that knowledge of the qualities of a body (except such as is purely tactile), which we derive through the sensory apparatus situated within the mouth. But it will be hereafter shown that a

¹ Among the best authenticated of these is that of a lady who became blind, and afterwards deaf, in consequence of an attack of confluent smallpox; cited in Dr. Kitto's "Lost Senses," vol. ii. p. 79, from the "Annual Register" for 1758.—Dr. Kitto's treatise may be referred to, as containing a large collection of interesting cases of a similar description.

² For some additional details in regard to the sense of Touch, see the Author's article "Touch," in the "Cyclopædia of Anatomy and Physiology," vol. iv.

considerable part of this is dependent upon the assistance of the *olfactive* sense; which is affected through the posterior nares by the odorous emanations of all such bodies as are capable of giving them off; and the indications of which are so combined with those of the true gustative sense as to make an apparently single impression upon the sensorium. Moreover, there are certain sensorial impressions received through the organ of taste, which are so nearly allied in their character to those of *touch* as to render it difficult to specify any fundamental difference between them: such are the *pungent* sensations produced by mustard, pepper, the essential oils, &c.; all of which substances produce a sensation when applied for a sufficient length of time to any part of the cutaneous surface, which can scarcely be distinguished from that excited through the organ of taste, in any other way than by its inferior intensity, and by the absence of the concurrent odorous emanations. The *taste* of such substances might, perhaps, be considered, therefore, as the composite result of the impressions made upon the sensorium through a refined and acute *touch*, and by the effect of their odorous emanations upon the organ of *smell*. After making full allowance, however, for all such as can be thus accounted for, there remains a large class of pure *sapors*, of which we take cognizance without the assistance of smell, and which are altogether dissimilar to any tactile impressions; such are the bitter of quinine, the sour of tartaric acid, the sweet of sugar, the saline of common salt, &c. The smell can give us no assistance in distinguishing small particles of these bodies, since they are either entirely inodorous, or so nearly so as only to be recognizable through its means when in large masses; and the most refined touch cannot afford any indication of that kind of difference among them, of which we are at once rendered cognizant by taste.—Of all the “special” senses, however, that of Taste is most nearly allied to that of touch, as appears from several considerations. In the first place, the *actual contact* of the object of sense with the organ through which the impression is received is necessary in the present case, as in the preceding. Again, it appears, from the considerations formerly adduced (§ 717), that there is no special nerve of Taste; for the gustative impressions upon the front of the tongue are conveyed by the Lingual branch of the 5th Pair, which also ministers to common sensibility; whilst those made upon the back of the organ are conveyed by the Glosso-pharyngeal, which also ministers to common sensibility; and pressure on the trunk of either of these nerves gives rise to pain, which is not the case with either the olfactory, the optic, or the auditory nerves. Moreover, the papillary apparatus, through which the gustative impressions are made upon the extremities of these nerves, is essentially the same in structure with that of the skin.—But for the gustative nerve-fibres to be impressed by the distinctive properties of sapid substances, it seems requisite that these substances should be brought into immediate relation with them, and that they should penetrate, in the state of solution, through the investments of the papillæ, into their substance. This would seem to be proved by the two following facts: first, that every substance which possesses a distinct taste is more or less soluble in the fluids of the mouth, whilst substances which are perfectly insoluble do not make their presence known in any other way than through the sense of touch; and, second, that if the most sapid substance be applied in a dry state to the papillary surface, and this be also dry, no sensation of taste is excited. Hence it may be inferred that, in the reception of gustative impressions, a change is produced in the molecular condition of the nerve-fibres, or, to use the language of Messrs. Todd and Bowman, their polarity is excited by the direct agency of the sapid matter itself. This change may be induced, however, both by electrical and mechanical stimulation. If we make the tongue form part of a galvanic circuit, a peculiar sensation is excited, which is certainly allied rather to the gustative than to the tactile, and which does not seem to be due (as was at one time supposed) to the decomposition of the salts

of the saliva. And, as Dr. Baly has pointed out,¹ "if the end of the finger be made to strike quickly, but lightly, the surface of the tongue at its tip, or its edge near the tip, so as to affect not the substance of the organ, but merely the papillæ, a taste sometimes acid, sometimes saline, like the taste produced by electricity, will be distinctly perceived. The sensation of taste thus induced will sometimes continue several seconds after the application of the mechanical stimulus." On the other hand, as Wagner has truly remarked, if the surface of the tongue near the root be touched with a clean dry glass rod, or a drop of distilled water be placed upon it, a slightly bitterish sensation is produced; and this, if the pressure be continued, passes into that of nausea, and, if the pressure be increased, even excites vomiting. The feeling of nausea may be excited by mechanical irritation of any part of the surface of the fauces and soft palate; and this feeling is certainly much more allied to that of taste than to that of touch. Further, it has been observed by Henle that, if a small current of air be directed upon the tongue, it gives rise to a cool saline taste like that of saltpetre. Thus we find that the peculiar effects of sapid substances upon the nerves of taste may be imitated to a certain extent by other agencies; and it

Fig. 197.

Tongue seen on its upper surface: *a*. One of the circumvallate papillæ. *b*. One of the fungiform papillæ. Numbers of the conical papillæ are seen about *d*, and elsewhere. *c*. Glottis, epiglottis, and glosso-epiglottidean folds of mucous membrane.—From Soemmering.

also appears that the sensations excited by these vary according to the part of the gustative surface on which they operate; mechanical or electrical stimulation of the front of the tongue giving rise to a kind of saline taste, whilst mechanical stimulation applied to the back of the tongue and fauces excites the feelings of bitterness and nausea.—One of the conditions requisite for the due exercise of the gustative sense is a temperature not departing far on either side from that which is natural to the body. It appears from the recent experiments of Prof. E. H. Weber,² that if the tongue be kept immersed for nearly a minute in water of about 125°, the taste of sugar brought in contact with it, either in powder or solution, is no longer perceived; the sense of touch, usually so delicate at the tip of the tongue, being also rendered imperfect. A similar imperfection of taste and touch was produced by immersing the tongue for the same length of time in a mixture of water and broken ice.

869. The surface of the tongue is undoubtedly the special seat of gustative sensibility in Man; though the sense of Taste is not by any means restricted to that organ, being diffused in a less degree over the soft palate, the arches of the palate, and the fauces. It is on the Tongue alone, however, that the papillary apparatus is fully

¹ Translation of "Müller's Physiology," p. 1062, note.

² "Müller's Archiv," 1847, S. 342.

developed; and its structure has been so carefully examined and described by Messrs. Todd and Bowman,¹ that little remains to be added to their account of it.—The lingual papillæ may be divided, in the first place, into the *Simple* and the *Compound*; the former of which had previously escaped observation, through not forming any apparent projection. The *Simple* papillæ (Fig. 198)

are scattered in the intervals of the compound, over the general surface of the tongue; and they occupy much of the surface behind the circumvallate variety, where no compound papillæ exist. They are completely buried and concealed beneath the continuous sheet of epithelium, and can only be detected when this membrane has been removed by maceration; they are then found to have the general characters of the cutaneous papillæ, but nerve-tubes have not yet been detected in them. The *Compound* papillæ are visible to the naked eye; and have been classified, according to their shape, into the *circumvallate*, the *fungiform*, and the *filiform*. The *circumvallate* or calyciform papillæ (Fig. 199), are eight or ten in number, and are situated in a V-shaped line at the base of the tongue. Each consists of a central flattened circular projection of the mucous membrane, surrounded by a tumid ring of about the same elevation, from which it is separated by a narrow circular fissure. The surface of both centre and border is smooth, and invested by a scaly epithelium, which conceals a multitude of simple papillæ. The *fungiform* papillæ (Figs. 201, 204, A) are scattered singly over the tongue, chiefly upon its sides and tip. They pro-

B. Another, with the capillary loops of its simple papillæ injected. *a*, Artery. *v*, Vein. The groove around the base of some of the fungiform papillæ is here represented as well as the capillary loops, *c, c*, of some neighboring simple papillæ.—Magnified 18 diameters.

ject considerably from the surface, and are usually narrower at their base than at their summit. They contain a complex capillary plexus (Fig. 202), the terminal loops of which enter the numerous simple papillæ that clothe the surface of the fungiform body. Amidst these lie nerve-tubes, which probably have a looped arrangement;¹ and the epithelium which covers them is so thin as to allow the red color of the blood to be seen through it. In this manner,

¹ The Author, in conjunction with Messrs. Bowman, T. Wharton Jones, and Kiernan, has most carefully examined the mode of termination of the nerves in the fungiform papillæ, with the view of testing the validity of the assertion of Dr. Waller ("Phil. Trans.," 1849) that they have free truncated extremities. No such terminations, however, could be exhibited to them by Dr. Waller; and the conclusion at which they arrived as most probable, has been already stated (§ 343).

of capillaries, and a bundle of nerve-fibres (Fig. 205), both terminating in loops which enter the simple papillæ that clothe the surface of the compound body ; but, instead of being covered with a thin scaly epithelium, they are fur-

nished with bundles of long pointed processes, some of which approach hairs in their stiffness and structure. These are immersed in the mucus of the mouth, and may be moved in any direction, though they are generally inclined backwards.—The simple papillæ which occur in an isolated manner, with those which are aggregated in the circumvallate and fungiform bodies, doubtless minister to the sense of Taste ; but there seems much reason to coincide in the opinion of Messrs. Todd and Bowman, with regard to the different office of the filiform papillæ. “The comparative thickness of their protective covering, the stiffness and brush-like arrangement of their filamentary productions, their greater development in that portion of the dorsum of the tongue which is chiefly employed in the movements of mastication, all evince the subservience of these papillæ to the latter function, rather than to that of taste ; and it is evident that their isolation and partial mobility on one another, must render the delicate touch with which they are endowed, more available in directing the muscular actions of the organ. The almost manual dexterity of the organ, in dealing with minute particles of food, is probably provided for, as far as sensibility conduces to it, in the structure and arrangement of these papillæ.” It may be added,

that the filiform papillæ of Man seem to be the rudimentary forms of those horny epithelial processes which acquire so great a development in the tongues of the Carnivora, and which are of such importance in the abrasion of their food.

870. The simple application of a sapid substance to the gustative surface is usually sufficient to excite the sensation; and if this application be restricted to one particular spot, we are able to recognize its place more or less distinctly. In this respect, then, the gustative impression resembles the tactile; for whilst we cannot, by our own consciousness, distinguish the parts of the retina or of the auditory apparatus on which visual or auditory impressions are made, we can make this distinction in regard to the surface which is supplied by the nerves of general sense. This determination is most precise when the impression is made on the parts of the tongue of which the gustative sensibility is most acute; namely, the apex, sides, and posterior part of the dorsum; being probably aided, however, near the tip, by the acuteness of its tactile sensibility. The impressibility of the middle portion of the dorsum is greatly inferior; but still, when the gustative sensation has been excited there, it is referred to the spot on which the sapid substance was laid. The contact of sapid substances much more readily excites a gustative sensation, when it is made to press upon the papillæ, or is moved over them. Thus there are some substances whose taste is not perceived when they are simply applied to the central part of the dorsum of the tongue, but of whose presence we are at once rendered cognizant by pressing the tongue against the roof of the mouth. The full flavor of a sapid substance, again, is more readily perceived when it is rubbed on any part of the tongue, than when it is simply brought in contact with it, or pressed against it. Even when liquids are received into the mouth, their taste is most completely discriminated by causing them to move over the gustative surface: thus the "wine-taster" takes a small quantity of the liquor into his mouth, carries it rapidly over every part of its lining membrane, and then ejects it. It is not improbable that this exaltation of the usual effects is simply due to mechanical causes; the sapid particles being brought by the pressure or movement into more rapid and complete operation on the nerve-fibres, than they would be if simply placed in contact with the papillæ.—The impressions made upon our consciousness by a large proportion of sapid substances are of a complex kind; being in part derived from their odorous emanations, of which we take cognizance through the organ of Smell. Of this any one may convince himself, by closing the nostrils, and inspiring and expiring through the mouth only, whilst holding in the mouth, or even rubbing between the tongue and the palate, some aromatic substance; for its taste is then scarcely recognized, although it is immediately perceived when its effluvia are drawn into the nose. It is well known, too, that, when the sensibility of the Schneiderian membrane is blunted by inflammation (as in an ordinary cold in the head), the power of distinguishing flavors is very much diminished. In fact, some Physiologists are of opinion that *all* our knowledge of the *flavor* of sapid substances is received through the Smell; but this, as already shown, would not be a correct statement; and there are cases on record in which the sense of Smell has been entirely lost, without any impairment of the true sense of Taste.¹

¹ An interesting case of this kind, occurring in a Negro who had gradually lost the characteristic hue of his skin, and had acquired the fair complexion of a European, has lately been put on record by Dr. J. C. Hutchison.—The Olfactory nerve seemed to be entirely paralyzed, whilst the branches of the 5th Pair retained their integrity; so that, whilst the proper sense of Smell was entirely lost, a pungent burning sensation was excited by irritating vapors, and the application of snuff induced sneezing. Notwithstanding this deficiency, the sense of Taste, properly so called, did not seem to be impaired; for substances which neither possessed odor nor pungency could be readily discriminated, even though their tastes were not widely different. (See "Amer. Journ. of Med. Sci." Jan. 1852.)

871. Taken in its ordinary compound acceptation, the sense of Taste has for its object to direct us in the choice of food, and to excite the flow of mucus and saliva, which are destined to aid in the preparation of the food for Digestion. Among the lower Animals, the instinctive perceptions connected with this sense are much more remarkable than our own; thus an omnivorous Monkey will seldom touch fruits of a poisonous character, although their taste may be agreeable; and animals, whose diet is restricted to some one kind of food, will decidedly reject all others. As a general rule, it may be stated that substances of which the taste is agreeable to us, are useful in our nutrition, and *vice versâ*;¹ but there are many signal exceptions to this.—Like other senses, that of Taste is capable of being rendered more acute by education; and this on the principles already laid down in regard to Touch. The experienced wine-taster can distinguish differences in age, purity, place of growth, &c., between liquors that to ordinary judgments are alike; and the epicure can give an exact determination of the spices that are combined in a particular sauce, or of the manner in which the animal, on whose flesh he is feeding, was killed. As in the case of other senses, moreover, impressions made upon the sensory surface remain there for a certain period; and this period is for the most part longer than that which is required for the departure of the impressions made upon the eye, the ear, or the organ of smell. Every one knows how long the taste of some powerful substances remains in the mouth; and even of those which make less decided impressions, the sensations remain to such a degree that it is difficult to compare them at short intervals. Hence if a person be blindfolded, and be made to taste substances of distinct, but not widely different flavors (such as various kinds of wine or of spirituous liquors), one after another in rapid succession, he soon loses the power of discriminating between them. In the same manner, the difficulty of administering very disagreeable medicines may be sometimes got over, by either previously giving a powerful aromatic, or by combining the aromatic with the medicine; its strong impression in both cases preventing the unpleasant taste from exciting nausea.

¹ It is justly remarked by Dr. Holland ("Medical Notes and Reflections," p. 85), that—"In the majority of instances of actual illness, provided the real feelings of the patient can be safely ascertained, his desires as to food and drink may be safely complied with. But undoubtedly much care is needful that we be not deceived as to the state of the appetites, by what is merely habit or wrong impression on the part of the patient, or the effect of the solicitation of others. This class of sensations is more nurtured out of the course of nature, than are those which relate to the temperature of the body. The mind becomes much more deeply engaged with them; and though in acute illness they are generally submitted again to the natural law, there are many lesser cases where enough remains of the leaven of habit to render every precaution needful. With such precautions, however, which every physician who can take schooling from experience will employ, the stomach of the patient becomes a valuable guide; whether it dictate abstinence from a recurrence of food; whether much or little in quantity; whether what is solid or liquid; whether much drink or little; whether things warm or cold; whether sweet, acid, or saline; whether bland or stimulating to the taste." Further, Dr. Holland remarks: "It is not wholly paradoxical to say that we are authorized to give greatest heed to the stomach when it suggests some seeming extravagance of diet. It may be that this is a mere deprivation of the sense of taste; but frequently it expresses an actual need of the stomach, either in aid of its own functions, or indirectly (under the mysterious law just referred to) for the effecting of changes in the whole mass of blood. It is a good practical rule in such cases to withhold assent, till we find after a certain lapse of time that the same desire continues or strongly recurs; in which case it may generally be taken as the index of the fitness of the thing desired for the actual state of the organs. In the early stage of recovery from long gastric fevers, I recollect many curious instances of such contrariety to all rule being acquiesced in, with manifest good to the patient. Dietetics must become a much more exact branch of knowledge, before we can be justified in opposing its maxims to the natural and repeated suggestions of the stomach, in the state either of health or disease."

4.—Sense of Smell.

872. Of the nature of Odorous emanations, the Natural Philosopher is so completely ignorant, that the Physiologist cannot be expected to give a definite account of the mode in which they produce sensory impressions. Although it may be surmised that they consist of particles of extreme minuteness, dissolved as it were in the air, and although this idea seems to derive confirmation from the fact that most odorous substances are volatile, and *vice versâ*—yet the most delicate experiments have failed to discover any diminution in weight, in certain

substances (as musk) that have been impregnating with their effluvia a large quantity of air for several years; and there are some volatile fluids, such as water, which are entirely inodorous. The true Olfactory nerves pass down from the Olfactory Ganglion (§729) in the form of very numerous minute threads, which form a plexus upon the surface of the Schneiderian or pituitary membrane (Fig. 206). The filaments composing this plexus are described by Messrs. Todd and Bowman¹ as differing widely from those of the ordinary cephalic nerves in structure; they contain no white substance of Schwann, are nucleated and finely granular in texture, and altogether bear a close resemblance to the gelatinous form of nerve-fibres (Fig. 207). It has been hitherto found impossible to trace the ultimate distribution of these fibres in the olfactory membrane, owing to

¹ "Physiological Anatomy," p. 397, *Am. Ed.*

their want of the characteristic white substance, and the absence of distinction

Fig. 207.

Olfactory filaments of the Dog: *a*. In water.
b. In acetic acid.—Magnified 250 diameters.

between the nuclei of the minuter fibres and those of the nucleated tissues through which they pass. It would appear that every part of the Schneiderian membrane is not equally endowed with the faculty of distinguishing odors, which is a very different power from that of becoming sensible of irritation from them. The distribution of the Olfactory nerves seems limited to the membrane covering the superior three-fourths of the septum of the nose, the superior turbinated bone and the upper half of the middle turbinated bone, and the upper wall of the nasal cavities beneath the cribriform plate of the ethmoid bone; all which surface is covered (as Messrs. Todd and Bowman have pointed out) with a tessellated epithelium of a rich sepia-brown hue. The remainder of the nasal

surface is supplied by the 5th Pair only; and hence it is that we cannot distinguish faint odors, unless, by a peculiar inspiratory effort, we draw the air charged with them to the upper part of the nose. In animals living in the air, it is a necessary condition of the exercise of the sense of Smell that the odorous matter should be transmitted by a respiratory current through the nostrils; and that the membrane lining these should be in a moist state. Hence, by breathing through the mouth, we may avoid being affected by odors even of the strongest and most disagreeable kind; and in the first stage of a catarrh, when the ordinary mucous secretion is suspended, the sense of Smell is blunted from this cause, as it afterwards is from the excess in the quantity of the fluid, which prevents the odoriferous effluvia from coming into immediate relation with the sensory extremities of the nerves. Hence we may easily comprehend how section of the 5th Pair, which exerts a considerable influence over the secretions, will greatly diminish the acuteness of this sense, and will have the further effect of preventing the reception of any impressions of irritation from acrid vapors, which are entirely different in their character from true odorous impressions, and are not transmitted through the Olfactory nerve (§ 739). The nasal passages may indeed be considered as having, in the air-breathing Vertebrata, two distinct offices; they constitute the organ of Smell, through the distribution of the olfactory nerve upon a part of their surface; but they also constitute the portals of the respiratory organs, having for their office to take cognizance of the aeriform matter which enters them, and to give warning of that which would be injurious; this latter function is performed by the 5th Pair, as by the Pneumogastric in the glottis. It is through this nerve that the act of Sneezing is excitable; the evident purpose of which is the ejection of a strong blast of air through the nasal passages, in such a manner as to drive out any offending matter they may contain.

873. The importance of the sense of Smell among many of the lower Animals, in guiding them to their food, or in giving them warning of danger, and also in exciting the sexual feelings, is well known. To Man its utility is comparatively small under ordinary circumstances; but it may be greatly increased when other senses are deficient. Thus, in the well-known case of James Mitchell, who was deaf, blind, and dumb from his birth, it was the principal means of distinguishing persons, and enable him at once to perceive the entrance of a stranger. It is recorded that a blind gentleman, who had an antipathy to cats,

was possessed of a sensibility so acute in this respect, that he perceived the proximity of one that had been accidentally shut up in a closet adjoining his room. Among Savage tribes, whose senses are more cultivated than those of civilized nations, more direct use being made of the powers of observation, the scent is almost as acute as in the lower Mammalia; it is asserted by Humboldt, that the Peruvian Indians in the middle of the night can thus distinguish the different races, whether European, American Indian, or Negro.¹—The agreeable or disagreeable character assigned to particular odors is by no means constant amongst different individuals. Many of the lower Animals pass their whole lives in the midst of odors, which are to Man (in his civilized condition at least) in the highest degree revolting; and will even refuse to touch food until it is far advanced in putridity. It more frequently happens in regard to odors and savors, than with respect to other sensory impressions, that habit makes that agreeable, and even strongly relished, which was at first avoided; the taste of the epicure for game that has acquired the *fumet*—for olives—for assafoetida, &c., are instances of this. As to the length of time during which impressions made upon the organ of smell remain upon it, no certain knowledge can be obtained. It is difficult to say when the effluvia have been completely removed from the nasal passages, since it is not unlikely that the odorous particles (supposing such to exist) are absorbed or dissolved by the mucous secretion; it is probably in this manner that we may account for the fact, well known to every medical man, that the cadaverous odor is frequently experienced for days after a *post-mortem* examination.²

5.—Sense of Vision.

874. The objects of this sense are bodies, which are either in themselves luminous, or which become so by reflecting the light that proceeds from others. Whether their light is transmitted by the actual emission of luminous particles, or by the propagation of undulations analogous to those of sound, is a question that has been long keenly debated amongst Natural Philosophers; but it is of little consequence to the Physiologist which is the true solution, since it is only with the laws according to which the transmission takes place that he is concerned. These laws it may be desirable here briefly to recapitulate.

875. Every point of a luminous body sends off a number of rays, which diverge in every direction, so as to form a cone, of which the luminous point is the apex. So long as these rays pass through a medium of the same density, they proceed in straight lines; but, if they enter a medium of different density, they are *refracted* or bent—*towards* the perpendicular to the surface at the point at which they enter, if they pass from a rarer into a denser medium, and *from* the perpendicular, when they pass from a denser medium into a rarer. It is easily shown to be a result of this law, that, when parallel rays passing through air fall upon a convex surface of glass, they will be made to converge; so as to meet at the opposite extremity of the diameter of the circle, of which the curve forms part. If, instead of continuing in the glass, they pass out again, through a second convex surface, of which the direction is the reverse of the first, they will be made to converge still more, so as to meet in the centre of curvature. Rays which are not parallel, but which are diverging from a focus, are likewise made to converge to a point or focus; but this point will be more distant from the lens, in proportion as the object is nearer to it, and the angle of divergence

¹ The Author has been assured by a competent witness, that a youth in the state of Hypnotism had his sense of Smell so remarkably heightened, as to be able to assign (without the least hesitation) a glove placed in his hand, to its right owner—in the midst of about thirty persons, the boy himself being blindfolded.

² This may partly be attributed also to the effluvia adhering to the dress. It has been remarked that *dark* cloths retain these more strongly than light.

consequently greater. The rays diverging from the several points of a luminous object are thus brought to a corresponding focus; and the places of all these foci hold exactly the same relation to each other, with that of the points from which the rays diverged; so that a perfect image of the object is formed upon a screen held in the focus of the lens. This image, however, will be inverted; and its size, in proportion to that of the object, will depend upon their respective distances from the lens. If their distances be the same, their size will also be the same; if the object be distant, and the image near, the latter will be much the smaller; and *vice versa*.

876. There are two circumstances, however, which interfere with the perfection of an image thus formed by a convex lens. The one is, that if the lens constitute a large part of the sphere from which it is taken, the rays which fall near its margin are not brought to a focus at the same point with those which pass through its centre, but at a point nearer the lens. This difference, which must obviously interfere greatly with the distinctness of the image, is termed *Spherical Aberration*; it may be corrected by the combination of two or more lenses, of which the curvatures are calculated to balance one another in such a manner, that all the rays shall be brought to the same focus; or by diminishing the aperture of the lens by means of a stop or diaphragm, in such a manner that only the central part of it shall be used. The latter of these methods is the one employed where the diminution in the amount of light transmitted is not attended with inconvenience. The nearer the object is to the lens (and the greater, therefore, the angle of divergence of its rays), the greater will be the spherical aberration, and the more must the aperture of the diaphragm be contracted in order to counteract it.—The other circumstance that interferes with the distinctness of the image is the unequal refrangibility of the differently colored rays, which together make up white or colorless light; the violet being more bent from their course than the blue, the blue more than the yellow, and the yellow more than the red; the consequence of which will be, that the violet rays are brought to a focus much nearer to the lens than the blue, and the blue nearer than the red. If a screen be held to receive the image in the focus of any of the rays, the others will make themselves apparent as fringes round its margin. This difference is termed *Chromatic Aberration*. It is corrected in practice, by combining together lenses of different substances, of which the *dispersive* power (that is, the power of separating the colored rays) differs considerably. This is the case with flint and crown glass for instance—the dispersive power of the former being much greater than that of the latter, whilst its refractive power is nearly the same: so that, if a convex lens of crown glass be united with a concave of flint, whose curvature is much less, the dispersion of the rays effected by the former will be entirely counteracted by the latter, which diminishes in part only its refractive power.

877. The Eye may be regarded as an optical instrument of great perfection, adapted to produce, on the expanded surface of the Optic nerve, a complete image or picture of luminous objects brought before it; in which the forms, colors, lights and shades, &c. of the object are all accurately represented. By the different refractive powers of the transparent media through which the rays of light pass, and by the curvatures given to their respective surfaces, both the Spherical and Chromatic aberrations are corrected in a degree sufficient for all practical purposes; so that, in a well-formed eye, the picture is quite free from haziness and from false colors. The power by which it adapts itself to variations in the distance of the object, so as to form a distinct image of it, whether it be six inches, six yards, or six miles off, is extremely remarkable, and cannot be regarded as hitherto completely explained. It is obvious that, if we fix upon any distance, as that for which the eye is naturally adjusted (say 12 or 14 inches, the distance at which we ordinarily read), the rays proceeding from an

object placed nearer to the eye than this would not be brought to a focus upon the retina, but would converge towards a point behind it; whilst, on the contrary, the rays from an object at a greater distance would meet before they

Fig. 208.

A longitudinal section of the globe of the Eye: 1, the sclerotic, thicker behind than in front; 2, the cornea, received within the anterior margin of the sclerotic, and connected with it by means of a bevelled edge; 3, the choroid connected anteriorly with (4) the ciliary ligament, and (5) the ciliary processes; 6, the iris; 7, the pupil; 8, the third layer of the eye, the retina terminating anteriorly by an abrupt border at the commencement of the ciliary processes; 9, the canal of Petit, which encircles the lens (12); the thin layer in front of this canal is the zonula ciliaris, a prolongation of the vascular layer of the retina to the lens; 10, the anterior chamber of the eye, containing the aqueous humor; the lining membrane by which the humor is secreted is represented in the diagram; 11, the posterior; 12, the lens more convex behind than before, and inclosed in its proper capsule; 13, the vitreous humor inclosed in the hyaloid membrane, and in cells formed in its interior by that membrane; 14, a tubular sheath of the hyaloid membrane, which serves for the passage of the artery of the capsule of the lens; 15, neurilemma of the optic nerve; 16, the arteria centralis retinae, imbedded in its centre.

reached the retina, and would have again diverged from each other when they impinge upon it; so that, in either case, vision would be indistinct. Now, two methods of adaptation suggest themselves to the Optician. Either he may vary the distance between the refracting surface and the screen on which the image is formed, in such a manner that the latter shall always be in the focus of the converging rays; or the distance of the screen remaining the same, he may vary the convexity of his lens in such a manner as to adapt it to the distance of the object. The mode in which this adaptation is effected in the Human Eye has not yet been clearly made out; and many hypotheses have been put forward respecting it. According to the calculations of Olbers, based on the ascertained refractive powers of the media of the eye, the difference between the focal distances of the images of two objects, the one so far off that its rays are parallel, and the other at the distance of only four inches from the eye, is about 0.143, or one-seventh of an inch; but, as the usual range of distinct vision does not extend to objects brought within six or seven inches, the amount of change required in the relative places of the refracting bodies and the retina would not ordinarily exceed a line. It has been thought that this change might be produced by an alteration in the convexity of the cornea, or by an elongation of the globe of the eye generally, or by both methods in combination; which alterations, it was supposed, might be effected by the action of the muscles of the eyeball. But no such changes have been detected by the most careful measurement; and it cannot be shown *how* any contractile action of the muscles of the eyeball could produce an elongation of the eye, since their tendency would be (when acting altogether) to draw it backwards into its socket, or, this being prevented by the fascia and cushion of fat against which

its posterior side rests, to flatten the globe against this, rather than to increase its projection. There is much more ground for the belief, however, that a change of place is effected in the crystalline lens, by the action of the ciliary muscle, and the erectile tissue of the ciliary processes; for, although no such change can be demonstrated by observation, yet it can be shown that the contraction of the ciliary muscle (Fig. 209) would tend to draw the lens forwards;

and the fact that this muscle is peculiarly powerful in the predaceous birds, which are distinguished for their great range of vision, and which have, in their circle of osseous sclerotic plates, an unusually firm point of attachment for it, is a strong argument in favor of this doctrine.¹ Further, the almost entire loss of the power of adapting the eye to distances, which is experienced after the removal of the Crystalline lens in the operation for Cataract, is a marked indication that some change in the place or figure of this body is the principal means whereby the ordinary adaptation is effected; and although it has been suggested that an alteration in the figure of the lens might participate in the result, yet no means can be pointed out as competent to produce it; so that, as far as we can at present judge, a change in the *place* of the lens is the sole means of adapting the eye to distinct vision at varying distances.—It is certain that the condition of *repose* is that of vision for *distant* objects, no fatigue being experienced from the prolonged direction of the eye to these; whilst the employment of the visual power upon *near* objects for some time is accompanied with a sense of *effort*, and is followed by fatigue. The movement which effects

the change of place of the crystalline lens is performed in obedience to Volition, and is guided by sensation; yet we are not conscious of performing it, all that we *will* being the *result*; and thus we have another apposite illustration of the really automatic nature of what are termed voluntary movements generally (757).

878. When both eyes are fixed upon an object, their axes converge so as to meet in it; and the degree of convergence is of course altered by variations in the distance of the object; since, when the object is very remote, the optic axes are virtually parallel, whilst its approach causes them to incline towards each other, and this the more rapidly as the object is brought nearer, the increase being the greatest when it has arrived within the ordinary distance of distinct vision. Here, again, we have an example of the automatic nature of voluntary actions; for the convergence of the eyes that may be produced by such a gradual approximation of an object on which the eyes are kept fixed by an effort of the Will, far exceeds that which most individuals can induce by an effort made directly for the purpose; and if, when an object has thus been gradually approximated to within a few inches of the nose, the effort be intermitted and the optic axes be allowed to regain their parallelism, they can seldom be brought to converge again upon it, without repeating the whole process.—It has been thought, from the close accordance between the changes required for the adaptation of the eyes to distinct vision at different distances, and the alterations in the direction of the optic axes which are required to bring the two eyes to bear upon objects at

¹ See, on this subject, Messrs. Todd and Bowman's "Physiological Anatomy," p. 412, *Am. Ed.*; and Dr. Clay Wallace on "The Adjustment of the Eye to Distances," New York, 1851.

varying degrees of proximity or remoteness, that the former of these movements is in some degree dependent upon the latter, or, at any rate, that the two proceed from a common motor impulse. But that the convergence of the axes is not itself in any way the occasion of the alteration of the focus of the eye, is shown by these two facts; first, that the adaptation is as perfect in a person who only possesses or uses one eye, as it is when both are employed; and second, that some persons possess the power of altering the focus of the eye by an effort of the will, whilst the convergence remains the same.—In regard to the adaptation of the eyes to varying distances, it is further to be remarked, that, when an object is being viewed as near to the eye as it can be distinctly seen, the pupil contracts in a considerable degree. The purpose of this change is evidently to exclude the outer rays of the cone or pencil, which, from the large angle of their divergence, would fall so obliquely on the convex surface of the eye as to be much affected by the spherical aberration; and thus to allow the central rays only to enter the eye, so as to preserve the clearness of the image. The channel through which it is effected is evidently the same as that by which the convergence of the eyes is produced—namely, the inferior branch of the 3d Pair of nerves; to the action of which, the sensations received through the retina form the immediate stimulus, in the same manner as they do to the ordinary variation in the diameter of the pupil under the influence of light; but the voluntary determination to fix the vision upon the object is the original source of the action.

879. The ordinary forms of defective vision, which are known under the names of *Myopia* and *Presbyopia*, or “short-sightedness” and “long-sightedness,” are entirely attributable to defects in the optical adaptation of the eye. In the former, its refractive power is too great; the rays from objects at the usual distance are consequently brought too soon to a focus, so as to cross one another and diverge before they fall upon the retina; whilst the eye is adapted to bring to their proper focus on the retina only those rays which were previously diverging at a large angle, from an object in its near proximity. Hence a “short-sighted” person, whose nearest limit of distinct vision is not above half that of a person of ordinary sight, can see minute objects more clearly; his eyes having, in fact, the same magnifying power which those of the other would possess, if aided by a convex glass that would enable him to see the object distinctly at the shortest distance. But, as the myopic structure of the eye incapacitates its possessor from seeing objects clearly at even a moderate distance, it is desirable to apply a correction; and this is done, by simply interposing between the object and the eye a *concave* lens, of which the curvature is properly adapted to compensate for the excess of that of the organ itself.—On the other hand, in the presbyopic eye, the curvature and refractive power are not sufficient to bring to a focus, on the retina, rays which were previously divergent in a considerable or even in a moderate degree; and indistinct vision in regard to all near objects is, therefore, a necessary consequence, whilst distant objects are well seen. This defect is remedied by the use of *convex* lenses, which make up for the deficiency of the curvature.—We commonly meet with myopia in young persons, and with presbyopia in old; but this is by no means the invariable rule; for even aged persons are sometimes “short-sighted,” and “long-sightedness” is occasionally met with amongst the young. In choosing spectacles, for the purpose of correcting the errors of the eye, it is of great consequence not to make an over-compensation; for this has a tendency to increase the defect, besides occasioning great fatigue in the employment of the sight. It may be easily found when a glass of the right power has been selected, by inquiring of the individual whether it alters the apparent size of the objects, or only renders them distinct. If it alter the size (increasing it, if it be a convex lens, and diminishing it, if it be a concave), its curvature is too great; whilst

the Retina, on account of their minute size, and the absence of their distinctive characters. According to Mr. Bowman,¹ the tubular membrane and the white substance of Schwann are deficient; and only the central part of the nerve-fibre, or axis-cylinder, is continued into this expansion. The plexus of nerve-fibres comes into relation with a plexus of capillary vessels (Fig. 210), very minutely distributed; and also with a layer of cells, which constitutes the *internal* layer of the true Retina, and which so closely resembles those of the cortical substance of the Brain that there can be no reasonable doubt of their correspondence in function.² We have here, then, all the elements of an apparatus for the *origination* of changes in the nervous trunks, in a fully developed condition; and it can scarcely be doubted that the essential parts of the same structures exist in connection with the peripheral expansions of the nerves distributed to other sensory organs.—The true Retina is covered externally by a very peculiar investment, the “Membrane of Jacob” (Fig. 213), which separates it from the pigmentary layer. This seems to be composed of cells having a cylindrical form; and these are sometimes arranged vertically to the surface of the membrane, so that their extremities only are seen; whilst in other instances they are found to present an imbricated arrangement, lying over each other obliquely, in which case they are of considerable length (Fig. 213). They are remarkable for the rapidity with which they undergo alterations after death, and especially for the changes in their form which are produced by the action of water.

881. The following statements on the Limits of Human Vision, in regard to the possible minuteness of the objects of which it can take cognizance, comprehend the result of numerous inquiries made by Prof. Ehrenberg, with the view of calculating the ultimate power of the Microscope.³ In opposition to the generally received opinion, Ehrenberg arrived at the conclusion that, in regard to the extreme limits of vision, there is little difference amongst persons of ordinarily good sight, whatever may be the focal distance of their eyes. The smallest square magnitude usually visible to the naked eye, either of white particles on a black ground, or of black upon a white or light-colored ground, is about the 1-405th of an inch. It is possible, by the greatest condensation of light, and excitement of the attention, to recognize magnitudes between the 1-405th and 1-540th of an inch; but without sharpness or certainty. Bodies which are smaller than these cannot be discerned with the naked eye when single; but may be seen when placed in a row. Particles which powerfully reflect light, however, may be distinctly seen when not half the size of the least of the foregoing; thus, gold dust,⁴ of the fineness of 1-1125th of an inch, may be discerned with the naked eye in common daylight. The delicacy of vision

¹ “Lectures on the Parts concerned in the Operations on the Eye,” p. 81.

² This doctrine, which has been taught by the Author for many years, has latterly received full confirmation from the researches of Mr. H. Gray upon the development of the Eye; for he has shown that the Retina is really an offset put forth (so to speak) from the Optic Ganglion, and that the Optic Nerve is to be considered in the light of a commissure. (See “Philos. Transact.,” 1850.)

³ Taylor’s “Scientific Memoirs,” vol. i. p. 576.

⁴ Ehrenberg mentions that he obtained the finest particles of gold by scraping gilt brass; by filing pure gold, he always obtained much coarser particles.

is far greater for *lines* than for mere points; since opaque threads of 1-4900th of an inch in diameter (about half the diameter of the Silk-worm's fibre) may be discerned with the naked eye, when held towards the light. The degree in which the attention is directed to them has a great influence on the readiness with which very minute objects can be perceived; and Ehrenberg remarks that there is a much greater difference amongst individuals in this respect than there is in regard to the absolute limits of vision. Many persons can distinctly see such objects, when their situation is exactly pointed out to them, who cannot otherwise distinguish them; and the same is the case with persons of acuter perception, with respect to objects at distances greater than those at which they can see most clearly. "I myself," says Ehrenberg, "cannot see 1-2700th of an inch, black or white, at twelve inches' distance; but having found it at from four or five inches' distance, I can remove it to twelve inches, and still see the object plainly." Similar phenomena are well known in regard to a balloon or a faint star in a clear sky, or a ship in the horizon: we easily see them after they have been pointed out to us; but the faculty of rapidly descreying depends on the habit of using the eyes in search of such objects, and of attending to the sensory impressions received through them.

882. The amount of light admitted to the Eye is regulated by the contraction and dilatation of the Pupil, which is due to the muscularity of the Iris; its smallest diameter being about 1-20th, and its largest about 1-3d of an inch. The *converging* fibres of the iris are easily made out, as the membrane is principally composed of them; they have the general characters of the non-striated muscular fibre, but their nuclei are rounder and more loosely attached to the contractile material. Although the principal direction taken by the fibres is from the circumference towards the centre of the iris, yet their course is by no means constantly straight, and they frequently anastomose with each other in their passage; these anastomoses are most frequent near the pupil. The *circular* fibres of the iris are by no means so distinct; and rarely, in Man, form more than a somewhat undefined band, immediately surrounding the pupil, and lying in front of the radiating fibres. Although the iris is so vascular, that some anatomists have endeavored to explain its movements on the hypothesis that they constitute a sort of erection, there is no ground for this idea; and it is more plainly demonstrated in many of the lower animals than it is in Man, that the movements of the Iris are truly muscular, since we find the annular as well as the radiating fibres very distinct, and in Birds (many of which seem to possess a power of voluntarily regulating the diameter of the pupil) the former are striated. The contraction of the annular fibres, whereby the diameter of the pupil is diminished, is effected, as already explained (§ 724), through the instrumentality of the 3d Pair of nerves; the contraction of the radiating fibres, on the other hand, whereby the pupil is dilated, is under the government of the Sympathetic (§ 847). The contraction of the Pupil takes place, as we have seen, not merely for the purpose of excluding superfluous light from the eye, but also that the most divergent rays may be cut off, when the object is brought near the convex surface (§ 878).

[Prof. Julius Budge and Augustus Waller have discovered the very interesting fact, that irritation of the cervical trunks of the sympathetic nerve, by means of the magneto-electric machine, produces an extraordinary dilatation of the pupil; and this alike in the rabbit, in which this trunk is isolated from that of the pneumogastric, and in the cat and dog, in which the two trunks are united. The phenomenon, they remark, is as constant as the contraction of the leg when the sciatic nerve is galvanized. Thus is explained the permanent contraction of the pupil after section of the sympathetic nerve in the neck, which was first observed by Petit in 1712, but which, though subsequently verified by other observers, has never led to more than a surmise that the cer-

vical portion of the sympathetic might afford the dilating power. By galvanizing the third pair and the cervical sympathetic alternately, alternate contraction and dilatation of the pupil are produced; but with this difference, that the *contraction* is immediate, as is also the return of the iris to its previous state after the irritation is withdrawn, whilst, on the other hand, the *dilatation* requires some seconds to attain its maximum, and the subsequent return of the iris to its previous condition is slow. Moreover, the third pair loses its power of conducting irritation after being several times excited in this manner, and also very soon after death; whilst the sympathetic retains it longer.

The authors next applied themselves to determine the precise centre of this power, and they ascertained, in the first place, by galvanizing the undivided trunk in the rabbit, that irritation of any part of the cervical portion of the sympathetic, from the first to the last ganglion inclusive, would produce this result; but that below the last cervical ganglion, no such effect could be produced by irritation. On exposing the spinal cord, they found that irritation of any part of it between the first cervical and sixth dorsal vertebræ (which they hence designate the *cilio-spinal* region) would produce dilatation of the pupil; but that the effect was most decided in the centre of this region, the maximum being at the junction of the second and third dorsal vertebræ, and decreasing in intensity on passing towards either of its limits. When both of the sympathetic trunks are entire, irritation of this region produces contraction in both pupils equally; but when one of the sympathetic trunks is divided, the dilatation does not take place on that side; and if both be divided, no irritation of the spinal cord produces any effect on the pupil. It is sufficient to irritate one side of the spinal cord only, to produce dilatation of both pupils; but if the spinal cord be divided longitudinally, and the two halves be kept asunder by a slip of glass, irritation of one side then acts only on the pupil of that side. When the spinal cord is divided transversely at different points, it is found that irritation of any part that is isolated from the centre of the *cilio-spinal* region is unproductive of effect. When the spinal cord was removed, and the galvanism was applied to the dura mater lining its canal, this limitation was still more precise; for it was then found that in no other point was any effect produced than at the intervertebral space between the second and third dorsal vertebræ. Thus it seems obvious that the motor fibres on which this action depends issue from the spinal cord with the second dorsal nerve; and this corresponds with the results of dissection, as compared with the lowest limit of the influence of the sympathetic trunk over the movement of the pupil. All the causes which diminish muscular irritability after death, such as imperfect nutrition of the animal lesions, of the medulla oblongata, &c., diminish or destroy the power of the *cilio-spinal* region over the pupils; and in all cases it is to be noted that after death the power gradually recedes from the extremities of the *cilio-spinal* region towards its centre.

The authors then proceed to study the action of the intercranial nerves; and, in the first place, that of the fifth pair, respecting which there has been so much contrariety of opinion. In order to remove all sources of fallacy so far as possible, they have divided all the other nerves connected with the eye (including the cervical sympathetic); and they have then found that sections of the ophthalmic branch of the fifth pair, or of the trunk from which it is given off, causes a slow and gradual constriction, which does not commence for a minute or two after the section, and does not attain its maximum for as much more. The constriction is very decided, the pupil being reduced from three lines in diameter to one. If, instead of division of the nerve, mechanical or galvanic irritation be applied to it, the same effect is produced, but in a less degree. The constriction is in no way permanent, but departs gradually. After section of the optic nerve, section of the third pair does not produce any change in the

diameter of the pupil. The fourth and sixth pairs, moreover, have not appeared to the authors to possess any influence over the movements of the iris. If the cervical sympathetic be galvanized without waiting for the gradual departure of the constriction produced by the section of the fifth pair, it is found to be powerless to overcome this constriction. If, moreover, the fifth pair be exposed and its trunk be divided progressively from the centre towards the eye, it is found that so soon as the section is carried in front of the anterior portion of the Gasserian ganglion, the power of the sympathetic over the pupil is entirely lost. Hence it seems evident that the sympathetic fibres which have this function pass through the Gasserian ganglion; and by other experiments it may be shown that they form part of the ophthalmic division of the fifth pair.—ED.]¹

883. The sense of Vision depends, in the first place, on the transference to our minds of the picture which is formed upon the retina; this picture puts us in possession of the outlines, lights and shades, colors, and relative positions, of the objects before us; and all the ideas respecting the real forms, distances, &c., of bodies, which we found upon these data, must be considered in the light of *perceptions*, either instinctive or acquired. Many of these are derived through the combination, in our minds, of the Visual sensations, with those derived from the sense of Touch. Thus, to take a most simple illustration, the idea of *smoothness* is one essentially tactile; and yet it constantly occurs to us, on looking at a surface which reflects light in a particular manner. But, if it were not for the association, which experience leads us to form, of the connection between *polish* as seen by the *eye*, and *smoothness* as felt by the *touch*, we should not be able to determine, as we now can do, the existence of both these qualities, from an impression communicated to us through either sense singly. The general fact that, in Man, the greater part of those notions of the external world, by which his actions in the adult state are guided, are acquired by the gradual association of the perceptions derived through the Sight and through the Touch, is substantiated by amply sufficient evidence. This evidence is chiefly derived from observations made upon persons born blind, to whom sight has been communicated by an operation at a period of life which enabled them to give an accurate description of their sensations. The case recorded by Cheselden is one of the most interesting of these. The youth (about twelve years of age), for some time after tolerably distinct vision had been obtained, saw everything *flat* as in a picture, simply receiving the consciousness of the impression made upon his retina; and it was some time before he acquired the power of judging, by his sight, of the real forms and distances of the objects around him. An amusing anecdote recorded of him shows the complete want of natural or intuitive connection which there is in Man between the ideas formed through visual and through tactile sensations. He was well acquainted with a Dog and a Cat by *feeling*; but could not remember their respective characters when he *saw* them. One day, when thus puzzled, he took up the Cat in his arms, and felt her attentively, so as to associate the two sets of ideas; and then, setting her down, said, "So, puss, I shall know you another time."—A similar instance has come under the Author's own knowledge; but the subject of it was scarcely old enough to present phenomena so striking. One curious circumstance was remarked of him, which fully confirms (if confirmation were wanting) the view here given. For some time after his sight was tolerably clear, the lad preferred finding his way through his father's house, to which he had been quite accustomed when blind, by touch rather than by sight, the use of the latter sense appearing to perplex rather than to assist him; but when learning a new locality, he employed his sight, and evidently perceived the

¹ "Brit. and For. Med.-Chir. Rev.," Jan. 1852, from "Gazette Médicale de Paris," Nos. 41 and 44, 1851.

increase of facility which he derived from it.—The question has been proposed, whether a person born blind, who was able by the sense of Touch to distinguish a cube from a sphere, would, on suddenly obtaining his Sight, be able to distinguish them by the latter sense. This question was answered by Locke in the negative; and, as appears from the facts just stated, with justice.

884. The actions performed by many new-born animals do not constitute any valid objection to this view; for all that is indicated by them is, that certain sensations give rise to movements adapted to supply the wants to which they relate. Such instinctive actions are, as already pointed out, much more numerous in the lower Animals than in the higher, and in the young of the Human species than in the adult (§ 792); and they do not afford any proof that definite notions, such as we acquire, of the forms and properties of external objects are possessed by the animals which exhibit them.—We shall now examine, a little more in detail, into the means by which we gain such notions, and the data on which they are founded.

885. The first point to be determined is one which has been a fruitful source of discussion—the cause of *Erect Vision*, the picture upon the retina being inverted. Many solutions of it have been attempted; but they are for the most part rather specious than really satisfactory. That which has been of late years the most in vogue is founded upon what was styled the “law of visible direction,” which has been supported by Sir D. Brewster, and other eminent Philosophers. This law affirms, that every object is seen in the direction of the perpendicular to that point of the retina on which its image is formed; or, in other words, that, as all the perpendiculars to the several points of the inner surface of a sphere meet in the centre, the line of direction of any object is identical with the prolonged radius of the sphere, drawn from the point at which its image is made upon the retina. Upon close examination, however, it is found that this law cannot be optically correct; since the lines of direction cross each other at a point much anterior to the centre of the globe; as may be determined by drawing a diagram upon a large scale, and laying down the course of the rays received by the eye, according to the curvatures and refractive powers of its different parts. In this manner it has been determined by Volkmann, that the lines of direction cross each other in a point a little behind the crystalline lens; and that they must thus fall at such different angles on different points of the retina, that no general law can be laid down respecting them. Moreover, even supposing that such a law were a correct statement of the general fact, it would not afford any real assistance in explaining the phenomenon; since, after all, it is requisite to assume an intuitive application of it, in supposing the mind to derive its ideas of the relative situations of objects from the imagined line of direction.—A much simpler and more direct explanation may be given. We must always bear that in mind, which we have had occasion to notice in regard to all the other Senses—the broad line of distinction between the *sensation*, and the *perception* or *elementary notion*; the latter being the result of the operation of the Sensory impression on the Cerebrum, but having a nature as distinct as that of any other *effect* can be from that of its *cause*. Further, it has been shown that there is in Man a complete absence of any relation but such as experience develops, between the perceptions derived through the Sight, and those acquired from the Touch. Hence there is no more difficulty in understanding, that an inverted picture upon the retina should convey to us a notion of the external world, which harmonizes with that acquired through the sense of touch, than there is in comprehending the existence of any of those intuitive perceptions of animals, which are so much more removed from the teachings of our own experience (§ 792). It is justly remarked by Müller that, “if we do see objects inverted [or rather, if the picture on the retina be inverted], the only proof we can possibly have of it is that afforded by the study of the laws of Optics; and, if

everything is seen reversed, the relative position of the objects remains unchanged. Hence it is, also, that no discordance arises between the sensations of inverted vision and those of touch, which perceives everything in its erect position; for the images of all objects, even of our own limbs, "on the retina, are equally inverted, and therefore maintain the same relative position. Even the image of our hand, when used in touch, is inverted." From what has been stated, it would appear quite conceivable, that a person just endowed with sight, should not at first know, by his visual powers, whether a pyramid placed before his eyes is the same body, and in the same position, as one with which he has become acquainted by the touch; and, if this be admitted, the inference necessarily follows, that the notion of *erectness*, which we form by the combined use of our eyes and our hands, is really the product of experience in ourselves, whilst it is probably innate or intuitional in the lower Animals.

886. The cause of *Single Vision with the two Eyes* has in like manner been the subject of much discussion, since the mode in which we are affected by the two simultaneous impressions is quite different from that in which we derive our knowledge of external things through the other senses. Some have even asserted that we do not really employ both eyes simultaneously, but that the mind is affected by the image communicated by one only; and this idea might seem to be confirmed by the fact heretofore mentioned (§ 861), respecting the alternate use of the two eyes, when they are looking through two differently colored media. But it is easily disproved in other ways.—It will presently be shown that all our estimates of the forms of bodies depend on the combination, by the mind, of the images simultaneously transmitted by the two eyes; and our knowledge of distances is in great part obtained in like manner. One condition of Single Vision, however, seems to be this, that the two images of the object should be formed on parts of the two retinæ which are *accustomed* to act in concert; and *habit* appears to be the chief means by which this conformity is produced. There can be no doubt, however, that double images are continually being conveyed to the Sensorium; but that, from their want of force and distinctness, and from the attention being fixed on something else, we do not take cognizance of them. This may be shown by a very simple experiment. If two fingers be held up before the eyes, one in front of the other, and vision be directed to the more distant, so that it is seen singly, the nearer will appear double; while, if the nearer one be regarded more particularly, so as to appear single, the more distant will be seen double. A little consideration will show, therefore, that our minds must be continually affected with sensations, which cannot be united into the idea of a single image; since, whenever we direct the axes of our eyes towards any object, everything else will be represented to us as double; but we do not ordinarily perceive this, from our minds being fixed upon a clear and distinct image, and disregarding, therefore, the vague undefined images formed by objects at a different focus. Of this it is very easy to convince one's self.—It is, moreover, evident, from this experiment, that double vision cannot result from *want of symmetry* in the position of the images upon the retina, to which some have attributed it; for it answers equally well if the line of the two fingers be precisely in front of the nose, so that the inclination of both eyes towards either object is equal; the position of the images of the second object must then be at the same distance on either side from the central line of the retina, and yet they are represented to the mind as double. Hence it seems clear that singleness of vision is also dependent upon the convergence of the optic axes in the object to which our gaze is directed.—Attempts have been made to explain the phenomena of Single Vision by the peculiar decussation of the Optic Nerves formerly described (§ 742), it being supposed that only one Optic Ganglion would be affected by an impression made upon both Retinæ. This explanation, however,

even supposing the fact to be as stated, would be far from affording the solution of the problem; and it would be entirely inapplicable to that very important series of phenomena to be next described, which show how large an amount of information we derive, not merely from the repetition, but from the difference, of the sensory impressions made by the same object upon our two retinæ; and which indicate that here, as in the case of erect vision, the mental interpretation of the sensory impressions is a process altogether removed from the simple affection of the consciousness by those impressions, and is not to be accounted for by any structural arrangements of the Sensorial apparatus.

887. We shall next consider the mode in which our notion of the *solid forms* and relative projection of objects is acquired; on which great light has been thrown by the interesting experiments of Prof. Wheatstone.¹ It seems perfectly evident, both from reason and experience, that the flat picture upon the retina, which is the immediate source of our sensation, could not itself convey to our minds any notion but that of a corresponding plane surface. In fact, any notion of *solidity*, which might be formed by a person who had never had the use of more than one eye, would entirely depend upon the combination of his visual and tactile sensations. This view is fully confirmed by the case already referred to, as recorded by Cheselden. The first visual idea formed by the youth was that the objects around him formed a flat surface, which touched his eyes, as they had previously been in contact with his hands; and after this notion had been corrected, through the education of his sight by his touch, he fell into the converse error of supposing that a picture, which was shown to him, was the object itself represented in relief on a small scale.—But where both eyes are employed, it has been ascertained by Prof. Wheatstone that they concur in exciting the perception of solidity or projection, which arises from the *mental* combination of the two *dissimilar* pictures formed upon the two retinæ. It is easily shown, that any near object is seen in two different modes by the two eyes. Thus let the reader hold up a thin book, in such a manner that its back shall be exactly in front of his nose, and at a moderate distance from it; he will observe, by closing first one eye and then the other, that his perspective view of it (or the manner in which he would represent it on a plane surface) is very different, according to the eye with which he sees it. With the right eye, he will see its right side, very much foreshortened; with the left, he will gain a corresponding view of the left side; and the apparent angles, and the lengths of the different lines, will be found to be very different in the two views. On looking at either of these views singly, no other notion of solidity can be acquired from it than that to which the mind is conducted by the association of such a view with the touch of the object which it represents. But it is capable of proof, that the mental association of the two different pictures upon the retinæ does of itself give rise to the idea of solidity. This proof is afforded by Prof. Wheatstone's ingenious instrument, the Stereoscope, first described by him in 1838.²

¹ "Philosophical Transactions," 1838 and 1852.

² Various modifications of this instrument have been subsequently introduced; and there is one which has recently (1852) come into very extensive use, in which the two monocular pictures placed side by side, as in Figs. 214, 215, are viewed by the two eyes respectively through two prisms, or two halves of a convex lens. The great advantage of this instrument is its portability; but it is limited to pictures of small size, since the distance between corresponding points of the two pictures must not exceed the distance between the centres of the two eyes; and it is incapable of many adaptations which can be made with the mirror-stereoscope.—As Sir D. Brewster has recently put forth his claim as an original discoverer in regard to the truths of binocular vision which have been established by the Stereoscope, on the strength of some trivial improvements in the construction of the instrument, the Author feels it due to Prof. Wheatstone to state his own conviction, founded upon a careful examination of the whole history of the invention, that

888. The *Stereoscope*, in its original form, essentially consists of two plane mirrors, inclined with their backs to one another at an angle of 90° . If two perspective drawings of any solid object, as seen at a given distance with the two eyes respectively, such as those at A and B, Fig. 214, be so placed before these mirrors, one before each, that their two images shall be made to fall upon the corresponding parts of the two retinae, in the same manner as the two images formed by the solid object itself would have done, the mind will perceive, not a single representation of the object, nor a confused union of the two, but a projecting or receding surface, the exact counterpart of that from which the drawings were made.¹ The solid form is forcibly impressed on the mind, even when outlines only are given, especially if these be delineations of simple geo-

Fig. 214.

metrical figures, easily suggested to the mind; and it may be easily shown that the very same outlines will suggest different conceptions, according to the mode in which they are placed. Thus, in Fig. 215, the upper pair of figures A, B, when combined in the Stereoscope, convey the idea of a *projecting* truncated pyramid, with the small square *in the centre*, and the four sides sloping equally *away from it*; whilst the lower pair of figures, C, D, which are the same as the upper, but transferred to the opposite sides, no less vividly bring before the mind the visual conception of a *receding* pyramid, still with the small square in the centre, and the four sides sloping equally *towards it*.—Prof. Wheatstone further shows, by means of the Stereoscope, that similar images, differing to a certain extent in magnitude, when presented to the corresponding parts of the two retinae, give rise to the perception of a single object, intermediate in size between the two monocular pictures. Were it not for this, objects would appear single,

the *entire* merit of the *idea*—that all our perception of solidity derived through the visual sense is consequent upon the mental combination of the two dissimilar pictures upon the two retinae—and further that the whole merit of the *realization* of that idea by means of the mirror-stereoscope, long before Sir D. Brewster's attention had been given to the subject at all—belongs to Prof. Wheatstone.

¹ The most striking effect is produced by two photographic pictures, taken at the same time by two cameras, so placed that their axes shall form the same angle with each other as that which the axes of the two eyes would form when looking at the same object. This adaptation, though the credit has been assumed by others, was originally devised by Prof. Wheatstone.

only when at an equal distance from both eyes, so that their pictures upon the retina are of the same size; which will only happen when they are directly in front of the median line of the face. Again, if pictures of dissimilar objects be simultaneously presented to the two eyes, the consequence will be similar to that which is experienced when the rays come to the eye through two differently colored media; the two images do not coalesce, nor do they appear permanently superposed upon one another; but at one time one image predominates to the exclusion of the other, and then the other is seen alone; and it is only at the moment of change, that the two seem to be intermingled. It does not appear to be in the power of the will, Prof. Wheatstone remarks, to determine the appearance of either; but, if one picture be more illuminated than the other, it will be seen during a larger portion of the time.—Many other curious experiments with this simple instrument are related by Prof. Wheatstone; and they all go to confirm the general conclusion, that the combination of the dissimilar images furnished by the two eyes is a *mental act*, resulting from an inherent law of our psychical constitution; and that our perceptions of the solidity and projection of objects, near enough to be seen in different perspective with the two eyes, result from this cause. In regard to distant objects, however, the difference in the images formed by the two eyes is so slight that

Fig. 215.

it cannot aid in the determination; and hence it is that, whilst we have no difficulty in distinguishing a picture, however well painted, from a solid object, when placed near our eyes (since the idea which might be suggested by the image formed on one eye, will then be corrected by the other), we are very liable to be misled by a delineation in which the perspective, light, and shade, &c., are faithfully depicted, if we are placed at a distance from it, and are prevented from perceiving that it is *but* a picture. In this case, however, a slight movement of the head is sufficient to undeceive us; since by this movement a great change would be occasioned in the perspective view of the object, supposing it to possess an uneven surface; whilst it scarcely affects the image formed by a picture. In the same manner, a person who only possesses one eye obtains, by a slight motion of his head, the same idea of the form of body which another would acquire by the simultaneous use of his two eyes.

889. The appreciation of the *distance* of objects may be easily shown to be principally derived from the association, in the Mind, of visual and tactile sensations; assisted, in regard to near objects, by the sensations derived from the muscles of the eyeballs. How much our right estimation of the relative distances of objects not too far removed from the eye depends upon the joint use

of *both eyes*, is made evident by the fact that, if we close one eye, we find ourselves unable to execute with certainty many actions (such as threading a needle or snuffing a candle) which require its guidance; and we can scarcely conceive of any other basis for this appreciation than that which is afforded by the muscular sensations produced by the different degrees in which the optic axes are made to converge, according to the distances of the objects to which we direct our eyes. For, in proportion as they are removed further and further, do the optic axes approach parallelism, and the power of appreciating differences of distance is lost; whilst, on the other hand, in proportion as the object is approximated to the eyes, slight differences of distance produce marked differences in the degree of convergence; and these are readily appreciated, so as to afford the means of very nice discrimination. The large extent to which our notion of the relative distances of near objects is due to variations in the angle of convergence of the optic axes, is further shown by the following experiment devised by Prof. Wheatstone. If two similar pictures be placed in his mirror-stereoscope, and be made to move to and from the mirrors, so as to vary their distances from these, and therefore from the eyes, without altering the *angle of convergence*, their apparent *sizes* are seen to change (in consequence of the alteration of the *visual angle*), but no positive change is seen in their apparent distances; the effect produced being very much like that of the enlargement or diminution of the images on the screen in the exhibition of the Phantasmagoria, *suggesting* the idea of approach or recession, although we perceive that the distance of the screen from our eyes has undergone no alteration. A converse effect, as we shall presently see (§ 890), is produced by alterations in the angle of convergence, without any real change in the distance of the pictures. This power of estimating distance, however is obviously, in Man, not an intuitive but an acquired endowment; for it is evident to any observer that infants, or older persons who have but recently acquired sight, form very imperfect ideas respecting the distance of objects, their attempts to grasp bodies which attract their attention being for a long time unsuccessful; and that they only gradually learn to measure distances by the sight through the medium of the touch. It is probable, however, that, in the lower Animals, especially such as have early to rely upon their own exertions for the supply of their natural wants, the perception of distance is more intuitive than it is in ourselves; since we may observe them very early performing actions which require an exact appreciation of it.—In regard to *distant* objects, our judgment is chiefly founded upon their apparent size, if their actual size be known to us; but, if this be not the case, and if we are so situated that we cannot judge of the intervening space, we principally form our estimate from that effect of different degrees of remoteness upon the distinctness of their color and outline, which is known to artists as “aerial perspective.” Hence this estimate is liable to be greatly affected by varying states of the atmosphere, as is particularly known to every one who has visited warmer climates; where the extreme clearness of the air sometimes brings into an apparently near proximity, a hill that rises some miles beyond a neighboring ridge (the intervening space being hidden, so as not to afford any datum for the estimate of the distance of the remote hill), whilst a slight haziness carries its apparent distance to three or four times the reality.

890. Our estimate of the *size* of an object is partly dependent upon the *visual angle* under which we see it, and partly upon our estimate of its *distance*. The “visual angle,” formed by imaginary lines drawn from the eye (Fig. 216, A) to the extreme points, B C, of the object, is the measure of the size of its image upon the retina; and it is obvious that, if two objects, B C, D E, the former being twice the length of the latter, be placed at the same distance, the visual angle B A C being twice as great as the angle D A E, the image of B C upon the retina will be twice as long as that of D E, and the mind will estimate their

relative sizes accordingly. But if the distance of the object $D E$ from the eye be diminished to one-half, so that it is brought into the position $F G$, its visual angle, and consequently the size of its image on the retina, will now be equal to that of $B C$; and the estimate we form of the relative sizes of the two will entirely depend upon the idea we entertain of their relative distances. Hence any circumstance which modifies that idea produces a corresponding difference

Fig. 216.

in our estimate of their size; so that the apparent size of an object, seen under the same visual angle, may be estimated as larger or smaller than the reality, according as we suppose it to be more or less distant than it really is. Of this we have a familiar instance in the fact that, if we meet a child whilst we are walking across a common (the flatness of the ground not giving us much power of estimating the intervening space) in a fog, it appears to have the stature of a man, and a man seems like a giant; for the indistinctness of outline causes the mind to conceive of the figures as at a greater distance than they really are, and their apparent dimensions are augmented in like proportion. For if the object $F G$ (Fig. 216) be *mentally carried back* to the distance of $D E$, being still seen under the visual angle $F A G$ (or $B A C$), it will appear to possess the length $B C$ instead of $D E$. On the other hand, if the object $B C$ were to be *mentally brought forwards* into the position $K L$, its apparent size being still determined by its visual angle, it will seem to be reduced to the length $F G$. This has been demonstrated by a very ingenious experiment devised by Prof. Wheatstone. For if two similar pictures placed in his mirror-stereoscope, be made so to change their places in regard to the mirrors (by moving in a horizontal circle of which the middle point between the mirrors is the centre), that the angle of convergence of the optic axis is increased, whilst the actual distance of the pictures from the mirrors, and consequently their visual angles, remain the same, their apparent size is progressively and most remarkably diminished; the mind being accustomed to interpret increase of the angle of convergence as a proof of diminution of distance, and being thus impressed by the change as if the pictures had really advanced to $K L$; and as they are still seen under the angle $B A C$ (or $F A G$), instead of under the angle $K A L$, their dimensions are reduced to the mind's eye from $B C$ to $F G$. A very simple and beautiful illustration of the same principle is furnished by the ordinary stereoscope, when two pairs of figures (such as those given in Fig. 215) are employed, the effect of one of which

is to develop a *projecting*, and that of the other a *receding* surface. For it will be observed that the relative size of the parts which appear to project is reduced, whilst that of the apparently receding parts is augmented; as is particularly the case with the square truncated end of the pyramid, which is estimated by most persons as from one-third to one-half larger in each of its dimensions in the receding, than it is in the projecting pyramid, notwithstanding that the actual sizes of the squares in the two sets of figures are precisely the same. For, supposing HI to represent the real side of one of the small squares, which becomes the truncated end of the pyramid; when this is brought forward by the mind into the position KL , as the truncated top of a projecting pyramid, being seen under the visual angle HAI , its apparent size is reduced to FG ; whilst, on the other hand, the very same square, carried back by the mind to the distance DE , as when it forms the truncated end of the receding pyramid, is mentally enlarged to the dimensions BC , the visual angle BAC being the same as HAI .—It is obvious, from what has been stated in regard to distance, that our power of forming a true estimate of the relative sizes is far greater with regard to *near* objects, whose relative distances we can estimate with tolerable accuracy, than it is with respect to more remote bodies, whose relative distances we have no means of appreciating; thus, the sun and the moon are of nearly the same apparent size to us, though one is about four million times the distance of the other; and we may cover either disk with a sixpence held near the eye, so as to be seen under the same visual angle, without the least power of estimating the relative sizes of these objects, save by a calculation based on a knowledge of their relative distances, because, whilst the one is near, the other is virtually almost infinitely remote.—The want of innate power in Man to form a true conception of either size or distance, is well shown by the effect produced on the mind unprepared for such delusions, by a skilfully painted picture; the view of which is so contrived, that its distance from the eye cannot be estimated in the ordinary manner; for the objects it represents are invested by the mind with their real sizes and respective distances, as if their real images were formed upon the retina.¹

891. From all these considerations, we are led to perceive the truth of the quaint observation made by Dr. Brown—that “vision is, in fact, the art of seeing things which are invisible;” that is, of acquiring information, by means of the eye, which is neither contained in the sensations of sight themselves, nor logically deducible from the intimations which those sensations really convey. We cannot too constantly bear in mind, in treating of this subject, that we do not take cognizance by our optic nerves, as we do by the nerves of touch, of material bodies themselves, but of the pictures or images formed by those objects; and whatever be the notions suggested by the picture, *that* can never be transformed into anything else. These notions appear to be, in the lower Animals, entirely of an intuitional or instinctive character; in Man they are so in a much less degree; and although it is impossible to come to a precise conclusion on the subject, from the want of sufficient data, it is indubitable that a large part of the knowledge of the external world, which he derives in the adult condition from the use of his eyes alone, is really dependent upon the early education of his perceptive powers, in which process, the sensations conveyed by different organs are brought into relation with one another.

892. The persistence, during a certain interval, of impressions made upon the retina, gives rise to a number of curious visual phenomena. The prolongation of the impression will be governed, in part, by its previous duration. Thus, when we rapidly move an ignited point through a circle, the impression itself

¹ This delusion has been extremely complete in some of those who have seen the panoramic view of London in the Coliseum. A lively and interesting account of it is given in the “Journal of the Parsee Shipbuilders,” who visited England some time ago.

is momentary, and remains but for a short time; whilst, if we have been for some time looking at a window, and then close our eyes, the impression of the dark bars traversing the illuminated space is preserved for several seconds. Such phenomena can here be only briefly adverted to. One of these is the combination, into a single image, of two or more objects presented to the eye in successive movements; but these must be of a kind which can be united, otherwise a confused picture is produced. Thus in a little toy, called the Thaumatrope, which was introduced some years ago, the two objects were painted on the opposite sides of a card—a bird, for instance, on one, and a cage on the other; and, when the card was made (by twisting a pair of strings) to revolve about one of its diameters, in such a manner as to be alternately presenting the two sides to the eye at minute intervals, the two pictures were blended, the bird being seen in the cage. A far more curious illusion, however, was that first brought into notice by Prof. Faraday; who showed that, if two toothed wheels, placed one behind the other, be made to revolve with equal velocity, a stationary spectrum will be seen; whilst, if one be made to revolve more rapidly than the other, or the number of teeth be different, the spectrum also will revolve. The same takes place when a single wheel is made to revolve before a mirror, the wheel and its image answering the purpose of the two wheels in the former case. On this principle, a number of very ingenious toys have been constructed; in some of these, the same figure or object is seen in a variety of positions; and the successive impressions, passing rapidly before the eye, give rise by their combination to the idea that the object is itself moving through these positions.¹ It is interesting to remark, moreover, that when the eye has been for some time contemplating an object in motion, and is then directed towards stationary objects, *these* appear for a short time to have a like movement. Any railroad traveller may try this simple experiment, by first looking at the hedges, &c., which he is rapidly passing, and then at some part of the interior of the carriage itself, especially one which presents a series of parallel lines. But when the impression of movement has been of longer duration, its effects upon the retina are less transient; thus a person who has been for some time on board ship, sees the floors, walls, and ceilings of his apartment on shore in a state of continual up-and-down motion, even for some days after he has landed.

893. When the Retina has been exposed for some time to a strong impression of some particular kind, it seems less susceptible of feebler impressions of the same kind. Thus, if we look at any brightly luminous object, and then turn our eyes on a sheet of white paper, we shall perceive a dark spot upon it; the portion of the retina, which had been affected by the bright image, not being able to receive an impression from the fainter rays reflected by the paper. The dark spectrum does not at once disappear, but assumes different colors in succession—these being expressions of the states through which the retina passes, in its transition to the natural condition. If the eye has received a strong impression from a colored object, the spectrum exhibits the *complementary* color;² thus, if the eye be fixed for any length of time upon a bright red

¹ A very beautiful “philosophical toy” was shown to the Author some years since, by its inventor, Mr. Roberts, the celebrated machinist of Manchester; consisting in an apparatus by which it was made possible to read words printed on a card, although the card itself was made to revolve on its axis even 30,000 times in a minute. The principle of its construction was simply this—that the eye caught a succession of glimpses of the card, through a narrow slit before which a disk with a single corresponding perforation was made to revolve; the rate of movement of this disk being so adjusted to that of the card, that, whenever the eye caught sight of the latter, it was *momentarily* in the same position, so that, by the succession of transient impressions thus made upon the retina, the words printed on the card could be distinctly read.

² By the “complementary” color is meant that which would be required to make white

spot on a white ground, and be then suddenly turned so as to rest upon the white surface, we see a spectrum of a green color. The same explanation applies to the curious phenomenon of colored shadows. It may not unfrequently be observed at sunset, that when the light of the sun acquires a bright orange color from the clouds through which it passes, the shadows cast by it have a blue tint. Again, in a room with red curtains, the light which passes through these produces green shadows. In both instances, a strong impression of one color is made on the general surface of the retina; and at any particular spots, therefore, at which the light is colorless but very faint, that color is not perceived, its complement only being visible. The correctness of this explanation is proved by the fact that, if the shadow be viewed through a tube, in such a manner that the colored ground is excluded, it seems like an ordinary shadow. It is not unlikely that, as Müller suggests, the predominant action of one color on the retina disturbs (as it were) the equilibrium of its condition, and excites in it a tendency to the development of a state corresponding to that which is produced by the impression of the complementary color; for the latter is perceived, according to him, even where it does not exist, as when the eye, after receiving a strong impression from a colored spot, and directed upon a completely dark surface or into a dark cavity, still perceives the spectrum. This change, indeed, extends beyond the spot on which the impression is made; for, as is well known to Artists, the sensory impression produced by any color is greatly affected by neighboring hues. Thus, if four strips of colored paper, or any other fabric, A, B, C, D—two of them, A, B, of one color (*e. g.* red), and the other two, C, D, of some different color (*e. g.* blue)—be laid side by side at intervals of about half an inch, the hues of the two central strips B, C, will be decidedly modified by each other's proximity, each approximating to the hue of the complementary color of the other; so that, instead of

A	B	C	D
red	red	blue	blue,
we shall see			
A	B	C	D
red	orange red	greenish blue	blue.

—Upon these properties of the eye are founded the laws of harmonious coloring, which have an obvious analogy with those of musical harmony. All complementary colors have an agreeable effect, when judiciously disposed in combination; and all bright colors, which are not complementary, have a disagreeable effect, if they are predominant: this is especially the case in regard to the simple colors, strong combinations of any two of which, without any color that is complementary to either of them, are extremely offensive. Painters who are ignorant of these laws, introduce a large quantity of dull gray into their pictures, in order to diminish the glaring effects which they would otherwise produce; but this benefit is obtained by a sacrifice of the vividness and force, which may be secured in combination with the richest harmony, by a proper attention to physiological principles.

894. Some persons, who can perfectly distinguish *forms*, are deficient, through some original peculiarity in the constitution of the retina, in the power of discriminating *colors*. This is most commonly seen in regard to the complementary colors, especially red and green; such persons not being able to perceive cherries

or colorless light, when mixed with the original. As red, blue, and yellow are the primary or elementary colors, red is the complement of green (which is composed of yellow and blue); blue is the complement of orange (red and yellow); and yellow of purple (red and blue); and *vice versâ* in all instances.

amidst the leaves on a tree, except by the difference of their form. Several distinct varieties of this affection may be distinguished, however; these have been classified by Seebeck and Wartmann.¹

895. Amongst other curious phenomena of Vision, is the vanishing of images which fall at the entrance of the optic nerve; as is shown in the following experiment. Let two black spots be made upon a piece of paper, about four or five inches apart; then let the left eye be closed, and the right eye be strongly fixed upon the left hand spot. If the paper be then moved backwards and forwards, so as to change its distance from the eye, a point will be found at which the right hand spot is no longer visible; though it is clearly seen when the paper is brought nearer or removed further. In this position of the eye and object, the rays from the right hand spot cross to the nasal side of the globe, and fall upon the point of the retina which has just been mentioned. The phenomenon is not confined to that spot, however; nor is it correct to say, as is sometimes done, that the retina is not sensible to light at that point; since, if such were the case, we should see a dark spot in our field of view whenever we use only one eye. The fact is, that a similar phenomenon may occur under somewhat different conditions, in any division of the retina, especially in its lateral parts. Thus, if we fix the eye for some time, until it is fatigued, upon a strip of colored paper lying upon a white surface, the image of the colored object will in a short time disappear, and the white surface will be seen in its place; the disappearance of the image, however, is only of a few seconds' duration. The truth seems to be, that there is a tendency in the retina to the propagation, over neighboring parts, of impressions which occupy a large proportion of its surface; and that this tendency is the strongest around the point at which the optic nerve enters, so that the state of this part will generally become similar to that of the surrounding portion of the retina. Hence, when we are using one eye only, we do not perceive any dark spot in the field, but only a certain degree of indistinctness in a portion of the image.

896. Under particular circumstances, we may receive a visual representation of the retina itself, as is shown by the experiment of Purkinje. "If in a room otherwise dark, a lighted candle be moved to and fro, or in a circle, at a distance of six inches before the eyes, we perceive, after a short time, a dark arborescent figure ramifying over the whole field of vision; this appearance is produced by the vasa centralia distributed over the retina, or by the parts of the retina covered by those vessels. There are, properly speaking, two arborescent figures, the trunks of which are not coincident, but on the contrary arise in the right and left divisions of the field, and immediately take opposite directions. One trunk belongs to each eye, but their branches intersect each other in the common field of vision. The explanation of this phenomenon is as follows: By the movement of the candle to and fro, the light is made to act on the whole extent of the retina, and all the parts of the membrane which are not immediately covered by the vasa centralia are feebly illuminated; those parts, on the contrary, which are covered with those vessels cannot be acted on by the light, and are perceived, therefore, as dark arborescent figures. These figures appear to lie before the eye, and to be suspended in the field of vision."² We have thus another demonstration of the fact that, in ordinary vision, the immediate object of our sensation is a certain condition of the retina, which is excited by the formation of a luminous image.

6.—*Sense of Hearing.*

897. In the Ear, as in the Eye, the impressions made upon the sensory nerve are not at once produced by the body which originates the sensation; but they are propagated to it through a medium capable of transmitting them. Here too, therefore, we take cognizance by the mind, not of the sonorous object, but of the condition of the auditory nerve; and all the ideas we form of sounds, as to their nature, intensity, direction, &c., must be based upon the changes which they produce in it. The complex contrivances which we meet with in the organ of Hearing among higher animals, are evidently intended to give them greater power of discriminating sounds, than is possessed by the lower tribes; in which last it is reduced to a form so simple, that it may be questioned whether they can be said to possess an organ of *hearing*, if by this term we imply anything more than the mere consciousness of sonorous vibrations.—There is a considerable difference, however, between the Eye and the Ear, in regard to the special purposes for which they are respectively adapted. In the former we have seen, that the whole object of the instrument is to direct the rays of light received by it, in such a manner as to occasion them to fall upon the expansion of the optic nerve in similar relative positions, and with corresponding proportional intensities, to those which they possessed when issuing from the object. We have no reason to believe anything of this kind to be the purpose of the Ear; indeed, it would be inconsistent with the laws of the propagation of sound. Sonorous vibrations having the most various directions, and the most unequal rates of succession, are transmitted by all media without modification, however numerous their lines of intersection; and wherever these undulations fall upon the auditory nerve, they must cause the sensation of corresponding sounds. Still it is probable that some portions of the complex organ of hearing, in Man and in the higher animals, are more adapted than others to receive impressions of a particular character; and that thus we may be especially informed of the direction of a sound by one part of the organ, of its musical tone by another, and of some other of its qualities by a third.

898. The essential part of an Organ of Hearing is obviously a nerve, endowed with the peculiar property of receiving sonorous undulations, and of transmitting their effects to the Sensorium. This nerve is spread out over the surface of a delicate membrane which lines the Vestibule and its prolongations; and this membrane incloses a fluid which is the medium whereby the sonorous vibrations received through the external ear are communicated to the nerve. We learn from an examination of the comparative structure of the auditory apparatus in the lower animals, and from the study of its development in the higher, that the part which, being most constantly present and being also the earliest in its development, may be considered as the most essential, is the simple *Vestibular* cavity, which exists where there are no vestiges either of Semicircular Canals, of Cochlea, or of Tympanic apparatus. Such a condition presents itself in some of the higher Invertebrata and in the lowest Fishes; but as we ascend the Vertebrated series, we find the semicircular canals growing out (as it were) of the Vestibule in Fishes, a tympanic apparatus superadded in Reptiles, and a Cochlea first acquiring a more than rudimentary development in the class of Birds, although only presenting in Mammalia that characteristic form from which it derives its name.¹ Of the mode in which the ultimate subdivisions of the Auditory nerve are distributed upon the lining membrane of the labyrinth, it does not yet seem possible to give a certain account; for although Wagner

¹ For a more detailed sketch of the Comparative Anatomy of the Organ of Hearing, see the Author's "*Princ. of Physiol., Gen. and Comp.*," §§ 822–825, *Am. Ed.*

and others have represented them as terminating in free loops, yet more careful observation has rendered this doubtful; and the general analogy between the simpler forms of the auditory and of the visual apparatus, as well as the

close correspondence which exists between them in the history of their development (the organ of hearing, like the eye, being budded off from its sensory ganglion), seems to indicate that the peripheral expansion of the auditory nerve might

be expected to have a structure analogous to that of the retina. The most exact observations yet made on this point seem to be those of the Marquis Corti on

the Cochlear nerve.¹ This nerve passes out from the *modiolus* into a series of anastomosing canals excavated in the osseous *lamina spiralis*; and it there comes into relation with a band of vesicular substance, which lies near the edge of the lamina along its whole length. The component vesicles are elongated,

Fig. 219.

A highly magnified view of a small piece of the Lamina Spiralis, showing the manner in which the nerves leave their Neurilemma as they anastomose; the natural size of the piece is seen on the side of the figure; 1, portion of the auditory nerve; 2, 2, osseous canals in the zona ossea of the lamina spiralis; 3, 3, anastomoses in the zona mollis; 4, 4, the neurilemma leaving the nervous loops, and interlocking to form the layer of the zona membranacea.

having a central and a peripheral extremity; by the former they are connected with the fibres of the cochlear nerve, the connecting filaments being destitute (as elsewhere) of the double contour, and being very fragile; and by the latter they are similarly connected with the fibres which issue forth from the osseous lamina, to be distributed upon its membranous continuation. These fibres form fasciculi, which traverse the membranous lamina nearly parallel to each other, and anastomose continually with one another, in such a manner as to present the appearance of looped terminations. According to Corti, however, the fibres really pass on further, losing their double contour, and becoming gradually incorporated, as it were, with the surrounding tissue.²

899. In order to gain any definite idea of the uses of different parts of the Ear, it is necessary to bear in mind, that sounds may be propagated amongst solid or fluid bodies in three ways: by *reciprocation*, by *resonance*, and by *conduction*.—1. Vibrations of *reciprocation* are excited in a sounding body, when it is capable of yielding a musical tone of definite pitch, and another body of the same pitch is made to sound near it. Thus if two strings of the same length and tension be placed along-side of each other, and one of them be sounded with a violin bow, the other will be thrown into reciprocal vibration; or if the same tone be produced near the string in any other manner, as by a flute or a tuning-fork, the same effect will result.—2. Vibrations of *resonance* are of somewhat the same character; but they occur when a sounding body is placed in connection with any other, of which one or more parts may be thrown into reciprocal vibration, even though the tone of the whole be different, or it be not capable

¹ See Kölliker and Siebold's "Zeitschrift für Wissenschaftliche Zoologie," 1851, band iii. heft 1.

² Such, also, is the account of their termination given by Messrs. Todd and Bowman, "Physiological Anatomy," p. 457, *Am. Ed.*

of producing a definite tone at all. This is the case, for example, when a tuning-fork in vibration is placed upon a sound-board; for, even though the whole board have no definite fundamental note,¹ it will divide itself into a number of parts, which will reciprocate the original sound, so as greatly to increase its intensity; and the same sound-board will act equally well for tuning-forks of several different degrees of pitch. When a smaller body is used for resonance, however, it is essential that there should be a relation between its fundamental note and that of the sonorous body; otherwise, no distinct resonance is produced. Thus, if a tuning-fork in vibration be held over a column of air in a tube of such a length that the same note would be given by its vibration, its sound will be reciprocated. And if it be held over a pipe, the column of air in which is a multiple of this, the column will divide itself into that number of shorter parts, each of which will reciprocate the original sound, and the total action will be one of resonance. But if the length of the pipe bear no such correspondence with the note sounded by the tuning-fork, no resonance is given by the column of air it contains.—3. Vibrations of *conduction* are the only ones by which sounds can strictly be said to be propagated. These are distinguishable into various kinds, into which it is not requisite here to inquire. It should be remarked, however, that all media, fluid, liquid, or solid, are capable of transmitting sound in this manner; a vacuum being the only space through which it cannot pass. The transmission is usually much more rapid through solid bodies than through liquid; and through liquid than through gaseous. The greatest diminution in the intensity of sound is usually perceived, when a change takes place in the medium through which it is propagated, especially from the aeriform to the liquid.

900. The detailed application of these principles has been most elaborately worked out by Müller; and the following statement of what may be regarded as the present condition of our knowledge of the subject is little more than an abstract of his results. Considering it desirable, in the first place, to establish the conditions under which those animals hear, that are constantly immersed in water, he made a series of experiments, from which he draws the following conclusions: I. Sonorous vibrations, excited in water, are imparted with considerable intensity to solid bodies.—II. Sonorous vibrations of solid bodies are communicated with greater intensity to other solid bodies brought in contact with them, than to water; but with much greater intensity to water than to atmospheric air.—III. Sonorous vibrations are communicated from air to water with great difficulty, this difficulty very much exceeding that with which they are propagated from one part of the air to another; but their transition from air to water is much facilitated by the intervention of a membrane extended between them.—IV. Sonorous vibrations are not only imparted from water to solid bodies with definite surfaces which are in contact with the water, but are also returned with increased intensity by these bodies to the water; so that the sound is heard loudly in the vicinity of those bodies, in situations where, if it had its origin in the conducting power of the water alone, it would be faint.—

¹ The *fundamental note* of a body is the lowest tone which it will yield, when the whole of it is in vibration together. By dividing the body into two or more distinct parts, it may be made to give a great variety of sounds. Thus, if a stretched string be divided by a bridge into two equal parts, each will sound the octave of the fundamental note, or the 8th note above it. If it be divided into three parts, each will give the 12th above the fundamental note; if into four, the 15th or double octave will be heard; if into five, the 17th; if into six, the 19th; if into seven, the 20 $\frac{1}{2}$ th (flat seventh above the second octave); if into eight, the 22d or triple octave. A string forcibly set in vibration has a tendency to sound these harmonics with the fundamental note, by spontaneous division into several distinct segments of vibration; as may be easily made evident, by striking one of the lower keys of the piano, and listening to the sounds heard whilst the fundamental note is dying away.

v. Sonorous undulations, propagated through water, are partially reflected by the surfaces of solid bodies.—vi. Thin membranes conduct sound in water without any loss of its intensity, whether they be tense or lax.—From III., IV., and VI., we learn the mode in which the sound is conducted to the ear, in aquatic animals not breathing atmospheric air. The labyrinth of such is either entirely inclosed within the bones of the head, as in the Cephalopoda, and in the Cyclostome and Osseous Fishes; or, its cavity being prolonged to the surface of the body, it is there brought into communication with the conducting medium, by means of a membrane, besides receiving the vibrations through the medium of the solids of the body, as is the case in Cartilaginous Fishes and Crustacea. It would seem as if, in the Osseous Fishes, the resonance of the cranial bones, in which the labyrinth is imbedded, were sufficient to give the requisite increase of intensity to the sound; whilst in the Cartilaginous orders, the softness of these bones renders some other means necessary. In addition to this, we find in many Fishes a communication with the air-bladder; which indeed seems to have, in these, but little other use. The mode in which this increases by resonance the intensity of the sounds will appear from the following experimental conclusions.—vii. When sonorous vibrations are communicated from water, to air inclosed in membranes or solid bodies, a considerable increase in the intensity of the sound is produced by the resonance of the air thus circumscribed.—viii. A body of air inclosed in a membrane, and surrounded by water, also increases the intensity of the sound by resonance, when the sonorous undulations are communicated to it by a solid body.—From these observations it may be concluded that the air-bladder of Fishes, in addition to other uses, serves the purpose of increasing by resonance the intensity of the sonorous undulations communicated from the water to the body of the Fish. Moreover, as the conducting and resonant power of the air in the air-bladder is greater in proportion to its density, the influence of this organ on the perception of sounds will, of course, be greater in deep waters, where the pressure upon it is considerably increased.

901. Most animals living in air are provided with an opening into the Vestibule, covered by a thin membrane; and, in the majority of cases, with a Tympanic apparatus also. The following experimental results bear upon the manner in which the Ear of such animals is affected by sound.—ix. Sonorous undulations, in passing from air directly into water, suffer a considerable diminution in their strength; while, on the contrary, if a tense membrane exist between the air and the water, the sonorous undulations are communicated from the former to the latter medium with great intensity.—x. The sonorous vibrations are also communicated, without any perceptible loss of intensity, from the air to the water; when, to the membrane forming the medium of communication, there is attached a short solid body, which occupies the greater part of its surface, and is alone in contact with the water.—xi. A small solid body, fixed in an opening by means of a border of membrane, so as to be movable, communicates sonorous vibrations, from air on one side, to water or the fluid of the labyrinth on the other, much better than solid media not so constructed. But the propagation of sound to the fluid is rendered much more perfect, if the solid conductor, thus occupying the opening, is by its other end fixed to the middle of the tense membrane, which has atmospheric air on both sides.—The fact stated in ix. is evidently one of great importance in the physiology of hearing; and fully explains the nature of the process in those animals which receive the sonorous vibrations through air, but which have no tympanic apparatus. In x. we have the elucidation of the action of the fenestra ovalis, and of the movable plate of the stapes which occupies it, in animals living in air but destitute of tympanic apparatus; this is naturally the case in many Amphibia; and it may happen as the result of disease in the Human subject. In

XI. we have a very interesting demonstration of the purpose and action of the tympanum, in the more perfect forms of the auditory apparatus.—We are now prepared to inquire, in somewhat more of detail, into the actions of the different parts of this apparatus; and it will be better to commence with those of the *Middle* and *Internal Ear*, the accessory organs being afterwards considered.

902. The *Membrana Tympani* consists of three layers: an *external* one, continuous with the cutis of the external meatus, and consisting of dermoid tissue with a covering of epidermic cells; an *internal* one, which is extremely thin, continuous in like manner with the mucous membrane lining the tympanic

cavity, and also composed of dermoid tissue and epithelium; and a *middle* layer, which, according to the recent researches of Mr. Toynbee,¹ may be separated into two distinct laminæ, whose fibres run in contrary directions, those of the external layer (which is the stronger of the two) *radiating* from the malleus towards the peripheral ring to which they are attached, whilst those of the internal are *annular*. The fibres of which these laminæ are composed do not appear to be muscular; nor do they present the longitudinal parallel wavy lines characteristic of ordinary fibrous membranes; and they are rendered opaque by acetic acid. Hence, although those laminæ appear to be derived, the external from the periosteum of the meatus, and the internal from that of the tympanic cavity, they differ from it in elementary structure, and seem to have more in common with the elastic tissue. Mr. Toynbee points out the existence of a tubular ligament, inclosing the tendon of the tensor tympani muscle; and considers that the membrane is maintained by this ligament in a state of moderate tension, the assistance of the muscle being only required to augment this.—The function

¹ "Philosophical Transactions," 1851.

of the *Membrana Tympani* seems obviously to be the reception of sonorous undulations from the air, in such a manner that it may be thrown by them into a reciprocal vibration, which is communicated to the chain of bones. This membrane, in its usual state, is scarcely on the stretch; and this is found by experiment to be, for a small membrane, the best condition for the propagation of

ordinary undulations. This is easily rendered sensible in one's own person; for an increased tension may be given to the membrana tympani, either by holding the breath and forcing air into the Eustachian tube, so as to distend it from within, or by exhausting the cavity, so as to cause the external air to make increased pressure upon it; and in either case, the hearing is found immediately to become indistinct. It is observed, however, that grave and acute sounds are not equally affected by this action; for the experimenter renders himself deaf to grave sounds, whilst acute sounds are heard even more distinctly than before. This fact is easily understood by referring to the laws of Acoustics already mentioned. The greater the tension to which the membrana tympani is subjected, the more acute will be its fundamental tone: and as no proper reciprocation can take place in it, to any sound *lower* than its fundamental tone, its power of repeating perfectly the vibrations proper to the deeper notes will diminish. The nearer a sound approaches to the fundamental note proper to the tense membrane, the more distinctly will it be heard. On the other hand, when the membrane is in its natural relaxed condition, its fundamental note is very low, and it is capable of repeating a much greater variety of sounds; for, when it receives undulations of a higher tone than those to which the whole membrane would reciprocate, it divides itself into distinct segments of vibration, which are separated by lines of rest; and every one of these reciprocates the sound,¹ at the same time rendering it more intense by multiplica-

¹ This is very easily proved by experiment on a membrane stretched over a resonant cavity; for if light sand be strewed upon it, and a strong musical tone be produced in its vicinity, the membrane will immediately be set in vibration, not as a whole (unless its fundamental note be in unison with that sounded), but in distinct segments, of which every one reciprocates the sound; from the vibrating parts, the sand will be violently thrown off; but it will settle on the intermediate lines of rest, forming a variety of curious figures which are known as the *nodal* lines.

tion. These facts enable us to understand the influence of the tensor tympani muscle, in modifying the tension of the membrane, and thus causing it to vibrate in reciprocation to sounds having a great variety of fundamental notes. Moreover, the fact that some persons are deaf to grave sounds, whilst they readily hear the more acute, is thus accounted for. The tensor tympani, like the iris, is probably excited to operation by a reflex action; and it is by no means improbable that one of its functions may be, to prevent the internal ear from being too violently affected by loud sounds, by putting the membrana tympani into such a state of tension as not readily to reciprocate them.

903. The uses of the *Tympanic Cavity* are very obvious. One of its purposes is to render the vibrations of the membrane quite free; and the other, to isolate the chain of bones, in such a manner as to prevent their vibrations from being weakened by diffusion through the surrounding solid parts. As to the objects of the Eustachian tube, however, opinions have been much divided. From the experiments of Müller it appears that it does not increase the intensity of sound, but that it prevents a certain degree of dulness which would attend it if the cavity of the tympanum were completely closed; of this dulness we are conscious, when any tumefaction of the fauces causes an occlusion of the extremity of the tube. It has been supposed that, among other uses, this canal serves for the conduction of the speaker's voice to his ears; but this is certainly not the case in any considerable degree; for, when the Eustachian tubes are obstructed by disease, the patient hears his own voice well, though other sounds are indistinct; and it is easily shown, that its transmission is chiefly accomplished in other ways. The common idea is, that it serves the same purpose with the hole in an ordinary drum; the effect of which is generally supposed to be the removal of an impediment to the vibrations of the membrane, that would be offered by the complete inclosure of the air within. It does not appear, however, that any such impediment is really offered; and the effect of the hole in the drum seems rather to be the communication, to the ear of the auditor, of the sonorous vibrations of the contained air; which are thus transmitted directly through the atmosphere, instead of being weakened by transmission through the walls of the instrument. Hence there is no real analogy in the two cases. The principal object of the Eustachian tube (which is always found where there is a tympanic cavity) seems to be, the maintenance of the equilibrium between the air within the tympanum and the external air; so as to prevent inordinate tension of the membrana tympani, which would be produced by too great or too little pressure on either side, and the effect of which would be imperfection of hearing. It also has the office of conveying away mucus secreted in the cavity of the tympanum, by means of the vibratile cilia which clothe its lining membrane; and the deafness, consequent on occlusion of this tube, is in part explicable by the accumulation which will then take place in the cavity.

904. From what has been stated, it is evident that sonorous undulations, taking place in the air, will be propagated to the fluid contained in the labyrinth—through the tympanum, the chain of bones, and the membrane of the *fenestra ovalis* to which the stapes is attached—without any loss, but rather an increase of intensity. Why water should be chosen as the medium through which the impression is to be made upon the nerve, it is impossible for us to say with anything like certainty, in our present state of ignorance as to the physical character of that impression. But the problem being to communicate to water the sonorous undulations of air, the experimental results already detailed satisfactorily prove that—whilst this may be accomplished, in a degree sufficient for the wants of the inferior animals, by the simple interposition of a tense membrane between the air and the fluid—the tympanic apparatus of the higher classes is most admirably adapted for this purpose. The *fenestra ovalis* is not, however, the only channel of communication between the tympanum and the

labyrinth; for there is, in most animals, a second aperture, the *fenestra rotunda*, leading into the cochlea, and simply covered with a membrane. It is generally supposed that, the labyrinth being filled with a nearly incompressible fluid, this second aperture is necessary to allow the free vibration of that fluid; the membrane of the *fenestra rotunda* being made to bulge out, as that of the *fenestra ovalis* is pushed in. It may, however, be easily shown by experiment, as well as by reference to comparative anatomy, that no such contrivance is necessary; for sonorous undulations may be excited in a non-elastic fluid, completely inclosed within solid walls at every part, except where these are replaced by the membrane through which the vibrations are propagated; and this is precisely the condition, not only of the Invertebrated animals, but even of Frogs; in which last a tympanic apparatus exists, without a second orifice into the labyrinth. Moreover, it is certain that the vibrations of the air in the cavity of the tympanum must of themselves act upon the membrane of the *fenestra rotunda*; and this is, perhaps, the most direct manner in which the fluid in the cochlea will be affected, although it will ultimately be thrown into much more powerful action by the transmission of vibrations from the vestibule. For it has been satisfactorily determined by experiment (XII.) that vibrations are transmitted with very much greater intensity to water, when a tense membrane, and a chain of insulated solid bodies capable of free movement, are successively the conducting media, than when the media of communication between the vibrating air and the water are the same tense membrane, air, and a second membrane: or, to apply this fact to the organ of hearing, the same vibrations of the air act upon the fluid of the labyrinth with much greater intensity, through the medium of the chain of auditory bones and the *fenestra ovalis*, than through the medium of the air of the tympanum and the membrane closing the *fenestra rotunda*.—

Fig. 223.

A view of the labyrinth of the Left Side, laid open in its whole extent so as to show its Structure; these figures are all magnified: 1, the thickness of the outer covering of the cochlea; 2, 2, the scala vestibuli, or upper layer of the lamina spiralis; 3, 3, the scala tympani or lower layer of the lamina spiralis; 4, the hamulus cochleæ; 5, centre of the infundibulum; 6, the foramen rotundum communicating with the tympanum; 7, the thickness of the outer layer of the vestibule; 8, the foramen rotundum; 9, the fenestra ovalis; 10, the orifice of the aqueduct of the vestibule; 11, the inferior semicircular canal; 12, the superior semicircular canal; 13, the external semicircular canal; 14, the ampulla of the inferior canal; 15, the ampulla of the superior canal; 16, the common orifice of the superior and inferior canals; 17, the ampulla of the external canal.

The fenestra rotunda is not to be considered as having any peculiar relation with the cochlea; since, in the Turtle tribe, the former exists without the latter.

905. It is obviously in the *Labyrinth*, as a whole, that the sonorous vibrations are brought to bear upon the Auditory nerve spread out to receive them.

Fig. 224.

only contains a liquid (the *endo-lymph*), but is also separated from the osseous wall by another collection of liquid, the *peri-lymph*; so that it is suspended, as it were, in a liquid which bathes both its surfaces. In the cavity of the *Vestibule*, which is subdivided by a membranous partition into two, are found small masses of concretionary particles, collectively named *otoconia*, or ear-powder; these are obviously the rudiments of the *otoliths*, or ear-stones, whose presence in animals with a less perfect auditory apparatus seems needful to intensify the undulations. It is commonly supposed that the *Semicircular Canals* have for their peculiar function, to receive the impressions by which we distinguish the

direction of sounds; and it is certainly a powerful argument in support of this view that, in almost every instance in which these parts exist at all, they hold the same relative position to each other as in Man, their three planes being

nearly at right angles to one another. The idea, however, must be regarded as a mere speculation, the value of which cannot be decided without an increased

knowledge of the laws according to which sonorous vibrations are transmitted. —Regarding the special function of the *Cochlea*, there is precisely the same uncertainty. This part of the organ is peculiar in one respect, that the expansion of the auditory nerve is here spread out (within the lamina spiralis) in closer proximity with the bone itself, than it is in any other part of the labyrinth; and moreover the peri-lymph is here deficient, so that the membranous lining of the cochlea is in absolute contact with its osseous wall. It is not easy to see, however, what can be the peculiar object of this disposition, in regard to the function of hearing. It has been surmised by M. Dugès that, by the cochlea, we are especially enabled to estimate the *pitch* of sounds, particularly of the voice; and he adduces, in support of this idea, the fact that the development of the cochlea follows a very similar proportion with the compass of the voice. This is much the greatest in the Mammalia; less in Birds; and in Reptiles, which have little true vocal power, the cochlea is reduced to its lowest form, disappearing entirely in the Amphibia. That there should be an

Fig. 228.

acoustic relation between the voice and ear of each species of animal, cannot be regarded as improbable; but the speculation of M. Dugès can at present only be received as a stimulus to further inquiry.

906. We have now to consider the functions of the accessory parts—the *External Ear*, and the *Meatus*. The Cartilage of the external ear may propagate sonorous vibrations in two ways; by reflection and by conduction. In reflection, the concha is the most important part, since it directs the reflected undulations towards the tragus, whence they are thrown into the auditory passage. The other inequalities of the external ear cannot promote hearing by reflection; and the purpose of the extension of its cartilage is evidently to receive the sonorous vibrations from the air, and to conduct them to its point of attachment. In this point of view, the inequalities become of importance; for those elevations and depressions upon which the undulations fall perpendicularly, will be affected by them in the most intense degree; and in consequence of the varied form and position of these inequalities, sonorous undulations, in whatever direction they may come, must fall advantageously upon

some of them.—The functions of the Meatus appear to be threefold. The sonorous undulations entering from the atmosphere are propagated directly, without dispersion, to the membrana tympani:—the sonorous undulations

Fig. 229.

Fig. 230.

An anterior view of the External Ear, as well as of the Meatus Auditorius, Labyrinth, &c.: 1, the opening into the ear at the bottom of the concha; 2, the meatus auditorius externus or cartilaginous canal; 3, the membrana tympani stretching upon its ring; 4, the malleus; 5, the stapes; 6, the labyrinth.

received on the external ear are conveyed along the walls of the meatus to the membrana tympani: the air which it contains, like all insulated masses of air, increases the intensity of sounds by resonance. That, in ordinary hearing, the direct transmission of atmospheric vibrations to the membrana tympani is the principal means of exciting the reciprocal vibrations of the latter, is sufficiently evident; the undulations which directly enter the passage will pass straight on to the membrane; while those that enter obliquely will be reflected from side to side, and at last will fall obliquely on the membrane, thus perhaps contributing to the notion of direction. The power of the lining of the meatus to conduct sound from the external ear is made evident by the fact that, when both ears are closely stopped, the sound of a pipe having its lower extremity covered by a membrane, is heard more distinctly when it is applied to the cartilage of the external ear itself, than when it is placed in contact with the surface of the head. The resonant action of the air in the tube is easily demonstrated, by lengthening the passage by the introduction of another tube; the intensity of external sounds, and also that of the individual's own voice, as heard by himself, are then much increased.

907. Many facts prove, however, that the fluid of the Labyrinth may be thrown into vibration in other ways than by the Tympanic apparatus. Thus, in Osseous Fishes, it is only by the vibrations transmitted through the bones of the head that hearing can take place. There are many persons, again, who can distinctly hear sounds which are thus transmitted to them; although, through some imperfection of the tympanic apparatus, they are almost insensible to those which they receive in the ordinary way. It is evident, where this is the case, that the nerve must be in a state fully capable of functional activity; and, on

the other hand, where sounds cannot thus be perceived, there will be good reason to believe that the nerve is diseased.

908. A single impulse communicated to the Auditory nerve, in any of the foregoing modes, seems to be sufficient to excite the momentary sensation of *sound*; but most frequently a series of such impulses is concerned, there being but few sounds which do not partake, in a greater or less degree, of the character of a *tone*. Any continuous sound or tone is dependent upon a succession of impulses; and its acuteness or depth is governed by the rapidity with which these succeed one another. It is not difficult to ascertain, by experiment, what number of such impulses or undulations are required, to give every tone which the ear can appreciate. Thus, if a circular plate, with a number of apertures at regular intervals, be made to revolve over the top of a pipe through which air is propelled, a succession of short *puffs* will be allowed to issue from this; and, if the revolution be sufficiently rapid, these impulses will unite into a definite tone. In the same manner, if a spring be fixed near the edge of a revolving toothed wheel, in such a manner as to be caught by every tooth as it passes, a succession of *clicks* will be heard; and these, too, if the revolution of the wheel be sufficiently rapid, will produce a tone. The number of apertures in the plate which pass the orifice of the pipe in a given time, or the number of teeth which pass the spring, being known, it is easy to see that this must be the number of impulses required to produce the given tone. Each impulse produces a double vibration—forwards and backwards (as seen when a string is put in vibration, by pulling it out of the straight line); hence the number of impulses is always half that of the single vibrations. The maximum and minimum of the intervals of successive pulses, still appreciable by the ear as determinate sounds, have also been determined by M. Savart, more satisfactorily and more accurately than had previously been done. If their intensity be great, sounds are still audible which result from the succession of 24,000 impulses in a second; and this, probably, is not the extreme limit to the acuteness of sounds perceptible by the ear. From some observations of Dr. Wollaston's, it seems probable that the ears of different individuals are differently constituted in this respect—some not being able to hear very acute tones produced by Insects, or even Birds, which are distinctly audible to others. Again, the sound resulting from 16 impulses per second, is not, as has been usually supposed, the lowest appreciable note; on the contrary, M. Savart has succeeded in rendering tones distinguishable which are produced by only 7 or 8 impulses in a second; and continuous sounds of a still deeper tone could be heard, if the individual pulses were sufficiently prolonged. In regard, however, to the precise time during which a sonorous impression remains upon the ear, it is difficult to procure exact information, since it departs more gradually than do visual impressions from the eye. This is certain, however—that it is much longer than the interval between the successive pulses in the production of tones; since it was found by M. Savart, that one or even several teeth might be removed from the toothed wheel, without a perceptible break in its sound—showing that, when the tone was once established, the impression of it remained during an intermission of some length.

909. The Ear, like the Eye, may vary considerably as regards general acuteness, amongst different individuals; and its power may be much increased by practice. A part of this increase depends, however, as in other instances, upon the greater attention which its fainter indications receive; but a part, also, upon an increased use of the organ. The power of hearing very faint sounds is as different from the power of distinguishing musical tones, as the power of discerning very minute objects, or of seeing with very faint degrees of light, is from that of distinguishing colors. Many persons are altogether destitute of what is termed a *musical ear*; whilst others are endowed with it in a degree

which is a source of great discomfort to them, since every discordant sound is a positive torment. The power of distinguishing the *direction* of sounds appears to be, in Man at least, for the most part acquired by habit. It is some time before the infant seems to know anything of the direction of noises which attract his attention. Now, although there can be no question that this perception is acquired by attention to certain variations in the impressions made upon the nerve, through the medium either of the tympanic apparatus, or of the bones of the head, yet it is equally evident, that there can be nothing in these variations themselves adequate to excite the idea, and that it must therefore be either intuitive or acquired by habit. This is a consideration of some importance, in regard to the similar question as to the sense of Visual direction. In some cases we are probably assisted by the relative intensity of the sensations communicated by the two ears respectively. The idea of the *distance* of the sonorous body is another acquired perception, depending principally upon the loudness or faintness of the sound, when we have no other indications to guide us. In this respect there is a great similarity between the perception of the distance of an object, through the Eye by its size, and through the Ear by the intensity of its sound. When we know the size of the object, or are acquainted with the usual intensity of its sound, we can judge of its distance; and *vice versâ*, when we know its distance, we can at once form an idea of its real from its apparent size, and of its real strength of tone from that which affects our ears. In this manner the mind may be affected with corresponding deceptions through both senses; thus, in the Phantasmagoria, the figure being gradually diminished whilst its distance remains the same, it appears to the spectators to recede, the illusion being more complete if its brightness be at the same time diminished; and the effect of a distant full military band gradually approaching, may be alike given by a corresponding *crescendo* of concealed instruments. It is upon the complete imitation of the conditions which govern our ideas of the intensity and direction, as well as of the character, of sounds, that the deceptions of the Ventriloquist are founded.

910. Some facts of much interest have lately been ascertained, in regard to an occasional variation in the rapidity of the perception of sensory impressions, received through the Eye and through the Ear. These facts are the result of comparisons made amongst different astronomical observers, who may be watching the same visual phenomenon, and *timing* their observations by the same clock; for it has been remarked, that some persons see the same occurrence a third or even a half of a second earlier than others. There is no reason to suppose from this, however, that there is any difference in the rate of transmission of the sensory impressions in the two nerves. The fact seems rather to be that the Sensorium does not readily perceive two different impressions with equal distinctness; and that, when several impressions are made on the senses at the same time, the mind takes cognizance of one only, or perceives them in succession. When, therefore, both sight and hearing are directed simultaneously to two objects, the communication of the impression through one sense will necessarily precede that made by the other. The interval between the two sensations is greater in some persons than in others; for some can receive and be conscious of many impressions, seemingly at the same moment; whilst in others a perceptible space must elapse.

911. Amongst other important offices of the power of Hearing, is that of supplying the sensations by which the Voice is regulated. It is well known that those who are born entirely deaf are also dumb; that is, they do not spontaneously or imitatively form articulate sounds, though not the least defect exist in their organs of voice. Hence it appears that the vocal muscles are usually guided in their action by the sensations received through the Ears, in the same manner as other muscles are guided by the sensations received

through themselves; but when the former are deficient, the action of the vocal muscles may be guided by the latter (§ 751).

CHAPTER XVI.

OF MUSCULAR MOVEMENTS.

1.—General Considerations.

912. By far the larger proportion of the Muscular apparatus of the Human Body may be considered in the light of an instrument whereby the Nervous System is enabled to give motion to its parts, and thus to effect those changes, in its relation to the external world, which are requisite for its physical well-being, or which are the expressions of its psychical powers. There is probably no part of the Muscular System which is altogether beyond the pale of Nervous agency; but a tolerably definite line of demarcation may be drawn, both structurally and functionally, between the two primary subdivisions of this system; in the first of which—the Muscular Apparatus of Organic Life—the actions are but little dependent upon nervous agency; whilst in the second—the Muscular Apparatus of Animal Life—scarcely any action takes place but what is called forth by nerve-force. The *First* group consists of the muscular envelops which surround the various open cavities of the body, and which form part of its general investment; its office being to aid in the performance of the Organic functions, by giving motion to the contents of the cavities, or by maintaining a proper state of tension around them; and it is composed almost entirely of the *non-striated* or smooth form of muscular fibre, the only marked exception being in the case of the heart. Under this category rank the proper muscular coat of the alimentary canal, from its commencement in the œsophagus to its termination at the anus; the muscular coats of the gland-ducts which discharge themselves into this; the muscular fibres of the trachea and bronchial tubes; the muscular substance of the heart, and the muscular coats of the bloodvessels and absorbents generally; the muscular walls of the ureters, bladder, urethra, and vasa deferentia in the male, and of the ureters, bladder, urethra, Fallopian tubes, uterus, and vagina of the female; and finally, the muscular substance of the skin. With regard to nearly all these parts, as already pointed out, it is difficult to obtain evidence that nervous agency has anything to do with their contractions; and all the evidence yet adduced tends only to show that contractions *may be* excited through the nervous system, *not* that they *habitually are so*; their ordinary contractions being produced either by their own motility (§ 499), or by stimuli directly applied to themselves.—The *Second* of the above-named divisions consists of all those muscles which are usually styled voluntary, since they can be put or retained in action by the mandates of the Will; but besides these, it includes a large group of muscles (those, namely, that are concerned in the functions of Deglutition, Respiration, Vomiting, Defecation, and Urination), over which the Will exerts only a partial control, their activity being usually called forth automatically. It would seem as if this group were placed under the same conditions, as regards their dependence on Nervous agency, with those more properly termed voluntary, in order that the Will, which is altogether powerless over the Muscular Apparatus of Organic Life, may bring their operations into harmony with the general requirements of the system; the functions in question being those which constitute (so to speak) the meeting-points between the Organic and Animal life. For as we descend the scale of animal

life, we find that they lose more and more of the character they possess in Man, becoming more and more exclusively automatic, and at last being even transferred from the more elaborate mechanism of muscular contraction, to the simple operation of ciliary vibration.¹ Nearly all those muscles in the Human body, which are ordinarily called into action by the Cranio-Spinal nerves, are composed of *striated* fibre; the most remarkable exception being the muscular structure of the Iris. And it is peculiarly characteristic of them that, whilst forcible and united contractions of all the fasciculi at once are called forth by irritating their nerves, the effect of direct stimulation is limited to the fasciculus irritated.

913. It is obvious, from what has preceded, that the system of classifying the Muscles under the categories of *voluntary* and *involuntary*, cannot be consistently maintained. It is quite true that all the Muscles of Organic Life may be truly styled "*involuntary*;" for, although they are capable of being influenced by emotional and ideational states of mind (§ 923), yet the Will cannot exert any direct influence upon them, only affecting them indirectly by its power of determining these states. But over those Muscles, also ministering to the Organic functions, and doing so in obedience to impulses purely automatic, which are called into action by the Cranio-Spinal nerves, the Will, as we have seen, exerts some power; and such, therefore, cannot be properly regarded as involuntary, since the Will can influence their actions; whilst they are far from being truly voluntary, since the Will cannot control their tendency to automatic action beyond a certain limited amount. On the other hand, every one of the Muscles usually styled voluntary, because ordinarily called into action by the Will, is liable to be thrown into action involuntarily; either by an Excito-motor stimulus, as in tetanic convulsions, or by Consensual action, as in tickling, or Emotionally, as in laughter or rage, or simply Ideationally, as in somnambulism and analogous states. Hence, although there are certain groups of muscles which are more frequently acted on by the Will than by any other impulse, and certain others which are more frequently played on by the Emotions, and so on, it becomes obvious that every muscle called into contraction by the Cranio-Spinal nervous system is capable of receiving its stimulus to movement from *any* of these sources; the nerve-force transmitted along the motor fibres being issued either from the Spinal Cord, from the Sensory Ganglia, or from the Cerebrum, as the case may be, but being in its nature and effects the same in every instance.

914. The grouping or combination of Muscular actions, which takes place in almost every movement of one part of the body upon another, must be attributed, not to any peculiar sympathy among the Muscles themselves, but to the mode in which they are acted on by the Nervous Centres. This is most obviously the case with regard to those of the primarily automatic class; but it cannot be in the least degree doubtful, as to those of the secondarily automatic kind (such as walking), which, though at first directed by the Will, come by habit to be performed under conditions essentially the same with the preceding; and when it is borne in mind that even in voluntary movements the Will cannot single out any one muscle from the group with which it usually co-operates, so as to throw this into separate contraction, but is limited to determining the result (§ 758), it seems pretty obvious that even here the grouping is effected by the endowments of the Automatic centres from which all the motor impulses immediately proceed to the muscles, and not by Cerebral agency. In fact, the whole process by which we acquire the power of adapting our muscular

¹ Thus in the Oyster and other Bivalve Mollusks, which have a complicated digestive, circulating, and respiratory apparatus, food is brought to the mouth, fecal matters are expelled from the anus, and a constant current of water is made to sweep over the respiratory surface, entirely by ciliary motion.

actions to the performance of some new kind of movement—as in the case of an infant learning to walk, a child learning to write, an artisan learning some occupation which requires nice manipulation, a musical performer learning a new instrument, and so on—is found, when attentively studied, to indicate that the Will is far from having that direct and immediate control over the contractions of the Muscles which it is commonly reputed to possess; and that the operation really consists in the gradual establishment of a new grouping of the separate actions, in virtue of which the stimulus of a Volitional determination, acting under the guidance of the muscular sensations, henceforth calls into contraction the group of muscles whose agency is competent to carry that determination into effect. For however amenable any set of muscles (as those of the arm and hand) may have become to the direction of the Will, in any operations which they have been previously accustomed to perform, it is only after considerable practice that they can be trained to any method of combined action which is entirely new to them; and even if we attempt to bring our anatomical knowledge into use for such a purpose, by mentally fixing upon certain muscles whose action we wish to intensify and to associate with those of others, we find that such a method of proceeding affords no assistance whatever, but rather tends to impede our progress, by drawing off the attention from the “guiding sensations” (visual, muscular, &c.), which are the only regulators that can be depended upon for determining the due performance of the volitional mandate.—Hence we are led by these considerations, as by those stated in the preceding paragraph, to the conclusion, that the agency which directly affects the muscles is of the same kind, and that it operates under the same instrumental conditions, whatever be the primal source of the motor power. And in watching the gradual acquirement of the capacity for different kinds of movement, during the periods of Infancy and Childhood in the Human subject, we find everything to confirm this conclusion. For it becomes obvious that the acquirement of Voluntary power over the movements of the limbs is just as gradual as it is over the direction of the thoughts (§ 839); all the activity of the body, as well as of the mind, being in the first instance automatic, and the Will progressively extending its domination over the former, as over the latter, until it brings under its control all those muscular movements which are not immediately required for the conservation of the body, and turns them to its own uses.¹

2.—Of the Symmetry and Harmony of Muscular Movements.

915. It might have been not unreasonably supposed, *à priori*, that those muscles would have been most readily put into simultaneous contraction which correspond to each other on the two sides of the body; in other words, that *symmetrical* movements would be those most readily performed. Such, however, is by no means the case; for in many of our most familiar actions, we consen-

¹ The aptitude which is acquired by practice, for the performance of certain actions that were at first accomplished with difficulty, seems to result as much from a change which the continual repetition of them occasions in the Muscle, as in the habit which the Nervous system acquires of exciting their performance. Thus, almost every person learning to play on a musical instrument finds a difficulty in causing the two shorter fingers to move independently of each other and of the rest; this is particularly the case in regard to the ring-finger. Any one may satisfy himself of the difficulty, by laying the palm of the hand flat on a table, and raising one finger after the other, when it will be found, that the ring-finger can scarcely be lifted without disturbing the rest—evidently from the difficulty of detaching the action of that portion of the *extensor communis digitorum*, by which the movement is produced, from that of the remainder of the muscle. Yet to the practiced musician, the command of the Will over all the fingers becomes nearly alike; and it can scarcely be doubted that some change in the structure of the muscle, or a new development of its nerve-fibres, takes place, which favors the isolated operation of its several divisions.

taneously exert different muscles on the two sides of the body. Thus, in ordinary walking, we advance one leg whilst we push backwards (so as to urge the body forwards) with the other; and in the swinging of the arms, which is in most persons a natural part of this mode of locomotion, the arms of the two sides move forwards and backwards alternately, and the arm of either side is advanced, not with the leg of its own side, but with that of the opposite side—any other combination being felt as unnatural, and being only performed by a conscious effort. Now it is plain that this grouping of the muscular movements arises out of its *felt* conformity to the end in view, and that it is regulated by the guiding sensations which indicate to us the progression and balance of the body. The infant, in learning to walk, is prompted by an instinctive tendency to put one foot before the other, as may be noticed at a very early period, when it is first held so as to feel the ground with its feet; and in attempting to balance itself when first left to stand alone, it moves its arms with a like intuitive impulse, not based upon experience. All that experience does, in either case, is to give that precise adjustment to the muscular action, which makes it perfectly conformable to the indications afforded by the muscular sensations. Thus, if we advance each arm with its corresponding leg, we feel that the balance of the body is not nearly so readily maintained, as it is when we advance the arm with the leg of the opposite side; and thus, without any design or voluntary determination on our own parts, the former comes to be our settled habit of action. This kind of adjustment, in the case before us, is by no means limited to the muscles of the limbs; for there is scarcely any muscle of the trunk or head that is not exerted with some degree of consentaneous energy, however unconsciously to ourselves, in the act of walking. The difficulty which would attend the voluntary harmonization of all these separate actions is remarkably evinced by the fact, that no mechanist, however ingenious, has ever succeeded in constructing an automaton that should *walk* like Man; the alternate shifting of the centre of gravity from one side to the other, upon so small a base as the human foot affords, simultaneously with its movement in advance, constituting the great difficulty of biped progression. But all this adjustment is effected in our own organisms, *for* us, rather than *by* us; the act of harmonization, when once fully mastered, being attended with no effort to ourselves, but the whole series of complex movements being performed in obedience to the simple determination *to walk*, under the automatic guidance of the senses, which instantly reveal to us any imperfection in the performance.—The same view extends itself readily to other combinations of dissimilar and non-symmetrical movements, which are less *natural* to Man, but which may be readily acquired *artificially* if they all harmonize in a common purpose, and are under the guidance of the same set of sensations. Thus, the performer on the organ uses his two hands to execute different movements (in very different positions, it may be) on the “manual” keys, one of his feet may be on the “swell” pedal, and the other may be engaged in playing on the “pedal” keys; but all these diverse actions are harmonized by their relation to the same set of auditory sensations; and if the result be not that which the performer anticipated, an immediate correction is made.

916. It would be easy to multiply instances of the same kind, all illustrative of the general principle, that the facility with which we voluntarily combine different movements is chiefly determined, not by their *symmetrical* character, but by their *conformableness to a common end*, and by the *harmony of their guiding sensations* with reference to that end;¹ but it will be desirable to dwell par-

¹ Two simple examples, however, may be cited, of the difficulty which attends the simultaneous performance of movements that are not harmonious. If we attempt to elevate one eyelid whilst we are depressing the other, we find that a considerable effort is required to accomplish the action, although the elevation or depression of both eyelids together is performed with so little effort that we are scarcely conscious of it; and the difficulty is in-

ticularly on the *Movements of the Eye*, as presenting certain points of peculiar interest, some of which have an important bearing on Surgical practice.—It will be recollected that, in the Human Orbit, six muscles for the movements of the eyeball are found—the four Recti, and the two Oblique muscles. The precise actions of these are not easily established by experiment on the lower animals; for in all those which ordinarily maintain the horizontal position, there is an additional muscle, termed the *retractor*, which embraces the whole posterior portion of the globe, and passes backwards to be attached to the bottom of the orbit.¹ If the origin and insertion of the four *Recti* muscles be examined, however, no doubt can remain that each of them, acting singly, is capable of causing the globe to revolve in its own direction—the superior rectus causing the pupil to turn upwards—the internal rectus causing it to roll towards the nose—and so on. A very easy and direct application of the laws of mechanics will further make it evident to us, that the combined action of any two of the Recti muscles must cause the pupil to turn in a direction intermediate between the lines of their single action; and that *any* intermediate position may thus be given to the eyeball by these muscles alone. This fact, which has not received the attention it deserves, leads us to perceive that the Oblique muscles must have some supplementary function. It may be objected that this is a theoretical statement only; and that there may be some practical obstacle to the performance of diagonal movements by the Recti muscles, which renders the assistance of the Obliques essential for this purpose. But to this it may be replied, that *no single* muscle can direct the ball either downwards and inwards, or upwards and outwards; and that, as we have good reason to believe *these* movements to be effected by the combination of the Recti muscles, there is no reason why the other diagonal movements should not also be due to them.—The most probable account of the functions of the *Oblique* muscles of the eye seems to be that which was long ago suggested by John Hunter, and which has received confirmation from the experiments of Dr. G. Johnson.² It has been just shown that the action of the Recti muscles upon the pupil is such as to cause it to *revolve* in any given direction; and this is put in force, not merely to alter the range of vision, the head remaining stationary, but also to keep the range of vision the same, and to cause the images of the objects upon which our gaze is fixed still to fall upon the same parts of the retinae, by maintaining the position of the eyes when the head is moved upwards, downwards, from side to side, or in any intermediate direction. But these muscles are not able to *rotate* the eyeball upon its antero-posterior axis; and such rotation is manifestly necessary to preserve the fixed position of the eyeball, and consequently to keep the image of

creased if we half shut both eyes, and then try to close one and to open the other. So if we try to move our two hands, as if they were simultaneously winding cord in *opposite directions* upon two reels placed in front of us, we shall find ourselves unable to do so without a constant exercise of the attention, and even then but slowly and with difficulty; although the very same movements may be separately performed, or a movement of both hands in the same direction, with the greatest facility.

¹ This muscle is most developed in Ruminating animals, which, during their whole time of feeding, carry their heads in a dependent position. In most Carnivorous animals, instead of the complete hollow muscular cone (the base inclosing the eyeball, whilst the apex surrounds the optic nerve), which we find in the Ruminants, there are four distinct strips, almost resembling a second set of recti muscles, but deep-seated, and inserted into the posterior instead of the anterior portion of the globe. It is obvious that the actions of these must greatly affect the results of any operations which we may perform upon the other muscles of the Orbit; and, as it is impossible to divide the former, without completely separating the eye from its attachments, we have no means of correcting such results, but by reasoning alone. Experiments upon animals of the order Quadrumana, most nearly allied to Man, would be more satisfactory; as in them, the retractor muscle is almost or entirely absent.

² “Cyclopædia of Anatomy and Physiology,” vol. iii. p. 790.

the object under survey upon the same part of the retina, when the head is inclined sideways, or bowed towards one shoulder and then towards the other. It appears, from the experiments of Dr. G. Johnson, that the action of the Oblique muscles is exactly adapted to produce such a rotation; the Inferior oblique, in its contraction, causing the eyeball to move upon its antero-posterior axis, in such a manner that a piece of paper, placed at the outer margin of the cornea, passes downwards and then inwards towards the nose; and the Superior oblique effecting precisely the reverse action, the paper at the outer margin of the cornea passing first upwards and then inwards. There was not the slightest appearance, in these experiments, of elevation, depression, abduction, or adduction of the cornea, as a result of the action of the Oblique muscles; all these movements being attributable to the Recti alone.¹

917. On studying the Voluntary movements of the Eyeballs, we are led to perceive that they are not so much *symmetrical* as *harmonious*; that is to say, the corresponding muscles on the two sides are rarely in action at once; whilst such a harmony or *consent* exists between the actions of the muscles of the two orbits, that they work to one common purpose, namely, the direction of both eyes towards the required object. They may be arranged under two groups: the first comprising those which are alike harmonious and symmetrical; the second including those which are harmonious but not symmetrical. To the first group belong the following: 1. *Both* eyeballs are *elevated* by the contraction of the two Superior Recti.—2. *Both* eyeballs are *depressed* by the conjoint action of the Inferior Recti muscles.—3. *Both* are drawn directly *inwards* or *inwards* and *downwards*, as when we look at an object placed on or near the nose; this movement is effected by the action of the Internal Recti of the two sides, with or without the Inferior Recti. It is evidently symmetrical, but might seem at first sight not to be harmonious, because the eyes do not move together towards one side or the other; it is, however, really harmonious, since their axes are directed towards the same point.²—Now it is to be observed, with regard to these movements, that we can never effect them in antagonism with each other, or with those of other muscles. We cannot, for example, raise one eye and depress the other; nor can we raise or depress one eye, when we adduct or abduct the other. The explanation of this will be found in the fact that we can never, by so doing, direct the eyes to the same point.—The harmonious but unsymmetrical movements, forming the *second* class, are those in which the Internal and External Recti of the two sides are made to act together, either alone, or in conjunction with the Superior and Inferior Recti. They are as follows: 4. *One* eye is made to revolve directly *inwards*, by the action of its Internal Rectus, whilst *the other* is turned *outwards* by the action of its External Rectus.—5. *One* eye is made to revolve *upwards* and *inwards*, by the conjoint action of the Superior and Internal Recti; *the other*, *upwards* and *outwards*, by the conjoint action of the Superior and External Recti.—6. *One* eye is made to

¹ The Author has been informed by his friend Mr. Bowman that he has met with two cases of double vision, in which the defect was not experienced when the head was held erect or turned upon its vertical axis, but only when it was inclined to the one shoulder or the other. Such a peculiarity is readily explained on the above hypothesis, by the supposition that one or both of the oblique muscles of one eye was paralyzed, so that the normal rotation was not performed on that side.

² Some persons can effect this voluntarily to a greater extent than others; but even then, they can only accomplish it by fixing the gaze upon some object situated between the eyes; and cannot call the adductor muscles into combined action in perfect darkness, or if the lids be closed. Even those who have the least power of effecting this extreme convergence by at once directing the eyes towards a very near object, can accomplish it by looking at an object placed at a moderate distance, and gradually bringing this nearer to the nose, keeping the eyes steadily fixed upon it. The unwonted character of the movement is shown in this—that it can only be maintained, even for a short time, by a strong effort, producing a sense of fatigue.

revolve *downwards* and *inwards*, by the conjoint action of the Inferior and Internal Recti; *the other, downwards* and *outwards*, by the conjoint action of the Inferior and External Recti.—In these movements, *two different* muscles, the External and Internal Recti, are called into action on the two sides, with or without the superior and inferior Recti; but they are so employed for the purpose of directing the axes of the eyes towards *the same* point; and although, as just noticed, we can put the two Internal Recti in action together, we cannot voluntarily cause the two External Recti to contract together, it not being possible that any object should be in such a position as to require this action for the direction of the axes of the eyes towards it.

918. The greater number of the foregoing movements may be performed even unconsciously to ourselves, in obedience to a voluntary determination to keep the direction of the eyes fixed, instead of to give motion to the eyeballs. Thus, if we gaze steadily at an object in front of us, and then depress the head forwards on its transverse axis, the eyeballs roll upwards upon their transverse axes (1) by the action of the Superior Recti, without our being aware of it; so if, while still maintaining the same fixed gaze, we raise the head into the vertical position and then depress it backwards, the eyeballs are rolled downwards (2) by the action of the Inferior Recti; if, under the same conditions, the head be made to rotate on its vertical axis from side to side, the eyeballs will be made to roll on their vertical axes in the contrary direction, by the External and Internal Recti (4) of the two sides respectively; so by causing the head to move obliquely in the opposite directions, the oblique movements (5 and 6) of the eyeballs are made to take place by the continued fixation of the vision upon the same object. To these we have to add one more action, which cannot be called forth in any other mode; namely, that rotation of the two eyes upon their antero-posterior axes which takes place, probably by the instrumentality of the oblique muscles, when we incline the head to one side or the other by rotating it upon its antero-posterior axis (§ 916). In all these movements, as in the preceding, the Will directs the *result*; and there is no other difference between them, than that which arises out of our consciousness of a change in the one case, and our unconsciousness in the other.—The truly Involuntary movements of the eyeballs, however, are performed under very different conditions; there being here no purposive direction or fixation of the gaze; and the muscular contractions not being determined by visual sensations, but being called forth by nerve-force excited in some remote part. Of this we have an example in the normal revolution of both eyes upwards and inwards, which takes place in the acts of coughing, sneezing, winking, &c.; but many more abnormal movements of the eyeballs, in which there is neither harmony nor symmetry, present themselves in convulsive diseases.

919. It is a condition of single and distinct vision, that the *usual* axes of the eyes should be directed towards the object, in order that its picture should be thrown upon the parts of the two retinae which are *accustomed* to act together (§ 886); and that this direction is afforded by the visual sensations which govern the muscular movements, the result of these merely being determined by the Will, seems sufficiently obvious from the considerations now stated. The following circumstances, however, afford additional confirmation of this doctrine.—It is well known that, in children born blind, the movements are not harmonious; they are frequently very far from being so, in cases of congenital cataract, where a considerable amount of light is evidently admitted, but where no distinct image can be formed; and in such cases, the movements are most harmonious where the object is bright or luminous, and more vivid impressions are therefore made upon the retinae. It is no objection to this doctrine to say, that persons who have become blind may still move their eyes in an harmonious manner; since, the habit of the association of particular movements having been

once acquired, the guidance of the muscles may be effected by sensations derived from themselves, in the manner in which it takes place in the laryngeal movements of the deaf and dumb; and, as a matter of fact, a want of consent may often be observed where the blindness is total. The peculiar vacant appearance, which may be noticed in the countenances of persons, completely deprived of sight by amaurotic or other affections, which do not alter the external aspect of the eyes, seems to result from this—that their axes are *parallel*, as if the individual were looking into distant space, instead of presenting that slight convergence which must always exist between them when the eyes are fixed upon a definite object. This convergence, which is, of course, regulated by the Internal Recti, varies in degree according to the distance of the object; and it is astonishing how minute an alteration in the axes of the eyes is perceptible to a person observing them. For instance, A sees the eyes of B directed towards his face, but he perceives that B is *not looking* at him; he knows this by a sort of intuitive interpretation of the fact, that his face is not the point of convergence of B's eyes. But if B, who might have been previously looking at something nearer or more remote than A's face, fix his gaze upon the latter, so that the degree of the convergence of the axes is altered, without the general direction of the eyes being in the least affected, the change is at once perceived by the person so regarded; and the *eyes* of the two then *meet*.

920. The physiological principles which have now been stated have an important application in the treatment of Strabismus by operation; a practice whose frequent want of success is due in great part to the injudicious selection of cases, and to the wrong measures pursued.—The degree in which habit accustoms parts of the retinae that did not originally correspond, to work together harmoniously, is remarkably shown by the fact, that patients who have been long affected with Convergent Strabismus, and who see equally well with both eyes (as many do), are not troubled with double vision. On the other hand, when a person whose eyes look straight before him, is the subject of a disorder which renders their motions in any degree irregular, he is at once affected with double vision; and the same has been frequently noticed as an immediate result of the successful operation for the cure of strabismus, where vision is good in both eyes. Although the images were previously formed on parts of the retinae which were very far from corresponding with each other, yet no sooner is the position of the eyes rectified (so that the relation between the situation of the images is the same as it would be in a sound eye), than the patient sees double. Now in these cases the difficulty very speedily diminishes, and the patient soon learns to see single. That there is a *greater* tendency to consent between the images, however, when they are formed upon the parts of the two retinae which normally correspond, may be freely admitted; and this seems to be a principle of some importance in determining the readjustment of the eyes, after the operation for Strabismus. This readjustment is not always immediate; for after the muscle has been freely divided, the eye often remains somewhat inverted for a few days, gradually acquiring its straight position. The Author has known one case, in which, after such a degree of temporary inversion as seemed to render the success of the operation very doubtful, eversion actually took place for a short time to a considerable extent: after which the axes became parallel, and have remained so ever since.—Another argument, derived from the results of this operation, in favor of the consensual movement being chiefly regulated by the correspondence in the seats of the impressions on the two retinae, is, that it is much more successful in those cases in which the sight of the most displaced eye is good, than in those in which (as not unfrequently happens from long disuse) it is much impaired. In cases of the latter class, the cure is seldom complete. There is another curious fact, which may be

adverted to in reference to this subject: Strabismus not unfrequently arises from the presence of an opaque spot on the centre of the cornea, which prevents the formation of any images on the retina, except by the oblique rays; and nature seems to endeavor (so to speak) to repair the mischief, by causing the eye to assume the position most favorable for the reception of these.¹

3.—*Energy and Rapidity of Muscular Contraction.*

921. The energy of Muscular contraction is, of course, to be most remarkably observed in those instances in which the continual exercise of particular

¹ In reference to this subject, the Author would add that he is well convinced, from repeated observation, that those Surgeons are in the right who have maintained that, in a large proportion of cases, strabismus is caused by an affection of *both* sets of muscles or nerves, and not of one only; and that it then requires, for its perfect cure, the division of the corresponding muscle on both sides. Cases will be frequently met with, in which this is evident; the two eyes being employed to nearly the same extent, and the patient giving to both a slight inward direction, when desired to look straight forwards. In general, however, one eye usually looks straight forwards, whilst the other is greatly inverted; and the sight of the inverted eye is frequently affected to a considerable degree by disuse; so that, when the patient voluntarily rotates it into its proper axis, his vision with it is far from being distinct. Some Surgeons have maintained that the inverted eye is usually the only one in fault, and consider that the division of the tendon of its Internal Rectus is sufficient for the cure. They would even divide its other tendons, if the parallelism be not restored, rather than touch the other eye. The Author is himself satisfied, however, that the restriction of the abnormal state to a single eye is the exception, and not the rule, in all but very slight cases of strabismus; and to this opinion he is led both by the consideration of the mode in which strabismus first takes place, and by the results of the operations which have come under his notice. If the eyes of an infant affected with cerebral disease be watched, there will frequently be observed in them very irregular movements; the axes of the two being sometimes extremely convergent, and then very divergent. This irregularity is rarely or never seen to be confined to one eye. Now, in a large proportion of cases of Strabismus, the malady is a consequence of some cerebral affection during infancy or childhood, which we can scarcely suppose to have affected one eye only. Again, in other instances we find the Strabismus to have resulted from the constant direction of the eyes to very near objects, as in short-sighted persons; and here, too, the cause manifestly affects both.—Now it is easy to understand, why one eye of the patient should *appear* to be in its natural position, whilst the other is greatly inverted. The cause of strabismus usually affects the two eyes somewhat unequally, so that one is much more inverted than the other. We will call the least inverted eye A, and the other B. In the ordinary acts of vision, the patient will make most use of the least inverted eye, A, because he can most readily look straight forwards or outwards with it; but to bring it into the axis, or to rotate it outwards, necessitates a still more decided inversion of B. This remains the position of things—the patient usually looking straight forwards with A, which is the eye constantly employed for the purposes of vision—and frequently almost burying under the inner canthus the other eye, B, the vision in which is of very little use to him. When, therefore, the tendon of the internal rectus of B is divided, the relative position of the two is not entirely rectified. Sometimes it appears to be so for a time; but the strabismus then begins to return, and it can only be checked by division of the tendon of the other eye, A; after which, the cure is generally complete and permanent. That it has not been so, in many of the patients on whom operations have been performed, the Author attributes, without the slightest doubt in his own mind, to the neglect of the second operation. As just now stated, the sight of the most inverted eye is frequently very imperfect; indeed it is sometimes impaired to such an extent, that the patients speak of it as entirely useless. That this impairment results in part from disuse merely, seems very evident from the great improvement which often succeeds the rectification of the axes. The Author cannot help thinking it probable, however, that the same cause which produced the distortion of the eye may, in some instances at least, have affected the Optic nerve, as well as the motor nerves of the orbit; and this idea seems borne out by the asserted restoration of sight, in certain cases of Amaurosis, by division of one or more tendons, where no Strabismus previously existed (See Adams “On Muscular Amaurosis”).—A valuable memoir on the operation for Strabismus, founded on the results of about 1000 cases, will be found in the “Philadelphia Medical Examiner,” vol. vii., and an abstract of it in the “Brit. and For. Med.-Chir. Review,” July, 1852, p. 262.

parts has occasioned an increased determination of blood towards them, and in consequence a permanent augmentation in their bulk. This has been the case, for example, with persons who have gained their livelihood by exhibiting feats of strength. Much will, of course, depend on the mechanically advantageous application of muscular power; and in this manner, effects may be produced, even by persons of ordinary strength, which would not have been thought credible. In lifting a heavy weight in each hand, for example, a person who keeps his back perfectly rigid, so as to throw the pressure vertically upon the pelvis, and only uses the powerful extensors of the thigh and calf, by straightening the knees (previously somewhat flexed), and bringing the leg to a right angle with the foot, will have a great advantage over one who uses his lumbar muscles for the purpose. A still greater advantage will be gained, by throwing the weight more directly upon the loins, by means of a sort of girdle, shaped so as to rest upon the top of the sacrum and the ridges of the ilia; and by pressing with the hands upon a frame, so arranged as to bring the muscles of the arms to the assistance of those of the legs: in this manner a single man, of ordinary strength, may raise a weight of 2000 lbs.; whilst few, who are unaccustomed to such exertions, can lift more than 300 lbs. in the ordinary mode. A man of great natural strength, however, has been known to lift 800 lbs. with his hands; and the same individual performed several other curious feats of strength, which seem deserving of being here noticed: "1. By the strength of his fingers, he rolled up a very large and strong pewter dish. 2. He broke several short and strong pieces of tobacco-pipe, with the force of his middle finger, having laid them on the first and third finger. 3. Having thrust in under his garter the bowl of a strong tobacco-pipe, his legs being bent, he broke it to pieces by the tendons of his hams, without altering the bending of the knee. 4. He broke such another bowl between his first and second fingers, by pressing them together sideways. 5. He lifted a table six feet long, which had half a hundred-weight hanging at the end of it, with his teeth, and held it in that position for a considerable time. It is true, the feet of the table rested against his knees; but, as the length of the table was much greater than its height, that performance required a great strength to be exerted by the muscles of his loins, neck, and jaws. 6. He took an iron kitchen poker, about a yard long, and three inches in circumference, and, holding it in his right hand, he struck it on his bare left arm between the elbow and the wrist, till he bent the poker nearly to a right angle. 7. He took such another poker, and, holding the ends of it in his hands, and the middle of it against the back of his neck, he brought both ends of it together before him; and, what was yet more difficult, he pulled it straight again."¹ Haller mentions an instance of a man who could raise a weight of 300 lbs. by the action of the elevator muscles of his jaw: and that of a slender girl, affected with tetanic spasm, in whom the extensor muscles of the back, in the state of tonic contraction or opisthotonos, resisted a weight of 800 lbs., laid on the abdomen with the absurd intention of straightening the body. It is to be recollected that the mechanical application of the power developed by

¹ "Desaguliers' Philosophy," vol. ii.—The energy of muscular contraction appears to be greater in Insects, in proportion to their size, than it is in any other animals. Thus a Flea has been known to leap sixty times its own length, and to move as many times its own weight. The short-limbed Beetles, however, which inhabit the ground, manifest the greatest degree of muscular power. The *Lucanus cervus* (Stag Beetle) has been known to gnaw a hole of an inch in diameter, in the side of an iron canister in which it had been confined. The *Geotrope stercorarius* (Dung or shard-born Beetle) can support uninjured, and even elevate, a weight equal to at least 500 times that of its body. And a small *Carabus* has been seen to draw a weight of 85 grains (about 24 times that of its body) up a plane of 25°; and a weight of 125 grains (36 times that of its body) up a plane of 5°; and in both these instances the friction was considerable, the weights being simply laid upon a piece of paper, to which the insect was attached by a string.

muscular contraction to the movement of the body, is very commonly disadvantageous as regards *force*; being designed to cause the part moved to pass over a much greater *space* than that through which the muscle contracts. Thus the Temporal muscle is attached to the lower jaw, at about one-third of the distance between the condyle and the incisors; so that a shortening of the muscle to the amount of half an inch will draw up the front of the jaw through an inch and a half; but a power of 900 lbs. applied by the muscle would be required to raise 300 lbs. bearing on the incisors. In the case of the forearm and leg, the disproportion is much greater; the points of attachment of the muscles, by which the knee and elbow-joints are flexed and extended, being much closer to the fulcrum, in comparison with the distance of the points on which the resistance bears.

922. The rapidity of the changes of position of the component particles of muscular fibres may, as Dr. Alison justly remarks,¹ be estimated, though it can hardly be conceived, from various well-known facts. The pulsations of the heart can sometimes be distinctly numbered in children, at more than 200 in the minute; and as each contraction of the ventricles occupies only one-third of the time of the whole pulsation, it must be accomplished in 1-600th of a minute, or 1-10th of a second. Again, it is certain that, by the movements of the tongue and other organs of speech, 1500 letters can be distinctly pronounced by some persons in a minute; each of these must require a separate contraction of muscular fibres; and the production and cessation of each of the sounds imply that each separate contraction must be followed by a relaxation of equal length; each contraction, therefore, must have been effected in 1-3000th part of a minute, or in 150th of a second. Haller calculated that, in the limbs of a dog at full speed, muscular contractions must take place in less than the 1-200th of a second, for many minutes at least in succession.—All these instances, however, are thrown into the shade, by those which may be drawn from the class of Insects. The rapidity of the vibrations of the wings may be estimated from the musical tone which they produce; it being easily ascertained by experiments, what number of vibrations are required to produce any note in the scale (§ 908). From these data, it appears to be the necessary result, that the wings of many Insects strike the air *many hundred*, or even *many thousand*, times in every *second*.—The minute precision with which the degree of muscular contraction can be adapted to the designed effect, is in no instance more remarkable than in the Glottis. The musical pitch of the tones produced by it is regulated by the degree of tension of the *chordæ vocales*, which are possessed of a very considerable degree of elasticity (§ 928). According to the observations of Müller,² the average length of these, in the male, in a state of repose, is about 73-100ths of an inch; whilst, in the state of greatest tension it is about 93-100ths; the difference being therefore 20-100ths, or one-fifth of an inch: in the female glottis, the average dimensions are about 51-100ths, and 63-100ths respectively; the difference being thus about one-eighth of an inch. Now the natural compass of the voice, in most persons who have cultivated the vocal organ, may be stated at about two octaves, or 24 semitones. Within each semitone, a singer of ordinary capability could produce at least ten distinct intervals; so that of the total number, 240 is a very moderate estimate. There must, therefore, be at least 240 different states of tension of the vocal cords, every one of which is producible by the will, without any previous trial; and the *whole* variation in the length of the cords being not more than one-fifth of an inch even in man, the variation required to pass from one interval to another will not be more than 1-1200th of an inch. And

yet this estimate is much below that which might be truly made from the performances of a practised vocalist.¹

4.—Of the Influence of Expectant Attention on Muscular Movements.

923. There is a very curious group of involuntary muscular movements, not yet specially considered, which may be ranked under the general category of *ideo-motor* actions; being induced by the state of *expectant attention*, in which the mind is fully possessed with the idea that a certain action will take place, and is eagerly looking out for its occurrence. Such movements are well known to occur in the muscles connected with the organic functions, and are among the means by which important modifications are produced in those functions by the direction of the mind to them. Thus, as Dr. Holland has remarked, "the action of the heart is often quickened or otherwise disturbed by the mere centring the consciousness upon it, without any emotion or anxiety. On occasions where its beats are audible, observation will give proof of this, or the physician can very often infer it while feeling the pulse; and where there is liability to irregular pulsation, such action is seemingly brought on, or increased, by the effort of attention, even though no obvious emotion be present." "The same may be said of the parts concerned in respiration. If this act be expressly made the subject of consciousness, it will be felt to undergo some change; generally to be retarded at first, and afterwards quickened." "The act of swallowing, again, becomes manifestly embarrassed, and is made more difficult by the attention fixed upon it when the morsel to be swallowed comes into contact with the part."² And there can be no doubt that the movements of the lower part of the alimentary canal are capable of being affected in a similar manner, since we may frequently trace the rapid descent of the fæcal mass into the rectum, when we expect to be shortly able to discharge it; and it is in great part in this mode that *habit* operates, in producing a readiness for defecation at particular times, and that bread-pills and other supposititious purgatives unload the bowels.³

¹ It is said that the celebrated Made. Mara was able to sound 100 different intervals between each tone. The compass of her voice was at least three octaves, or 21 tones; so that the total number of intervals was 2100, all comprised within an extreme variation of one-eighth of an inch; so that it might be said that she was able to determine the contractions of her vocal muscles to nearly the seventeen-thousandth of an inch.

² See Dr. Holland's "Chapters on Mental Physiology," pp. 16-19.

³ The Author may mention the two following cases, which have fallen within his own knowledge, as curious illustrations of the influence of mental states upon the movements of the alimentary canal.—The first of these occurred in the person of a literary man, of a somewhat hypochondriacal temperament, who had been troubled with continual costiveness, for which he had been accustomed to take an aperient pill daily. Finding that this ceased to have its usual effect, and being fearful of increasing his regular dose, he applied for advice to a practitioner, who, having had former experience of what mental agency alone would do, determined to try its effect in this instance. Seating his patient before him, with the abdomen uncovered, he desired him to fix his attention intently upon his abdominal sensations, and assured him that in a short time he was quite certain that he would begin to feel a movement in his bowels, which would end in a copious evacuation. He himself did nothing but look steadily at his patient, with an air of great determination and confidence, and point his finger at the abdomen, moving it along the arch of the colon, and (as it were) in the course of the convolutions of the small intestines, so as to aid the patient in fixing his attention upon them. In a short time, the expected movements were felt, and a copious evacuation soon followed; and for some time afterwards, the bowels continued to act freely without medicine.—In the other case, a Lecturer at a public Institution was seized with a strong impulse to defecation during his lecture; and was greatly inconvenienced by the effort necessary to restrain it. Before every subsequent lecture in the same place, the same impulse returned upon him, notwithstanding that he might have previously unloaded his bowels elsewhere. In this case, there was obviously a state of apprehension combined with the simple anticipation; but the influence of the latter is shown by the fact, that in no other place did this individual experience the impulse in question under the like circumstances.

924. But it is with the involuntary movements produced by the same agency in the muscles ordinarily accounted voluntary, that we are at present especially concerned. This is a very curious subject of inquiry, and one to which adequate attention has scarcely yet been given; the phenomena which are referable to the principle of action just enunciated, having been very commonly explained by the agency of some other force. Thus, if a button or ring be suspended from the end of the finger or thumb, in such a position that, when slightly oscillating, it shall strike against a glass tumbler, it has been affirmed by many who have made the experiment, that the button continues to swing with great regularity, striking the glass at tolerably regular intervals, until it has sounded the hour of the day, after which it ceases for a time to swing far enough to make another stroke. This certainly does come to pass, in many instances, without any intention on the part of the performer; who may, in fact, be doing all in his power to keep his hand perfectly stationary. Now it is impossible, by any voluntary effort, to keep the hand absolutely still, for any length of time, in the position required; an involuntary tremulousness is always observable in the suspended body; and if the attention be fixed upon the part, with the expectation that the vibrations will take a determinate direction, they are very likely to do so.¹ Their persistence in this direction, however, *only takes place so long as they are guided by the visual sensations*; a fact which at once indicates the real spring of their performance. When the performer is impressed with the conviction that the hour *will* be thus indicated, the result is very likely to happen; and when it has once occurred, his confidence is sufficiently established to make its recurrence a matter of tolerable certainty. On the other hand, the experiment seldom succeeds with sceptical subjects; the expectant idea not having in them the requisite potency. That it is through the mind that these movements are regulated, however involuntarily, appears evident from these two considerations: first, that if the performer be entirely ignorant of the hour, the strokes on the glass do not indicate its number, except by a casual coincidence; and second, that the division of the entire period of the earth's rotation into twenty-four hours, and the very nomenclature of these hours, being entirely arbitrary and conventional, cannot be imagined to operate in any other mode.² These phenomena, in which no hypothetical "odylie" or other concealed agency can be reasonably supposed to operate, are here alluded to only for the sake of illustrating those next to be described, which have been imagined to prove the existence of a new force in Nature.—If "a fragment of anything, of any shape," be suspended from the end of the fore-finger or thumb, and the attention be intently fixed upon it, regular oscillations will be frequently seen to take place in it; and if changes of various kinds be made in the conditions of the experiment, by placing bodies of different sorts beneath the pendulum, or by the contact of different persons or things with the person of the suspender, corresponding changes in the direction of the movements will very commonly take place.³ Now this will occur, notwithstanding the strong desire of the experimenter to maintain a complete immobility in the suspending finger; but it is very easily proved that the movements are guided

¹ This was long since pointed out by M. Chevreuil, who investigated the subject in a truly philosophic spirit. See his letter to M. Ampère, in the "Dublin Journal of Medical and Chemical Science," vol. iv.

² For instance, the button which strikes *eleven* at night in London, should strike *twenty-three* in Rome, where the cycle of hours is continued through the whole twenty-four hours; and if an Act of Parliament were to introduce the Italian horary arrangement into this country, all the swinging buttons in her Majesty's dominions would have to add twelve to their number of post-meridian strokes; all which would doubtless come to pass, if the experimenters' faith in the result were sufficiently strong.

³ See Dr. H. Mayo on "The Truths contained in Popular Superstitions," 3d edition, Letter xii.

by his visual sensations, and that the impulse to them is entirely derived from his expectation of a given result. For, if he close his eyes, or withdraw them from the vibrating body, its oscillations (as in the previous case) immediately lose their constancy; manifestly proving that the influence which directs them acts through his consciousness. And, again, if he be ignorant of the change which is made in the conditions of the experiment, and should expect or guess something different from that which really exists, the movement will be in accordance with *his idea*, not with the reality.¹—Thus, then, we have here a most distinct proof that a state of mind exists, which is neither volitional nor emotional, but which consists in the complete engrossment of the attention by a fixed idea, whereby definite muscular movements are produced, in spite of a determined exertion of the Will. The Will is concerned, however, in the induction of the mental state in question, by the fixation of the attention on the oscillating body; and it is only in those individuals who possess the power of voluntary abstraction (§ 823) to a considerable extent that the experiment is likely to succeed. It is scarcely necessary to add, that as *faith* in its results is essential to their production, those who are acquainted with the mode in which they are really brought about, are not likely to be good subjects for it.

925. It is doubtless on the very same physiological principle, that we are to explain the mysterious phenomena of the "Divining-Rod," which have been accepted as true, or rejected as altogether fabulous, according to the previous habits of thought of those who have given their attention to the subject. Now that the end of a hazel-fork, whose limbs are grasped firmly in the hands of a person whose good faith can scarcely be doubted, frequently points upwards or downwards without any intentional direction on his part, and often thus moves when there is metal or water beneath the surface of the ground at or near the spot, is a fact which is vouched for by such testimony that we have scarcely a right to reject it; and when we come to examine into the conditions of the occurrence, we shall find that they are such as justify us in attributing it to a state of *expectant attention*, which (as we have seen) is fully competent to induce muscular movement. For, in the first place, as not above one individual in forty, even in the localities where the virtues of the divining-rod are still held as an article of faith, is found to succeed in the performance of this experiment, it is obvious that the agency, whatever be its nature, which produces the deflections, must operate by affecting the holder of the rod, and not by attracting or repelling the rod itself. And when experiments are carefully made with the view of determining the nature of this agency, they are found to indicate most clearly that the state of expectant attention, induced by the anticipation of certain results, is fully competent to produce them. For the mere act of hold-

¹ A most remarkable and convincing exemplification of this fact is afforded by Dr. Henry Madden's experiments with Mr. Rutter's "Magnetometer," at Brighton, as detailed in the "Lancet" for Nov. 15, 1851.—Dr. Madden had satisfied himself, in the first instance, that the vibrations of the suspended body were affected by the reception, into his other hand, of homœopathic globules, whose differences of composition were indicated by corresponding changes in the direction of the oscillations. But having been led to re-examine the question, and to apply that test which he ought to have employed from the first—namely, to have various globules put into his hand, without being himself made aware of their composition—he found that the results entirely lost their previous constancy, which was thus evidently due to his expectation of a particular movement in each case. It is a manifestation of the very imperfect analysis which is commonly made of such phenomena, that, from the moment when they are found referable to a physiological principle, instead of demonstrating (as they were at first supposed to do) the existence of a new force, they seem to lose all their interest for those who had previously watched them with eagerness, and to be set down as illusory, or as the product of the "imagination;" notwithstanding that they are as real in the one case as in the other, and are not in any degree less curious and interesting when considered under the former aspect, than when viewed in the latter.

ing the rod for some time in the required position, and of attending to its indications, is sufficient to produce a tendency to spasmodic contraction in the grasping muscles, notwithstanding a strong effort of the will to the contrary; and when, by such contractions, the limbs of the fork are made to approximate towards or to separate from each other, the point of the fork will be caused to move either upwards or downwards, according to the position in which it is held. If, when the muscles have this tendency to contract, occasioned by their continued restraint in one position, the mind be possessed with the expectation that a certain movement will ensue, that movement will actually take place, even though a strong effort may be made by the Will to prevent any change in the condition of the muscles. And a sufficient ground for such expectation exists, on the part of those who are possessed with the idea of the peculiar powers of the divining-rod, in the belief, or even in the surmise, that water or metal may be beneath particular points of the surface over which they pass.¹

¹ This was admitted even by Dr. H. Mayo, notwithstanding his belief in the existence of an "Od-force," governing the movements of the divining-rod. For he found, in the course of his experiments, that when his "diviner" knew which way he expected the fork to move, it invariably answered his expectations; but when he had the man blindfolded, the results were uncertain and contradictory. Hence he became certain that several of those in whose hands the divining-rod moves, set it in motion, and direct its motion (however unintentionally and unconsciously) by the pressure of their fingers, and by carrying their hands nearer to or apart from each other. (See his Letters "On the Truths contained in Popular Superstitions," Letter 1.)—The following statement of the results obtained by a very intelligent friend of the Author, who took up the inquiry some years ago, with a strong prepossession (derived from the assurances of men of high scientific note) in favor of the reality of the supposed influence, but yet with a desire to investigate the whole matter carefully and philosophically for himself, will serve as a complete illustration of the doctrine enunciated above. Having duly provided himself with a hazel-fork, he set out upon a survey of the neighborhood in which he happened to be staying on a visit; this district was one known to be traversed by mineral veins, with the direction of some of which he was acquainted. With his "divining-rod" in his hand, and with his attention closely fixed upon his instrument of research, he walked forth upon his experimental tour; and it was not long before, to his great satisfaction, he observed the point of the fork to be in motion, at the very spot where he knew that he was crossing a metallic lode. For many less cautious investigators, this would have been enough; but it served only to satisfy this gentleman that he was a favorable subject for the trial, and to stimulate him to further inquiry. Proceeding in his walk, and still holding his fork *secundum artem*, he frequently noticed its point in motion, and made a record of the localities in which this occurred. He repeated these trials on several consecutive days, until he had pretty thoroughly examined the neighborhood, going over some parts of it several times. When he came to compare and analyze the results, he found that there was by no means a satisfactory accordance amongst them; for there were many spots over which the rod had moved on one occasion, at which it had been obstinately stationary on others, and *vice versa*; so that the constancy of a physical agency seemed altogether wanting. Further, he found that, whilst some of the spots over which the rod had moved were those known to be traversed by mineral veins, there were many others in which its indications had been no less positive, but in which those familiar with the mining geology of the neighborhood were well assured that no veins existed. On the other hand, the rod had remained motionless at many points where it *ought* to have moved, if its direction had been affected by any kind of terrestrial emanation. These facts led the experimenter to a strong suspicion that the cause existed in himself alone; and carrying out his experiments still further, he ascertained that he could not hold the fork in his hand for many minutes consecutively, concentrating his attention fixedly upon it, without an alteration in the direction of its point, in consequence of an involuntary though almost imperceptible movement of his hands; so that in the greater number of instances in which the rod exhibited motion, the phenomenon was clearly attributable to this cause, and it was a matter of pure accident whether the movement took place over a mineral vein, or over a blank spot. But further he ascertained on a comparison of his results, that the movement took place more frequently where he knew or suspected the existence of mineral veins, than in other situations; and thus he came, without any knowledge of the theory of *expectant attention*, to the practical conclusion that the actions of his nerves and muscles were in great degree regulated by the ideas which possessed his mind.

Until, therefore, it shall have been proved by an extended course of carefully conducted experiments, that this mode of explanation is inadequate to account for the phenomena in question, all that is genuine in what is at present known may be set down to the category of Ideo-motor actions, or reflex actions of the Cerebrum (§ 683).

926. To this same category are doubtless to be referred a large number of those actions of Mesmeric "subjects" which have been considered by some as most unequivocal indications of the existence of an agency *sui generis*, whilst by others they have been regarded as the results of intentional deception. Now many of them are of a kind which the Will *could* not feign, being violent convulsive movements, such as no voluntary effort could produce; but the Mesmeric "subject" being previously possessed with the expectation that certain results will follow certain actions (as, for instance, that convulsive movements will be brought on by touching a piece of mesmerized metal), and the whole nervous power being concentrated, as it were, upon the performance, the movements follow when the subject *believes* the conditions to have been fulfilled, whether they *have* been, or not. These facts were most completely established by the commission appointed to investigate the pretensions of Mesmer himself; and whilst they demonstrate the unreality of the supposed mesmeric influence (so far, at least, as this class of phenomena is concerned), they also prove the position here contended for, namely, the sufficiency of the state of *expectant attention*, in those whose minds can be completely possessed by it, to produce effects of the same nature with those which are induced in Hysterical subjects by emotional excitement.¹

CHAPTER XVII.

OF THE VOICE AND SPEECH.

1.—Of the Larynx, and its Actions.

927. THE sounds produced by the organ of Voice constitute the most important means of communication between Man and his fellows; and the power of Speech has, therefore, a primary influence, as well on his physical condition as on the development of his mental faculties. In order to understand the nature of this organ as a generator of Sound, it is requisite to inquire, in the first instance, into the sources from which sounds at all corresponding to the Human voice are elsewhere obtained. It is necessary to bear in mind that Vocal sounds, and speech or articulate language, are two things entirely different; and that the former may be produced in great perfection, where there is no capability for the latter. Hence we should at once infer that the instrument for the production of vocal sounds was distinct from that by which these sounds are modified into articulate speech; and this we easily discover to be the case, the voice being unquestionably produced in the larynx, whilst the modifications of it by which language is formed are effected for the most part in the oral cavity. —The structure and functions of the former, then, first claim our attention.

¹ On the whole of this subject, the Author has the satisfaction of referring to the essay on "The Effects of Attention on Bodily Organs," in Dr. Holland's "Chapters on Mental Physiology," as showing the essential coincidence between the opinions of this distinguished Physician, and those at which he had himself arrived by independent inquiry.

Fig. 231.

External and Sectional views of the *Larynx*: A n B, the cricoid cartilage; E C G, the thyroid cartilage; G, its upper horn; C, its lower horn, where it is articulated with the cricoid; F, the arytenoid cartilage; E, F, the vocal ligament; A K, crico-thyroides muscle; F e m, thyro-arytenoideus muscle; x e, crico-arytenoideus lateralis; s, transverse section of arytenoideus transversus; m n, space between thyroid and cricoid; B L, projection of axis of articulation of arytenoid with thyroid.

928. It will be remembered that the *Trachea* is surmounted by a stout cartilaginous annulus, termed the *Cricoid* cartilage; which serves as a foundation for the superjacent mechanism. This is embraced (as it were) by the *Thyroid*, which is articulated to its sides by its lower horns, round the extremities of which it may be regarded as turning, as on a pivot. In this manner the lower front border of the thyroid cartilage, which is ordinarily separated by a small interval from the upper margin of the cricoid, may be made to approach it or recede from it; as any one may easily ascertain by placing his finger against the little depression which may be readily felt externally, and observing its changes of size, whilst a range of different tones is sounded; for it will then be noticed that the higher the note the more the two cartilages are made to approximate, whilst they separate in proportion to the depth of the tones.¹ Upon the upper surface of the back of the cricoid, are seated the two small *Arytenoid* cartilages; these are fixed in one direction by a bundle of strong ligaments, which tie them to the back of the cricoid; but they have some power of moving in other directions, upon a kind of articulating surface. The direction of the surface, and the mode in which these cartilages are otherwise attached, cause their movement to be a sort of rotation in a plane which is nearly horizontal but partly downwards; so that their vertical planes may be made to separate from each other, and at the same time to assume a slanting position. This change of place will be better understood, when the action of the muscles is described. To the summit of the arytenoid cartilages are attached the *chordæ vocales* or Vocal Ligaments, which stretch across to the front of the thyroid cartilage; and it is upon the condition and relative situation of these ligaments that their action depends. It is evident that they may be rendered more or less tense, by the movement of the

¹ In making this observation, it is necessary to put out of view the general movement to the larynx itself, which the finger must be made to follow up and down.

the lower part of its back ; their action is to draw the outer corners backwards and downwards, so that the points to which the vocal ligaments are attached, are separated from one another, and the rima glottidis is thrown *open*. This will be at once seen from the preceding diagram, in which the direction of traction of the several muscles is laid down.—The action of these muscles is partly antagonized by that of the *Crico-arytenoidei laterales*, which run forwards and

Part of Fig. 232 enlarged, to show the *Direction of the Muscular Forces* which act on the Arytenoid cartilage: *QNV*, the right Arytenoid cartilage; *TV*, its vocal ligament; *BRS*, bundle of ligaments uniting it to Cricoid; *OP*, projection of its axis of articulation; *hg*, direction of the action of the Thyro-arytenoideus; *nx*, direction of Crico-arytenoideus lateralis; *nw*, direction of Crico-arytenoideus posticus; *nx*, direction of Arytenoideus transversus.

downwards from the outer corners of the Arytenoid cartilages, and whose action is to bring the anterior points of the arytenoid cartilages into the same straight line, at the same time depressing them, so as thus to *close* the glottis. These muscles are assisted by the *Arytenoideus transversus*, which connects the posterior faces of the Arytenoid cartilages, and which, by its contraction, draws them together. By the conjoint action, therefore, of the Crico-arytenoidei laterales and of the Arytenoideus transversus, the whole of the adjacent faces of the Arytenoid cartilages will be pressed together, and the points to which the vocal ligaments are attached will be depressed.—But if the Arytenoideus be put in action in conjunction with the Crico-arytenoidei postici, the tendency of the latter to separate the Arytenoid cartilages being antagonized by the former, its backward action only will be exerted ; and thus it may be caused to aid the Crico-thyroidei in rendering tense the vocal ligaments. This action will be further assisted by the *Sterno-thyroidei*, which tend to depress the Thyroid cartilage, by pulling from a fixed point below ;¹ and the *Thyro-hyoidei* will be the antagonist of these, when they act from a fixed point above, the Os Hyoides being secured by the opposing contraction of several other muscles.—The respective actions of these muscles will be best comprehended by the following Table :—

¹ These are not usually reckoned among the principal muscles concerned in regulating the voice ; but that they are so, any one may convince himself by placing his finger just above the sternum, whilst he is sounding high notes ; a strong feeling of muscular tension is then at once perceived.

Govern the Pitch of the Notes.

Antagonists.	{ CRICO-THYROIDEI STERNO-THYROIDEI }		{ Depress the front of the Thyroid cartilage on the Cricoid, and <i>stretch</i> the vocal ligaments; assisted by the Arytenoideus and Crico-arytenoidei postici.

930. The muscles which stretch or relax the Vocal ligaments are entirely concerned in the production of Voice; those which govern the aperture of the Glottis have important functions in connection with the Respiratory actions in general, and stand as guards (so to speak) at the entrance to the lungs. Their separate actions are easily made evident. In the ordinary condition of rest, it seems probable that the Arytenoid cartilages are considerably separated from each other; so as to cause a wide opening to intervene between their inner faces, and between the vocal ligaments, through which the air freely passes; and the vocal ligaments are at the same time in a state of complete relaxation.—We can close the aperture of the Glottis by an exertion of the will, either during inspiration or expiration; and its closure by an automatic impulse forms part of the acts of Coughing and Sneezing (§ 555), besides giving rise to those more prolonged impediments to the ingress and egress of air which have been already noticed as resulting from disordered states of the Nervous system (§ 849, XVII). With these actions, the muscles which regulate the tension of the vocal ligaments have nothing to do; and we have seen that they are performed by the instrumentality of the Pneumogastric or proper Respiratory nerve (§ 718). A slight examination of the recent Larynx is sufficient to make it evident, that when once the borders of the rima glottidis are brought together by muscular action, the effect of strong aerial pressure on either side (whether produced by an expulsive blast from below, or by a strong inspiratory effort, occasioning a partial vacuum below, and consequently an increased pressure above), will be to force them into closer apposition.—In order to produce a Vocal sound, it is not sufficient to put the ligaments into a state of tension; they must also be brought nearer to each other. That the aperture of the glottis is greatly narrowed during the production of sounds, is easily made evident to one's self, by comparing the time occupied by an ordinary expiration, with that required for the passage of the same quantity of air during the sustenance of a vocal tone. Further, the size of the aperture is made to vary in accordance with the note which is being produced; of this, too, any one may convince himself, by comparing the times during which he can hold out a low and a high note; from which it will appear, that the aperture of the glottis is so much narrowed in producing a high note, as to permit a much less rapid passage of air than is allowed when a low one is sounded. This adjustment of the aperture to the tension of the vocal ligaments is a necessary condition for the production of a clear and definite tone. It further appears that, in the narrowing of the glottis which is requisite to bring the vocal ligaments into the necessary approximation, the upper points of the Arytenoid cartilages are caused to approximate, not only by being made to rotate horizontally towards each other, but also by a

degree of elevation; so that the inner faces of the vocal ligaments are brought into parallelism with each other—a condition which may be experimentally shown to be necessary for their being thrown into sonorous vibration. The muscular movements concerned in the act of vocalization appear to be called forth by the instrumentality of the fibres of the Spinal Accessory nerve which are contained in the Pneumogastric (§ 719).

931. We have now to inquire what is the operation of the Vocal Ligaments in the production of sounds; and in order to comprehend this, it is necessary to advert to the conditions under which tones are produced by instruments of various descriptions having some analogy with the Larynx. These are chiefly of three kinds; strings, flute-pipes, and reeds or tongues.—The Vocal Ligaments were long ago compared by Ferrein to vibrating *strings*; and at first sight there might seem a considerable analogy, the sounds produced by both being elevated by increased tension. This resemblance disappears, however, on more accurate comparison; for it may be easily ascertained by experiment, that no string so short as the vocal ligaments could give a clear tone, at all to be compared in depth with that of the lowest notes of the human voice; and also, that the scale of changes produced by increased tension is fundamentally different. When the strings of the same length, but of different tensions, are made the subject of comparison, it is found that the number of vibrations is in proportion to the square-roots of the extending forces. Thus, if a string extended by a given weight produce a certain note, a string extended by four times that weight will give a note in which the vibrations are twice as rapid; and this will be the octave of the other. If nine times the original weight be employed, the vibrations will be three times as rapid as those of the fundamental note, producing the twelfth above it. Now by fixing the larynx in such a manner that the vocal ligaments can be extended by a known weight, Müller has ascertained that the sounds produced by a variation of the extending force do not follow the same ratio; and therefore the condition of these ligaments cannot be simply that of vibrating cords. Further, a cord of a certain length, which is adapted to give out a clear and distinct note, equal in depth to the lowest of the human voice, may be made by increased tension to produce all the superior notes, which, in stringed instruments, are ordinarily obtained by shortening the strings.¹ But it does not follow that a short string, which, with moderate tension, naturally produces a high note, should be able, by a diminution of the tension, to give out a deep one; for, although this might be theoretically possible, yet it cannot be accomplished in practice; since the vibrations became irregular on account of the diminished elasticity.² These considerations are in themselves sufficient to destroy the supposed analogy; and to prove that the Chordæ Vocales cannot be reduced to the same category with vibrating strings.—The next kind of instrument with which some analogy might be suspected is the *flute-pipe*, in which the sound is produced by the vibration of an elastic column of air contained in the tube; and the pitch of the note is determined almost entirely by the length of the column, although slightly modified by its diameter, and by the nature of the embouchure or mouth from which it issues. This is exemplified in the German Flute, and in the English Flute or Flageolet; in both of which

¹ Thus in the Piano-forte, where there are strings for each note, a gradual shortening is seen from the lowest to the highest; and in the Violin the change of tone is produced by *stopping* the strings with the finger, so as to diminish their acting length.

² Thus it would be impossible to produce good Bass notes on the strings of a Violin, by diminishing their tension; the length afforded by the Violoncello or Double Bass is requisite. The striking difference between the tone of the Bass strings in the Grand Piano-forte and the small upright Piccolo is another exemplification of the same principle; being chiefly due to the length and tension of the former, as contrasted with the shortness and slackness of the latter.

instruments, the acting length of the pipe is determined by the interval between the embouchure and the nearest of the side apertures; by opening or closing which, therefore, a modification of the tone is produced. In the Organ, of which the greater number of pipes are constructed upon this plan, there is a distinct pipe for every note; and their length increases in a regular scale. It is, in fact, with flute-pipes as with strings—that a diminution in length causes an increase in the number of vibrations, but in a simply inverse proportion; so that of two pipes, one being half the length of the other, the shorter will give a tone which is the octave above the other, the vibrations of its column of air being twice as rapid. Now there is nothing in the form or dimensions of the column of air between the larynx and the mouth, which can be conceived to render it at all capable of such vibrations as are required to produce the tones of the Human voice; though there is some doubt whether it be not the agent in the musical tones of certain Birds. The length of an open pipe necessary to give the lowest G of the ordinary bass voice is nearly six feet; and the conditions necessary to produce the higher notes from it are by no means those which we find to exist in the process of modulating the human voice.—We now come to the third class of instruments, in which sound is produced by the vibration of *reeds* or *tongues*; these may either possess elasticity in themselves, or be made elastic by tension. The “free” reeds of the Eolian, Accordion, Seraphine, Harmonium, &c., are examples of instruments of this character, in which the lamina vibrates in a sort of frame that allows the air to pass out on all sides of it through a narrow channel, thus increasing the strength of the blast: whilst in the Hautboy, Bassoon, &c., and in Organ-pipes of similar construction, the reed covers an aperture at the side of one end of a pipe. In the former kind, the sound is produced by the vibration of the tongue alone, and is regulated entirely by its length and elasticity; whilst in the latter, its pitch is dependent upon this, conjointly with the length of the tube, the column of air contained in which is thrown into simultaneous vibration. Some interesting researches on the effect produced on the pitch of a sound given by a reed, through the union of it with a tube, have been made by M. W. Weber; and, as they are important in furnishing data by which the real nature of the vocal organ may be determined, their chief results will be here given.—I. The pitch of a reed may be lowered, but cannot be raised, by joining it to a tube. II. The sinking of the pitch of the reed thus produced is at the utmost not more than an octave. III. The fundamental note of the reed, thus lowered, may be raised again to its original pitch, by a further lengthening of the tube; and by a further increase is again lowered. IV. The length of tube, necessary to lower the pitch of the instrument to any given point, depends on the relation which exists between the frequency of the vibrations of the tongue of the reed and those of the column of air in the tube, each taken separately.—From these data, and from those of the preceding paragraph, it follows that, if a wind instrument can, by the prolongation of its tube, be made to yield tones of any depth in proportion to the length of the tube, it must be regarded as a flute-pipe; whilst if its pitch can only be lowered an octave or less (the embouchure remaining the same) by lengthening the tube, we may be certain that it is a reed instrument. The latter proves to be the case in regard to the Larynx.

932. It is evident from the foregoing considerations that the action of the Larynx has more analogy to that of *reed* instruments than it has to that either of vibrating *strings*, or of *flute-pipes*. There would seem, at first sight, to be a marked difference in character, between the vocal ligaments and the tongue of any reed instrument; but this difference is really by no means considerable. In a reed, elasticity is a property of the tongue itself, when fixed at one end, the other vibrating freely; but by a membranous lamina, fixed in the same manner, no tone would be produced. If such a lamina, however, be made elastic

by a moderate degree of tension, and be fixed in such a manner as to be advantageously acted on by a current of air, it will give a distinct tone. It is observed by Müller, that membranous tongues made elastic by tension may have either of three different forms: I. That of a band extended by a cord, and included between two firm plates, so that there is a cleft for the passage of air on each side of the tongue. II. The elastic membrane may be stretched over the half or any portion of the end of a short tube, the other part being occupied by a solid plate, between which and the elastic membrane a narrow fissure is left. III. Two elastic membranes may be extended across the mouth of a short tube, each covering a portion of the opening, and having a chink left open between them. —This last is evidently the form most allied to the Human Glottis; but it may be made to approximate still more closely by prolonging the membranes in a direction parallel to that of the current of air, so that not merely their edges, but their whole planes shall be thrown into vibration. Upon this principle, a kind of *artificial glottis* has been constructed by Mr. Willis; the conditions of action and the effects of which are so nearly allied to that of the real instrument, that the similar character of the two can scarcely be doubted. The following is his description of it:

“Let a wooden pipe be prepared of the form of Fig. 235, *a*, having a foot, *c*, like that of an organ-pipe, and an upper opening, long and narrow, as at *B*, with a point, *A*, rising at one end of it. If a piece of leather, or still better, of sheet India-rubber be doubled round this point, and secured by being bound round the pipe at *D*, with strong thread, as in Fig. 235, *b*, it will give us an artificial glottis with its upper edges *G H*, which may be made to vibrate or not, at pleasure, by inclining the planes of the edges. A couple of pieces of cork, *E*, *F*, may

be glued to the corners, to make them more manageable. From this machine, various notes may be obtained by stretching the edges in the direction of their length *G H*; the notes rising in pitch with the increased tension, although the length of the vibrating edge is increased. It is true that a scale of notes equal in extent to that of the human voice cannot be obtained from edges of leather; but this scale is much greater in India-rubber than in leather; and the elasticity of them both is so much inferior to that of the vocal ligaments, that we may readily infer that the greater scale of the latter is due to its greater elastic powers.” By other experimenters, the tissue forming the middle coat of the arteries has been used for this purpose, in the moist state, with great success; with this tissue of the vocal ligaments is nearly identical. It is worthy of remark, that in all such experiments, it is found that the two membranes may be thrown into vibration, when inclined *towards* each other in various degrees, or even when they are in parallel planes, and their edges only approximate; but that the least inclination *from* each other (which is the position the vocal ligaments have during the ordinary state of the glottis, § 930), completely prevents any sonorous vibrations from being produced.

933. The pitch of the note produced by membranous tongues may be affected in several ways. Thus, an increase in the strength of the blast, which has little influence on metallic reeds, raises *their* pitch very considerably; and

Fig. 235.

Artificial Glottis.

in this manner the note of a membranous reed may be raised by semitones, to as much as a fifth above the fundamental. The addition of a pipe has nearly the same effect on their pitch as on that of metallic reeds; but it cannot easily be determined with the same precision. The effect of the junction of a pipe with a double membranous tongue is well shown in the Trumpet, Horn, and other instruments, which require the vibration of the lips, as well as a blast of air, for the production of their sound, having no reed of their own. By some, these instruments have been classed with Flute-pipes; but the conditions of their action are entirely different. The mouth-piece of the horn or trumpet is incapable of yielding any tone, when a current of air is merely blown through it; and the lips are necessary to convert it into a musical reed, being rendered tense by the contraction of their sphincter, partly antagonized by the slightly dilating action of other muscles. The variation of the tension of the lips is effected by muscular effort; and several different notes may be produced with a pipe of the same length; but there is a certain length of the column of air which is the one best adapted for each tone; and different instruments possess various contrivances for changing this. It has been recently ascertained that the length of the pipe prefixed to the reed has also a considerable influence on its tone, rendering it deeper in proportion as it is prolonged, down to nearly the octave of the fundamental note; but the pitch then suddenly rises again, as in the case of the tube placed beyond the reed. The researches of Müller, however, have not succeeded in establishing any very definite relation between the lengths of the two tubes, in regard to their influence on the pitch of the reed placed between them.

934. From the foregoing statements, it appears that the true theory of the Voice may now be considered as well established, in regard to this essential particular—that the sound is the result of the vibrations of the vocal ligaments, which take place according to the same laws with those of metallic or other elastic tongues: and that the pitch of the notes is chiefly governed by the tension of these laminae.¹ With respect, however, to the mode and degree in which these tones are modified by the shape of the air-passages, both above and below the larynx, by the force of the blast, and by other concurrent circumstances, little is certainly known; but no doubt can be felt that these modifications are of great importance, when we observe the great amount of muscular action which takes place consentaneously with the production of vocal tones, and which seems designed to modify the length and tension of the various parts of the Vocal Tube, so that they may vibrate synchronously with the Vocal Cords. Thus, during the ascent of the voice from the deeper to the higher notes of the scale, we find the whole larynx undergoing an elevation towards the base of the cranium, the thyroid cartilage being drawn up within the os hyoides, so as even to press on the epiglottis; at the same time, the small space between the thyroid and cricoid cartilages, or crico-thyroid chink, is closed by the depression of the front of the former upon the latter (§ 928); the velum palati is depressed and curved forwards; and the tonsils approach one another. The reverse of all

¹ It is considered, however, by Mr. Bishop ("Cyclop. of Anat. and Physiol.," vol. iv. p. 1486), that the vocal apparatus combines the properties of a stretched cord, a membranous pipe with a column of air vibrating in it, and a reed; and is the perfect type, of which these instruments are only imperfect adaptations. The Author is unable, however, to deduce from Mr. Bishop's previous statements the grounds upon which he makes this assertion; and does not understand how any instrument *can* combine the actions of *strings* and of *tongues*, the laws of whose vibration are so different. That the column of air in the air-passages is thrown into vibration consentaneously with the production of sound by the vocal cords, and intensifies that sound by reciprocation, can scarcely be doubted; but the reasons previously given appear to the Author sufficient to disprove the notion, that this vibration is at all more essential to the production of the vocal tone than it is in the reed-pipe of an organ.

these movements takes place during the descent of the voice.—A very important adjunct to the production of the higher notes has been pointed out by Müller, as being afforded by the modification in the space included between the two sides of the thyroid cartilage, which is effected by the thyro-arytenoidei. He had experimentally ascertained that the introduction of a hollow plug into the upper end of the pipe beneath his artificial larynx (and therefore just below the reed), by diminishing its aperture, produced a considerable elevation of the tone. The action may be imitated in the human larynx, when made the subject of experiment, by compressing the thyroid cartilage laterally; and in this manner, the natural voice could be made to extend through a range that could otherwise be only reached by a falsetto.—The influence of the prefixed and super-added tubes, in modifying the tones produced by the Human larynx, has been found by Prof. Müller not to be at all comparable to that which they exercised over the artificial larynx; the reason of which difference does not seem very apparent. It appears, however, that there is a certain length of the prefixed tube—as there is a certain distance of the vibrating laminae, and a certain length or form of the tube above—which is most favorable to the production of each note; and the downward movement of the whole vocal organ, which takes place when we are sounding deep notes, and its rise during the elevation of the tones, have been supposed to have the purpose of making this adjustment in the length of the trachea; but this requires the supposition that the real length of the trachea is shortened whilst it appears extended—for which there seems no foundation. It is considered by Mr. Wheatstone that the column of air in the trachea may divide itself into “harmonic lengths,” and may produce a *reciprocation* of the tone given by the vocal ligaments (§ 899); and in this manner he considers that the falsetto notes are to be explained. It may be added, that the partial closing of the epiglottis seems to assist in the production of deep notes, just as the partial covering of the top of a short pipe fixed to a reed will lower its tone; and that something of this kind takes place during natural vocalization, would appear from the retraction and depression of the tongue, which accompany the lowering of the front of the head, when the very lowest notes are being sounded. The experiments of Savart have shown, that a cavity which only responds to a shrill note, when its walls are firm and dry, may be made to afford a great variety of lower tones when its walls are moistened and relaxed in various degrees. This observation may probably be applied also to the trachea.

935. The *falsetto* is a peculiar modification of the voice, differing from the “chest voice,” not merely in the higher pitch of its notes, but also in their quality; its tones being less reedy, and more like the “harmonic notes” of stringed and wind instruments. In some individuals, the chest voice passes by imperceptible gradations into the falsetto, whilst in others the transition is abrupt; and some persons can sound the same notes in the two different registers, these notes forming the upper part of the scale of the chest voice, and the lower part of the falsetto. Thus, a gentleman of the author’s acquaintance has a bass voice of a harsh, reedy character, ranging from the D below the bass cleff to the D above it (two octaves); whilst his falsetto, which is remarkable for its clearness and smoothness, ranges from the A on the highest line of the bass cleff to the E in the highest space of the treble cleff. Thus, there are five notes common to the two registers, and the entire voice ranges through more than three octaves; but from want of a gradual passage from one to the other, this gentleman can only sing bass parts with his chest voice, or alto parts with his falsetto, the tenor scale extending above the range of one, and below that of the other.—With regard to the theory of the production of the falsetto voice, there has been considerable difference of opinion amongst Physiologists; and it cannot be regarded as fully determined. By Magendie and Mayo it was maintained that these tones are produced by the vibration of the vocal cords along

only half their length, the rima glottidis being partly closed; and this explanation is consistent with the fact that a far smaller quantity of air is required for sustaining a falsetto note, than for a note of the ordinary register, even though they should be of the same pitch. By Müller, again, it is asserted that in the production of the falsetto notes merely the thin border of the glottis vibrates, so that the fissure remains distinctly visible; whilst in the production of the ordinary vocal tones, the whole breadth of the vocal ligaments is thrown into strong vibrations which traverse a wider space, so that a confused motion is seen in the lips of the glottis, rendering its fissure indefinite. It is not impossible that both these doctrines are correct; and that, in the production of falsetto notes the vocal ligaments are in contact with each other for part of their length, and that only their thin edges are in vibration in the remainder. It has been pointed out by Mr. Bishop (*loc. cit.*) that at the moment of transition from the "chest voice" to the "falsetto voice," the crico-thyroid chink, which was closed during the production of the highest note of the former, suddenly opens on the production of the lowest note of the latter; thus indicating that the Vocal Cords are *relaxed* in the passage from the one to the other, as must be the case, if, for the production of the same note, they be only put in vibration along a part of their length; so that it would not seem improbable that the cause of those differences in the mode of transition which have been already noticed, lies in the difference in the proportional amount of the vocal cords which is thus thrown out of use by the partial approximation of the two lips of the rima glottidis. It is further remarked by Mr. Bishop, that, in the passage from the chest to the falsetto voice, the larynx descends from its previously elevated position, and gradually rises again with the ascending scale of falsetto notes; and he mentions a case of *double falsetto*, in which a third register existed, and in which the relaxation of the Vocal cords and the descent of the larynx were observed at its commencement, as at the commencement of the second or ordinary falsetto register.—An entirely different theory of the falsetto has been given, however, by MM. Pétrequin and Diday;¹ who consider that the falsetto notes are not produced by the vibration of the vocal cords, but are really "flute notes," formed by the vibrations of the column of air to which the rima glottidis then serves as the embouchure. This view harmonizes well with some of the phenomena of the falsetto voice; but it is open to the objections already stated in regard to the flute theory generally. It may be added that some have attempted to show that the falsetto depends upon a peculiar action of the parts above the larynx; but for this doctrine there is no foundation whatever.

936. The various muscular actions, which are employed in the production and regulation of the voice, are called forth by an impulse which has been shown (§ 751) to be really *automatic* in its operation, and to be completely under the influence of guiding sensations, although usually originating in a Volitional determination, or giving expression to Emotions or simply to Ideas. This, however, has been proved to be true of *all* Volitional movements; so that the production of vocal tones constitutes no real exception. It may be safely affirmed, that the simple utterance of sounds is in itself an Instinctive action; although the combination of these, whether into music or articulate language, is a matter of acquirement, which is much more readily made by some individuals than by others. No definite tone can be produced by a Voluntary effort, unless that tone be present to the Consciousness during an interval—however momentary—either as immediately produced by an act of Sensation, recalled by an act of Conception, or anticipated by an effort of the Imagination. When thus present, the Will can enable the muscles to assume the condition requisite to produce it; but under no other circumstances does this happen,

¹ "Gazette Médicale," 1844.

except through the particular mode of discipline by which the congenitally deaf may be trained to speak. Such persons are debarred from learning the use of Voice in the ordinary manner; for the necessary guidance cannot be afforded, either through sensations of the present or conceptions of the past, and the imagination is entirely destitute of power to suggest that which has been in no shape experienced. But they may be taught to acquire an imperfect speech, by causing them to imitate particular muscular movements, which they may be made to see; being guided in the imitation of those movements, in the first place by watching their own performance of them in a looking-glass, and afterwards by attending to the muscular sensations which accompany them. Many instances, indeed, are on record, in which persons entirely deaf were enabled to carry on a conversation in the regular way; judging of what was said by the movements of the lips and tongue, which they had learned to connect with particular syllables; and regulating their own voices in reply, by their voluntary power, guided in its exercise by their muscular sensations.¹

[In the foregoing account of the Physiology of Voice, the Author has been chiefly guided by the excellent paper by Mr. Willis in the "Transactions of the Cambridge Philosophical Society," vol. iv.; and by the elaborate investigations of Müller and his coadjutors, as detailed in the Fourth Book of his Physiology. Mr. Bishop's account of the Physiology of Voice, in the Fourth Volume of the "Cyclopædia of Anatomy and Physiology" may also be advantageously consulted.]

2.—Of Articulate Sounds.

937. The larynx, as now described, is capable of producing those *tones* of which Voice fundamentally consists, and the sequence of which becomes Music: but *Speech* consists in the modification of the laryngeal tones, by other organs intervening between the Glottis and the Os externum, so as to produce those *articulate sounds* of which language is formed. It cannot be questioned that Music has its language; and that it is susceptible of expressing the emotional states of the mind, among those at least who have been accustomed to associate these with its varied modes, to even a higher degree than articulate speech. But it is incapable of addressing the intellect, by conveying definite ideas of objects, properties, actions, &c., in any other way than by a kind of imitation, which may be compared to the signs used in hieroglyphic writing. These ideas it is the peculiar province of articulate language to convey; and we find that the vocal organ is adapted to form a large number of simple sounds, which may be readily combined into groups, forming words. The number of combinations which can be thus produced is so inexhaustible, that every language has its own peculiar series; no difficulty being found in forming new ones to express new ideas. There is considerable diversity in different languages, even with regard to the use of the simplest of these combinations; some of them are more easy of formation than others, and these accordingly enter into the composition of all languages; whilst of the more difficult ones, some are employed in one language, some in another—no one language possessing them all. Without entering into any detailed account of the mechanism required to produce each of these simple sounds, a few general considerations will be offered in regard to the classification of them; and the peculiar defect of articulation, termed *Stammering*, will be briefly treated of.

938. Vocal sounds are divided into Vowels and Consonants; and the distinctive characters of these are usually considered to be, that the Vowels are produced by the Voice alone, whilst the sound of the Consonant is formed by some kind of interruption to the voice, so that they cannot be properly expressed

¹ See Dr. Johnstone "On Sensation," p. 128.

unless conjoined with a vowel. The distinction may be more correctly laid down, however, in this manner: the Vowel sounds are continuous tones, modified by the form of the aperture through which they pass out; whilst in sounding Consonants, the breath suffers a more or less complete interruption, in its passage through parts anterior to the larynx. Hence the really simple Vowel sounds are capable of prolongation during any time that the breath can sustain them; this is not the case, however, with the *real* Diphthongal sounds (of which it will presently appear that the English *i* is one); whilst it is true of some Consonants. It seems to have been forgotten by many of those who have written upon this subject, that the laryngeal voice is not essential to the formation of either vowels or consonants; for all may be sounded in a whisper. It is very evident, therefore, that the larynx is not primarily concerned in their production; and this has been fully established by the following experiment: A flexible tube was introduced by M. Deleau through his nostril into the pharynx, and air was impelled by it into the fauces; then, closing the larynx, he threw the fauces into the different positions requisite for producing articulate sounds, when the air impelled through the tube became an audible whisper. The experiment was repeated, with this variation—that laryngeal sounds were allowed to pass into the fauces; and each articulated letter was then heard double, in a proper voice and in a whisper.

939. That the Vowels are produced by simple modifications in the form of the external passages, is easily proved, both by observation and by imitative experiment. When the mouth is opened wide, the tongue depressed, and the velum palati elevated, so as to give the freest possible exit to the voice, the vowel *a* in its broadest form (as in *ah*) is sounded.¹ On the other hand, if the oral aperture be contracted, the tongue being still depressed, the sound *oo* (the Continental *u*) is produced. If attention be paid to the state of the buccal cavity during the pronunciation of the different vowel sounds, it will be found to undergo a great variety of modifications, arising from varieties of position of the tongue, the cheeks, the lips, and velum palati. The position of the tongue is, indeed, one of the primary conditions of the variation of the sound; for it may be easily ascertained that, by peculiar inflexions of this organ, a great diversity of vowel sounds may be produced, the other parts remaining the same. Still there is a certain position of all the parts, which is most favorable to the formation of each of these sounds; but this could not be expressed without a lengthened description. The following table, slightly altered from that of Kempelen, expresses the relative dimensions of the buccal cavity and of the oral orifice, for some of the principal of these; the number 5 expressing the largest size, and the others in like proportion:—

Vowel.	Sound.	Size of oral opening.	Size of buccal cavity.
a	as in <i>ah</i>	5	5
ä	as in <i>name</i>	4	2
e	as in <i>theme</i>	3	1
o	as in <i>cold</i>	2	4
oo	as in <i>cool</i>	1	5

These are the sounds of the five vowels, *a*, *e*, *i*, *o*, *u*, in most Continental languages; and it cannot but be admitted that the arrangement is a much more natural one than that of our own vowel series. The English *a* has three distinct sounds capable of prolongation;²—the true broad *a* of *ah*, slightly modified in

¹ This sound of the vowel *a* is scarcely used in our language, though very common in most of the continental tongues; the nearest approach to it in English is the *a* in *far*; but this is a very perceptible modification, tending towards *au*.

² The short vowel sounds, as *a* in *fat*, *e* in *met*, *o* in *pot*, &c., are not capable of prolongation.

far; the *a* of *fate*, corresponding to the *e* of French; and the *a* of *fall*, which should be really represented by *au*. This last is a simple sound, though commonly reckoned as a diphthong. In Kempelen's scale, the oral orifice required to produce it would be about 3, and the size of the buccal cavity 4.¹ On the other hand, the sound of the English *i* cannot, like that of a true vowel, be prolonged *ad libitum*; it is in fact a sort of diphthong, resulting from the transition from a peculiar indefinite murmur to the sound of *e*, which takes its place when we attempt to continue it. The sound *oy* or *oi*, as in *oil*, is a good example of the true diphthong; being produced by the transition from *au* to *e*. In the same manner, the diphthong *ou*, which is the same with *ow* in *owl*, is produced in the rapid transition from the broad *a* of *ah*, to the *oo* of *cool*.—Much discussion has taken place as to the true character of *y*, when it commences a word, as in *yet*, *yawl*, &c.; some having maintained that it is a consonant (for the very unsatisfactory reason, that we are in the habit of employing *a* rather than *an*, when we desire to prefix the indefinite article to such words), whilst others regard it as a peculiar vowel. A slight attention to the position of the vocal organs during its pronunciation makes it very clear that its sound in such words really corresponds with that of the long (English) *e*; the pronunciation of the word *yawl* being the same as that of *ēaul*, when the first sound is not prolonged, but rapidly transformed into the second. The sound of the letter *w*, moreover, is really of the vowel character, being formed in the rapid transition from *oo* to the succeeding vowel; thus *wall* might be spelt *ōōall*. Many similar difficulties might be removed, and the conformity between spoken and written language might be greatly increased (so as to render far more easy the acquirement of the former from the latter), by due attention to the state of the vocal organs in the production of the simple sounds.

940. It is not very difficult to produce a tolerably good artificial imitation of the Vowel sounds. This was accomplished by Kempelen, by means of an India-rubber ball, with an orifice at each end, of which the lower one was attached to a reed: by modifying the form of the ball, the different vowels could be sounded during the action of the reed. He also employed a short funnel-like tube, and obtained the different sounds by covering its wide opening to a greater or less extent. This last experiment has been repeated by Mr. Willis; who has also found that the vowel sounds might be imitated by drawing out a long straight tube from the reed. In this experiment he arrived at a curious result: with a tube of a certain length, the series of vowels, *i*, *e*, *a*, *o*, *u*, was obtained, by gradually drawing it out; but, if the length was increased to a certain point, a further gradual increase would produce the same sequence in an inverted order, *u*, *o*, *a*, *e*, *i*; a still further increase would produce a return to the first scale, and so on. When the pitch of the reed was high, and the pipe short, it was found that the vowels *o* and *u* could not be distinctly formed—the proper tone being injured by the elongation of the pipe necessary to produce them; and this, Mr. Willis remarks, is exactly the case in the Human voice, most singers being unable to pronounce *u* and *o* upon their highest notes.

941. The most natural primary division of the Consonants is into those which require a total stoppage of the breath at the moment previous to their being pronounced, and which, therefore, cannot be prolonged; and those in pronouncing which the interruption is partial, and which can, like the vowel sounds, be

¹ The mode of making a determination of this kind may here be given, for the sake of example. If the broad *a* be sounded, the mouth and fauces being opened wide, and we contract the oral orifice by degrees, at the same time slightly elevating the point of the tongue, we gradually come to the sound of *au*; by still further contracting the orifice, and again depressing the tongue, we form *oo*. On the other hand, in sounding *e*, the tongue is raised nearly to the roof of the mouth; if it be depressed, without the position of the lips being altered, *au* is given.

prolonged *ad libitum*. The former have received the designation of *explosive*; and the latter of *continuous*.—In pronouncing the *explosive* consonants, the posterior nares are completely closed, so that the exit of air through the nose is altogether prevented; and the current may be checked in the mouth in three ways, by the approximation of the lips—by the approximation of the point of the tongue to the front of the palate—and by the approximation of the middle of the tongue to the arch of the palate. In the first of these modes, we pronounce the letters *b*, and *p*; in the second, *d*, and *t*; in the third, the hard *g*, and *k*. The difference between *b*, *d*, and *g*, on the one hand, and *p*, *t*, and *k*,¹ on the other, seems to depend on this—that in the former group the approximating surfaces are larger, and the breath is sent through them more strongly at the moment of opening than in the latter.—The *continuous* consonants may be again subdivided, according to the degree of freedom with which the air is allowed to make its exit, and the compression which it consequently experiences.

I. The first class includes those, in which no passage of air takes place through the nose, and in which the parts of the mouth that produce the sound are nearly approximated together, so that the compression is considerable. This is the case with *v*, and *f*, which are produced by approximating the upper incisors to the lower lip; and which stand in nearly the same relation to each other, as that which exists between *d* and *t*, or *b* and *p*. The sibilant sounds, *z* and *s*, also stand in a similar relation to each other; they are produced by the passage of air between the point of the tongue and the front of the palate, the teeth being at the same time nearly closed. The simple sound *sh* is formed by narrowing the channel between the dorsum of the tongue and the palate; the former being elevated towards the latter, through a considerable part of its length. If, in sounding *s*, we raise the point of the tongue a very little, so as to touch the palate, the sound of *t* is evolved; and in the same manner *d* is produced from *z*. This class also includes the *th*; which, being a perfectly simple sound, ought to be expressed by a single letter, as in Greek, instead of by two, whose combination does not really produce anything like it. For producing this sound, the point of the tongue is applied to the back of the incisors, or to the front of the palate, as in sounding *t*;² but, whilst there is complete contact of the tip, the air is allowed to pass out around it.

II. In the second class of continuous consonants, including the letters *m*, *n*, *l*, and *r*, the nostrils are not closed; and the air thus undergoes very little compression, even though the passage of air through the oral cavity is almost or completely checked. In pronouncing *m* and *n*, the breath passes through the nose alone: and the difference of the sound of these two letters must be due to the variation in the form of the cavity of the mouth, which acts by resonance. The letter *m* is a labial, like *b*; and the only difference between the two is, that in the former the nasal passage is open, whilst the mouth remains closed; whilst in the latter, the nose is entirely closed, and the sound is formed at the moment of opening the mouth. The same correspondence exists between *n* and *t*, or *n* and *g* (the particular part of the tongue approximated to the palate not being of much consequence in the pronunciation of *n*); and hence it is that the transition from *n* to *t*, or from *n* to *g*, is so easy, that the combinations *nt* and *ng* are found abundantly in most languages. The sound of *l* is produced by bringing the tip of the tongue into contact with the palate, and allowing the air to escape around it, at the same time that a vocal tone is generated in the larynx; it differs, therefore, from *th* in the position at which the obstruction is interposed, as well as in the slight degree of compression of the air which it involves. The sound of the letter *r* depends on an absolute vibration of the point of the tongue

¹ For the sake of proper comparison, this letter should be sounded not as *kay*, but as *key*.

² Hence it is easy to understand the substitution of *t* or *d*, for the English *th*, by foreigners.

in a narrow current of air forced between the tongue itself and the palate. III. The sounds of the third class are scarcely to be termed consonants, since they are merely *aspirations* caused by an increased force of breath. These are *h*, and the guttural *ch*¹ of most foreign languages (the Greek χ). The first is a simple aspiration; the second an aspiration modified by the elevation of the tongue, causing a slight obstruction to the passage of air, and an increased resonance in the back of the mouth. This sound would become either *g* or *k*, if the tongue, whilst it is being produced, were carried up to touch the palate.²

942. These distinctions come to be of much importance, when we apply ourselves to the treatment of defects of articulation. Great as is the number of muscles employed in the production of definite vocal sounds, the number is much greater for those of articulate language; and the varieties of combination which we are continually forming unconsciously to ourselves, would not be suspected, without a minute analysis of the separate actions. Thus, in uttering the explosive sounds, we check the passage of air through the posterior nares, in the very act of articulating the letter; and yet this important movement commonly passes unobserved.—We must regard the power of forming the several articulate sounds which have been adverted to, and their simple combinations, as so far resulting from intuition, that it can in general be more readily acquired by early practice than other actions of the same complexity; but we find that among different Races of Men, there exist tendencies to the production of different sounds, which, though doubtless influenced in great degree by early habit (since we find that children, when first learning to speak, form their habits of vocalization in great degree in accordance with the examples amidst which they are placed), are certainly also dependent in part upon congenital constitution, as we often see in the case of children among ourselves, who grow up with certain peculiarities of pronunciation of which they do not seem able to divest themselves. It is, however, in the want of power to *combine* the different muscular actions concerned in vocalization, that the defect termed *Stammering* essentially consists.

943. Many theories regarding the nature of Stammering have been proposed; and there can be little doubt that the impediment may be attributed to a great variety of exciting causes. A disordered action of the nervous centres must, however, be regarded as the proximate cause; though this may be (to use the language of Dr. M. Hall) either of *centric* or of *excentric* origin—that is, it may result from a morbid condition of the ganglionic centre, or from an abnormal impression conveyed through its afferent nerves. When of centric origin (and this is probably the most general case), the phenomena of Stammering and Chorea have a close analogy to each other; in fact stammering is frequently one of the modes in which the disordered condition of the nervous system in Chorea manifests itself.—It is in the pronunciation of the Consonants of the *explosive* class, that the stammerer experiences the greatest difficulty. The total interruption to the breath which they occasion frequently becomes quite spasmodic; and the whole frame is thrown into the most distressing semi-convulsive movement, until relieved by expiration.³ In the pronunciation of the *continuous* Consonants of the first class, the stammerer usually prolongs them, by a spasmodic continuance of the same action; and there is, in consequence, an impeded, but not a suspended respiration. The same is the case with the *l* and *r* in the second class. In pronouncing the *m* and *n*, on the other hand, as well as the aspirates and vowels, it is sometimes observed that the stammerer

¹ The English *ch* is merely a combination of *t* with *sh*; thus *chime* might be spelt *tshime*.

² The general classification proposed by Dr. M. Hall has been here adopted, with some modification as to the details.

³ By Dr. Arnott this interruption is represented as taking place in the larynx; that such is not usually the case, the Author believes that a little attention to the ordinary phenomena of voice will satisfactorily prove.

prolongs the sound, by a full and exhausting expiration. In all these cases, then, it seems as if the muscular sense, resulting from each particular combination of actions, became the stimulus to the involuntary prolongation of that action. It is possible that the defect may result, in some instances, from malformation of the parts about the fauces, producing an abnormal stimulus of this kind in some particular positions of the organ; and such cases *may be* really benefited by an operation for the removal of these parts. But the effect of such an operation is certainly exerted in most cases through the *mind* of the patient; the expectation of benefit from it tending to improve his command over the muscles of vocalization, which Emotional excitement always impairs; and the improvement is usually proportional to the confidence which he has been led to feel in the result. The slightest disturbance of the feelings is sufficient in most Stammerers to induce a complete perturbation of the vocal powers; the very fear that stammering will occur, particularly under circumstances which render it peculiarly annoying, is often sufficient to bring it on in a predisposed subject; and the tendency to consensual imitation sometimes occasions stammering in individuals (especially children) who never show the slightest tendency to it except when they witness the difficulty in others.

944. The method proposed by Dr. Arnott for the prevention of Stammering, consists in the connection of all the words by a vocal intonation, in such a manner, that there shall never be an entire stoppage of the breath. It is justly remarked by Müller, however, that this plan may afford some benefit, but cannot do everything; since the main impediment occurs in the middle of words themselves. One important remedial means, on which too much stress cannot be laid, is to study carefully the mechanism of the articulation of the difficult letters, and to practise their pronunciation repeatedly, slowly, and analytically. The patient would at first do well to practise sentences from which the explosive consonants are omitted; his chief difficulty, arising from the spasmodic suspension of the expiratory movement, being thus avoided. Having mastered these, he may pass on to others, in which the difficult letters are sparingly introduced; and may finally accustom himself to the use of ordinary language. One of the chief points to be aimed at is to make the patient feel that he *has* command over his muscles of articulation; and this is the best done by gradually leading him from that which he finds he *can* do, to that which he fears he cannot. The fact that stammering people are able to *sing* their words better than to *speak* them, has been usually explained on the supposition that, in singing, the glottis is kept open, so that there is less liability to spasmodic action; if, however, as here maintained, the spasmodic action is not in the larynx, but in the velum palati and the muscles of articulation, the difference must be due to the direction of the attention rather to the muscles of the larynx than to those of the mouth. One of the most important objects to be aimed at in the treatment of stammering, consists in the prevention of all Emotional disturbance in connection with the act of Speech; and this requires the exercise of the Voluntary power over the direction of the thoughts, in the following modes: 1. To *reduce* mental emotion, by a daily, hourly habit of abstracting the mind from the subject of stammering, both while speaking and at other times. 2. To *avoid exciting* mental emotion by attempting unnecessarily to read or speak when the individual is conscious that he shall not be able to perform these actions without great distress. 3. To *elude* mental emotion, by taking advantage of any little artifice to escape from stammering, so long as the artifice continues to be a successful one.—Much may frequently be done, also, by constitutional treatment, adapted to improve the general condition of the nervous system.¹

¹ See on the subject of "Stammering and its Treatment," a useful pamphlet under this title, by Bacc. Med. Oxon., 1850; and Mr. Bishop's treatise "On Articulate Sounds, and on the Causes and Cure of Impediments of Speech."

CHAPTER XVIII.

INFLUENCE OF THE NERVOUS SYSTEM ON THE ORGANIC FUNCTIONS.

945. OF the modes in which the Nervous System influences the Organic Functions, a great part have been already considered: for it has been shown to be concerned in providing the conditions, either immediate or remote, under which alone these functions can be performed; so that, when its activity ceases, they cannot be much longer maintained. But the influence of the Nervous System is not alone exerted upon the motor or contractile tissues of the body; for there is good evidence that it has a direct operation upon the molecular changes which constitute the functions of Nutrition, Secretion, &c.; and it is quite conformable to the general views formerly expressed (CHAP. III.) respecting the relations of the different kinds of Vital Force, that the *nerve-force*, which is itself generated by cell-development, should in its turn be able to modify other processes of cell-development (§ 111). And this view may be admitted to its fullest extent, without our thereby being led to regard the processes in question as *dependent* upon Nervous agency—a doctrine for which there seems no valid foundation, since they go on with the greatest rapidity and energy in the Vegetable kingdom, in which nothing approaching to a Nervous System exists; whilst in the Animal kingdom they take place with equal vigor, long before the least vestige of it appears. We shall see that in the earliest condition of foetal life, the germ consists but of a congeries of cells, which have all originated in a single one (§ 993); and from this mass, the several tissues and organs are successively generated by the processes of histological and morphological transformation—one set of cells being converted into muscular tissue, another into nervous tissue, another into mucous membrane, and so on. Now since this is the case, it is evident that all these processes of development must take place, in virtue of the inherent properties of the primitive substance itself; since no nervous influence can be supposed to operate before nerves are called into existence. Throughout the Animal body, it may be observed that the more Vegetative the nature of any function, the less is it connected with the Nervous System; and all the experiments which have been regarded as proving that the Organic functions are *dependent upon* Nervous influence, are really explicable, fully as well, upon the supposition that they are capable of being *affected by* it, either in the way of excitement or retardation. (See § 447.) Moreover, there is abundant evidence that Secretion may take place after the death of the general system, through the persistence of certain molecular changes whose essential conditions are not immediately altered; thus, Mr. T. Bell mentions that, in dissecting the poison-apparatus of a Rattlesnake which had been dead for some hours, the poison continued to be secreted so fast as to require being occasionally dried off. This is precisely what might have been anticipated, from the independent power of growth in the secreting cells; and other acts of Nutrition are recorded to have occurred under similar circumstances. In such a case, the Animal body is reduced to the condition of a Plant; since the influence of the Nervous system must then be entirely extinct. Upon those who maintain that Nervous agency is a condition *essential* to those molecular actions of which Nutrition and Secretion consist,

it is incumbent, therefore, to offer some more unexceptionable proof of their position than has yet been given; since their doctrine is opposed by so many considerations of great weight.

946. That many of the Organic Functions, however, are directly influenced by the Nervous System, is a matter which does not admit of dispute; and this influence, exerted sometimes in exciting, sometimes in checking, and sometimes in otherwise modifying them, may well be compared to that which the hand and heel of the rider have upon his horse, or which the engine-driver exerts over a locomotive. It is most remarkably manifested in the result of severe injury of the Nervous centres, such as concussion of the Brain or of the Solar plexus (§ 321); for this does not merely bring about a suspension of the respiratory and other movements which minister to the Organic functions, hence inducing a gradual stagnation of the latter; but occasions a sudden and complete cessation of the whole train of action, which cannot be attributed to any other cause than a *positive* depressing influence of some kind, propagated through the Nervous System. In such cases, even the vitality of the Blood is often affected; the usual coagulation not taking place after death, so long, at least, as the blood remains within the vessels. A similar general depression may result from Mental Emotion, operating through the same channel; but this more commonly has rather a local action, or operates more gradually (§ 797).

947. The influence of the Nervous System is often especially exerted in giving temporary excitement to a Secreting process which need not be kept in constant activity, or of which circumstances may occasionally require an increase. This is the case, for example, in regard to the secretions connected with the process of digestion—the Saliva, Gastric fluid, Bile, Pancreatic fluid, &c.; all of these being excited by the contact of the substances on which they act, with the surfaces on which their respective ducts open. The secretion of Milk, again, in a nursing female, may be excited by irritation of the nipple; and the determination of blood to the Mammæ during pregnancy arises from an increased action in the part, which is probably excited sympathetically by the changes occurring in the Uterus; and for this kind of communication, the Sympathetic System seems to afford the readiest channel, since the organs in question are for the most part supplied by it. There is an apparent exception, however, in the case of the Salivary and Lachrymal glands, which are supplied by the 5th Pair: but this nerve contains so many organic filaments, and is so intimately connected with the Sympathetic, as evidently to supply (in the head) the place of a separate ganglionic system. It is by Nervous influence, that the mucous secretion covering the membranes is caused to be regularly formed for their protection; for it is shown by pathological facts, that when this influence is interrupted, and the secretion is no longer supplied, the membrane, losing its protection, is irritated by the air or the fluids with which it may be in contact, and passes into an inflammatory condition. This is partly the explanation of the fact, which has been well ascertained, that the eye is liable to suppurate when the 5th pair has been divided; and that the mucous membrane of the bladder becomes diseased in paraplegia.

948. The influence of particular conditions of the Mind, in exciting various Secretions, is a matter of daily experience. The flow of Saliva, for example, is stimulated by the idea of food, especially that of a savory character. Lachrymal secretion, again, which is continually being formed to a small extent for the purpose of bathing the surface of the eye, is poured out in great abundance under the moderate excitement of the emotions, either of joy, tenderness, or grief. It is checked, however, by violent emotions; hence in intense grief, the tears do not flow; and it is a well-known proof of moderated sorrow when the gush takes place, this very act affording a further relief (§ 797). Violent emotion may also suspend the Salivary secretion; as is shown by the well-known

test, often resorted to in India, for the discovery of a thief amongst the servants of a family—that of compelling all the parties to hold a certain quantity of rice in the mouth during a few minutes—the offender being generally distinguished by the comparative dryness of his mouthful at the end of the experiment. The influence of the emotion of love of offspring in increasing the secretion of Milk is well known. The formation of this fluid is continually going on during the period of lactation; but it is greatly increased by the sight of the infant, or even by the thought of him, especially when associated with the idea of suckling; this gives rise to the sudden rush of blood to the gland, which is known by nurses as the *draught*, and which occasions a greatly increased secretion. The strong desire to furnish milk, together with the irritation of the gland through the nipple, has often been effectual in producing the secretion in girls and old women, and even in men. The quantity of the Gastric secretion is increased by exhilaration, at least if we may judge from the increase of the digestive powers under such circumstances. Freedom from mental anxiety favors the secretion of Fat; whilst continual solicitude effectually checks the disposition. It has been stated that total despair has an equal tendency, with absence of care, to produce this effect; persons left long to pine in condemned cells, without a shadow of hope, frequently becoming remarkably fat, in spite of their slender fare.¹ The odoriferous secretion of the Skin, which is much more powerful in some individuals than in others, is increased under the influence of certain mental emotions (as fear or bashfulness), and commonly also by sexual desire. The Sexual secretions themselves are strongly influenced by the condition of the mind. When it is frequently and strongly directed towards objects of passion, these secretions are increased in amount, to a degree which may cause them to be a very injurious drain on the powers of the system. On the other hand, the active employment of the mental powers on other objects has a tendency to render less active, or even to check altogether, the processes by which they are elaborated.²

¹ Fletcher's "Rudiments of Physiology," Part II., b, p. 11.

² This is a simple physiological fact, but of high moral application. The Author would say to those of his younger readers, who urge the wants of Nature as an excuse for the illicit gratification of the sexual passion, "Try the effects of close mental application to some of those ennobling pursuits, to which your profession introduces you, in combination with vigorous bodily exercise (for the effects of which see § 771), before you assert that the appetite is unrestrainable, and act upon that assertion." Nothing tends so much to increase the desire, as the continual direction of the mind towards the object of its gratification. The following observations, which the Author believes to be strictly correct, are extracted from a valuable little work (anonymous) entitled "Be not deceived," addressed to Young Men; they are directed to those who maintain that, the married state being natural to Man, illicit intercourse is necessary for those who are prevented by circumstances from otherwise gratifying the sexual passion. "When the appetite is naturally indulged, that is, in marriage, the necessary energy is supplied by the nervous stimulus of its natural accompaniment of love before referred to, which prevents the injury that would otherwise arise from the increased expenditure of animal power: and in like manner also, the function being in itself grateful, this personal attachment performs the further necessary office of preventing immoderate indulgence, by dividing the attention, through the numerous other sources of sympathy and enjoyment which it simultaneously opens to the mind. But, when the appetite is irregularly indulged, that is in fornication, for want of the healthful vigor of true love, its energies become exhausted; and from the want of the numerous other sympathetic sources of enjoyment in true love, in similar thoughts, common pursuits, and above all in common holy hopes, the mere gross animal gratification of lust is resorted to with unnatural frequency, and thus its powers become still further exhausted, and, therefore, still more unsatisfying, while, at the same time, a habit is thus created, and these jointly cause an increased craving; and the still greater deficiency in the satisfaction experienced in its indulgence further, continually, ever in a circle, increases—the habit, demand, indulgence, consequent exhaustion, diminished satisfaction, and again demand—till the mind and body alike become disorganized." Such considerations as these may, to some persons, appear mis-

949. No secretion so evidently exhibits the influence of the depressing Emotions, as that of the Mammæ; but this may be partly due to the fact, that the digestive system of the Infant is a more delicate apparatus for testing the qualities of that secretion, than any which the Chemist can devise; affording proof, by disorder of its function, of changes in the character of the Milk, which no examination of its physical properties could detect. The following remarks on this subject are abridged from Sir A. Cooper's valuable work on the Breast: "The secretion of milk proceeds best in a *tranquil state of mind*, and with a cheerful temper; then the milk is regularly abundant, and agrees well with the child. On the contrary, a *fretful temper* lessens the quantity of milk, makes it thin and serous, and causes it to disturb the child's bowels, producing intestinal fever and much griping. *Fits of anger* produce a very irritating milk, followed by griping in the infant, with green stools. *Grief* has a great influence on lactation, and consequently upon the child. The loss of a near and dear relation, or a change of fortune, will often so much diminish the secretion of milk as to render adventitious aid necessary for the support of the child. *Anxiety of mind* diminishes the quantity, and alters the quality, of the milk. The reception of a letter which leaves the mind in anxious suspense lessens the draught, and the breast becomes empty. If the child be ill, and the mother is anxious respecting it, she complains to her medical attendant that she has little milk, and that her infant is griped, and has frequent green and frothy motions. *Fear* has a powerful influence on the secretion of milk. I am informed by a medical man who practises much among the poor, that the apprehension of the brutal conduct of a drunken husband will put a stop for a time to the secretion of milk. When this happens, the breast feels knotted and hard, flaccid from the absence of milk, and that which is secreted is highly irritating, and some time elapses before a healthy secretion returns. *Terror*, which is sudden and great fear, instantly stops this secretion." Of this, two striking instances, in which the secretion, although previously abundant, was completely arrested by this emotion, are detailed by Sir A. C. "Those passions which are generally sources of pleasure, and which, when moderately indulged, are conducive to health, will, when carried to excess, alter, and even entirely check the secretion of milk."

950. There is even evidence that the Mammary secretion may acquire an actually *poisonous* character, under the influence of violent mental excitement; for certain phenomena which might otherwise be regarded in no other light than as simple coincidences, appear to justify this inference, when interpreted by the less striking but equally decisive facts already mentioned. "A carpenter fell into a quarrel with a soldier billeted in his house, and was set upon by the latter with his drawn sword. The wife of the carpenter at first trembled from fear and terror, and then suddenly threw herself furiously between the combatants, wrested the sword from the soldier's hand, broke it in pieces, and threw it away. During the tumult, some neighbors came in and separated the men. While in this state of strong excitement, the mother took up her child

placed in a Physiological Treatise—yet the Author feels sure that, by his well-judging readers, he will not be blamed for adverting to this subject, or for the introduction of the above quotation from a writer of whom he has no personal knowledge, but whose object must be confessed by all to be laudable. There seems to be something in the process of training young men for the Medical Profession, which encourages in them a laxity of thought and expression on these matters that generally ends in a laxity of principle and of action. It might have been expected that those who are so continually witnessing the melancholy consequences of the violation of the Divine law in this particular, would be the last to break it themselves; but this is unfortunately very far from being the case. The Author regrets to be obliged further to remark, that some works which have issued from the Medical press contain much that is calculated to excite, rather than to repress, the propensity; and that the advice sometimes given by practitioners to their patients is immoral as well as unscientific.

from the cradle, where it lay playing, and in the most perfect health, never having had a moment's illness; she gave it the breast, and in so doing sealed its fate. In a few minutes the infant left off sucking, became restless, panted, and sank dead upon its mother's bosom. The physician, who was instantly called in, found the child lying in the cradle, as if asleep, and with its features undisturbed; but all his resources were fruitless. It was irrecoverably gone."¹ In this interesting case, the milk must have undergone a change, which gave it a powerful sedative action upon the susceptible nervous system of the infant.—The following, which occurred within the Author's own knowledge, is perhaps equally valuable to the Physiologist, as an example of the similarly fatal influence of undue emotion of a different character; and both should serve as a salutary warning to mothers, not to indulge either in the exciting or depressing passions. A lady having several children, of which none had manifested any particular tendency to cerebral disease, and of which the youngest was a healthy infant a few months old, heard of the death (from acute hydrocephalus) of the infant child of a friend residing at a distance, with whom she had been on terms of close intimacy, and whose family had increased almost contemporaneously with her own. The circumstance naturally made a strong impression on her mind; and she dwelt upon it the more, perhaps, as she happened, at that period, to be separated from the rest of her family, and to be much alone with her babe. One morning, shortly after having nursed it, she laid the infant in its cradle, asleep and apparently in perfect health; her attention was shortly attracted to it by a noise; and, on going to the cradle, she found her infant in a convulsion, which lasted a few moments and then left it dead. Now, although the influence of the mental emotion is less unequivocally displayed in this case than in the last, it can scarcely be a matter of doubt; since it is natural that no feeling should be stronger in the mother's mind, under such circumstances, than the fear that her own beloved child should be taken from her, as that of her friend had been; and it is probable that she had been particularly dwelling on it, at the time of nursing the infant on that morning.—Another instance, in which the maternal influence was less certain, but in which it was not improbably the immediate cause of the fatal termination, occurred in a family nearly related to the Author's. The mother had lost several children in early infancy, from a convulsive disorder; one infant, however, survived the usually fatal period; but whilst nursing him one morning, she had been strongly dwelling on the fear of losing him also, although he appeared a very healthy child. In a few minutes after the infant had been transferred into the arms of the nurse, and whilst she was urging her mistress to take a more cheerful view, directing her attention to his thriving appearance, he was seized with a convulsion-fit, and died almost instantly. Now, although there was here unquestionably a predisposing cause, of which there is evidence in the other cases, it can scarcely be doubted that the *exciting* cause of the fatal disorder is to be referred to the mother's anxiety. This case offers a valuable suggestion—which, indeed, would be afforded by other considerations—that an infant, under such circumstances, should not be nursed by its mother,

¹ Dr. Von Ammon, in his treatise "Die ersten Mutterpflichten und die erste Kindespflege," quoted in Dr. A. Combe's excellent little work on "The Management of Infancy."—Similar facts are recorded by other writers. Mr. Wardrop mentions ("Lancet," No. 516), that having removed a small tumor from behind the ear of a mother, all went well, until she fell into a violent passion; and the child, being suckled soon afterwards, died in convulsions. He was sent for hastily to see another child in convulsions, after taking the breast of a nurse who had just been severely reprimanded; and he was informed by Sir Richard Croft that he had seen many similar instances. Three others are recorded by Burdach ("Physiologie," § 522); in one of them, the infant was seized with convulsions on the right side, and hemiplegia on the left, on sucking immediately after its mother had met with some distressing occurrence. Another case was that of a puppy, which was seized with epileptic convulsions, on sucking its mother after a fit of rage.

but by another woman of placid temperament, who has reared healthy children of her own.

951. Other Secretions are in like manner vitiated by mental Emotions, although the influence is not always so manifest. Thus, the halitus from the lungs is sometimes almost instantaneously affected by bad news, so as to produce fetid breath. A copious secretion of fetid gas not unfrequently takes place in the intestinal canal, under the influence of any disturbing emotion; or the usual fluid secretions from its walls are similarly disordered. The tendency to Defecation which is commonly excited under such circumstances is not, therefore, due simply to the relaxation of the sphincter ani (as commonly supposed); but is partly dependent on the unusually stimulating character of the fæces themselves. The same may be said of the tendency to Micturition, which is experienced under similar conditions; the change in the character of the urine becoming perceptible enough among many animals, in which it acquires a powerfully disagreeable odor under the influence of fear, and thus answers the purpose which is effected in others by a peculiar secretion. It is a prevalent, and perhaps not an ill-founded opinion that melancholy and jealousy have a tendency to increase the quantity, and to vitiate the quality of the biliary fluid; perhaps the disorder of the organic function is more commonly the source of the former emotion, than its consequence; but it is certain that the indulgence of these feelings produces a decidedly morbid effect by disordering the digestive processes, and thus reacts upon the nervous system by impairing its healthy nutrition.

952. The influence of the Nervous System upon those formative processes which constitute the function of Nutrition is less evident than it is upon the Secretory operations; and the nature of this influence is rather to be inferred from the results of its withdrawal, than to be demonstrated in any more direct manner. These results are chiefly to be seen in the altered nutrition of parts exposed to external impressions, as the integuments generally, but particularly those of the extremities; and they may be generally expressed by the statement, that the withdrawal of nervous influence from a part renders it less able to withstand the destructive influence of physical agencies. It is certain, however, that a great part of the injurious effects which may be observed to follow injuries of the nerves of the extremities experimentally inflicted, are traceable to want of power on the part of the animal, consequent upon the paralyzed state of the limbs, to withdraw them from irritating impressions (§ 394, *note*), and must not be attributed to any direct deterioration of the formative operations, consequent upon the withdrawal of nervous agency. The following case, however, which is given by Mr. Paget¹ on the authority of Mr. Hilton, seems more unequivocally to establish this connection: "A man was at Guy's Hospital, several years ago, who, in consequence of a fracture at the lower end of the radius, repaired by an excessive quantity of new bone, suffered compression of the median nerve. He had ulceration of the thumb, and of the fore and middle fingers, which had resisted various treatment, and was cured only by so binding the wrist that the parts on the palmar aspect being relaxed, the pressure on the nerve was removed. So long as this was done, the ulcers became and remained well; but as soon as the man was allowed to use his hand, the pressure on the nerves was removed, and the ulceration in the parts supplied by it returned." Mr. Paget also mentions the following curious case: "A lady, who is subject to attacks of what are called nervous headaches, always finds next morning that some patches of her hair are white, as if powdered with starch. The change is effected in a night; and in a few days after, the hairs gradually regain their dark brownish color."—That such effects are rather to be attributed to the loss or

¹ "Lectures on Nutrition," &c., in "Medical Gazette," 1847.

perversion of the influence of the Sympathetic System, than to that of the Cerebro-spinal, would appear from the fact noticed by Magendie and Longet, that destructive inflammation of the eye ensues more quickly after division of the Trigeminal nerve in front of the Gasserian ganglion, than when the division is made through the roots of the nerve, between that ganglion and the brain; the sympathetic filaments which exist largely in this nerve being interrupted in their course to the tissues in the former case, but not in the latter. And this inference would be supported by the fact that increased secretion of tears and mucus from the eye, and increased redness of the conjunctiva, are ordinary consequences of extirpation of the superior cervical ganglion of the sympathetic in dogs; and also with the general result of observation, that atrophy of parts supplied by the spinal nerves is much greater when the sensory as well as the motor roots are involved, than when the latter alone are paralyzed—it being through the ganglia, and connecting filaments of the former that the true Sympathetic fibres become incorporated with the Cerebro-spinal nerves.

953. The influence of the state of *expectant attention*, in modifying the processes of Nutrition and Secretion, is not less remarkable than we have already seen it to be in the production or modification of Muscular movements (§ 923). It seems certain that the simple direction of the consciousness to a part, independently of emotional excitement, but with the expectation that some change will take place in its organic activity, is often sufficient to induce such an alteration; and would probably always do so, if the concentration of the attention were sufficient. The most satisfactory exemplification of this principle has been given by the experiments of Mr. Braid, who has succeeded in producing very decided changes in the secretions of particular organs, by the fixation of the attention upon them in the “hypnotic” state (§ 827). Thus he brought back an abundant flow of milk to the breast of a female who was leaving off nursing from defect of milk, and repeated the operation upon the other breast a few days subsequently, after which the supply was abundant for nine months; and in another instance he induced the catamenial flow on several successive occasions, when the usual time of its appearance had passed. It is not requisite, however, to produce the state of Somnambulism for this purpose, if the attention can be sufficiently drawn to the subject in any other mode; thus Mr. Braid has repeatedly produced the last-named result on a female who possessed considerable power of mental concentration, by inducing her to fix her thoughts upon it for ten or fifteen minutes, so as to bring on a state of reverie.—Now the effects which are producible by this *voluntary* direction of the consciousness to the result, are doubtless no less producible by that *involuntary* fixation of the attention upon it, which is consequent upon the eager expectation of benefit from some curative method in which implicit confidence is placed, or, on the other hand, upon that anticipation of unpleasant results in which some individuals are led to indulge by the morbid state of their feelings. It is to such a state that we may fairly attribute most, if not all, the cures which have been worked by what is popularly termed the “imagination.” The cures are real facts, however they may be explained; and there is scarcely a malady in which amendment has not been produced not merely in the estimation of the patient, but in the more trustworthy opinion of medical observers, by practices which can have had no other effect than to direct the attention of the sufferer to the part, and to keep alive his confident expectation of the cure. The “charming-away” of warts by spells of the most vulgar kind, the imposition of royal hands for the cure of the “evil,” the pawings and strokings of Valentine Greatrakes, the manipulations practised with the “metallic tractors,” the invocations of Prince Hohenlohe, *et hoc genus omne*—not omitting the globulistic administrations of the Infinitesimal doctors, and the manipulations of the Mesmerists, of our own times—have all worked to the same end,

and have all been alike successful. It is unquestionable that, in all such cases, the benefit derived is in direct proportion to the *faith* of the sufferer in the means employed; and thus we see that a couple of bread pills will produce copious purgation, and a dose of *red* poppy syrup will serve as a powerful narcotic (as has happened within the personal knowledge of the Author), if the patient have been led to feel a sufficiently confident expectation of the respective results of these medicaments.¹—This state of confident expectation, however, may operate for evil, no less than for good. A fixed belief that a mortal disease had seized upon the frame, or that a particular operation or system of treatment would prove unsuccessful, has been in numerous instances (there is no reason to doubt) the direct cause of a fatal result. And thus the morbid feelings of the hypochondriac, who is constantly directing his attention to his own fancied ailments, tend to induce real disorder in the action of the organs which are supposed to be affected. In the same category, too, may be placed those instances (to which alone any value is to be attached), wherein a *strong and persistent impression* upon the mind of a mother has appeared to produce a corresponding effect upon the development of the *fœtus in utero*. In this case, the effect (if admitted to be really exerted) must be produced upon the maternal blood, and transmitted through it to the fœtus; since there is no nervous communication between the parent and offspring. There is no difficulty, however, in understanding how this may occur, after what has been stated on a former occasion (§ 203) of the influence of minute alterations in the condition of the blood, in determining local alterations of nutrition.

CHAPTER XIX.

OF GENERATION.

1.—*General Character of the Function.*

954. HAVING now passed in review the various operations which are concerned in maintaining the life of the *individual*, we have next to proceed to those which are destined to the perpetuation of the *race*, by the production of successive generations of similar beings. In Man and the higher animals, this function is performed in only one method; namely, by the development of an *ovum* in the Female, which, when fertilized by the *spermatozoon* of the Male, gives origin within itself to a new being; the embryo, if supplied with the requisite nourishment, warmth, &c., gradually evolving itself into the likeness of its parents. This process appears, as will presently be shown, to be performed in a manner essentially the same, not only throughout the Animal kingdom, but through the Vegetable kingdom also. But among Plants, and the lower tribes of Animals, we find an additional method of propagation; for, without any

¹ It is commonly said that these effects are produced by the *imagination*; but this only serves to induce the belief that the *sham* remedy is one of *real* efficacy; and it is the state of "expectant attention" which is the *immediate* operating agent, and which is necessary to the result.—In whatever mode this can be induced, the effect will be the same. Thus Dr. Haygarth, of Bath (in conjunction with Mr. Richard Smith, of Bristol), tested the value of the "metallic tractors," by substituting two pieces of wood painted in imitation of them, or even a pair of tennenny nails disguised with sealing-wax, or a couple of slate-pencils; which they found to possess all the virtues that were claimed for the real instruments, because the state of "expectant attention" was equally induced by either.

sexual process whatever, new beings may be formed by *gemmation* or "budding" from the parent-stock, and these, gradually becoming less and less dependent upon it, at last detach themselves and maintain a separate existence. Now this process may be regarded as essentially the same with that of the multiplication of cells by *subdivision*, which we have seen to be the most common mode of propagation in the simplest cellular Plants (§ 104); and it differs from the ordinary operations of growth and development in no other particular than this—that the newly-formed structure, instead of remaining as a constituent and dependent part of the parental fabric, is capable of living independently of it, and of thus existing as a distinct individual when spontaneously or artificially detached. Among the higher tribes of animals, as in Man, this mode of multiplication of individuals does not present itself, at least in the adult state; for in no instance do we find that a part of the body separated from the rest can develop the organs which are necessary for the sustenance of its existence; and the power which the organism possesses of regenerating parts which it has lost by disease or accident is restrained within very narrow limits (§ 599). But there is good ground to believe that such a multiplication by subdivision *may* take place at that earliest period of embryonic life at which the germ is nothing else than a mass of cells, wherein no distinction of parts has as yet manifested itself; and that the production of two complete individuals, only held together by a connecting band, may arise from some cause which determines the subdivision of the germinal mass, at the period when its grade of development corresponds with that of the Hydra or Planaria.¹ And this view of the case is confirmed by the facts already stated (§ 599), in regard to the higher degree of the regenerating power during embryonic life, infancy, and childhood, as compared with that which remains after the development of the fabric has been completed.

955. We have now to consider, however, the proper act of Generation, which uniformly involves the union of the contents of two peculiar cells, which may be designated "sperm-cells," and "germ-cells."² Recent discoveries render it almost certain that this true generative process occurs throughout the Vegetable kingdom, and is not confined, as was formerly supposed, to Flowering Plants.³ It appears to take place in three modes; which are all, however, but variations of one fundamental plan: 1. In the simplest Cellular Plants, in which every cell appears to possess the same endowments, so that there is no kind of specialization of function, the generative act consists in the "conjugation" of two of the ordinary cells, between which no difference can be traced. In what may be considered the lowest types of this process, *both* cells discharge their contents, and the new body or *sporangium* is formed between them by the mixture of their "endochromes;" each cell appearing to have precisely the same share in the process, so that no distinction of "sperm-cells" and "germ-cells" can be said here to exist. This, however, is precisely what might be expected, when it is remembered that no distinction presents itself between any other organs, such as the root and leaf; each cell having endowments to all appearance identical with those of the rest of the mass. But the generative process, in this which may be regarded as its simplest and most essential form, shows itself to be the precise counterpart of the process of "fission" already described (§ 104); for as in the latter one cell divides itself into equal halves, between which no difference can be traced, so, in the act of "conjugation," the contents of two cells, ap-

¹ See Prof. Allen Thomson on "Double Monstrosity," in the "Edinb. Monthly Journ.," June and July, 1844; and Prof. Vrolik's Article "Teratology" in the "Cyclop. of Anat and Phys.," vol. iv.

² These terms are adopted from Prof. Owen. See his "Lectures on Parthenogenesis," London, 1849.

³ For a general account of these discoveries, see the "British and Foreign Medico-Chirurgical Review," Oct. 1849; and "Princ. of Phys., Gen. and Comp.," CHAP. XVIII., *Am. Ed.*

parently similar, reunite, and form but a single new cell between them. In virtue of that union, a new force seems to be developed, which leads to the multiplication of this first cell by repeated subdivision, until the germ-force is expended, when a fresh conjugation occurs. This reunion of the cell contents may take place, either by the rupture of both cells and the discharge of their endochromes, around which, after their admixture, a new cell-wall is formed (Fig. 236, A, 1), or by the formation of a direct communication from the interior of one to that of the other; in which latter case the union of the two endochromes may take place either in the connecting channel (A, 2), or in one of the cells of the pair (A, 3), within which the sporangium is formed and matured. It is in certain of the Desmidiæ and Zygnemata that we meet with this latter type; which presents us with the first distinction between the "sperm-cell" and the "germ-cell."—2. In the higher Algæ, and in all the superior Cryptogamia, the process is effected by the agency of moving filaments, precisely resembling the spermatozoa of Animals, and developed within special "sperm-cells" in a mode precisely the same with the evolution of the spermatozoa of Animals (§ 959); these appear to find their way to the germ-cells, which are sometimes developed within the same receptacles, sometimes in distinct receptacles on the same plant, and sometimes in different plants; and as the result of their contact with the germ-cells, the embryo originates in the interior of the latter (Fig. 236, B). This embryo, in the lower Cryptogamia, is at once cast upon its own resources;

Fig. 236.

Diagram representing the three principal forms of the *Generative Process in Plants*: A, conjugation of inferior Cryptogamia; formation of the sporangium, *b*, by admixture of the discharged endochromes of the parent-cells, *a, a*. 2, production of the sporangium, *b*, within a dilatation formed by the union of the two parent-cells. 3, production of the sporangium, *b*, by the passage of the endochrome of cell *a* into that of cell *a**, marking out a sexual difference. B, fertilization of germ in higher Cryptogamia; *a*, sperm-cell discharging its spiral filament; *a**, germ-cell, against which one of these filaments is impinging; *b*, germ produced by their contact. C, fertilization of germ in Phanerogamia; *a*, sperm-cell, or pollen-grain, sending its prolonged tube down the style, until it reaches *a**, the germ-cell, inclosed in the ovule, the section of whose coats is shown at *c*; from the contact of the two, is produced the germ *b*.

whilst in the higher it is nourished, during its early development, by food supplied to it by the parent. In no case, however, does the parent appear to furnish that accumulation of nutritive matter for the development of the product of the germ-cell, which, when included in a common envelop with it, would constitute a true "seed."—3. In the Flowering Plants, the "sperm-cell" (or pollen-grain) does not evolve a self-moving filament, as in the Cryptogamia; but puts forth a long tube, which, insinuating itself between the soft loose tissue of the "style,"

conveys the fertilizing influence to the "germ-cell" (or embryonic vesicle of the ovule) after a different fashion (Fig. 236, c); still, however, fulfilling the same essential purpose as that which the simple "conjugation" of the lowest *Algæ* effected, namely, the mingling of the contents of the "sperm-cell" and "germ-cell," which takes place by transudation through the thin membranes of the pollen-tube and of the embryonic vesicle. The germ-cell is here surrounded by a mass of nutritious matter, which, with the embryo, constitutes the "seed;" and it is upon this store, that the young plant subsists during the early stages of its development.

956. The "act of Generation" in animals may be said to combine the principal features of the second and third of the above methods; for, as in the higher *Cryptogamia*, the "sperm-cells" of Animals seem invariably to form the self-moving filaments known as *Spermatozoa*; whilst the "germ-cells," instead of being naked (as in the *Cryptogamia*), are surrounded (as in Flowering Plants) by a mass of nutriment destined to serve for the early development of the embryo; this mass with its contained germ-cell being known as the *ovule* before it has been fertilized, and as the *ovum* or egg after fecundation has taken place. There is a great difference, however, among the different tribes of Animals, as to the degree of assistance thus afforded to the embryo; the general rule being, that the higher the form which the embryo is ultimately to attain, the longer is it supported by its parent. Hence we find the embryos of most Invertebrated animals coming forth from the egg in a condition very much unlike their perfect type, and only acquiring this after a long succession of subsequent alterations, which frequently involve a complete change of form, or *metamorphosis*. In Fishes, however, the embryo, though far from having completed its embryonic development at the time of its emersion from the egg, does not differ so widely from the adult type. In Birds, there is a provision for a much more advanced development; the store of nutritious matter, or "yolk," being so large as to allow the whole series of changes requisite for the formation of the complete chick to take place before it leaves the egg. In the *Mammalia*, on the contrary, the quantity of yolk contained in the ovum is very small, but the embryo is only dependent upon it for the materials of its increase during the earliest stages of its evolution; for it speedily forms a special connection with the parent structure, by means of which it is enabled to receive a continual supply of newly-prepared aliment, so as to be supported at the expense of this until far advanced in its development. Some approaches to this arrangement are met with among certain of the lower Animals, but it is only in the higher *Mammalia* that it is completely carried out; and it is only in this class, too, that we find a supplemental provision for the nutrition of the offspring after it has come forth into the world. In many of the lower tribes of Animals, the fertilization of the ova is accomplished without any sexual congress; the spermatic fluid effused by the male coming into direct contact with the ova previously deposited by the female; but in all the higher tribes, as in Man, the spermatic fluid is conveyed into the oviducts of the female, that it may impregnate the ovum shortly after it has quitted the ovary, or even before its final escape from it. —With these general views, we shall now be prepared to examine into the history of the act of Generation in Man, and to consider the share which each sex has in its performance.

2.—Action of the Male.

957. The Spermatic fluid of the Male is secreted by glandular organs, known as *Testes*. Each of these consists of several lobules which are separated from each other by processes of the *Tunica Albuginea* that pass down between them, and also by an extremely delicate membrane (described by Sir A. Cooper under

the name of *Tunica Vasculosa*) consisting of minute ramifications of the spermatic vessels united by areolar tissue. Each lobule is composed of a mass of convoluted *tubuli seminiferi*, throughout which bloodvessels are minutely distributed. The lobules differ greatly in size, some containing one, and others

A view of the minute structure of the Testis: 1, 1, tunica albuginea; 2 2, corpus Highmorianum; 3, 3, tubuli seminiferi convoluted into lobules; 4, vasa recta; 5, rete testis; 6, vasa efferentia; 7, coni vasculosi constituting the globus major of the epididymis; 8, body of the epididymis; 9, its globus minor; 10, vas deferens; 11, vasculum aberrans, or blind duct.

many of the tubuli; the total number of the lobules is estimated at about 450 in each testis, and that of the tubuli at 840. The convolutions of the tubuli are so arranged, that each lobule forms a sort of cone, the apex of which is directed towards the Rete Testis. It is difficult to trace the free extremities of the Seminiferous tubes, owing to the frequency of their anastomoses with each other; in this respect, therefore, the structure of the testis accords closely with that of the Kidney. The diameter of the tubuli is, for the most part, very uniform; in the natural condition they seem to vary from about the 1-195th to the 1-170th of an inch; but when injected with mercury, they are distended to a size nearly double the smaller of these dimensions. When they have reached to within a line or two of the rete testis, they cease to be convoluted, several unite together into tubes of larger diameter, and these enter the rete testis under the name of *tubuli recti*. The *rete testis* consists of from seven to thirteen vessels, which run in a waving course, anastomose with each other, and again divide, being all connected together. The *vasa efferentia* which pass to the head of the epididymis are at first straight, but soon become convoluted, each forming a sort of cone, of which the apex is directed towards the rete testis, the base to the head of the epididymis. The number of these is stated to vary from nine to thirty; and their length to be about eight inches. The *epididymis* itself consists of a very convoluted canal, the length of which is about twenty-one feet. Into its lower extremity, that is, the angle which it makes where it terminates in the vas deferens, is poured the secretion of the *vasculum aberrans* or

appendix; which seems like a testis in miniature, closely resembling a single lobule in its structure. Its special function is unknown.—The fluid secreted by

the Testis is thick, tenacious, and of a grayish or yellowish color. It is mingled, during or before emission, with fluid secreted by the Prostate, Cowper's gland, &c.; and it cannot, therefore, be obtained pure but by drawing it from the tes-

ticle itself; hence no accurate analysis can be made of it in the Human subject. The peculiar odor which the Semen possesses does not appear to belong to the proper spermatic fluid; but is probably derived from one or other of the secretions with which it is mingled. The chemical analyses which have been made of this fluid are all defective, inasmuch as they do not distinguish the real secretion of the testes from the mucus, prostatic fluid, &c., with which it is mingled. It may be stated, however, that it has an alkaline reaction, and contains albumen, with a peculiar animal principle termed *Spermatin*; and also saline matter, consisting chiefly of *muriates* and *phosphates*, especially the latter, which form crystals when the fluid has stood for some little time.

958. The essential peculiarity of the Spermatic fluid consists in the presence of a large number of very minute bodies, only discernible with a high power of the Microscope; and these, in ordinary cases, remain in active motion for some time after they have quitted the living organism. The Human Spermatozoon (of which representations are given in Plate I., Fig. 1) consists of a little oval flattened "body" between the 1-600th and the 1-800th of a line in length, from which proceeds a long filiform "tail," gradually tapering to the finest point, of 1-50th or at most 1-40th of a line in length. The whole is perfectly transparent; and nothing that can be termed structure can be satisfactorily distinguished within it. Its movements are principally executed by the tail, which has a kind of vibratile undulating motion. They may continue for many hours after the emission of the fluid; and they are not checked by its admixture with other secretions, such as the urine and the prostatic fluid. Thus, in cases of nocturnal emission, the Spermatozoa may not unfrequently be found actively moving through the urine in the morning; and those contained in the seminal fluid collected from females that have just copulated, are frequently found to live many days. Their presence may be readily detected by a Microscope of sufficient power, even when they have long ceased to move, and are broken into fragments; and the Physician and the Medical Jurist will frequently derive much assistance from an examination of this kind. Thus, cases are of no uncommon occurrence, especially among those who have been too much addicted to sexual indulgence, in which seminal emissions take place unconsciously and frequently, and produce great general derangement of the health; and the true nature of the complaint is obscure, until the fact has been detected by ocular examination. Again, in charges of rape, in which evidence of actual emission is required, a microscopic examination of the stiffened spots left on the linen will seldom fail in obtaining proof, if the act have been completed: in such cases, however, we must not expect to meet with more than fragments of Spermatozoa; but these are so unlike anything else, that little doubt need be entertained regarding them. It has been proposed to employ the same test in juridical inquiries respecting doubtful cases of death by suspension, seminal emissions being not unfrequent results of this kind of violence; but there are many obvious objections which should prevent much confidence being placed in it.¹

959. The mode of evolution of the Spermatozoa, first discovered by Wagner, and more perfectly elucidated by Kölliker, is such as to indicate that these bodies are true products of the formative action of the organs in which they are found, and cannot be ranked (as they long were) in the same category with *Animalcules*. They are developed in the interior of cells, or "vesicles of evolution," such as are visible in the seminal fluid in various stages of development (Plate I., Fig. 2, A, B, C), and have been known under the name of "seminal granules." These appear to have been themselves formed within parent-cells, which are probably to be regarded as the epithelial cells of the

¹ See the Author's Article "*Asphyxia*," in the "*Library of Practical Medicine*," and the authorities there referred to.

tubuli seminiferi; constituting, like the analogous cells of other glands, the essential elements of the spermatie apparatus.¹ These parent-cells are sometimes observed to contain but a single "vesicle of evolution," as shown at D; but more commonly three, four, six, or seven are to be seen within them (E). When taken from a body recently dead, and examined without being treated with water or any other agent, they are quite pellucid, and exhibit a delicate contour, with perfectly homogeneous contents; very speedily, however, a sort of coagulation takes place within them, by which their contents are rendered granular. Each of these "vesicles of evolution" gives origin to a spermatozoon, and to one only; the earliest stages of its development have not yet been distinctly made out, since it does not at first exhibit those sharp distinct contours, dependent on its great refractive power, which afterwards distinguish it; but it is seen lying in the interior of the cell as a slight linear shadow, at first partly hidden by the surrounding granules (Fig. 3, B), but afterwards without any such obscuration. When the vesicle is completely matured, it bursts, and gives exit to the contained spermatozoon, which, thenceforth, in the Mammalia, usually moves freely in the spermatie fluid; in Birds, however, it is more common for the parent-cells to retain the vesicles of evolution during the development of the Spermatozoa within the latter; so that when these set free the Spermatozoa, they are still enveloped by the parent-cell. In this condition they have a tendency to aggregation in bundles; and these bundles are finally liberated by the rupture of the parent-cell, after which the individual spermatozoa separate from one another. Such bundles may be occasionally seen in the Human semen.—That the Spermatozoa are the essential elements of the spermatie fluid, may be reasonably inferred from several considerations. There are some cases in which the "liquor seminis" is altogether absent, so that they constitute the sole element of the semen; whilst, on the other hand, they are never wanting in the semen of animals capable of procreation; but are absent, or imperfectly developed, in the semen of hybrids, which are nearly or entirely sterile. Moreover, we have every reason to believe that, in the higher animals, the absolute contact of the spermatozoa with the ovum is requisite for its fecundation; whilst, on the other hand, if the spermatozoa be carefully removed from the liquor seminis by filtration, the latter is found to be entirely destitute of fertilizing power.²—It is interesting to remark that the perfectly developed spermatozoa possess the same chemical composition with the epithelial tissues in general.³

960. The power of procreation does not usually exist in the Human Male, until the age of from 14 to 16 years; and it may be considered probable that no Spermatozoa are produced until that period, although a fluid is secreted by the testes. At this epoch, which is ordinarily designated as that of Puberty, a considerable change takes place in the bodily constitution: the sexual organs undergo a much-increased development; various parts of the surface, especially the chin and the pubes, become covered with hair; the larynx enlarges, and the voice becomes lower in pitch, as well as rougher and more powerful; and new feelings and desires are awakened in the mind. Instances, however, are by no means rare, in which these changes take place at a much earlier period; the full development of the generative organs, with manifestations of the sexual

¹ In the Hydra and other Zoophytes, such cells are found imbedded in the general substance of the body, instead of being developed within a special organ.

² This point has been completely established by the researches of Mr. Newport ("Phil. Trans.," 1851), who has repeated and confirmed the experimental results previously obtained by Spallanzani and by Prevost and Dumas.

³ For the latest researches on the development, &c., of the Spermatozoa, see the elaborate Article "Semen," in the "Cyclop. of Anat. and Physiol.," by Drs. Wagner and Leuckardt.

passion, having been observed in children of but a few years old. The procreative power may last, if not abused, during a very prolonged period. Undoubted instances of virility at the age of more than 100 years are on record; but in these cases, the general bodily vigor was preserved in a very remarkable degree. The ordinary rule seems to be that sexual power is not retained by the male to any considerable amount, after the age of 60 or 65 years.—To the use of the sexual organs for the continuance of his race, Man is prompted by a powerful instinctive desire (§ 772), which he shares with the lower animals. This Instinct, like the other propensities, is excited by sensations; and these may either originate in the sexual organs themselves, or may be excited through the organs of special sensation. Thus in Man it is most powerfully aroused by impressions conveyed through the sight or the touch; but in many other animals, the auditory and olfactive organs communicate impressions which have an equal power; and it is not improbable that, in certain morbidly-excited states of feeling, the same may be the case in ourselves. That local impressions have also a very powerful effect in exciting sexual desire, must have been within the experience of almost every one; the fact is most remarkable, however, in cases of Satyriasis, which disease is generally found to be connected with some obvious cause of irritation of the generative system, such as pruritus, active congestion, &c. That some part of the Encephalon is the seat of this as of other instinctive propensities, appears from the considerations formerly adduced; but that the Cerebellum is the part in which this function is specially located, cannot be regarded as by any means sufficiently proved (§§ 767—772). The instinct, when once aroused (even though very obscurely felt), acts upon the mental faculties and moral feelings; and thus becomes the source, though almost unconsciously so to the individual, of the tendency to form that kind of attachment towards one of the opposite sex which is known as *love*. This tendency cannot be regarded as a simple passion or emotion, since it is the result of the combined operations of the reason, the imagination, and the moral feelings; and it is in this engraftment (so to speak) of the psychical attachment, upon the mere corporeal instinct, that a difference exists between the sexual relations of Man and those of the lower animals. In proportion as the Human being makes the temporary gratification of the mere sexual appetite his chief object, and overlooks the happiness arising from spiritual communion, which is not only purer but more permanent, and of which a renewal may be anticipated in another world—does he degrade himself to the level of the brutes that perish. Yet how lamentably frequent is this degradation!

961. When impelled by sexual excitement, the Male seeks intercourse with the Female, the erectile tissue of the genital organs becomes turgid with blood (§ 534), and the surface acquires a much increased sensibility; this is especially acute in the Glans penis. By the friction of the Glans against the rugous walls of the Vagina, the excitement is increased; and the impression which is thus produced at last becomes so strong, that it calls forth, through the medium of the Spinal Cord, a reflex contraction of the muscles which surround the Vesiculæ Seminales. These receptacles discharge their contents (partly consisting of semen and partly of a secretion of their own) into the Urethra; and from this they are expelled with some degree of force, and with a kind of convulsive action, by its own Compressor muscles. Now although the sensations concerned in this act are ordinarily most acutely pleasurable, there appears sufficient evidence that they are by no means essential to its performance; and that the impression which is conveyed to the Spinal Cord need not give rise to a sensation, in order to produce the reflex contraction of the Ejaculator muscles (§ 723). The high degree of nervous excitement which the act of coition involves produces a subsequent depression of corresponding amount; and the too frequent repetition of it is productive of consequences very injurious to the

general health. This is still more the case with the solitary indulgence, which (it is to be feared) is practised by too many youths; for this, substituting an unnatural degree of one kind of excitement for that which is wanting in another, cannot but be still more trying to the bodily powers. The secretion of seminal fluid being, like other secretions, very much under the control of the nervous system, will be increased by the continual direction of the mind towards objects which awaken the sexual propensity (§ 948, *note*); and thus, if intercourse be very frequent, a much larger quantity will altogether be produced, although the amount emitted at each period will be less. The formation of the secretion seems of itself to be a much greater tax upon the corporeal powers than might have been supposed *a priori*: and it is a well-known fact that the highest degree of bodily vigor is inconsistent with more than a very moderate indulgence in sexual intercourse; whilst nothing is more certain to reduce the powers, both of body and mind, than excess in this respect. These principles, which are of great importance in the regulation of the health, are but results of the general law, which prevails equally in the Vegetable and Animal kingdoms—that the Development of the Individual, and the Reproduction of the Species, stand in an inverse ratio to each other.

3.—Action of the Female.

962. The essential part of the Female Generative system is that in which the Ova are prepared; the other organs are merely accessory, and are not to be found in a large proportion of the Animal kingdom. In many of the lower animals, the Ovaria and Testes are so extremely like each other, that the difference between them can scarcely be distinguished; and the same is true regarding the condition of these organs in Man, at an early period of development. The fact is one of no small interest. In many of the lower animals, the Ovarium consists of a loose tissue containing many cells, in which the Ova are formed, and from which they escape by the rupture of the cell-walls; in the higher animals, as in the Human female, the tissue of the Ovarium is more compact, forming what is known as the *stroma*; and the Ova, except when they are approaching maturity, can only be distinguished in the interstices of this, by the

Fig. 241.

aid of a high magnifying power. The Ovum in all Vertebrated animals is produced within a capsule or bag, the exterior of which is in contact with the stroma of the ovarium; this has been termed, in Mammalia, the *Graafian vesicle*,

after the name of its first discoverer; but the more general and appropriate designation of *Ovisac* has been given to it by Dr. Barry, who has shown that it exists in other classes of Vertebrata. Between the Ovum and the Ovisac, in Oviparous animals, there is scarcely any interval; but in the Mammalia, a large amount of granular matter (composed of nucleated cells, loosely aggregated together) is present; being especially found adherent to the lining of the ovisac, to which it forms a sort of epithelium, or internal tunic, known as the *membrana granulosa*; whilst it also forms a disk-like investment to the ovum, which is termed the *discus proligerus*. The membrane which incloses the yolk in Mammalia has received, on account of its thickness and peculiar transparency, the distinctive appellation of *zona pellucida* (Fig. 242, *m v*).—The yolk, or *vitellus* (*j*), which is composed of albumen and oil-particles, with traces of cells, is very small in the Mammalian ovum, its function being limited to the sustenance of the germ during its earliest period of development; and it corresponds rather with that part of the yolk of the egg of the higher Ovipara which has been distinguished as the “germ-yolk,” in consequence of its direct participation in the formation of the germinal substance than with that which has been termed the “food-yolk,” as not being incorporated with the germ, but being destined for its subsequent nutrition by undergoing conversion into blood.¹ Occupying the centre of the vitelline mass, in the immature ovulum, is a peculiar cell, very different in its aspect from the surrounding substance, which is termed the *germinal vesicle* (Fig. 242, *v g*); and this has a very distinct nucleus (*t g*) known as the *germinal spot*. This cell must be considered as the essential part of the ovum, and as homologous with the “germ-cell” or “embryonic vesicle” of the Vegetable ovule.—The Human Ovum is extremely minute; not measuring above 1-120th of an inch in diameter, and being sometimes of no more than

Fig. 242.

Constituent parts of Mammalian Ovum: A, entire; B, ruptured, with the contents escaping;—*m v*, vitelline membrane; *j*, yolk; *v g*, germinal vesicle; *t g*, germinal spot.

half that size. The diameter of the germinal vesicle of the human ovum has not yet been ascertained, owing to the difficulty of isolating it from the yolk; in the ovum of the rabbit, it is about 1-720th of an inch; and that of the germinal spot, in the Mammalia generally, is from 1-3600th to 1-2400th of an inch.

963. It appears, from the researches of Valentin and Biscoff, that the Graafian vesicle, or Ovisac, is formed previously to the Ovum, which is subsequently developed in its interior; and it would seem that we may regard it as

¹ It has been recently maintained by Reinhardt that the Bird's egg is really homologous with the Graafian vesicle of the Mammal, and its entire contents; the “food-yolk” of the former being represented in the latter by the cellular substance surrounding the *zona pellucida*, which is afterwards developed into the corpus luteum.

a *vesicle of evolution* for the ovum, in the same way that the gland-cells of the testis act as vesicles of evolution for the spermatozoa. The development of ovisacs commences at a very early period of life; in the ovaries of some animals, they can be detected almost as soon as these organs are themselves evolved; and in all, they show themselves soon after birth. In Fig. 4 (Plate I.), is represented the condition of the Graafian vesicles in various stages of development, as they are seen imbedded in the fibrous stroma of the ovarium, in a thin slice from the ovary of a sow three weeks old; by which time the germinal vesicle, which is the first part of the ovum that makes its appearance, has been developed in their interior. The germinal vesicle, which distinctly shows the germinal spot, is surrounded by an assemblage of granules, which is the first indication of a yelk; and around these the zona pellucida appears to be subsequently developed. The Ovum at first occupies the centre of the Graafian vesicle, but it subsequently removes to its periphery; and, when the contents of the ovisac are undergoing maturation, prior to their escape, the ovum is always found on the side of it nearest to the surface of the ovary. The proper ovisac, whose wall is formed of a non-vascular membrane, is surrounded by a vascular layer, which is formed by a condensation of the ordinary stroma of the ovarium; it is this, which is reckoned as the outer layer of the Graafian vesicle.

964. A continual change seems to be taking place in the contents of the ovarium, during the greater part of life; certain of the ovisacs or Graafian vesicles, and their contents, successively arriving at maturity, whilst others degenerate and die. According to the valuable inquiries of Dr. Ritchie,¹ it appears that, even during the period of childhood, there is a continual rupture of ovisacs and discharge of ova, at the surface of the ovarium. The Ovaria are studded with numerous minute copper-colored maculæ, and their surface presents delicate vesicular elevations, which are occasioned by the most matured ovisacs; the dehiscence of these takes place by minute punctiform openings in the peritoneal coat, and no cicatrix is left. At the period of puberty, the stroma of the ovarium is crowded with ovisacs; which are still so minute, that in the Ox (according to Dr. Barry's computation) a cubic inch would contain 200 *millions* of them. The greatest advance is seen in those which are situated nearest the surface of the Ovarium; and in such the Graafian vesicle, with its two coats, may be distinctly traced. In those animals whose aptitude for conception is periodical, the development of the ova to such a degree that they become prepared for fecundation is periodical also. This development is made evident, when the parts are examined in an animal which is "in heat," by the projection of the Graafian vesicles from the surface (Fig. 243); and it consists not merely in an increase of size, but in certain internal changes presently to be described.

965. In the Human female, the period of Puberty, or of commencing aptitude for procreation, is usually between the 13th and 16th years; it is generally thought to be somewhat earlier in warm climates than in cold,² and in densely populated

of the extrusion of ova.

¹ "London Medical Gazette," 1844.

² It has been stated, by almost all physiological writers, that women (like fruits) reach maturity and that menstruation commences much earlier in hot climates, particularly between the tropics, than in temperate and very cold countries; from many elaborate and interesting papers which have been published within a few years, however, especially from those of Mr. Robertson, of Manchester (recently collected in his "Essays on Menstruation,

manufacturing towns than in thinly peopled agricultural districts. The mental and bodily habits of the individual have also considerable influence upon the time of its occurrence; girls brought up in the midst of luxury or sensual indulgence undergoing this change earlier than those reared in hardship and self-denial. The changes in which puberty consists are for the most part connected with the reproductive system. The external and internal organs of generation undergo a considerable increase of size; the mammary glands enlarge; and a deposition of fat takes place in the mammæ and on the pubes, as well as over the whole surface of the body, giving to the person that roundness and fulness, which are so attractive to the opposite sex at the period of commencing womanhood. The first appearance of the Catamenia usually occurs whilst these changes are in progress, and is a decided indication of the arrival of the period of puberty; but it is not unfrequently delayed much longer; and its absence is by no means to be regarded as a proof of the want of aptitude for procreation, since many women have borne large families, without having ever menstruated. The Catamenial discharge, as it issues from the uterus, appears to be nearly or quite identical with ordinary blood; but in its passage through the vagina, it becomes mixed with the acid mucus exuded from its walls, which usually deprives it of the power of coagulating. If the discharge should be profuse, however, a portion of its fibrin remains unaffected, and clots are formed. In cases in which, by the death of women at this period, an opportunity has been afforded for the examination of the lining membrane of the uterus during menstruation, it is found to be unusually turgid with blood, the veins in particular being much distended, and opening upon the internal surface by capillary orifices, to which valvules are occasionally found attached.¹ Hence it is scarcely correct to designate the menstrual flux as a "secretion;" although there is reason to think that it may carry off, besides blood, certain matters which would be appropriate to the formation of a decidual membrane, but which, if not so employed, become excrementitious.—The interval which usually elapses between the successive appearances of the discharge is about four weeks; and the duration of the flow is from three to six days. There is great variety, however, in this respect among the inhabitants in different climates, and among individuals; in general, the appearance is more frequent, and the duration of the flow greater, among the residents in warm countries, and among individuals of luxurious habits and relaxed frame, than among the inhabitants of colder climes, or among individuals inured to bodily exertion. The first appearance of the discharge is usually preceded and accompanied by considerable general disturbance of the system; especially pain in the loins and a sense of fatigue in the lower extremities; and its periodical return is usually attended with the same symptoms, which are more or less severe in different individuals.

966. Much discussion has taken place respecting the causes and purposes of the Menstrual flow; and recent inquiries have thrown much light upon them. The state of the female generative system, during its continuance, appears to be analogous to the *heat* of the lower animals, many of which have a sero-sanguinolent discharge at that period. There is good reason to believe that in the

and on Practical Midwifery," 1851), it would seem that the natural period of puberty in temperate climates occurs in a much more extended range of ages, and is much more equally distributed through that range, than others have alleged; and that in other countries the supposed parallel between plants and fruits does not hold good. The fact seems to be that this, like other *periodic* phenomena of warm-blooded animals, is but little influenced by external temperature, simply because the rate of growth and development, of which these phenomena are the exponents, is determined by the temperature of the body itself, not by that of the surrounding medium. Still it is quite possible that external warmth may have a slight influence in determining early puberty; since, as already shown, it tends to maintain a somewhat higher degree of bodily heat (§ 651).

¹ See Whitehead "On Abortion and Sterility," pp. 13—37.

Human female the sexual feeling becomes stronger at that epoch; and it is quite certain that there is a greater aptitude for Conception immediately before and after menstruation than there is at any intermediate period. Observations to this effect were made by Hippocrates, and were confirmed by Boerhaave and Haller; indeed coitus immediately after menstruation appears to have been frequently recommended as a cure for sterility, and to have proved successful. It is well known that, among many of the lower animals, the ova are entirely extruded by the female, before the spermatie fluid of the male reaches them; and that even in Birds, this occasionally takes place. This question has been made the subject of special inquiry by M. Raciborski; who affirms that the exceptions to the rule—that conception occurs immediately before or after, or during menstruation—are not more than 6 or 7 per cent. Indeed, in his latest work on this subject,¹ he gives the details of 15 cases, in which the date of conception could be accurately fixed, and the time of the last appearance of the catamenia was also known; and in all but one of them, the correspondence between the two periods was very close. Even in the exceptional case, the catamenia made their appearance shortly after the coitus; which took place at about the middle of the interval between the two regular periods. When conception occurs immediately before the menstrual period, the catamenia sometimes appear, and sometimes are absent; if they appear, their duration is generally less than usual. The fact that conception often takes place immediately *before* the last appearance of the catamenia (and not *after* it, as commonly imagined), is one well known to practical men.—Numerous cases have been collected by Mr. Girdwood, Dr. Robert Lee, MM. Gendrin, Negrier, Raciborski, and others, in which the menstrual period was evidently connected with the maturation and discharge of ova; but the most complete observations yet made upon this subject are those of Dr. Ritchie (loc. cit.). He states that about the period of puberty a marked change usually takes place in the mode in which the ovisacs discharge their contents; but that this change does not necessarily occur simultaneously with the first appearance of the catamenia; as, in some cases, the conditions which obtain in the period before puberty are extended into that of menstruation. The ovaries now receive a much larger supply of blood; and the ovisacs show a great increase in bulk and vascularity; so that, when they appear at the surface of the ovary, they present themselves as pisiform turgid elevations; and the discharge of their contents leaves a much larger cicatrix, and is accompanied by an effusion of blood into their cavity, with other subsequent changes, to be presently described. It would appear, however, that although such a discharge takes place *most frequently* at the menstrual period, yet the two occurrences are not necessarily coexistent; for menstruation may take place without any such rupture; whilst, on the other hand, the maturation and discharge of mature ova may occur in the intervals of menstruation, and even at periods of life when that function is not taking place. Perhaps the most correct general statement on the subject would be this: that there is a periodic return of Ovarian excitement, which *tends* to the maturation and extrusion of ovules, though it may not always reach that point; whilst there is also a periodic turgescence of the vessels of the lining membrane of the Uterus which *tends* to the production of a decidual membrane;—but that these two periods, though usually coincident, are not necessarily so; and that either change *may* occur without the concurrence of the other.

967. The duration of the period of aptitude for procreation, as marked by the persistence of the Catamenia, is more limited in Women than in Men, usually terminating at about the 45th year; it is sometimes prolonged, however, for ten or even fifteen years further; but cases are rare in which women

¹ "Sur la Ponte des Mammifères," Paris, 1844.

above 50 years of age have borne children. There is usually no menstrual flow during pregnancy and lactation; in fact, the cessation of the catamenia is generally one of the first signs, indicating that conception has taken place. But it is by no means uncommon for them to appear once or twice subsequently to conception; and in some women, there is a regular monthly discharge, though probably not of the usual secretion, through the whole period. Some very anomalous cases are on record, in which the catamenia never appeared at any other time than during pregnancy; and were then regular. The absence of the catamenia during lactation is by no means constant, especially if the period be prolonged; when the menstrual discharge recurs, it may be considered as indicating an aptitude for conception; and it is well known that, although pregnancy seldom recurs during the continuance of lactation, the rule is by no means invariable.

968. The function of the Female, during the coitus, is essentially passive. When the sexual feeling is strongly excited, there is a considerable degree of turgescence in the erectile tissue surrounding the vagina, and composing the greater part of the nymphæ and the clitoris; and there is an increased secretion from various glandular follicles.¹ But these changes are by no means necessary for effectual coition; since it is a fact well established, that fruitful intercourse may take place, when the female is in a state of narcotism, of somnambulism, or even of profound ordinary sleep. It has been supposed by some, that the os uteri dilates, by a kind of reflex action, to receive the semen; but of this there is no evidence. The introduction of a small quantity of the fluid just within the vagina appears to be all that is absolutely necessary for conception; for there are many cases on record, in which pregnancy has occurred, in spite of the closure of the entrance to the vagina by a strong membrane, in which but a very small aperture existed. That the spermatozoa make their

¹ The glands of Duverney have been very accurately described by Professor Tiedemann (1840), his attention having been directed to those organs by the late Dr. Fricke, of Hamburg. These glands are situated at either side of the entrance of the vagina, beneath the integument covering the inferior part of the vagina, as well as the superficial perineal fascia and the constrictor vaginae muscle. The space they occupy lies between the lower end of the vagina, the ascending ramus of the ischium, the crus clitoridis, and the erector clitoridis muscle. Superiorly are the fibres of the levator ani which are attached to the ischium, and behind these are the transversi-perinei muscles. They are surrounded by very loose cellular tissue. They are rounded, but somewhat elongated, being flat and bean-shaped. Their long diameter is from 5 to 10 lines; their transverse diameter $2\frac{1}{2}$ to $4\frac{1}{4}$ lines, and they are from $2\frac{1}{4}$ to 3 lines thick. Their excretory duct is at the anterior edge of the superior part of the gland, and runs beneath the constrictor vaginae, horizontally forwards and inwards, to the inner face of the nymphæ, opening in front of the carunculæ myrtiformes, in the midst of a number of small mucous follicles. These glands were first discovered by Duverney in the cow, about the middle of the seventeenth century. Bartholinus subsequently found them in the human female, and his observations were confirmed by Duverney, Morgagni, Santorini, Peyer, &c. Haller denied their existence; and their presence seems to have been forgotten until they were again described by Mr. Taylor ("Dublin Journal," vol. xiii., 1838). They are analogous to Cowper's glands in the male, according to Tiedemann, and like them are sometimes wanting, and differ in size. In advanced age they are said to diminish in size, and even to disappear. They are present in the females of all animals, where Cowper's glands exist in the males. They secrete a thick, tenacious, grayish-white fluid, which is emitted in large quantity at the termination of the sexual act, most likely from the spasmodic contraction of the constrictor vaginae muscle, under which they lie. Its admixture with the male semen has been supposed to have some connection with impregnation; but no proof whatever has been given that any such admixture is necessary. It seems not improbable, however, that it may serve, like the prostatic fluid of the male, to give a *dilution* to the seminal fluid that is favorable to its action. These glands were probably known to the ancients, and it is doubtless their secretion which Hippocrates and others describe as the female semen.—These glands have been since described by M. Huguier, in the "Archives d'Anatomie" (1847). His description corresponds in every respect with that given above.

way towards the ovarium, and fecundate the ovum either before it entirely quits the ovisac or very shortly afterwards, appears to be the general rule in regard to the Mammalia; and the question naturally arises—by what means do they arrive there? It has been supposed that the action of the cilia which line the Fallopian tubes might account for their transit; but the direction of this is *from* the ovaria towards the uterus, and would therefore be opposed to it. A peristaltic action of the Fallopian tubes themselves may generally be noticed in animals killed soon after sexual intercourse; and in those which have a two-horned membranous uterus, such as is evidently but a dilatation of the Fallopian tube, this partakes of the same movement, as may be well seen in the Rabbit; but this peristaltic action, like the ciliary movement, is *from* instead of towards the ovaries. Among the tribes whose ova are fertilized out of the body, the power of movement inherent in the spermatozoa is obviously the means by which they are brought in contact with the ova; and it does not seem unreasonable to suppose that the same is the case in regard to the higher classes, and that the transit of these curious particles, from the vagina towards the ovaries, is effected by the same kind of action as that which causes them to traverse the field of the microscope.—We shall now consider the changes in the Ovum and its appendages, by which it is prepared for fecundation.

969. Up to the period when the Ovum is nearly brought to maturity, it remains in the centre of the ovisac or inner layer of the Graafian follicle; and it is supported in its place by the “*membrana granulosa*,” which is continuous with its proligerous disk. The movement of the ovum towards the surface, which has been already referred to as a part of the changes by which it is prepared for fecundation, appears from the observations of Valentin to be due to the following cause. In the immature ovisac, the space between its inner layer and the ovum is for the most part filled up with cells; these, however, gradually dissolve away, especially on the side nearest the surface of the ovary; whilst an albuminous fluid is effused from the deeper part of the ovisac, which pushes the residual layer (forming the *discus proligerus*) before it, and thus carries it against the opposite wall. At the same time, there is a gradual thinning away of the various envelops of the Graafian follicle, as well as of its own walls, in the situation of its most projecting part; and thus it is preparing to give way at that point, for the discharge of the contained ovum. Before rupture takes place, however, the ovisac itself undergoes a considerable change. Its walls become more vascular externally, and are thickened on their interior by the deposit of a fleshy-looking substance, which, in many of the lower Mammalia, is of a reddish color, whilst in the Human female it is rather of yellowish hue. This substance is at first entirely composed of an aggregation of cells (Fig. 244), and may, in fact, be considered as an increased development, or hypertrophy, of the “*membrana granulosa*” or epithelial lining of the ovisac. In domestic quadrupeds, this growth, which sprouts like a mass of granulations from the lining of the ovisac, is often so abundant, if the ovum be impregnated, as not only to fill the cavity of the ruptured vesicle, but even to protrude from the orifice on the surface of the ovary; this orifice, however, subsequently closes; and the contained growth becomes gradually firmer, its color changing from red to yellow. In the Human female, however, the new formation consequent upon impregnation is less abundant; it does not form mammillary projections from the interior of the ovisac, but lies as a uniform layer upon its

Fig. 244.

Cells forming the original substance of the Corpus Luteum.

lining; and this is thrown into wrinkles or folds, in consequence of the contraction of the ovisac. An irregular cavity is thus at first left in the interior of the ovisac, after the discharge of the ovum; but this gradually diminishes, partly in consequence of the increased growth of the yellow substance, and partly owing to the general contraction of the ovisac, until it is at last nearly obliterated or reduced to a sort of stellate cicatrix. An effusion of blood fre-

Fig. 245.

Successive stages of the formation of the Corpus Luteum, in the Graafian follicle of the Sow, as seen in vertical section: at *a* is shown the state of the follicle immediately after the expulsion of the ovum, its cavity being filled with blood, and no ostensible increase of its epithelial lining having yet taken place; at *b*, a thickening of this lining has become apparent: at *c*, it begins to present folds which are deepened at *d*, and the clot of blood is absorbed *pari passu*, and at the same time decolorized; a continuance of the same process, as shown at *e*, *f*, *g*, *h*, forms the complete Corpus Luteum, with its stellate cicatrix.

quently takes place into this cavity, in the Human female, at the time of the rupture of the ovisac; but the coagulum which is left takes no share in the formation of the yellow body. It generally loses its coloring matter, and acquires the characters of a fibrinous clot; and this may either form a sort of membranous sac, lining the cavity, or it may become a solid mass, occupying the centre of the stellate cicatrix.

970. The cells which line the Graafian follicle undergo a great increase of size at the time of the discharge of the ovule, and are also partially metamorphosed into fibres, especially where they come into apposition with the enveloping wall of the follicle; in fact, a gradual transition may be traced between the cellular substance of the interior of the follicle, and the fibrous stroma of the Ovarium itself. In this manner is formed that reddish-yellow granulation-like substance, friable in consistence, and very vascular, which occupies that part of the ovary of a pregnant female whence the ovum has been discharged, and is known under the name of the *Corpus Luteum*. Its size varies according to the length of time which has elapsed since conception. At first, it is usually so large as to occasion a considerable projection on the surface of the ovary; its form is oval, or resembles that of a bean. When cut across, its dimensions are usually found to be from 4 to 5-8ths of an inch in its long diameter, and from 3 to 4-8ths in its short; and it thus occupies from a fourth to a half of the whole area of the ovarium; but these dimensions are not unfrequently exceeded. The centre of this substance is hollow; and by a proper acquaintance with this character, the true Corpus Luteum may be distinguished from substances bearing a general resemblance to it, but very different in their character. The following is Dr. Montgomery's account of it: "Its centre exhibits either a cavity, or a radiated or branching white line, according to the period at which the examination is made (Fig. 246). If within the first three or four months after conception, we shall, I believe, always find the cavity still

existing, and of such a size as to be capable of containing a grain of wheat at least, and very often of much greater dimensions ; this cavity is surrounded by a strong white cyst ; and as gestation proceeds, the opposite parts of this cyst

Fig. 246.

Corpora lutea of different periods : B. Corpus luteum of about the sixth week after impregnation, showing its plicated form at that period. 1. Substance of the ovary. 2. Substance of the corpus luteum. 3. A grayish coagulum in its cavity ; after Dr. Patterson. A. Corpus luteum, two days after delivery. D. In the twelfth week after delivery. After Dr. Montgomery.

approximate, and at length close together, by which the cavity is completely obliterated, and in its place there remains an irregular white line, whose form is best expressed by calling it radiated or stelliform. This is visible as long as any distinct trace of the corpus luteum remains."¹ The true corpus luteum is further distinguished by its capability of being injected from the vessels of the ovary ; which is not the case with tubercular deposits or other substances which may simulate it. After delivery, the size of the corpus luteum rapidly diminishes ; and in a few months it ceases to be recognizable as such. The cicatrix by which the ovum has escaped is visible for some time longer ; but this, too, according to the careful researches of Dr. Montgomery, cannot be distinguished at a subsequent period. Hence there is no correspondence between the number of corpora lutea found in the ovaries of a woman, or of cicatrices on their surface, and the number of children she may have borne. The number of corpora lutea must always be less, when there have been many conceptions, in consequence of the complete disappearance of some of them ; but the number of cicatrices may be greater ; for several causes, such as the escape of unimpregnated ova, or the bursting of little abscesses, may give rise to such appearances.

971. It is a question of much scientific interest, and one that occasionally becomes of importance in Juridical investigations, what extent of resemblance may exist between the condition of the Ovisac after the expulsion of an ovum that does *not* become impregnated, and that of a pregnant female in which a true "corpus luteum" is present. This question cannot be decided by observations on domesticated quadrupeds ; since it appears certain that in them there is altogether a more abundant production of the yellow substance than in the Human female, and that it is more persistent after the discharge of the ovum ; which may perhaps be accounted for by the greater functional activity or excitement of the ovarian apparatus in an animal "in heat," than usually exists in the Human female at the menstrual period. There is reason, moreover, to believe that the amount of this may vary considerably in different females, and in the same females at different times. The general fact certainly is, that a thin layer of yellow substance, composed chiefly of cells and of fibres originating in the metamorphosis of cells, is ordinarily formed on the lining of the ovisac ; that this is greatly increased in thickness, if the ovum be impregnated ; but that

¹ "Signs of Pregnancy," p. 226.

if it be not, it gradually disappears; so that, from this difference in the subsequent changes (which may be probably attributed to the increased determination of blood to the whole Generative apparatus when it is in a state of excessive functional activity), the corpus luteum which is characteristic of the pregnant state is usually a much larger and more highly organized body, than that which is commonly found in the ovary of the unimpregnated female. But it is also unquestionable that an unusual development of the fibro-cellular substance may sometimes take place without impregnation; whilst, on the other hand, the changes which usually follow impregnation may take place so much less characteristically than usual, that the corpus luteum, even at an early period of pregnancy, may be no larger than that which is often found where pregnancy has not occurred. These variations, which seem mainly to depend upon differences in the degree of vascular excitement of the ovaries, accompanying and succeeding the extrusion of ova, render it impossible to draw any definite line of demarcation, by which we may at once determine what are, and what are not, the results of conception; but the following practical rules, deduced from a consideration of all the circumstances yet known, may be laid down for the guidance of those who find it desirable to have some standard of judgment: "1. A Corpus Luteum, in its earliest stage (that is, a large vesicle filled with coagulated blood, having a ruptured orifice, and a thin layer of yellow matter in its walls), affords no proof of impregnation having taken place.—2. From the presence of a Corpus Luteum, the opening of which is closed, and the cavity reduced or obliterated, only a stellate cicatrix remaining, also no conclusion as to pregnancy having existed or fecundation having occurred can be drawn, if the corpus luteum be of small size, not containing as much yellow substance as would form a mass the size of a small pea.—3. A similar Corpus Luteum of larger size than a common pea would be strong presumptive evidence, not only of impregnation having taken place, but of pregnancy having existed during several weeks at least; and the evidence would approximate more and more to complete proof, in proportion as the size of the corpus luteum was greater."¹

¹ See Dr. Baly's "Supplement to Müller's Physiology," p. 57; where a comprehensive account will be found of all the recent researches bearing upon this question.—[The reader is also referred to the elaborate prize essay of Dr. J. C. Dalton, in the "Transactions of the American Medical Association" for 1851, in which the difference between the corpora lutea of menstruation and pregnancy is clearly made out. The following are some of the characteristic marks by which the two may be recognized:—

I. The corpus luteum of pregnancy arrives more slowly at its maximum of development, and afterward remains for a long time as a very noticeable tumor, instead of undergoing a process of rapid atrophy.

II. It retains a globular or only slightly flattened form, and gives to the touch a sense of considerable resistance and solidity.

III. Internally, it has an appearance of advanced organization, which is wanting in the corpus luteum of menstruation.

IV. Its convoluted wall, particularly, attains a greater development, this portion measuring sometimes so much as three-sixteenths to one-fourth of an inch in thickness, while in the corpus luteum of menstruation it never exceeds one-eighth, and is almost always less than that. This difference in the thickness of the convoluted wall is one of the most important points of distinction. It will be much more striking when viewed *relatively to the size of the central coagulum*.

V. The color is not, by any means, so decided a yellow, but a more dusky and indefinite hue.

VI. If the period of pregnancy is at all advanced, it is not found, like the corpus luteum of menstruation, in company with unruptured vesicles in active process of development.

The histories and observations detailed by Dr. Dalton will serve to show how very imperfect are some of the marks which various writers have heretofore laid down as distinguishing 'true' from 'false' corpora lutea. Dr. Montgomery* gives seven characteristics by which, he says, the 'false,' or 'virgin' corpora lutea may be recognized.

* "Signs and Symptoms of Pregnancy," p. 245.

972. It cannot now be doubted that the maturation and discharge of ova from the Ovaries is, in the Human female, and in Mammalia in general, an operation quite as independent of conception, and even of sexual intercourse, as it is in those animals in which the ova are fertilized out of the body;¹ and it is no longer considered essential, therefore, that the seminal fluid should reach the ovarium in order to effect the fertilization of the ova, since this end may be answered by the contact of the two in the Fallopian tubes, or even in the Uterus itself. From the experiments of Bischoff, however, it appears that in rabbits, bitches, and probably in most other Mammalia, sexual union usually takes place previously to the escape of the ova from the ovary, and that sufficient time often elapses for the seminal fluid to reach the ovary before their extrusion occurs; in such cases, therefore, it would seem probable that fecundation is effected at the ovary itself. That such occasionally happens in the Human female seems to be unequivocally proved by the occurrence of tubal or even of ovarian foetation; the ovum having received the fertilizing influence imme-

‘I. There is no prominence or enlargement of the ovary over them.’

This is manifestly incorrect, for the corpora lutea of menstruation often causes a noticeable protuberance on the surface of the ovary.

‘II. The external cicatrix is almost always wanting.’ According to Dr. Dalton’s observations, an external cicatrix is always present in the corpus luteum of menstruation, and, in fact, must necessarily be so, since these bodies result from the rupture of a vesicle, in the same manner with the corpora lutea of pregnancy.

‘III. There are often several of them found in both ovaries,’ &c. This is, no doubt, a very important distinction, since we never find more than one corpus luteum of pregnancy at a time, unless in cases of twins; and then the two corpora lutea are evidently of the same date, and have the same aspect, while the coexistent corpora lutea of menstruation are usually in many different stages of retrogression.

‘IV. They present no trace whatever of vessels in their substance, of which they are, in fact, entirely destitute, and, of course, cannot be injected.’

According to the author’s observations, the distribution of vessels in the two different kinds of corpora lutea is the same. In both, the substance of the convoluted wall itself is non-vascular; and the vessels exist only in the interstices of the folds. This fact is very easily demonstrated in a corpus luteum of menstruation when completely developed, as the convolutions are here pretty easily separated from each other; but, in the corpus luteum of pregnancy, the new growth from the internal surface of the vesicle has been so abundant, and the convolutions are consequently pressed so firmly together, that it is not always easy to decide whether a section has divided the substance of the wall, or only by accident passed between two convolutions; particularly as we have not so strong a contrast in color, to assist us, between the yellow wall and red vessels, as exists in the corpus luteum of menstruation.

‘V. Their texture is sometimes so infirm that it seems to be merely the remains of a coagulum,’ &c. This is frequently a good distinguishing mark.

‘VI. In figure they are often triangular, or square, or of some figure bounded by straight lines.’ This has already been seen to be an appearance frequently presented by the corpus luteum of menstruation, at an advanced period of atrophy.

‘VII. They never present either the central cavity, or the radiated or stelliform white line which results from its closure.’ This last distinction is so exceedingly incorrect that it is difficult to understand how it could have been laid down by such an observer as Dr. Montgomery. The corpus luteum of menstruation *always* presents a central cavity, *i. e.*, a space included by the convoluted wall, which space is filled by a coagulum; and, as the whole yellow body becomes atrophied, the coagulum is transformed into a radiated or stelliform cicatrix, more or less colored with blood, according to the rapidity with which the absorption of the hæmatin has proceeded.

There can be no doubt, therefore, of the existence of certain distinct and reliable marks by which the corpus luteum may be recognized as a sign of pregnancy, and distinguished from all other appearances, either morbid or physiological, to be met with in the ovary.”—Ed.]

¹ Two cases in which Ovules, or their remains, were discovered in the Fallopian tubes of Women who had died during the Menstrual period, under circumstances which entirely precluded the idea of previous sexual intercourse, have been lately recorded by Dr. Letheby (“Phil. Trans.,” 1852, p. 57).

diately upon quitting the ovisac, or even before it has entirely extricated itself from the ovary, and having been in some way checked in its transit towards the uterus, so that its development has taken place in the spot at which it has been arrested. It is affirmed by Bischoff that by the time the ovum reaches the uterus, or even the lower end of the Fallopian tube, its capacity for impregnation is lost; but this assertion chiefly rests on the cessation of sexual desire, observed in those animals in which, after death, it was found that the ova had passed into the uterus, or had arrived at the lower part of the Fallopian tube. There is every reason to believe that this is not the case in the Human female; for, although the sexual desire may be the strongest about the period of the maturation and escape of the ova, yet it is by no means wanting at other times; and the occasional occurrence of cases in which impregnation has taken place from a single coitus in the middle of the interval between the menstrual periods, shows either that the ovum may retain its capacity for impregnation for some time after its escape from the ovary, or that its maturation and extrusion are not by any means invariably coincident with the menstrual period.¹—The ova, when set free from the ovaries by the rupture of the ovisacs and the giving way of their several envelopes, are received by the fimbriated extremities of the Fallopian tubes, which, during the period of sexual excitement, appear to be closely applied to the surface of the ovaries. Their conveyance along the Fallopian tubes is probably due in part to their peristaltic movement, and in part to the action of the cilia which clothe their internal surface.

973. The object of the changes which have been already described is to bring the Ovum within reach of the fecundating influence, and to convey it into the uterus after it has been fertilized: we have now to consider the changes in the Ovum itself, which take place during the same epoch. At about the same period that the ovum moves towards the periphery of the Graafian follicle, the germinal vesicle moves towards the periphery of the yelk; and it always takes up its position at the precise point of the zona pellucida which is nearest the ovisac, and which is closest, therefore, to the surface of the ovary. Moreover, the germinal spot is always on that part of the germinal vesicle which is in closest contact with the zona pellucida. Thus, the germinal spot is very near the exterior of the ovary; but is separated from it by the peritoneal coat of the latter, by a thin layer of its stroma forming the external layer of the Graafian follicle, by the ovisac forming its internal membrane, and by the zona pellucida. As soon as these give way, there is nothing to prevent the spermatozoa from coming into direct contact with the ovum, even before it quits the ovisac. That such contact is an essential condition of fecundation, there is every reason to believe; although, as to the precise manner in which it operates, we are at present in the dark. There can be no doubt that it is in the contact of the spermatozoa with the ovum, and in the changes which occur as the immediate consequence of that contact, that the act of Fecundation essentially consists. We have already seen that the Spermatozoa constitute the essential part of the Seminal fluid (§ 959); and although it has been ascertained by Mr. Newport, that the spermatic fluid as secreted by the testes is inferior in fertilizing power

¹ See a case of this kind recorded by Dr. Oldham in the "Medical Gazette," July 13, 1849.—Instances are certainly not unfrequent in which conception has taken place five or six days after the conclusion of the menstrual period; the Author has himself known one in which this occurred, after the menstrual flow itself had persisted for a week. It has been urged that the known fertility of the Jewish females, who abstain from sexual intercourse for eight days, or even thirteen days, after the termination of the catamenia, is opposed to the idea that the menstrual period is that of "heat"; but there is reason to believe that this is to be accounted for in another way—namely, by the usual occurrence of conception from intercourse immediately *before* the access of the catamenia. (See Mr. Girdwood, in the "Lancet," Dec. 14, 1844.)

to that which has been mingled with the prostatic fluid, yet it seems that this inferiority simply results from its state of too great concentration, and not from any endowments peculiar to the prostatic fluid, since dilution with other fluids answers the same purpose. Mr. Newport's most recent observations upon the process of impregnation in the Frog (which the Author, through the kindness of Mr. N., has had the opportunity of verifying) show that the spermatozoa become imbedded in the gelatinous envelop of the ovum, within a few seconds after they come into contact with it, and that they are thus brought into close approximation with (if they do not absolutely pass through) the vitelline membrane; in this situation they probably undergo a gradual diffuence; and thus the product of the "sperm-cell" may be absorbed into the "germ-cell," and may intermingle with its contents, just as in the fecundation of the ovule of Flowering-plants; the Spermatozoon being nothing else than an embodiment of the fertilizing material developed within the sperm-cell, which is endowed with a temporary power of movement in order that it may find its way to the Ovum. It has been remarked by Mr. Newport that Spermatozoa whose spontaneous *motility* has ceased, no longer possesses the fecundating power; and this fact concurs with other phenomena to indicate that it is not only a certain *material*, but a *vital force* of which that material is (so to speak) the vehicle, which is required to effect this most important operation.

974. The precise share which the Germinal Vesicle and Germinal Spot perform in the changes which take place in the ovum about the period of fecundation, has not yet been satisfactorily determined. According to Dr. Barry, the germinal vesicle becomes filled with a new development of cells, which sprout, as it were, from its nucleus (the germinal spot): and after fecundation a pair of cells is seen in the space previously occupied by the pellucid centre of the nucleus which is developed at the expense of the rest, and is the true foundation of the embryonic structure. This view is to a certain extent confirmed by the observations of Wagner on the ova both of Frogs and Mammalia, and by those of Vogt on those of the *Rana obstetricans*: both of which lead to the belief that such a process of cell-formation does take place within the germinal vesicle, but that, instead of the further development being carried on within the germinal vesicle, as maintained by Dr. Barry, this ruptures and sets free the cells that had been developed in its interior, which are now dispersed through the yelk, whose ulterior changes take place under their influence. Mr. Newport's view is nearly the same as this; and he states that, in the Frog, this dissolution of the germinal vesicle and diffusion of its contents take place as a preparation for fecundation, and not in consequence of it.¹ That the germinal vesicle is no longer to be seen when the metamorphoses of the yelk have commenced, is now universally admitted; but with regard to the antecedent process just described, there is still a want of accordance amongst Embryologists, its existence being altogether denied by Bischoff, who maintains that the germinal vesicle simply dissolves away shortly after coition, as had been supposed by Dr. Barry's predecessors. The Author is strongly inclined to believe, however, from his own observations, as well as from *à priori* considerations, based on the history of Vegetable fertilization, that there is a development of cells within the germinal vesicle, at the time of its maturation; and that it is by the influence of the spermatic fluid upon one of these cells, after it has been set free in the midst of the yelk by the rupture or diffuence of the germinal vesicle, that the first cell of the embryonic fabric is generated.

975. Whatever be the precise nature and history of the Fecundating process, there can be no doubt that the properties of the germ depend upon conditions, both material and dynamical, supplied by *both* parents. This is most obviously

¹ "Philosophical Transactions," 1851, p. 178.

shown by the *fusion* of the characters of the parents, which is exhibited by hybrids between distinct species or strongly-marked varieties among the lower animals, such as the Horse and Ass, the Lion and Tiger, or the various breeds of Dogs; or in the offspring of parents belonging to two strongly-contrasted Races of Men, such as the European, on the one hand, and the Negro or American Indian on the other. But it is rare to meet with instances, even when the differences between the parents are far less strongly marked, in which some distinctive traits of both may not be readily traced; these traits showing themselves in peculiarities of manner and gesture, in tendencies of thought or feeling, in proneness to particular constitutional disorders, &c., even where there is no personal resemblance, and where there has been no possibility that these peculiarities should have been gained by imitation. And it is well known, too, that such peculiarities will often reappear in a subsequent generation, after being apparently extinct; as if the agency which produced them had been overpowered for a time by some stronger influence, but had subsequently been left free to operate. This phenomenon is known as *atavism*.—The influence of particular perversions of the regular nutritive operations, brought about by causes to which the parents have been exposed, is often manifested in the offspring; thus we find gout, scrofula, syphilis, &c., hereditarily transmitted; and the children of habitual drunkards are distinguished by their tendency to Idiocy and Insanity.¹—There seems good reason to believe, moreover, that the attributes of the germ are in great degree dependent, not merely upon the *habitual* conditions of the parents which have furnished its original components, but even upon the condition in which those parents may be at the time of sexual congress. Of this we have a remarkable proof in the phenomenon well known to breeders of animals, that a strong mental impression made upon the female by a particular male will give the offspring a resemblance to him even though she has had no sexual intercourse with him; a circumstance for which there is no difficulty in accounting, on the hypothesis already put forth regarding the dynamical relation of Mental states to the Organic processes (§ 945). And there is no improbability, therefore, in the idea that the offspring of parents ordinarily healthy and temperate, but begotten in a fit of intoxication on both sides, would be likely to suffer permanently from the abrogation of the reason, which they have temporarily brought upon themselves.² There is another class of facts which seems referable to the same category, that, namely, which exhibits the influence of a male parent upon the subsequent offspring of a different parentage; as in the well-known case of the transmission of the Quagga-marks to a succession of colts both whose parents were of the species Horse, the mare having been once impregnated by the Quagga male;³ and in the not unfrequent occurrence of a similar phenomenon in the Human species, as when a widow who marries a second time bears children strongly resembling her first husband. Some of these cases appear referable to the strong mental impression left by the first male parent upon the female; but there are others which seem to render it more likely that the blood of the female has imbibed from that of the foetus, through the placental circulation, some of the attributes which the latter has derived from its male parent; and that the female may communicate these, with those proper to herself, to the subsequent offspring of a different male parentage.⁴—On the whole, then, we seem entitled to con-

¹ See the Author's "Prize Essay on Alcoholic Liquors," § 86, *Am. Ed.*, and Dr. Howe's "Report on Idiocy in Massachusetts," in the *Am. Journ. of Med. Sci.*, April, 1849.

² See a case of this kind related by Mr. G. Combe, in the "*Phrenological Journal*," vol. viii. p. 471.

³ "*Philosophical Transactions*," 1821.

⁴ See an interesting discussion of this question, by Dr. Alex. Harvey, in the "*Edinb. Monthly Journ.*," Oct. 1849, and Oct. and Nov. 1850; and in his pamphlet "*On a Remarkable Effect of Cross-breeding*," Edinb. 1851.

clude that the attributes of the embryo will be influenced in a most important degree by the entire condition (as relates both to the organic and the psychical life) of both parents at the time of the sexual congress; and it is probably on account of the perpetual changes taking place in the bodily and mental state of each individual (his condition at any one time being the general resultant of all those changes), that we almost constantly witness marked differences between children born at successive intervals, however strong may be the "family likeness" among them, whilst the resemblance between twins is almost invariably much closer.¹

976. Having thus noticed the principal points of the history of the development and impregnation of the ovum, we shall proceed to consider the provisions made for the Nutrition of the Embryo, through the generative apparatus of the female, up to the time of parturition; deferring the history of the development of the ovum for that separate consideration which the importance of that subject demands.—About the time that the ovum is leaving the ovary, the cells of the proligerous disk which immediately surrounds the zona pellucida become club-shaped (Fig. 247); their small ends being applied to the surface of the ovum, so as to give it somewhat of a stellate appearance. According to Bischoff, these cells entirely disappear from the ovum of the rabbit, as soon as it has entered the Fallopian tube; whilst in the bitch they become round, and continue to invest the ovum in this form throughout its whole transit to the uterus. During its passage, the ovum acquires a sort of gelatinous envelop, which is inclosed in a membrane of fibrous texture, termed the *Chorion*. This envelop is probably of an *albuminous* nature in reality, corresponding with the *white* of the Bird's egg: whilst the fibrous texture of the chorion seems to be

Fig. 247.

A. An ovarian ovum from a Bitch in heat, exhibiting the elongated form and stellate arrangement of the cells of the discus proligerus or membrana granulosa around the zona pellucida. B. The same ovum after the removal of most of the club-shaped cells.

produced, like the membranous basis of the eggshell of the bird,² by the exudation of fibrin from the lining membrane of the Fallopian tube or oviduct. The outer layer of this envelop, in the egg of the bird, is consolidated by the deposition of particles of carbonate of lime in its areolæ; and none of it undergoes any higher organization. The Chorion of the Mammal, on the other hand, subsequently undergoes changes of a much higher order; which adapt it for participating, to a most important degree, in the nutrition of the included embryo. The first of these changes consists in the extension of the surface of

¹ This strong resemblance, it is true, is occasionally deficient; but this may perhaps be fairly attributed to the circumstance of the twins being the offspring of different conceptions, which is undoubtedly sometimes the case, as is shown by the long interval that elapses between their births (§ 990).

² "Princ. of Phys., Gen. and Comp.," § 160, *Am. Ed.*

the membrane into a number of villous prolongations, at first composed entirely of cells, which give it a spongy or shaggy appearance (Plate I. Fig. 10). These serve as absorbing radicles, and form the channel through which the embryo is nourished by the fluids of the parent, until a more perfect communication is formed, in the manner to be presently explained.

977. We have now to speak of the changes in the Uterus which take place in consequence of Conception, and which prepare it to receive the ovum. Of these the most important is the formation of the *Membrana Decidua*, so called from its being cast off at each parturition. This membrane has been usually supposed to be a new formation; and has been described as originating in coagulable lymph thrown out on the inner surface of the uterus, into which vessels are prolonged from the subjacent surface. It appears, however, from the researches of Dr. Sharpey and Prof. Weber,¹ that this is not the true account of it; and that the *Decidua vera* is really composed of the inner portion of the Mucous membrane itself, which undergoes a considerable change in its character. The Mucous membrane of the uterus possesses on its free surface a tubular structure (Figs. 248, 249); not very unlike that which has been described as existing in the lining membrane of the stomach (§ 440). This tubular portion becomes thickened and increased in vascularity, within a short time after conception; and when the inner surface of a newly-impregnated uterus is examined with a low magnifying power, the orifices of its tubes are very distinctly seen, being lined with a white epithelium. The bloodvessels form a very minute network, which extends in loops from the subjacent portion of the membrane. According to the observations of Prof. Goodsir,² the interfollicular spaces also are crowded with nucleated particles; and it is to the development of this interfollicular substance, as well as to the enlargement of the follicles themselves, and the copious development of epithelial cells in their interior, that the mucous membrane in this condition owes its increased thickness. This increased development appears to have reference in part to the temporary nutrition of the ovum, and in part to the further evolution of the decidual substance itself in the formation of the

Section of the lining membrane of a Human Uterus at the period of commencing pregnancy, showing the arrangement and other peculiarities of the glands *d, d, d*, with their orifices *a, a, a*, on the internal surface of the organ. Twice the natural size. After E. H. Weber.

Placenta. The cavity of the uterus shortly becomes filled with a fluid, evidently poured out from the follicles in its walls, and containing a large number of nucleated cells; and in this the villi of the chorion are imbedded, obviously for the purpose of deriving from it the materials required for the development of the embryonic structures. These villi are easily traced in the bitch (as Dr. Sharpey first pointed out) into the mouths of the uterine glandulæ, some of which are composite in their structure, a single outlet being common to a number of follicles; but they have not yet been so traced in the Human subject.

At 1, the lining of epithelium is seen within the orifices; at 2, it has escaped. From Dr. Sharpey (xxxii.).

978. The Deciduous membrane is found at a later period to consist of two layers; the *Decidua vera* lining the uterus, and the *Decidua reflexa* covering the exterior of the ovum. Regarding the origin of this second layer, there has been a good deal of difference of opinion. The doctrine first propounded by Dr. W. Hunter, which is indicated by the name which he bestowed upon the membrane, was that the decidua reflexa is a portion of the true decidua, which has been pushed before the ovum at its entrance into the uterus; it being supposed that the true decidua forms a completely closed sac (like that of a serous membrane), against the *outside* of which the ovum is applied, so that it comes to be invested by a double layer of it, as the heart is by the pericardium, or the lungs by the pleura. But this view is negatived by a number of considerations. For, in the first place, the original decidua does not form the closed sac which this supposition involves, but extends (like the mucous membrane of which it is a metamorphosed form) into the Fallopian tubes; and the ovum, at its entrance into the uterus, really lies upon its internal surface. But, again, the texture of the two layers is very different; for, as was first pointed out by Prof. Goodsir (loc. cit.), the decidua reflexa is almost entirely composed of cells, exhibiting few or none of the orifices of the glandular follicles which are characteristic of the decidua vera, except near the part where the two layers are continuous. According to the observations of M. Coste, however, there is a considerable resemblance between the two layers at an early period; and he considers the following to be the mode in which the second investment is formed: When

Fig. 251.

First stage of the formation of the Decidua reflexa around the ovum.

the ovum enters the uterus, it becomes partially imbedded in the substance of the decidua, which is as yet quite soft (Fig. 251); and this, receiving an increased nutrition at the part with which the ovum comes into contact, grows up

Fig. 252.

More advanced stage of the same.

around it, very much after the manner in which the fleshy granulations grow up around the pea imbedded in a caustic issue. This extension of the decidua substance continues (Fig. 252), until it has completely enveloped the ovum; and it is thus, according to him, that the decidua reflexa is formed, in continuity with the decidua vera.¹ As the ovum increases in size, the cavity between the decidua vera and the decidua reflexa gradually diminishes; and by the end of the third month the two layers come into contact, and are

henceforth scarcely or not at all distinguishable.

979. The surface of the Ovum, thus surrounded by the double layer of the deciduous membrane, is rendered shaggy by the growth of villous tufts from the surface of its investing chorion (Plate I. Fig. 10, *f, f*). Each of these tufts, as was first pointed out by Prof. Goodsir,² is composed of an assemblage of nucleated cells, which are found in various stages of development; and these are always inclosed within a layer of basement-membrane, which seems to be itself composed of flattened cells united by their edges. At the free extremity of each villus is a bulbous expansion, the cells composing which are arranged round a central spot; and it is at this point that the most active processes of growth take place, the villus elongating by the development of new cells from its germinal spot, and (like the spongiole of the plant) drawing in nutriment from the soil in which it is imbedded. In its earliest grade of development, the chorion and its villi contain no vessels; and the fluid drawn in by the tufts is communicated to the embryo, by the absorbing powers of the germinal membrane of the latter. But when the tufts are penetrated by bloodvessels, and their communication with the embryo becomes more direct, the means by which they communicate with the parent are found to be still essentially the same; namely, a double layer of nucleated cells, one layer belonging to the foetal tuft, and the other to the vascular maternal surface. It is from these elements that the *Placenta* is formed, in the manner next to be described.

980. The first stage in this process consists in the extension of the foetal vessels into the villi of the Chorion over its entire surface, in the manner hereafter to be detailed (§ 1001); so that the nutriment which these villi imbibe, instead of being merely added to the albuminous fluid surrounding the yelk-bag, is now conveyed directly to the embryo. This—the earliest and simplest mode by which the Fœtus effects a new connection with the parent—is the only one in which it ever takes place in the lower Mammalia, which are hence properly designated as “non-placental,” rather than as ovo-viviparous. In the higher Mammalia, however, there soon occurs a great extension of the vascular

¹ This doctrine was first announced by M. Coste, in a communication to the Parisian Academy of Sciences, on the basis of observations on two Uteri at the 20th and 25th days of gestation. (See “Comptes Rendus,” Mai 24, 1847.) It seems to be altogether that which is most in harmony with observed facts; and especially with those which have been noticed by Professors Weber and Sharpey. See, also, the Memoir of M. Robin, on the Mucous Membrane of the Uterus, in the “Archiv. Gén. de Méd.,” 4e Ser., tom. xvii. xviii.

² “Anatomical and Pathological Observations,” chap. ix.

tufts of the foetal chorion, at certain points; and a corresponding adaptation, on the part of the uterine structure, to afford them an increased supply of nutritious fluid. These specially prolonged portions are scattered, in the Ruminantia and some other Mammalia, over the whole surface of the chorion, forming what are termed the "cotyledons;" but in the higher orders, and in Man, they are concentrated in one spot, forming the Placenta. In some of the lower tribes, the maternal and the foetal portions of the placenta may be very easily separated; the former consisting of the thickened decidua; and the latter being composed of the prolonged and ramifying vascular tufts of the chorion, dipping down into it. But in the Human placenta, the two elements are mingled together through its whole substance.—On looking at the foetal surface of the Human placenta, we perceive that the Umbilical vessels diverge in every direction from the point at which they enter it; and their subdivisions form a large mass of capillaries, arranged in a peculiar manner (Fig. 254), and constituting what are known as the *foetal villi*. Each villus contains one or more capillary loops, communicating with an artery on one

Fig. 253.

side and with a vein on the other; but the same capillary may pass into several villi, before re-entering a larger vessel. The capillaries of the villi are covered, as in the chorion, by a layer of cells (Fig. 255, *f*), inclosed in basement-membrane (*e*); but the foetal tuft thus formed is inclosed in a second series of envelops (*a*, *b*, *c*), derived from the maternal portion of the placenta (Fig. 256),—a space (*d*) being left, however, between the two, at the extremity of the tuft.

981. Whilst the foetal portion of the Placenta is thus being generated by the extension of the vascular tufts of the chorion, the maternal portion is formed by the enlargement of the vessels of the decidua, between which they dip down. "These vessels assume the character of sinuses; and at last swell out (so to speak) around and between the villi; so that finally the villi are completely bound up or covered by the membrane which constitutes the walls of the vessels, this membrane following the contour of all the villi, and even passing to a certain extent over the branches and stems of the tufts. Between this membrane, or wall of the enlarged decidual vessels, and the internal membrane of the villi, there still remains a layer of the cells of the decidua."¹ In this manner is

formed the maternal portion of the placenta, which may be regarded in its adult state (as was well pointed out by Dr. J. Reid¹) in the light of a large sac (Fig.

259, *c*) formed by a prolongation of the inner coat of the uterine vessels; against the foetal surface of which sac, the tufts just described may be said to push themselves, so as to dip down into it, carrying before them a portion of its thin wall, which constitutes a sheath to each tuft. Now, as every extension of the

uterine vessels carries the decidua before it, every one of the vascular tufts that dips down into it will be covered with a layer of the cellular structure of the

¹ "Edinb. Med. and Surg. Journ.," Jan. 1841; and "Anat. Phys., and Pathol. Researches," chap. VIII.

latter; and the foetal portion of each tuft will thus be inclosed in a layer of *maternal* cells and basement-membrane (Fig. 255, *a, b, c*; and Fig. 256, *a, b, e*). In this manner, the whole interior of the placental cavity is intersected by numerous tufts of foetal vessels, disposed in fringes, and bound down by reflections of the delicate membrane that forms its proper wall; just as the intestines are held in their places by the reflections of the peritoneum that covers them. This view was suggested to Dr. R. by the very interesting fact that the tufts of foetal vessels not unfrequently extend beyond the uterine surface of the placenta, and dip down into the uterine sinuses (Fig. 258); where they are still covered and held in their places, by reflections of the same membrane. All the bands which connect and tie down the tufts (Fig. 257, *g*) are formed of the same elements as the envelops of the tufts themselves; namely, a fold of the lining membrane of the decidual sinuses, and a layer of the cellular decidua.

982. The blood is conveyed into the Placental cavity by the "curling arteries" of the uterus (Fig. 259, *a*); and is returned from it by the large veins, that are commonly designated as sinuses (Fig. 259, *b*). The foetal vessels, being bathed in this blood, as the branchiæ of aquatic animals are in the water that surrounds them, not only enable the foetal blood to exchange its venous character for the arterial, by parting with its carbonic acid to the maternal blood, and receiving oxygen from it; but they also serve as rootlets, by which certain nutritious ele-

ments of the maternal blood (probably those composing the liquor sanguinis) are taken into the system of the foetus. In this, they closely correspond with the villi of the intestinal canal; and there is this further very striking analogy—that the nutrient material is selected and prepared by two sets of cells, one of which (the maternal) transmits it to the other (the foetal), in the same manner as the epithelial cells of the intestinal villi seem to take up and prepare the nutrient matter, which is destined to be still further assimilated by the cells that float in the circulating current (§ 461). It is probable, too, that the placenta is to be regarded as an excreting organ; serving for the removal, through the maternal blood, of excrementitious matter whose continued circulation through the blood of the foetus would be prejudicial to the latter. And it will be in this mode that the blood of the mother may become impregnated with substances, or impressed with attributes, originally belonging to the male parent, so as to impart these to the products of subsequent conceptions by a different father (§ 975). There is no more direct communication between the mother and foetus than that which is afforded by this immersion of the foetal tufts in the maternal blood; all the observations which have been supposed to prove the existence of real vascular continuity, having been falsi-

fied by the extravasation of fluid, probably consequent upon the force used in injecting the vessels. Moreover, the different size of the blood-corpuscles in the foetus and in the parent (§ 149) shows the non-existence of any such communication.

983. The formation of the Placenta, in the manner just described, commences in the latter part of the second month; during the third, the organ acquires its proper character; and it subsequently goes on increasing in accordance with the growth of the ovum. Towards the end of the term of gestation, however, it becomes more dense and less vascular; owing, it would seem, to the obliteration of several of the minuter vessels, which are converted into hard fibrous filaments. The vessels of the uterus undergo great enlargement throughout, but especially at the part to which the placenta is attached; and the blood in moving through them produces a peculiar murmur, which is usually distinctly audible at an early period of pregnancy, and may be regarded (when due care is taken to avoid sources of fallacy) as one of its most unequivocal positive signs. The "placental bruit" is thus described by Dr. Montgomery:¹ "The characters of this phenomenon are, a low murmuring or somewhat cooing sound, resembling that made by blowing gently over the lip of a wide-mouthed phial, and accompanied by a slight rushing noise, but without any sensation of impulse. The sound is, in its return, exactly synchronous with the pulse of the mother at the time of examination; and varies, in the frequency of its repetitions, with any accidental variation which may occur in the maternal circulation. Its situation does not vary during the course of the same pregnancy; but in whatever region of the uterus it is first heard, it will in future be found, if recognized at all—for it is liable to intermissions—at least, we shall occasionally be unable to hear it where we have already heard it a short time before, and where we shall shortly again recognize it. According to my experience, it will be most frequently heard about the situation of the Fallopian tube of the right side; but it may be detected in any of the lateral or anterior parts of the uterus." That the cause of this sound exists in the uterus itself, is distinctly proved by the fact, that it has been heard when that organ was so completely *anteverted*, that the fundus hung down between the patient's thighs. A sound so much resembling this as to be scarcely distinguishable from it may be occasioned, however, by a cause of a very different nature—namely, an abdominal tumor, pressing upon the aorta, iliac arteries, or enlarged vessels of its own; and, in doubtful cases, it is necessary to give full weight to the possibility of such an explanation. The sound may be imitated at any time, by pressing the stethoscope on the iliac arteries. The placental bruit has been not unfrequently heard in the eleventh week; but it cannot generally be detected before the fourth month, when the fundus uteri rises above the anterior wall of the pelvis.

984. The amount of the peculiar tissue of the Uterus (§ 305) greatly increases during pregnancy. At the same time, the Mammary gland and its appendages undergo a fuller development; and from this a valuable, but not unequivocal, indication of pregnancy may be drawn. Occasional shooting pains in the Mammæ are not unfrequently experienced within a short period after conception; and more continued tenderness is also not unusual. A sense of distension is very commonly experienced at about the end of the second month; and from that time a distinct "knottiness" usually begins to present itself, increasing with the advance of pregnancy. In many instances, however, these mammary sympathies are entirely absent; and they may be simulated by changes that take place in consequence of various affections of the uterus. A change of color in the areola is a very common, but not an invariable, occurrence in the early months of pregnancy; but another sign is afforded by the areola and nipple, which is of more value because more constant—namely, a

¹ "Signs of Pregnancy," p. 121.

puffy turgescence, and an increased development of the little glandular follicles, or tubercles, which commonly secrete a dewy moisture.—Many other changes in the constitution take place during pregnancy; indicated by the buffiness of the blood, the irritability of the stomach, and the increased excitability of the mind. All these, however, are discussed with sufficient amplification in works on Obstetric Medicine.

985. The act of Conception, being one of a purely organic nature, is not itself productive of any sensation on the part of the mother; but there are some women in whom it is attended with certain sympathetic affections, such as faintness, vertigo, &c., that enable them to fix upon the particular time at which it has taken place. From that period, however, the mother has no direct consciousness of the change going on in the uterus (save by the effects of its increasing pressure on other parts), until the occurrence of what is termed “quickening.” This is generally described as a kind of fluttering movement, attended with some degree of syncope or vertigo. After it has once occurred, and has strongly excited attention, it is occasionally renewed once or twice, and then gives place to the ordinary movements of the fœtus. Not unfrequently, however, no movement whatever is felt, until near the end of the term of gestation, or even through the whole of it. As to the cause of the sensation, Obstetricians are much divided; and no satisfactory account has been given of it. It has been vulgarly supposed to be due to the first movement of the fœtus, which was imagined then to become possessed of an independent life: and the English law recognizes the truth of this doctrine, in varying the punishment of an attempt to procure Abortion, according to whether the woman be “quick with child” or not; and in delaying execution when a woman can be proved to be so, though it is made to proceed if she is not, even if she be unquestionably pregnant. Whether or not the first *sensible* notions of the fœtus are the cause of the peculiar feeling in question, there can be no doubt that the embryo has as much independent vitality before, as after, the quickening. From the time that the ovum quits the ovary, it ceases to be a part of the parent, and is dependent on it only for a due supply of nourishment, which it converts, by its own inherent powers, into its proper fabric. This dependence cannot be said to cease at the moment of quickening; for the connection must be prolonged during several weeks, before the fœtus becomes capable of sustaining life without such assistance. The earliest period at which this may occur will be presently considered (§ 990).

986. At the conclusion of about nine (solar) months from the period of conception, the time of Parturition arrives. In this act, the muscular walls of the uterus are primarily concerned; for a kind of peristaltic contraction takes place in them, the tendency of which is to press the contents of the cavity from the fundus towards the os uteri, and finally to expel them; and this contraction is alone sufficient to empty the uterus; when no impediment is presented to the exit of the fœtus, as we see in the occasional occurrence of *post-mortem* parturition. It is, in fact, in the contraction of the fibres of the fundus and body of the uterus, and in a relaxation of those about the cervix (which relaxation is something quite different from a mere yielding to pressure, and is obviously a vital phenomenon that marks a peculiarity in the actions of this part), that the first stage of an ordinary labor essentially consists. There is no proof whatever that these changes are dependent upon nervous influence; in fact, there is much evidence that the parturient action of the uterus is *not* the result (as some have maintained it to be) of a “reflex” action of the Spinal Cord, but is due to its inherent contractility; for numerous instances have occurred, in which normal parturition has taken place, notwithstanding the destruction of the lower part of the Cord, or the existence of a state of complete paraplegia which marked its functional inactivity; and the continuance of the peristaltic action

for some time after somatic death, when neither the Cerebro-spinal nor the Sympathetic system can afford any supply of nervous power, is yet a more satisfactory proof of the same position. Nevertheless, it seems quite certain that muscular contractions of the uterus *may* be induced by reflex action; for in no other way can we account for numerous phenomena, which distinctly mark the operation of remote causes acting through the nervous system, such as the induction of uterine contractions by the dash of cold water on the abdominal surface, by the injection of cold water into the vagina, by the ingestion of cold water into the stomach, or even by dipping the hands into cold water, or again by the suctorial application of the infant's lips to the nipple, by the introduction of the hand into the vagina, by violent movements of other parts of the body, and by various other means. This general fact has an important practical bearing; since there are various occasions on which it is most important to life, that the previously flaccid uterus should be excited to vigorous contraction, for the sake of accelerating parturition or of suppressing hemorrhage; whilst, on the other hand, it is often no less important to be able to prevent or to antagonize the operation of causes which would prematurely induce uterine contractions, to the destruction of the offspring and the danger of the mother. When, in the normal act of Parturition, the head has so far made its way through the os uteri as to begin to distend the lower part of the genital canal, a new kind of expulsive effort is superadded to that of the uterus itself; the assistance of the Expiratory muscles being then called in (§ 723), through the intermediation of the Spinal Cord, which is probably excited to this action by the stimulus thus applied to the afferent nerves of the compressed parts; and it is chiefly by the instrumentality of these muscles, that the normal act of parturition is usually completed. The same action which expels the fœtus also detaches the placenta; and if the uterus contract with sufficient force after this has been thrown off, the orifices of the vessels which communicated with it are so effectually closed, that little or no hemorrhage takes place. If, however, the uterus does not contract, or relaxes after having contracted, a large amount of blood may be lost in a short time from the open orifices. For some little time after parturition, a sero-sanguineous discharge, termed the *lochia*, is poured out from the uterus; and this commonly contains shreds of the deciduous membrane, which had not been previously detached, together with a quantity of fat globules, and of other products of disintegration of the uterine tissue (§ 593).¹ Within a few weeks after delivery, the uterus regains (at least in a healthy subject) its previous condition; and it is probable that the portion of its mucous membrane which had been thrown off as Decidua, is very early reproduced.

987. As to the reason why the period of Parturition should be just nine months after the occurrence of Conception, we know nothing more than we do of that of similar *periodical* phenomena in the history of the life of Man and of other living beings; all of which must be considered as *occasional* manifestations of changes that are constantly in progress, whose rate, being dependent upon the degree of Heat supplied, is so uniform in warm-blooded animals as to secure a very close conformity to a common standard.² There is evidence that

¹ In addition to the evidence already cited, of the rapid occurrence of fatty degeneration of the uterine structure after parturition, the Author may mention that he has been informed by Dr. Retzius (Professor of Midwifery at Stockholm) that he has detected a large number of fat globules in the urine of puerperal women. Is it not possible, it may be further asked, that some of the oleaginous matter so copiously poured forth by the mammary glands, may be derived from this source? Such an economy of nutrient material would be consistent with what we elsewhere meet with; and the idea is conformable to the fact, that the proportion of butyric in the milk is much greater in the earlier, than in the later months of lactation.

² This may be best illustrated by the analogy of a Leyden jar which is being charged by the *continuous* action of an Electrical Machine, and which is so arranged as to discharge

the occurrence of the uterine *nisus* may be induced by a variety of causes, several of which probably concur in the normal act of Parturition. For, in the first place, the state of development of the muscular substance of the uterus can scarcely be without a considerable influence on this operation. We see it undergoing a gradual augmentation during the period of pregnancy, without any demand being made upon its functional activity; it gradually becomes more and more irritable, contractions being far more readily excited in it by electrical or other stimulation, in the later, than in the earlier months of pregnancy; and at last this irritability seems to reach its *acme*, in virtue of the nutritive changes which have been progressively taking place in it, and to discharge itself in one powerful effort.—That the parturient effort, however, is not solely dependent upon the state of development of the Uterus, appears from several considerations: and, in the first place, from the very curious fact that, in cases of Extra-uterine pregnancy, contractions resembling those of labor take place in its walls. Moreover, various states of constitution, especially that which is designated as irritability, may induce the occurrence of the parturient efforts at an earlier period; and this constitutes Abortion, or Premature Delivery, according to the *viability* of the child. There are some women, in whom this regularly happens at a certain month, so that it seems to be an action natural to them; but it is always to be prevented, if possible, being injurious alike to the mother and the child; and this prevention is to be attempted by rest and tranquillity of mind and body, and by a careful avoidance of all the exciting causes which may produce uterine contractions by their operation on the Nervous system. Among the causes of Abortion, however, the death of the fœtus, or an abnormal state of the placental structure, is one of the most common; and thus we have a very distinct proof of the influence which the state of the *contents* of the uterus has on the induction of parturient effort. In fact, what may be termed the *maturation* of the uterus and its contents—a condition analogous to that which precedes the dropping of ripe fruit, and which is acquired by the completion of the developmental process—appears to have more influence in determining the normal parturient effort, than any other cause which can be assigned. Certain preparatory changes are known to be taking place in the uterus itself during the last two or three weeks of gestation; for its upper part contracts itself more closely around its contents, as if it were bracing itself up for the coming encounter; whilst there is a greater disposition to relaxation of its lower part, as also in the soft parts surrounding the orifice of the pelvis, so that the whole mass descends. It is well known that there is far less aptitude for dilatation in the os uteri before this change takes place; so that premature labors are frequently rendered very difficult and tedious by the resistance which the fœtus encounters from the soft parts, notwithstanding that its smaller size enables it to pass more readily through the pelvic canal. The placenta of the fully developed fœtus, again, is somewhat in the condition of the footstalk of a ripening fruit; that is, having attained its full evolution as an organ of temporary function, its connection tends to become dissevered in virtue of the further changes which take place in itself, quite irrespectively of any external agency.¹ This is very strikingly evinced by the fact, that when the uterus contains two fœtuses, and one of them is expelled—either in consequence of impeded development or of disease in itself, or because it has attained its own

itself spontaneously whenever the disturbance in its equilibrium attains a certain intensity. If the movement of the machine be uniform, and other conditions remain the same, the discharge will take place at regular intervals.

¹ Such a change may be easily verified in the placenta of many of the lower animals, such as the cat, in which the fœtal and maternal portions remain more distinct than they do in the human female; for these become far more easily separable from each other, as the period of parturition draws near, than they are at any previous time.

full term of development (as in cases of superfœtation, § 990)—the other, if its development at this period is far from complete, is often retained, and goes on to its full term, *its* placenta not being detached in the first parturient effort, because it was not then prepared for the separation. It is obvious that this view affords a rational explanation of the occurrence of uterine action in cases of extra-uterine fœtation; for, if the condition of the placental attachment furnish its exciting cause, it will do so equally, whether the placenta be attached to the lining of the uterus, or to that of the Fallopian tube, or to any other organ. It is an additional indication that the immediate stimulus to the parturient effort of the uterus is given by some change in the condition of its fœtal connections, that the term of gestation seems capable of being prolonged by peculiarities in the constitution or rate of development of the fœtus, which are derived from the male parent; for it was ascertained by the late Earl Spencer,¹ that of 75 cows in calf by a particular bull, the average period was 288½ days, instead of 280; none of these having gone less than 281 days, and two-fifths of them having exceeded 289 days.²

988. Although the duration of Pregnancy is commonly stated at nine solar months, it would be more correct to fix the period at 40 weeks, or 280 days; which exceeds nine calendar months by from 5 to 7 days, according to the months included.³ This, at least, is the average result of observation, in cases in which the period of Conception could be fixed, from peculiar circumstances, with something like certainty; but there can be no doubt that variations of a few days, more or less, are of continual occurrence. The period of Quickening may be relied on in some women, in whom it occurs with great regularity in a certain week of Pregnancy; but in general there is great latitude as to the time of its occurrence. The usual or average time is probably about the 18th week.

989. The question of the *extreme limit* of Gestation is one of great importance both to the Practitioner and to the Medical Jurist; but it is one which cannot yet be regarded as satisfactorily decided. Many persons, whose experience should give much weight to their opinion, maintain that the regular period of 40 weeks is never extended for more than two or three days; whilst,

¹ See Dr. J. C. Hall in "Medical Gazette," May 6, 1842.

² The very ingenious doctrine has been propounded by Dr. Tyler Smith ("Parturition, and the Principles and Practice of Obstetrics," London, 1849), that the exciting cause of parturition is to be found in the recurrence of the periodical excitement of the ovary, acting by reflection on the uterus through the spinal system of nerves, the ovarian nerves being the *excitors* and the uterine the *motors*; this excitement continuing during the entire period of gestation, and giving a special tendency to abortion at each return; and acting with such potency at the eleventh recurrence as then to induce the parturient effort. He assigns no other cause, however, why this eleventh recurrence should be so much more effectual than the rest, than that by this time there is a much greater aptitude to contraction in the uterus itself, and an increased readiness to be thrown off on the part of the placenta—conditions which seem to the Author to be in themselves adequate to account for the result. Dr. Tyler Smith's hypothesis is distinctly negatived by the following facts: 1. The period of gestation, although *commonly* a multiple of the menstrual interval, is by no means *constantly* so; the former remaining normal when the latter is shorter or longer than usual. 2. Parturient efforts take place in the uterus, notwithstanding the previous removal of the lower part of the spinal cord. 3. The removal of the ovaries in the later part of gestation does not interpose the least check to the parturient action, as Prof. Simpson, of Edinburgh, has experimentally ascertained. The Author considers himself fully justified, therefore, in asserting that this hypothesis does not possess the slightest claim even to be entertained as a *possible* one; and would refer, for a more detailed examination of it, to the "Brit. and For. Med.-Chir. Review," vol. iv. p. 1.

³ The mode of reckoning customary among women, is to date from the middle of the month after the last appearance of the Catamenia; but it is certain that Conception is much more likely to take place *soon* after they have ceased to flow, or even just before their access, than in the intervening period (§ 966); so that, in most instances, it would be most correct to expect labor at forty weeks and a few days after the last recurrence of the Menses.

on the other hand, there are numerous cases on record, which, if testimony is to be believed at all (and in many of these, the character and circumstances of the parties place them above suspicion), furnish ample evidence that Gestation may be prolonged for at least three weeks beyond the regular term.¹ The English law fixes no precise limit; and the decisions which have been given in our courts, when questions of this kind have been raised, have been mostly formed upon the collateral circumstances. The law of France provides that the legitimacy of a child born within 300 days after the death or departure of the husband shall not be questioned; and a child born after more than 300 days is not declared a bastard, but its legitimacy may be contested. By the Scotch law, a child is not declared a bastard unless born after the tenth month from the death or departure of the husband.—Very important evidence on this subject is afforded by observations on the lower animals, which are free from those sources of fallacy which attend human testimony. The observations of Tessier, which were continued during a period of forty years, with every precaution against inaccuracy, have furnished a body of results which seems quite decisive. In the Cow, the ordinary period of gestation is about the same as in the Human female; but out of 577 individuals, no less than 20 calved beyond the 298th day, and of these, some went on to the 321st, making an excess of nearly six weeks. Of 447 Mares, whose natural period of gestation is about 335 days, 42 foaled between the 359th and the 419th days, the greatest protraction being thus 84 days; or just one-fourth of the usual term. Of 912 Sheep, whose natural period is about 151 days, 96 yeaned beyond the 153d day; and of these 7 went on until the 157th day, making an excess of 6 days. Of 161 Rabbits, whose natural period is about thirty days, no fewer than 25 littered between the 32d and 35th; the greatest protraction was here one-sixth of the whole period, and the proportion in which there was a manifest prolongation was also nearly one-sixth of the total number of individuals. In the incubation of the common Hen, Tessier found that there was not unfrequently a prolongation to the amount of three days, or one-seventh of the whole period.—In regard to Cows, the observations of Tessier have been confirmed by those of Earl Spencer, who has published² a table of the period of gestation as observed in 764 individuals; he considers the average period to be 284 or 285 days; but no fewer than 310 calved after the 285th day; and of these, 3 went on to the 306th day, and 1 to the 313th. It is curious that among the calves born between the 290th and 300th days, there was a decided preponderance of males—these being 74 to 32 females; whilst all of those born after the 300th day were females. The additional series of observations subsequently made by Earl Spencer, in regard to the constant protraction of the period in 75 cows in calf by a particular bull, has been already noticed (§ 987).—Another series of observations has been published by Mr. C. N. Bement, of Albany, U. S.,³ who has recorded the period of gestation of 62 cows. The longest period was 336 days; the shortest, 213 days. The average period for male calves was 288 days; and for females, 282 days.—On the whole, it may be considered, that in regard to the Human female, the French law is a very reasonable one; and there is quite sufficient analogical evidence to support the assertions of females of good character, having no motive to deceive, which lead to the conclusion that a protraction of at least four weeks is quite possible, and that a protraction to the extent of six weeks is scarcely to be denied.⁴

¹ A good collection of such cases will be found in Dr. Montgomery's excellent work on the "Signs of Pregnancy," and in Dr. A. Taylor's "Medical Jurisprudence."

² "Journal of the English Agricultural Society," 1839.

³ "American Journal of the Medical Sciences," October, 1845.

⁴ See especially two cases, 183 and 184, detailed by Dr. Murphy in his "Report of the Obstetric Practice of University College Hospital" for 1844; and another case since published by him in the "Medical Gazette" for 1849, vol. xlviii. p. 683.

990. In regard to the *shortest* period at which Gestation may terminate, consistently with the viability of the Child, there is a still greater degree of uncertainty. Most practitioners are of opinion, that it is next to impossible for a foetus to live and grow to maturity, which has not nearly completed its seventh month; but it is unquestionable that infants born at a much earlier period have lived for some months, or even to adult age. It is rare in such cases, however, that the date of conception can be fixed with sufficient precision to enable a definite statement to be given. Of the importance of the question, a case which some time since occurred in Scotland affords sufficient proof. A vast amount of contradictory evidence was adduced on this trial; but, on the general rule of accepting positive in preference to negative testimony, it seems that we ought to consider it possible that a child may live for some months, which has been born at the conclusion of 24 weeks of gestation. In the case in question, the Presbytery decided in favor of the legitimacy of an infant born alive within 25 weeks after marriage.¹ A very interesting case is on record,² in which the mother (who had borne five children) was confident that her period of gestation was less than 19 weeks; the facts stated respecting the development of the child are necessarily very imperfect, as it was important to avoid exposing his body, in order that his temperature might be kept up; but at the age of three weeks, he was only 13 inches in length, and his weight was no more than 29 oz. At that time, he might be regarded, according to the calculation of the mother, as corresponding with an infant of 22 weeks or 5½ months; but the length and weight were greater than are usual at that period, and he must have been probably born at about the 25th week. It is an interesting feature in this case, that the calorific power of the infant was so low, that artificial heat was constantly needed to sustain it; but that, under the influence of heat of the fire, he evidently became weaker, whilst the warmth of a person in bed rendered him lively and comparatively strong. During the first week, it was extremely difficult to get him to swallow; and it was nearly a month before he could suck. At the time of the report, he was four months old, and his health appeared very good.—Another case of very early viability has been more recently put on record by Mr. Dodd:³ in this, as in the former instance, the determination of the child's age rests chiefly on the opinion of the mother; but there appears no reason for suspecting any fallacy. The child seems to have been born at the 26th or 27th week of gestation; and having been placed under judicious management, it has thriven well.—One of the most satisfactory cases on record is that detailed by Dr. Outrepoint⁴ (Professor of Obstetrics at Wurzburg), and stated by Dr. Christison in his evidence on the case first alluded to. The evidence is as complete as it is possible to be in any case of the kind; being derived not only from the date assigned by the mother to her conception, but also from the structure and history of the child. The gestation could have only lasted 27 weeks, and was very probably less. The length of the child was 13½ inches, and its weight was 24 oz. Its development was altogether slow; and at the age of eleven years, the child seemed no more advanced in body or mind than most other lads of seven years old. In this last point, there is a very striking correspondence with the results of other observations upon premature children, made at an earlier age. A very remarkable case has been since put on record by Dr. Barker of Dumfries,⁵ in which the child is affirmed to have been born on the 158th day of gestation, or in the middle of the *twenty-third* week after intercourse. Its size, weight, and grade of development were con-

⁵ "Medical Times," Sept. 7 and Oct. 12, 1850.

formable to the asserted period : for it weighed only 1 lb. and measured 11 inches ; it had only rudimentary nails, and scarcely any hair except a little of reddish color on the back of the head ; the eyelids were closed, and did not open until the second day ; the skin was shrivelled. When born it was wrapped up in a box and placed before the fire. The child did not suck properly until after the lapse of a month, and did not walk until she was nineteen months old. Three years and a half afterwards, this child was in a thriving state, and very healthy, but of small make ; she then weighed 29½ lbs.

991. There is another question regarding the function of the Female in the Reproductive act, which is of great interest in a scientific point of view, and which may become of importance in Juridical inquiries : namely, the possibility of *Superfoetation*, that is, of two distinct conceptions at an interval of greater or less duration ; so that two fetuses of different ages, the offspring perhaps of different parents, may exist in the uterus at the same time.—The simplest case of Superfoetation, the frequent occurrence of which places it beyond reasonable doubt, is that in which a female has intercourse on the same day with two males of different complexions, and bears twins at the full time ; the two infants resembling the two parents respectively. Thus, in the slave States of America, it is not uncommon for a black woman to bear at the same time a black and a mulatto child ; the former being the offspring of her black husband, and the latter of her white paramour. The converse has occasionally, though less frequently occurred : a white woman bearing at the same time a white and a mulatto child. There is no difficulty in accounting for such facts, when it is remembered that nothing has occurred to prevent the uterus and ovaria from being as ready for the second conception as for the first ; since the orifice of the former is not yet closed up ; and, at the time when one ovum is matured for fecundation, there are usually more in the same condition.—But it is not easy thus to account for the birth of two children, each apparently mature, at an interval of five or six months ; since it might have been supposed that the uterus was so completely occupied with the first ovum, as not to allow of the transmission of the seminal fluid necessary for the fecundation of the second. In cases where two children have been *produced* at the same time, one of which was fully formed, whilst the other was small and seemingly premature, there is no occasion whatever to imagine that the two were *conceived* at different periods ; since the smaller fetus may have been “blighted,” and its development retarded, as not unfrequently happens in other cases. Nor is it necessary to infer the occurrence of Superfoetation in every case, in which a living child has been produced a month or two after the birth of another ; since the latter may have been somewhat premature, whilst the former has been carried to the full term. But such a difference can scarcely be, at the most, more than 2½ or 3 months ; and there are several cases now on record, in which the interval was from 110 to 170 days, whilst neither of the children presented any indication of being otherwise than mature.¹

4.—*Development of the Embryo.*

992. The history of the evolution of the germ, from its first appearance as a *single cell* lying in the midst of the yelk, to the time when it presents the form and structure characteristic of its parent species, and is capable of maintaining an independent existence—including the details of the progressive development of each separate organ and tissue, from its first appearance as an aggregation of simple cells formed by the duplicative subdivision of the primordial vesicle, to

¹ See the Article “Superfoetation,” in Dr. Beck’s “Elements of Medical Jurisprudence.”

that stage of completeness in which it is able to bear a part in the vital economy of the new being—and embracing, also, the succession of changes in the provisions for the nutrition of the embryo in the successive phases of its existence, and the adaptations of its general organization to each respectively—constitutes one of the most interesting departments of Physiological Science, and one which has of late years received more attention than any other. It is a branch of the inquiry, however, which has, and seems likely to have less *practical* bearing than any other; for neither as regards the preservation of the body in health, nor in its restoration from disease, is it easy to see what direct benefit the most exact knowledge of Embryonic Development is likely to afford. The chief subject on which it throws light, is that of Congenital Malformations and Deficiencies; many of which are now distinctly traceable to *arrest* or *irregularity* of the developmental processes, some of them, indeed, to *excess* (§ 596).—For these reasons, the topic before us will be passed over much more lightly in the present Treatise than its scientific importance might seem to demand; and all that will be here attempted, will be a mere sketch of the mode in which the evolution of the germ takes place, this being followed in the first instance as a whole, whilst its principal organs will be afterwards separately considered as they successively present themselves.

993. This sketch, however, will serve to convey an idea of the nature of the process, and to illustrate its conformity in Man to that great law of progress *from the general to the special*, which is equally manifested in the development of every other organized being. For, when we first discern the primordial cell which is to evolve itself into the Human organism, we can trace nothing that essentially distinguishes it from that which might give origin to *any* other form of organic structure, either Vegetable or Animal; its condition, in fact, being permanently represented by the humblest single celled Plants and Animals. The earliest stage of its development consists in simple multiplication by duplicative subdivision, so that a mass of cells comes to be produced, amidst the several individuals of which no difference can be traced; and this also finds its parallel among the simpler organisms of both kingdoms. Soon, however, this *homogeneous* condition gives rise to a *heterogeneous* one; the further changes which different parts of the mass undergo not being of the same uniform character, so that a marking out of *organs*, or instrumental parts adapted for different purposes in the economy, comes to be discernible. The organs, however, whose distinctness first becomes apparent, are not usually those which we trace in the completed structure, but have a merely temporary character; being evolved either as a sort of scaffolding or framework for the building up of the more permanent parts, or with a view to the nutrition of the embryo during the evolution of these. Although the first indications of heterogeneity in the germinal mass are of nearly the same kind in all animals—consisting in the formation of a *blastodermic membrane* (composed, however, of nothing else than layers of cells) upon its exterior, which serves as a sort of temporary stomach, whilst a large part of the included mass undergoes liquefaction, and serves as the nutrient material for the tissues which are to be evolved from it—yet indications are very speedily manifested, of the *primary division* of the Animal Kingdom, of which the new being is a member;—thus, in the case of the Human embryo, as that of all Vertebrated animals, the first indication of the permanent organization is shown in the “primitive trace” which marks out the line of the vertebral column (Plate II. Fig. 11); and in this we very soon discern the foundations of the separate vertebræ (Fig. 12, c). But there is nothing at this period to distinguish the germ of Man from that of *any other* Vertebrated animal, this early part of the developmental process being carried on upon the same plan in every member of that sub-kingdom; and it is not until we meet with indications of the plans which are peculiar to the respective

classes of that sub-kingdom, that we can discover whether the germ in course of evolution is to become a Mammal, Bird, Reptile, or Fish. So, even when it has been recognized as belonging to the Mammalian class, there is, at first, nothing to distinguish it from that of any other Mammal; and it is only with the advance of the developmental process that indications successively present themselves, which enable us to distinguish, one after another, the characters of the order, the family, the genus, the species, the variety, the sex, and the individual—the *more special features progressively evolving themselves out of the more general*, which is the expression of the law of development, common to all Organized beings.¹

994. With this progressive alteration in the condition of the embryo itself, a very remarkable series of alterations takes place, *pari passu*, in the mode in which it is supplied with nutrient material, and in the provisions for the aeration of its circulating fluid.—The first evolution of the germ takes place entirely at the expense of the *yolk*; of which, however, the store contained in the Mammalian ovum is very small. The whole of this is very speedily incorporated in the substance of the germ, by the peculiar process to be presently described; and there is no residual store of “food-yolk,” such as that which, in the Bird, serves for the nutrition of the embryo during the whole remainder of the developmental process, being gradually absorbed into the substance of the blastodermic membrane, and there converted into blood. The Mammalian ovum, however, from the time it reaches the Uterus, is furnished with a new supply of nourishment in the fluid secreted by the Decidual membrane (§ 977); and for the absorption of this, it is particularly adapted by the villositities which develop themselves from its own external envelop. These, at first entirely destitute of bloodvessels, are subsequently penetrated at a certain part of the surface by the foetal capillaries brought to them by an organ, the *Allantois*, which is developed in Birds as the temporary instrument of respiration; and thus is originated the *foetal* portion of the Placenta, of whose formation details will be presently given. From the time that this organ is completed, up to the birth of the Infant, the embryo draws its nutrient materials direct from the maternal blood, though not receiving that blood *as such* into its own organism; and it is through the same medium that the aeration of its own blood is effected, its pulmonary apparatus being as yet inoperative. Its circulating system, arranged in accordance with these requirements, presents many peculiarities which mark its foetal character; and the alteration in the course of the blood, which takes place as soon as the respiratory organs come into play, constitutes the essential difference between intra-uterine and extra-uterine life. If, as sometimes happens, the lungs of the new-born infant expand but imperfectly or scarcely at all, the circulation continues to be carried on, in a greater or less degree, upon its intra-uterine plan; and this, when the placenta is no longer capable of supplying the needed aeration, is incompatible with the persistence of life.

995. Our knowledge of the first stages of the developmental process in the Mammalian ovum is in many respects incomplete; and it is requisite to interpret what has been obscurely seen in the ova of this class, by the clearer views derived from observation of those of the lower animals.²—As already stated,

¹ See, on this subject, the Author's “Princ. of Phys., Gen. and Comp.,” CHAPS. VIII. and XVIII., *Am. Ed.*; in the former of which will be found an examination of the commonly received doctrine, that the higher forms in the course of their development pass through the phases which remain permanently characteristic of the lower.

² The researches of Kölliker (“Muller's Archiv,” 1843, p. 68), and Bagge (“De Evolut. Strongyli et Ascarid., Diss. Inaug.,” 1841) on the ova of Entozoa—those of Mr. Newport (“Philos. Transact.,” 1851) on the ova of Batrachia, and those of Bischoff (“Entwickelungsgeschichte des Hunde-eies,” 1845) on the ova of the Bitch—are the most valuable which we at present possess.

the germinal vesicle disappears at or about the time of fecundation ; but its disappearance is not a result of fecundation, since it also takes place in the unim-

Fig. 260.

pregnated egg, in consequence (it may be presumed) of the completion of its term of life, and of those operations which it was developed to perform. Its place is seen to be occupied at an early period after fecundation, by a new and peculiar cell, the origin of which is obscure, but the destination of which is most important ; for it is by the duplicative subdivision of this cell, first into 2, then

Fig. 261.

A. Ovum of a Bitch, from the Fallopian tube, half an inch from its opening into the uterus, showing the zona pellucida with adherent spermatozooids, the yolk divided into its first two segments, and two small granules or vesicles contained with the yolk in the cavity of the zona. B. Ovum of a bitch from the lower extremity of the Fallopian tube : the cells of the tunica granulosa have disappeared : the yolk is divided into four segments. C. Ovum of bitch from the lower extremity of the Fallopian tube, in a latter stage of the division of the yolk. D. An ovum from the uterus : it is larger, the zona thicker, and the segments of the yolk are very numerous. E. Ovum from the lower extremity of the Fallopian tube burst by compression : the segments of the yolk have partly escaped, and in each of them a bright spot or vesicle is visible.

into 4, then into 8, and so on, and by the metamorphoses which its progeny undergo, that the whole embryonic fabric is gradually evolved. Hence this cell may be termed the *embryo-cell*.¹ At the same time a peculiar change begins to

¹ The embryo-cell has not yet been clearly made out in the Mammalian ovum ; but from the conformity of the subsequent appearances to those which are seen in the ova of the lower animals, there is every reason to believe that the formation of either a complete cell, or of a nucleus having the same essential endowments, is a preliminary to the cleavage of the yolk.

take place in the yelk, the whole sphere of which is first marked out by a furrow into two hemispheres, and is at last completely divided by the extension of this fission to the centre; each half is again furrowed and then cleft in the same manner, and thus the entire yelk is broken up into a mass of segments (Fig. 261, A, B, C). This "segmentation" takes place *pari passu* with the multiplication of the embryo-cells, each of which is surrounded by a distinct portion of the yelk; and there seems every probability that it is determined by that multiplication, and that each cell of the pair that is formed by the duplicative subdivision of its predecessor draws around itself its proper share of the nutritive material.—These changes take place in the Mammalian Ovum, during its transit along the Fallopian tube to the uterus; so that, by the time of its arrival there, the whole cavity of the *Zona pellucida* is occupied by minute spherules of yelk, each containing a transparent vesicle,¹ the aggregation of which gives it a mulberry-like aspect (Fig. 261, D); and by a continuance of the same process of subdivision, the component segments becoming more and more minute, the mass comes to present a finely granular aspect.

996. At this stage it does not appear that the several segments of the yelk have a distinct enveloping membrane; but an envelop is now formed around each of them, converting it into a cell, of which the included vesicle constitutes the nucleus, and of which the portion of the yelk surrounding this forms the contents. This happens first to the peripheral portions of the mass; and as its cells are fully developed, they arrange themselves at the surface of the yelk into a kind of membrane, and at the same time assume a pentagonal or hexagonal shape from mutual pressure, so as to resemble pavement-epithelium (Plate I. Fig. 5). As the globular masses of the interior are gradually converted into cells, they also pass to the surface and accumulate there, thus increasing the thickness of the membrane already formed by the more superficial layer of cells, while the central part of the yelk remains filled only with a clear fluid. By this means the exterior of the yelk is speedily converted into a kind of secondary vesicle situated within the *Zona pellucida*, and named by Bischoff the *blastodermic vesicle*. This vesicle, very soon after its formation, presents at one point an opaque, roundish spot (Plate I. Fig. 6), which is produced by an accumulation of cells and nuclei of less transparency than elsewhere; this is termed the *area germinativa*. The wall of the vesicle, which is termed the *germinal membrane*, increases in extent and thickness by the formation of new cells (whose mode of production has not been clearly made out); and it subdivides into two layers (Plate I. Fig. 7), which, although both at first composed of cells, soon present distinctive characters, and are concerned in very different ulterior operations. The outer one of these is commonly known as the *serous* layer (Fig. 8); but being the one in whose substance the foundation is laid for the vertebral column and the nervous system, it is sometimes called the *animal* layer. The inner one is usually known as the *mucous* layer (Fig. 9); and being the one chiefly concerned in the formation of the nutritive apparatus, it is sometimes called the *vegetative* layer. This division is at first most evident in the neighborhood of the *area germinativa*; but it soon extends from this point, and implicates nearly the whole of the *germinal membrane*.

997. The *Area Germinativa*, at its first appearance, has a rounded form; but it soon loses this, becoming first oval, and then pear-shaped (Plate II. Fig. 11). While this change is taking place in it, there gradually appears in its centre a clear space, termed the *area pellucida* (*a*); and this is bounded externally by a

¹ This vesicle has not yet been made out, in the Mammalian ovum, to be a true cell, which it certainly is in the ovum of many of the lower animals; its appearance, when liberated from the yelk-granules which surround it, being rather that of a fat or oil-globule.

more opaque circle (whose opacity is due to the greater accumulation of cells and nuclei in that part than in the area pellucida), which subsequently becomes the *area vasculosa*. In the formation of these two spaces, both the serous and mucous layers of the germinal membrane seem to take their share; but the foundation of the embryonic structure, known as the *primitive trace*, is laid in the serous lamina only. This consists in a shallow groove (*c*), lying between two oval masses (*b*), known as the *laminæ dorsales*. The form of these changes with that of the area pellucida; at first they are oval, then pyriform, and at last become of a guitar-shape. At the same time, they rise more and more from the surface of the area pellucida, so as to form two ridges of higher elevation, with a deeper groove between them; and the summits of these ridges tend to approach each other, and gradually unite, so as to convert the groove into a tube. At the same time, the anterior portion of the groove dilates into three recesses or vesicles (Plate II. Fig. 12, *b*), which indicate the position of the three principal divisions of the Encephalon, afterwards to be developed as the *prosencephalon*, the *mesencephalon*, and the *epencephalon* (§ 1012). The most internal parts of these laminæ, bounding the bottom and sides of the groove, appear to furnish the rudiments of the nervous centres which this cranio-vertebral canal is to contain; whilst the outer parts are developed into the rudiments of the vertebral column and cranium. Even before the laminæ dorsales have closed over the primitive groove, a few square-shaped and at first indistinct plates, which are the rudiments of vertebræ (*c*), begin to appear at about the middle of each. The position of the bodies of the vertebræ is indicated at this period, in the embryos of Birds and Fishes, by a distinct cylindrical rod of nucleated cells, termed the *chorda dorsalis*; and this retains its embryonic type in the Myxinoid Fishes (§ 1010). While this is going on, an accumulation of cells takes place between the two laminæ of the germinal membrane at the "area vasculosa;" and these cells speedily form themselves into a distinct layer, the *vascular lamina*, in which the first bloodvessels of the embryo are developed, as will be presently described (§ 998). From the dorsal laminæ on either side, a prolongation passes outwards and then downwards, forming what is known as the *ventral lamina*; in this are developed the ribs and the transverse processes of the vertebræ; and the two have the same tendency to meet on the median line, and thus to close in the abdominal cavity, which the dorsal laminæ have to inclose the spinal cord. At the same time, the layers of the germinal membrane which lie beyond the extremities of the embryo, are folded in, so as to make a depression on the yolk; and their folded margins gradually approach one another under the abdomen. The first rudiment of the intestinal canal presents itself as a channel along the under surface of the embryonic mass, formed by the rising up of the inner layer of the germinal membrane into a ridge on either side. The two ridges gradually arch over and meet, so as to form a tube, which is thus (so to speak) pinched off the general vitelline sac; and it remains in connection with this, by means of an unclosed portion, which constitutes the "vitelline duct" (Figs. 262, 263).

998. Whilst these new structures are being produced, a very remarkable change is taking place in that part of the serous lamina which surrounds the area pellucida. This rises up on either side in two folds; and these gradually approach one another, at last meeting in the space between the general envelop and the embryo, and thus forming an additional investment to the latter. As each fold contains two layers of membrane, a double envelop is thus formed; of this, the outer lamina adheres to the general envelop; whilst the inner remains as a distinct sac, to which the name of *Amnion* is given. (See Figs. 264, 265, and 266.) This takes place during the third day in the Chick; the period at which it occurs in the Human Ovum is difficult to be ascertained, owing to the small number of normal specimens which have come under observation at a

sufficiently early stage.—During the same period, a very important provision for the future support of the embryo begins to be made, by the development of bloodvessels and the formation of blood. Hitherto, the embryonic structure has been nourished by direct absorption of the alimentary materials supplied to

Fig. 262.

it by the yolk; but its increasing size, and the necessity for a more free communication between its parts than any structure consisting of cells alone can permit, call for the development of vessels through which the nutritious fluid may be conveyed. These vessels are first seen in that part of the Vascular lamina of the germinal membrane (§ 294) which immediately surrounds the embryo; and they form a network, bounded by a circular channel, which is known under the name of the *Vascular Area* (Plate II. Fig. 13). This gradually extends itself, until the vessels spread over the whole of the membrane that contains the yolk. The first blood-disks appear to be formed from the nuclei of the cells, whose cavities have become continuous with each other to form the vessels (§ 149); and from these, the subsequent blood-disks of the first series are probably generated. This network of bloodvessels serves the purpose of absorbing the nutritious matter of the yolk, and of conveying it towards the embryonic structures, which are now in process of rapid development. The first movement of the fluid is *towards* the embryo; and this can be witnessed before any distinct heart is evolved. The same process of absorption from the yolk, and of conversion into blood, probably continues as long as there is any alimentary material left in the sac.

999. The Yolk-sac is early separated in the Mammalia, by a constriction of the portion which is continuous with the abdomen of the Embryo; and it is known from that time under the name of the *Umbilical Vesicle* (Plate I. Fig. 10, *v*). The communication, however, remains open for a time through the vitelline duct; and even after this has been cut off, the trunks which connect the circulating system of the embryo with that of the vascular area are discernible; these are called *Omphalo-Mesenteric*, *Meseraic*, or *Vitelline* vessels (Figs. 266, 267, *q*, *r*). It was formerly believed that the nutrient matter of the yolk passes directly through the vitelline duct into the (future) digestive cavity of the embryo, and is from it absorbed into its structure; but there can now be little doubt, that the vitelline vessels are the real agents of its absorption, and that they convey it, through the general circulating system, to the tissues in process of formation. They correspond, in fact, to the Mesenteric veins of Invertebrated animals, which are the sole agents in the absorption of nutriment from their digestive cavity (§ 459); and the blastodermic vesicle is to be regarded

as the temporary stomach of the embryo—remaining as the permanent stomach in the Radiated tribes.¹

1000. The formation of the *Heart*, which is the first of the permanent organs of the Embryo that comes into functional activity, takes place in the substance of the vascular layer, beneath the upper part of the spinal column. Its first rudiment consists of an aggregation of cells, of which the inner part break down to form its cavity, whilst the outer remain to constitute its walls. For a long time after it has distinctly commenced pulsating, and is obviously exerting a contractile force, its walls obviously retain the cellular character, and only become muscular by a progressive histological transformation (§ 310). The first appearance of the Heart in the Chick is at about the 27th hour; the time of its formation in Mammalia has not been distinctly ascertained. In its earliest form it has the same simple character which is presented by the central impelling cavity of the lower Invertebrata; being a mere prolonged canal, which at its posterior extremity receives the veins, and at its anterior sends forth the arteries. After a short time, however, it becomes bent upon itself (Plate II. Fig. 13, *d*); and it is soon subdivided into three cavities, which exist in all Vertebrata, viz., a simple *auricle* or receiving cavity, a simple *ventricle* or propelling cavity, and a *bulbus arteriosus* at the origin of the aorta. The circulation is at first carried on exactly upon the plan which is permanently exhibited by Fishes. The Aorta subdivides into four or five arches on either side of the neck (Figs. 266, 267, *e*, *e'*, *e''*), which are separated by fissures much resembling those forming the entrances to the gill-cavities of Cartilaginous Fishes; and these arches reunite to form the descending aorta, which transmits branches to all parts of the body.—Such is the first phase or aspect of the Circulating Apparatus, which is common to all Vertebrata during the earliest period of their development, and which may therefore be considered as its most general form. It remains permanent in the class of Fishes; and in them the vascular system undergoes further development on the same type, a number of minute tufts being sent forth from each of the arches, which enter the filaments of the gills, and serve for the aeration of the blood. In higher Vertebrata, however, the plan of the circulation is afterwards entirely changed, by the formation of new cavities in the heart, and by the production of new vessels; these changes will be presently described. It is incorrect, therefore, to speak of the vascular arches in *their* necks as *branchial* arches; since no branchiæ or gills are ever developed from them. The clefts between them may be very distinctly seen in the Human Fœtus towards the end of the first month; during the second, they usually close up and disappear.

1001. With the evolution of a Circulating apparatus, adapted to absorb nourishment from the store prepared for the use of the Embryo, and to convey it to its different tissues, it becomes necessary that a Respiratory apparatus should also be provided, for depurating the blood from the carbonic acid with

¹ Previously to the ninth day of incubation (in the Fowl's egg), a series of folds are formed by the lining membrane of the yelk-bag, which project into its cavity; these become gradually deeper and more crowded, as the bag diminishes in size by the absorption of its contents. The vitelline vessels that ramify upon the yelk-bag send into these folds (or valvulæ conniventes) a series of inosculating loops, which immensely increase the extent of this absorbing apparatus. But these minute vessels are not in immediate contact with the yelk; for there intervenes between them (as was first noticed by Mr. Dalrymple) a layer of nucleated cells, which is easily washed away. (See Dr. Baly's Translation of "Müller's Physiology," pp. 1557–1559.) It was from the color of these, communicated to the vessels beneath, that Haller termed the latter *vasa lutea*; when the layer is removed, the vessels present their usual color. There seems good reason to believe that these cells, like those of the Intestinal Villi in the adult (§ 461), are the real agents in the process of absorbing and assimilating the nutritive matter of the yelk; and that they deliver this up to the vessels, by themselves undergoing rupture or dissolution, being replaced by new layers.

which it becomes charged during the course of its circulation. The temporary Respiratory apparatus now to be described bears a strong resemblance in its own character, and especially in its vascular connections, to the gills of the Mollusca, which are prolongations of the external surface (usually near the termination of the intestinal canal), and which almost invariably receive their vessels from that part of the system. This apparatus, which is termed the *Allantois*, sprouts forth from the caudal extremity of the embryo at first as a little mass of cells, which soon exhibits a cavity (probably formed by the liquefaction of the cells of the internal part), so that a vesicle is formed (Figs. 264, 265, *g*), which looks like a diverticulum from the lower part of the digestive

Fig. 264.

cavity. This vesicle, in Birds, soon becomes so large as to extend itself around the whole yelk-sac, intervening between it and the membrane of the shell, and coming through the latter into relation with the external air; but in the embryos of Mammalia, being early superseded by another provision for the aeration of the blood, the allantois seldom attains any considerable dimensions. Its chief office in them is to convey the vessels of the embryo to the chorion; and its extent bears a pretty close correspondence with the extent of surface through which the chorion comes into vascular connection with the decidua. Thus, in the Carnivora, whose placenta extends like a band around the whole ovum, the allantois also lines nearly the whole inner surface of the chorion; on the other hand, in Man and the Quadrumana, whose placenta is restricted to one spot, the allantois is small, and conveys the foetal vessels to one portion only of the chorion. When these vessels have reached the chorion, they ramify in its substance, and send filaments into its villi; and in proportion as these villi form that connection with the uterine structure which has been already described (§§ 977-982), do the vessels increase in size. They then pass directly from the foetus to the chorion; and the allantois, being no longer of any use, shrivels up; and remains as a minute vesicle, only to be detected by careful examination. The same thing happens in regard to the umbilical vesicle, from which the entire contents have been by this time withdrawn; and from henceforth the foetus is completely dependent for the materials of its growth upon the supply it

receives through the placenta, which is conducted to it by the vessels of the umbilical cord. This state of things is represented in Figs. 266, 267, *n n'*, *o o'*.—The allantois has a correspondence in origin with the Urinary Bladder; but it is only the lowest part of it, pinched off as it were, from the rest, which remains as such. The duct by which it is connected with the abdomen gradually shrivels; and a vestige of this is permanent, forming the Urachus or suspensory ligament of the Bladder by which it is connected with the Umbilicus. Before this takes place, however, the Allantois is the receptacle for the secretion of the Corpora Wolfiana, and of the true Kidneys, when they are formed (§ 1007).

1002. It will be seen, from the succeeding diagram, that the Umbilical Cord receives an investment from the Amnion, which forms a kind of tubular sheath around it; it is continuous at the umbilicus with the integument of the fœtus; and at the point where the cord enters the placenta, it is reflected over its internal or foetal surface. The Amnion (which thus forms a shut sac, like that

of the pleura, arachnoid, &c.) contains a fluid known as the *liquor amnii*; this consists of water holding in solution a small quantity of albumen and saline matter, and resembling, therefore, very diluted serum. During the first two months of gestation, the amnion and the inner lining of the chorion (which is

really the reflected layer of the amnion, just as the lining of the abdominal cavity is formed by the peritoneum) are separated by a gelatinous-looking substance, which probably aids in the nutrition of the embryo previously to the formation of the placenta. This is absorbed during the second month; and the amnion is then found immediately beneath the chorion.—In the Umbilical Cord, when it is completely formed, the following parts may be traced: 1. The tubular sheath afforded by the Amnion. 2. The Umbilical Vesicle (Fig. 266, *t*), with its pedicle, or vitelline duct. 3. The Vasa Omphalo-Meseraica (*q*, *r*), or mesenteric vessels of the embryo, by which the yolk was absorbed into its body; these accompany the pedicle. 4. The Urachus, and remains of the Allantois. 5. The Vasa Umbilicalia (*nn*, *o*), which, in the later period of gestation, constitute the chief part of the Cord. These last vessels consist in Man of two arteries and one vein. The arteries are the main branches of the Hypogastric; and they convey to the placenta the blood which has to be aerated and otherwise revived, by being brought into relation with that of the mother. The vein returns this to the foetus, and discharges a part of it into the Vena Portæ, and a part directly through the Ductus Venosus into the Vena Cava.

1003. A change in the type of the Circulating system of the foetus, from that at first presented by it (§ 1000), takes place at a very early period. At about the 4th week, in the Human Embryo, a septum begins to be formed in the ventricle; and by the end of the 8th week it is complete. The septum auriculorum is formed at a somewhat later period, and it remains incomplete during the whole of foetal life; it is partly closed by the valvular fold covering the foramen ovale, which fold is developed in the 3d month. During the same period, a transformation takes place in the arrangement of the large vessels proceeding from the heart; which ends in their assumption of the form they present until the end of Foetal life; and this undergoes but a slight alteration, when the plan of the circulation is changed at the moment of the first inspiration. The number of aortic arches on each side, which was five at first, soon becomes reduced in the Mammalia to three, by the obliteration of the two highest pairs. The “bulbus aorticus” is subdivided, by the adhesion of its walls at opposite points, into two tubes, of which one becomes the Aorta and the other the Pulmonary Artery: and of the three pairs of (branchial) arches, the highest, being connected with the aortic trunk, contributes to the formation of the Subclavian and Carotid arteries; whilst of the middle pair, the arch on the right side is obliterated, and the other becomes the “arch of the aorta.” The lowest pair arises from the Pulmonary trunk, and forms the right and left Pulmonary arteries; that on the left side, however, goes on to join the descending aorta as before, and thus constitutes the Ductus Arteriosus. A knowledge of these different stages in the development of the Heart and Arterial system enables us to explain many of the malformations which they occasionally present in Man; these being for the most part due to arrest of development, whereby the circulating apparatus is permanently fixed in conditions that are properly characteristic of cold-blooded animals. And it is interesting to remark, too, that the varieties which not unfrequently present themselves in the arrangement of the principal trunks, given off from the Aorta, find their analogues in the arrangements that are normally characteristic of some or other of the Mammalia.¹—The Venous system undergoes changes which are even more remarkable than those of the arterial trunks. In its earliest condition, it has been ascertained by Rathke² to present essentially the same type in the embryos of all Vertebrated animals, the peculiarities of each group being acquired by a process of subsequent transformation. There is at first a pair of anterior venous trunks (Figs. 266, 267,

¹ See “Princ. of Phys., Gen. and Comp.” *Am. Ed.*, §§ 491, 492.

² “Ueber den Bau und die Entwicklung des Venensystems der Wirbelthiere,” 1838.

g, g'), receiving the blood from the head, and a pair of posterior trunks (*k, k'*), formed by the confluence of the veins of the trunk, Wolffian bodies, &c.; the former are persistent as the jugular veins; the latter remain separate in most Fishes, where they are designated the cardinal veins; but in Man (as in warm-blooded Vertebrata generally) they are only represented by the *venæ azygos*, major and minor,¹ which coalesce into a common trunk for a considerable part of their length. One of the anterior trunks and one of the posterior unite on either side, to form a canal which is known as the Ductus Cuvieri; and the ducts of the two sides coalesce to form a shorter main canal, which enters the auricle, at that time an undivided cavity. This common canal is absorbed into the auricle at an early period, in all Vertebrata above Fishes; and after the septum auriculorum is formed, the two Cuvierian ducts separately enter the right auricle. This arrangement is persistent in Birds and the inferior Mammals, in which we find two *Venæ Cavæ superiores*, entering the right auricle separately; but in the higher Mammalia and in Man, the left duct is obliterated and the right alone remains as the single *Vena Cava superior*, a transverse communicating branch being formed, to bring to it the blood of the left side.² The double *Vena Cava* sometimes presents itself as a monstrosity in the Human subject. As the anterior extremities are developed, the subclavian veins are formed to return the blood from them; and these discharge themselves into the jugulars. The Omphalo-Mesenteric vein (§ 999), which is another primitive trunk common to all Vertebrata, is formed by the confluence of the veins of the yolk-bag and intestinal canal, and passes by itself, with the two Cuvierian ducts, into the auricle. The upper part of this remains to constitute the upper part of the Inferior Cava (Figs. 266, 267, *j*), the lower portion of which arises between the Wolffian bodies, and originally enters the omphalo-mesenteric vein above the liver. When the liver is formed, the omphalo-mesenteric vein becomes connected with it both by afferent and by efferent trunks, the former remaining as the *Vena Portæ*, and the latter as the Hepatic vein; and after giving off the former trunks, the omphalo-mesenteric vein is itself obliterated, so that all the blood which it conveys passes through the liver. The Inferior Cava, which receives the hepatic vein, is gradually enlarged by the reception of most of the veins from the inferior part of the trunk and the lower extremities, and the *vena azygos* is reduced in the same proportion; in some rare cases of abnormal formation, however, the *vena cava* fails to be developed, and then the blood from the lower parts of the body is conveyed to the superior cava through the system of the *vena azygos*. The Umbilical Vein is to be regarded as a product of the combination of the veins of the allantois with an anterior vein of the abdominal parietes; it being probably through this latter channel that it comes to discharge itself into the *vena portæ*, which lies in a part of the body very distant from that at which the allantois was developed. As the omphalo-mesenteric vein diminishes in size, the umbilical vein increases, becoming the chief source of supply to the *vena portæ*; and it also forms an anastomosis with the inferior cava, which constitutes the Ductus Venosus.

1004. The following is the course of the Circulation in the mature Fœtus: The fluid brought from the placenta by the umbilical vein is partly conveyed at once to the ascending Cava by means of the ductus venosus, and partly flows through the *vena portæ* into the liver, whence it reaches the ascending Cava by the hepatic vein. Having thus been transmitted through the two great depu-

¹ See Müller's "Verleichende Anatomie der Myxinoiden," Berlin, 1840.

² The stages of this transformation have been particularly well made out by Mr. Marshall, in his elaborate Memoir "On the Development of the Great Anterior Veins in Man and Mammalia" ("Phil. Trans.," 1850); and he has further shown that some vestiges of the original arrangement may be traced even in the normal condition of the venous system in the adult.

rating organs, the Placenta and the foetal Liver, it is in the condition of arterial blood; but, being mixed in the vessels with that which has been returned from the trunk and lower extremities, it loses this character in some degree by the time that it arrives at the Heart. In the right auricle, which it then enters, it

Fig. 268.

The Foetal Circulation : 1. The umbilical cord consisting of the umbilical vein and two umbilical arteries, proceeding from the placenta (2). 3. The umbilical vein dividing into three branches; two (4, 4) to be distributed to the liver; and one (5), the ductus venosus, which enters the inferior vena cava (6). 7. The portal vein, returning the blood from the intestines, and uniting with the right hepatic branch. 8. The right auricle; the course of the blood is denoted by the arrow proceeding from 8 to 9, the left auricle. 10. The left ventricle; the blood following the arrow to the arch of the aorta (11), to be distributed through the branches given off by the arch to the head and upper extremities. The arrows 12 and 13 represent the return of the blood from the head and upper extremities through the jugular and subclavian veins, to the superior vena cava (14), to the right auricle (8), and in the course of the arrow through the right ventricle (15) to the pulmonary artery (16). 17. The ductus arteriosus, which appears to be a proper continuation of the pulmonary artery; the offsets at each side are the right and left pulmonary artery cut off; these are of extremely small size as compared with the ductus arteriosus. The ductus arteriosus joins the descending aorta (18, 18), which divides into the common iliacs, and these into the internal iliacs, which become the umbilical arteries (19) and return the blood along the umbilical cord to the placenta and external iliacs (20), which are continued into the lower extremities. The arrows at the termination of these vessels mark the return of the venous blood by the veins to the inferior cava.

would be also mixed with the venous blood brought thither by the descending Cava, were it not that a very curious provision exists, to prevent (in great degree, if not entirely) any such further dilution. The Eustachian valve has

been found, by the experiments of Dr. J. Reid,¹ to serve the purpose of directing the *arterial* blood, which flows upwards from the *ascending* Cava, through the foramen ovale, into the *left* auricle, whence it passes into the *left* ventricle; whilst it also directs the *venous* blood, that has been returned by the *descending* Cava, into the *right* ventricle. When the ventricles contract, the arterial blood which the left contains is propelled into the ascending Aorta, and supplies the branches that proceed to the head and upper extremities, before it undergoes any admixture; whilst the venous blood, contained in the right ventricle, is forced through the Pulmonary artery and Ductus Arteriosus into the descending Aorta, mingling with the arterial current which that vessel previously conveyed, and passing thus to the trunk and lower extremities. Hence the head and superior extremities, whose development is required to be in advance of that of the lower, are supplied with blood nearly as pure as that which returns from the placenta; whilst the rest of the body receives a mixture of this with what has previously circulated through the system; and of this mixture a portion is transmitted to the placenta, to be renovated by coming into relation with the maternal fluid. At birth, the course of the current is entirely changed by its diversion into the Lungs, which takes place immediately on the first inspiration. The Ductus Venosus and Ductus Arteriosus soon shrivel into ligaments; the Foramen Ovale becomes closed by its valve; and the circulation,

which was before carried on upon the plan of that of the higher Reptiles, now becomes that of the complete Bird or Mammal. It is by no means unfrequent, however, for some arrest of development to prevent the completion of these changes; and various malformations, involving an imperfect discharge of the function, may hence result.

1005. The *Alimentary Canal* has been shown (§ 997) to have its origin in the blastodermic vesicle; being a portion pinched off (as it were) from that part of it which is just beneath the spinal column of the embryo, whilst the remainder, which is at that time the largest part of it, forms the vitelline or umbilical vesicle. In its earliest form it is merely a long narrow tube (Fig. 269, *m*), nearly straight, and communicating with the umbilical vesicle (*n, n*) at about the middle of its length; thus it may be regarded as composed of the union of two divisions, an upper and a lower. At first, neither mouth nor anus exists; but these are formed early in the second month, if not before. The tube gradually manifests a distinction into its special parts, œsophagus, stomach, small intestine, and large intestine; and the first change in its position occurs in the stomach, which, from being disposed in the line of the body, takes an oblique direction. The curves of the large and small intestines present themselves at a later period. It is at the lower part of the small intestine, near its termination in the large, that the entrance of the vitelline duct exists; and a remnant of this canal is not unfrequently preserved throughout life, in the form of a small pouch or diverticulum from that part of the intestine.—In immediate connection with the intestinal tube, we find the first rudiment of the *Liver*, which is formed by the thickening of the cells in the wall of the canal, at the spot at which the hepatic duct is subsequently to discharge itself. This thickening increases, so as to form a projection upon the exterior of the canal; and soon afterwards the lining membrane of the intestine dips down into it, so that a kind of cæcum is formed, surrounded by a mass of cells, as shown in Fig. 270. The increase of the organ seems to take place by a continual new budding forth of cells from its peripheral portion; and a considerable mass is thus formed, before the cæcum in its interior undergoes any extension by ramifications into it. Gradually, however, the cells of the exterior become metamorphosed into fibrous tissue for the investment of the organ; those of the interior break down into ducts, which are developed in continuity with the cæcum derived from the intestine, and which are lined by muscular and fibrous tissues developed from the primitive cellular blastema; whilst those which occupy the intervening space, and which form the bulk of the gland, give origin to the proper secreting cells, which are now to come into active operation. As this

Fig. 270.

Origin of the Liver from the intestinal wall, in the embryo of the Fowl, on the fourth day of incubation; —*a*, heart; *b*, intestine; *c*, everted portion giving origin to liver; *d*, liver; *e*, portion of vitelline vesicle.

By the third lunar month, the liver extends nearly to the pelvis, and almost fills the abdomen; the right side now

begins to gain upon the left; the gall-bladder begins to appear at this time. The subsequent changes chiefly consist in the consolidation of the viscus, and the diminution of its proportional size. Up to the period of birth, however, the bulk of the liver, relatively to that of the entire body, is much greater than in the adult; the proportion being as 1 to 18 or 20 in the new-born child, whilst it is about 1 to 36 in the adult; and the difference between the right and left sides is still inconsiderable. During the first year of extra-uterine life, however, a great change takes place; the right lobe increases a little or remains stationary, whilst the left lobe undergoes an absolute diminution, being reduced nearly one-half; and as, during the same period, the bulk of the rest of the body has been rapidly increasing, the proportion is much more reduced during that period than in any subsequent one of the same length. According to Meckel, the liver of the newly-born infant weighs one-fourth heavier than that of a child of eight or ten months old; and as the weight of the whole body is more than double during the same time, it is obvious that the change in the proportion of the two must be principally effected at this epoch. The liver seems to be actively engaged, during foetal life, in the depuration of the blood (as appears from the accumulation of meconium, which is chiefly altered bile, in the intestinal canal at birth), whilst at the same time it is serving as a blood-making organ (§ 150, *note*).—The general history which has just been given of the development of the Liver seems equally applicable to the other glands that are evolved from the parietes of the Alimentary canal, such as the *Salivary glands* and *Pancreas*; since they all seem to commence in little masses of cells, formed by an increased development, at certain spots, of the layer of blastema which originally constitutes its wall; and whilst some of these cells give origin to the proper tissues of each gland, others form its ducts and tubuli by their deliquescence.

1006. The *Lungs* also are developed in immediate relation with the upper part of the Alimentary canal, their first rudiments shooting forth as a pair of budlike processes (Fig. 271, *a*) from its œsophageal portion. These were originally described by Von Bär as hollow, and as in reality *diverticula* from the tube itself. But most later observers agree in stating that the budlike processes are not at first hollow, but are solid aggregations of cells, formed by a multiplication of the cells constituting the external wall of the alimentary tube, into which its internal tunic is not prolonged. These gradually increase in size, extending downwards by the multiplication of their component cells in that direction; and cavities are formed in them (probably, as in the preceding instances, by the deliquescence or fusion of some of the cells of their interior), which at first communicate with the pharynx by separate apertures; these, however, coalescing into one, as the channels are elongated into tubes, and the pulmonary organs are removed to a distance from their point of exit. This process commences, in the Chick, about the 4th day

Fig. 271.

First appearance of the Lungs: *a*, in a Fowl at four days; *b*, in a Fowl at six days; *c*, termination of bronchus in a very young Pig.

of incubation; and on the 5th or 6th, the lungs are completely detached from the œsophagus, and each has its own bronchial tube connecting it with the trachea common to both (Fig. 271, *b*). The upper portion of the lung has much thicker walls than the lower; and these appear to contain a large quantity of vesicular parenchyma, in which the ramifications of the bronchial tubes subsequently extend themselves. About the tenth or eleventh day of incubation,

these ramifications possess nearly their permanent character and situation. The

first trace of the Glottis appears about the fifth day; it is then a mere slit in the walls of the œsophagus, resembling that by which the ductus pneumaticus of some Fishes opens into the alimentary canal. The formation of the cartilaginous rings of the trachea does not commence until after the twelfth day, when they first appear as transverse striæ on the median line of the front only; they gradually become solid, and extend themselves on either side, until at last they nearly meet on the median line, on the back or vertebral side of the tube.—The history of the process, in the Human embryo, appears to be very nearly the same. The first appearance of the Lungs takes place at about the 6th week, at which time they are simple elevations of the external layer of the œsophageal wall. Their surface, however, soon becomes studded with numerous little wart-like projections; and these are caused by the formation of corresponding enlargements of their cavity. These enlargements soon become prolonged, and develop corresponding budlike enlargements from their sides; and in this manner, the form of the organs is gradually changed, a progressive increase in their bulk taking place from above downwards, in consequence of the extension of the bronchial ramifications from the single tube at the apex. At the same time, however, a corresponding increase in the amount of the parenchymatous tissue of the lung is taking place; for this is deposited in all the interstices between the bronchial ramifications, and might be compared with the soil filling up the spaces amongst the roots of a tree. It is in this parenchyma that the pulmonary vessels are distributed; and the portion of it which extends beyond the terminations of the bronchial tubes seems to act as the nidus for their further extension. It can be easily shown that, up to a late period of the development of the lungs, the dilated terminations of the bronchi constitute the only air-cells (Fig. 271, c); but, as already mentioned, the parenchyma subsequently has additional cavities formed within it.—It is a fact of some interest, as an example of the tendency of certain diseased conditions to produce a return to forms which are natural to the foetal organism, or which present themselves in other animals, that up to a late period in the development of the Human embryo, the lungs do not nearly fill the cavity of the chest, and the pleura of each side contains a good deal of serous fluid.

1007. The embryological development of the *Urinary* organs in Vertebrated animals is a subject of peculiar interest; owing to the correspondence which may be traced between the transitory forms they present in the higher classes, and their permanent condition in the lower. In this respect there is an evident analogy with the Respiratory system. The first appearance of anything resembling a Urinary apparatus in the Chick, is seen on the second half of the third day. The form at that time presented by it, is that of a long canal, extending on each side of the spinal column, from the region of the heart, towards the allantois (Fig. 269, o, o); on the sides of this are a series of elevations and depressions, indicative of the incipient development of cæca. On the fourth day, the *Corpora Wolfiana*, as they are then termed, are distinctly recognized as composed of a series of cæcal appendages which are attached along the whole course of the first-mentioned canal, opening into its outer side (Fig. 272, 1). On the 5th day, these appendages are convoluted; and the body which they form acquires increased breadth and thickness. They evidently then possess a secreting function, and the fluid which they separate is poured by their long

Fig. 272.

State of the Urinary and Genital Apparatus in the early embryo of the Bird: 1, corpora Wolfiana; 2, 2, their excretory ducts; 3, kidneys; 4, ureter; 5, 5, testis.

straight canals (2, 2) into the cloaca. Between their component shut sacs, numbers of small points appear, which consist of little clusters of convoluted vessels, exactly analogous to the Corpora Malpighiana of the true kidney. These bodies remain as the permanent urinary organs of Fishes; but in the higher Vertebrata they give place to the true Kidneys, the development of which commences in the Chick about the 5th day. These are seen on the 6th day, as lobulated grayish masses (3), which seem to sprout from the outer edges of the Wolffian bodies, but which are really independent formations springing from a mass of blastema behind them; and as they gradually increase in size and advance in development, the Wolffian bodies retrograde; so that, at the end of foetal life, the only vestige of them is to be found as a shrunk rudiment, situated (in the male) near the testes.—The history of the development of the Urinary organs in the Human embryo seems to correspond closely with the foregoing. The Wolffian bodies begin to appear towards the end of the first month; and it is in the course of the 7th week that the true Kidneys first present themselves. From the beginning of the 3d month, the diminution in the size of the Wolffian bodies goes on *pari passu* with the increase of the Kidneys; and, at the time of birth, scarcely any traces of the former can be found. At the end of the 3d month, the kidneys consist of seven or eight lobes, the future pyramids; their excretory ducts still terminate in the same canal, which receives those of the Wolffian bodies, and of the sexual organs; and this opens, with the rectum, into a sort of cloaca, or sinus uro-genitalis, analogous to that which is permanent in the oviparous Vertebrata. The Kidneys are at this time covered by the Suprarenal capsules, which equal them in size; about the 6th month, however, these have decreased, whilst the kidneys have increased, so that their proportional weight is as 1 to 2½. At birth, the weight of the Kidneys is about three times that of the Supra-Renal capsules, and they bear to the whole body the proportion of 1 to 80; in the adult, however, they are no more than 1 to 240. The Corpora Wolffiana are, when at their greatest development, the most vascular parts of the body next to the liver; four or five branches from the aorta are distributed to each, and two veins are returned from each to the vena cava. The upper veins and their corresponding arteries are converted into the Renal or emulgent vessels; and the lower into Spermatic vessels. The lobulated appearance of the kidney gradually disappears; partly in consequence of the condensation of the areolar tissue which connects the different parts, and partly through the development of additional tubuli in the interstices. The Urinary Bladder is formed quite independently of the secreting apparatus, being a part of the *allantois*, which itself serves as the receptacle for the urinary secretion formed by the Corpora Wolffiana. The part of the tube below this forms the Cloaca, or common termination of the intestinal and vesical apparatus. The sides of this cloaca, however, gradually approach one another, so as to form a transverse partition, which separates the Rectum from the Genito-urinary canal; and the urethra of the female is afterwards separated from the Vagina by a similar process.

1008. The essential parts of the *Generative Apparatus*, namely, the Testes in the male, and the Ovaria in the female, are first developed in immediate proximity with the Corpora Wolffiana (Fig. 272, 5, 5), and have been supposed to sprout forth from them; this, however, is not really the case, as they have an independent origin in a mass of blastema peculiar to themselves. They make their first appearance in the Chick about the fourth day, as delicate striæ on the Wolffian bodies; and at this period no difference can be detected between the Testes and the Ovaria, which originate in precisely the same manner. Like the kidneys, the germ-preparing organs increase in proportion with the diminution in the temporary structures; at first, their efferent ducts open into those of the Wolffian bodies, but they are subsequently separated by the formation of a partition, like that which separates the rectum from the cloaca. In the

Human embryo, the rudiments of the sexual organs—whether testes or ovaria,—first present themselves soon after the kidneys make their appearance, that is, towards the end of the 7th week. They are at first much prolonged, and seem to consist of a kind of soft, homogeneous blastema, in which the structure characteristic of each subsequently develops itself. The *Testis* gradually assumes its permanent form; the epididymis appears in the tenth week; and the gubernaculum (a membranous process from the filamentous tissue of the scrotum, analogous to the round ligament arising from the labium and attached to the ovary of the female), which is originally attached to the vas deferens, gradually fixes itself to the lower end of the testis or epididymis. The Testes begin to descend at about the middle period of pregnancy; at the seventh month they reach the inner ring; in the eighth they enter the passage; and in the ninth they usually descend into the scrotum. The cause of this descent is not very clear: it can scarcely be due merely, as some have supposed, to the contraction of the gubernaculum; since that does not contain any fibrous structure, until after the lowering of the testes has commenced. It is well known that the testes are not always found in the scrotum at the time of birth, even at the full period. Upon an examination of 97 new-born infants, Wrisberg found both testes in the scrotum in 67, one or both in the canal in 17, in 8 one testis in the abdomen, and in 3 both testes within the cavity. Sometimes one or both testes remain in the abdomen during the whole of life; but this circumstance does not seem to impair their function. This condition is natural, indeed, in the ram.—The *Ovary* undergoes much less alteration, either in its intimate structure, or in its position. The efferent canal of the genital apparatus, which in the male forms a continuous connection with the tubular structure of the testes, remains detached from the ovary in the female, having a free terminal aperture, and thus constituting the Fallopian tube. These tubes are at first distinct on the two sides, but they gradually coalesce higher and higher up;¹ and it is by an increased development of this coalesced portion, that the Uterus is formed, the homologue of which in the male seems to be the (so called) *Vesicula prostatica*, or “sinus pocularis,” which is sometimes developed to a considerable size, and the relation of which to the orifices of the vasa deferentia is then seen to be essentially the same as that of the female uterus to the Fallopian tubes.²

1009. The history of the development of the External Organs of Generation in the two sexes presents matter of great interest, from the light which is thrown by a knowledge of it upon the malformations of these organs, which are among the most common of all departures from the normal type of Human organization.—Not only is the distinction of sexes altogether wanting at first; but the conformation of the external parts of the apparatus is originally the same in Man and the higher Mammalia, as it permanently is in the Oviparous Vertebrata. For, about the 5th or 6th week of embryonic life, the opening of a *cloaca* may be seen externally, which receives the termination of the intestinal canal, the ureters, and the efferent ducts of the sexual organs; but at the 10th or 11th week, the anal aperture is separated from that of the genito-urinary canal or “uro-genital sinus,” by the development of a transverse band; and the uro-genital sinus itself is gradually separated, by a process of division extending from before backwards or from above downwards, into a “pars urinaria” and a “pars genitalis,” the former of which, extending towards the urachus, is converted into the urinary bladder. A partial representation of this phase of development

¹ For a sketch of those different conditions presented by the Uterus in the several orders of the Mammalian class, which depend upon the degree of this coalescence, see the Author's “Princ. of Phys., Gen. and Comp.” § 326, *aa*, *Am. Ed.*

² See Prof. E. Weber's “Zusätze zur Lehre vom Baue und den Verrichtungen der Geschlechtsorgane,” Leipzig, 1846.

is found in the permanent condition of the Struthious Birds and of the Placental Mammalia. The external opening of this canal is soon observed to be bounded by two folds of skin, the rudiments of the labia majora in the female, and of the two halves of the scrotum in the male; whilst between and in front of these, there is formed a penis-like body, surmounted by a gland, and cleft or furrowed along its under surface. This body in the female is retracted into the genito-urinary canal, and becomes the clitoris; whilst the margins of its furrow are converted into the nymphæ or labia minora. In the male, on the other hand, it increases in prominence, and becomes the penis; and the margins of the furrow at its under surface unite (at about the 14th week), and form a continuation of the now contracted genito-urinary canal—the previous orifice of which then closes up. Now in a large proportion of cases of so-called *Herma-*

Fig. 273.

Urinary and Generative Organs of a Human Embryo measuring $3\frac{1}{2}$ inches in length. A. General view of these parts: 1, suprarenal capsules; 2, kidneys; 3, ovary; 4, Fallopian tube; 5, uterus; 6, intestine; 7, the bladder. B. Bladder and generative organs of the same embryo viewed from the side: 1, the urinary bladder; 2, urethra; 3, uterus (with two cornua); 4, vagina; 5, part as yet common to the vagina and urethra; 6, common orifice of the urinary and generative organs; 7, the clitoris. C. Internal generative organs of the same embryo: 1, the uterus; 2, the round ligaments; 3, the Fallopian tubes; 4, the ovaries; 5, the remains of the Wolffian bodies. D. External generative organs of the same embryo: 1, the labia majora; 2, the nymphæ; 3, the clitoris. After Müller.

phrodism, there has been either a want of completeness in the development of the male organs, so that they present a greater or less degree of resemblance to those of the female; or the developmental process has gone on to an abnormal extent in the female organs, so that they come to present a certain degree of resemblance to those of the male. One of the most common malformations of the *male* organs is "hypospadias," or an abnormal opening of the urethra at the base of the penis; this arises from incompleteness in the closure of the edges of its original furrow. But when the developmental process has been checked at an earlier period, the uro-genital sinus may retain more nearly its original character, and may have a wide external opening beneath the root of the penis, so

as to resemble the female vagina, whilst the penis is itself destitute of any trace of the urethral canal; in some of these cases, again, the testes have not descended into the scrotum; whilst the absence of beard, the shrillness of the voice, and the fulness of the mammae, have contributed to impart a feminine character to these individuals, their male attributes, however, being determined by the *semiferous* character of the essential organ, the testes.¹ In the *female* organs, on the other hand, a greater or less degree of resemblance to those of the male may be produced by the enlargement of the clitoris, by its furrowing or complete perforation by the urethra, by the closure of the entrance of the vagina and the cohesion of the labia, so as to present a likeness to the unfissured perineum and scrotum of the male, by the descent of the ovaries through the inguinal ring into the position of the male testes, by the imperfect development of the uterus and mammae; and with these are usually associated roughness of the voice and growth of hair on the chin, and a psychical character more or less virile. *True Hermaphroditism*, in which there is an absolute combination of the essential male and female organs in the same individual, is comparatively rare. It may occur under the forms of *lateral* hermaphroditism, in which there is a genuine ovary on one side and a testis on the other, in which case the external organs are usually those of a hypospadiac male; *transverse* hermaphroditism, in which the external and internal organs do not correspond, the former being male and the latter female, or *vice versa*;—and *double* or *vertical* hermaphroditism, in which the proper organs characteristic of one sex have existed, with the addition of some of those of the other; this is the rarest of all, and it is not certain that the coexistence of testes and ovaria on the same side has ever been observed in the Human species.²

1010. We have now to follow the course of the development of the principal organs of *Animal* life; and shall first notice that of the *Skeleton*.—We have seen that, in the embryo of the Vertebrated animal, the future vertebral column is marked out at an earlier period than any other permanent organ (§ 997); and that indications of a division into vertebræ are very speedily presented in the embryo of the higher classes. The earliest formation, however, is one of which we recognize no traces in the adult condition of Man; namely, a longitudinal column, tapering off to a point at the cranial and caudal extremities of the embryo, and occupying the place of the future bodies of the vertebræ. This, which is termed the “*chorda dorsalis*,” is of gelatinous consistence, and is composed entirely of cells; it is inclosed in a sheath, which gradually acquires the structure of a fibrous membrane, and which also invests the neural axis itself; and this condition is persistent in the *Amphioxus* and the *Myxinoid Fishes*,³ which have never any other spinal column than the *chorda dorsalis*. The vertebræ seem to be developed, in the inferior Vertebrata, in the fibrous sheath of the *chorda dorsalis*; but in Birds and Mammals, the quadrangular plates which show themselves at a very early period (Plate II. Fig. 12) appear to have an independent origin. These gradually increase in number and size, so as to surround the *chorda* both above and below; sending out, at the same time, prolongations from the inferior surface, to form the arches destined to inclose the Spinal Cord or neural axis, which are hence termed by Prof. Owen the *neural arches*. In this primitive condition, the body and arches of each vertebra are formed by one piece on each side; and these, becoming cartilaginous, are united inferiorly by a suture, so as to inclose the *chorda* in a sort of case formed by

¹ The *vesicula prostatica*, or “uterus masculinus,” has presented an unusual development in some of these cases; see Prof. Weber (*loc. cit.*), and Prof. Theile’s “Account of a Case of Hypospadias,” in “Müller’s Archiv.,” 1847.

² On the subject of Hermaphroditism, see Prof. Simpson’s Article in the “Cyclop. of Anat. and Phys.,” vol. ii.

³ “Princ. of Phys., Gen. and Comp.,” §§ 321 a, 322, and 322 a, *Am. Ed.*

the bodies of the vertebræ, which are still hollow, so as to allow the segments of the chorda, partially separated from each other, to communicate together. This condition also remains persistent in certain of the Cartilaginous Fishes. With the concentric growth of the bodies of the vertebræ, however, the chorda dorsalis gradually wastes, and at last disappears; but previously to its disappearance, the ossification of the bodies and neural arches of the vertebræ begins, the former from a single point on the median line, the latter by separate points on the two sides.—The complete *typical vertebra* (Fig. 274, A) essentially consists, according to Prof. Owen,¹ of the *centrum*, around which are arranged four arches inclosed by processes in connection with it: viz., superiorly, the *neural arch*, which incloses the neural axis, and is formed by a pair of “neurapophyses” (*n, n*) and a “neural spine” (*n, s*); inferiorly, the *hæmal arch*, which is in like special relation with the centres of the circulation, but may be expanded around the visceral cavity generally, and which is formed of a pair of “hæmapophyses” (*h, h*), and the “hæmal spine” (*h, s*); and two *lateral arches*, inclosing vascular canals, which are bounded by the “diapophyses” (*d, d*) and the “parapophyses” (*p, p*), and are completed by the “pleurapophyses” (*pl, pl*). Of these elements, the centrum is the most constant; and next to these are the neural arches, which we find in every part of the vertebral column through which the neural axis passes, and which are enormously developed in the cranial segments, in accordance with the high development of the nervous mass. The hæmal arches are often almost entirely deficient, as in the

Fig. 274.

Elements of a Vertebra, according to Prof. Owen: A, ideal typical vertebra; B, actual thoracic vertebra of a Bird; c, centrum, giving off *d, d*, the diapophyses, and *p, p*, the parapophyses; the neural arch, inclosing the spinal cord *, is formed by *n, n*, the neurapophyses and *n, s*, the neural spine; the hæmal arch, inclosing the great centres of the circulation, is formed by *h, h*, the hæmapophyses, and *h, s*, the hæmal spine. From both the neurapophyses and hæmapophyses may be given off the zygapophyses, *z, z*. The lateral arches, which may inclose the vertebral arteries *o o*, are completed by the pleurapophyses, *p, l*; these in B are bent downwards, so as to form part of the hæmal arch, and give off the diverging appendages *a, a*.

cervical and lumbar vertebræ of Man and the Mammalia: but in the dorsal vertebræ they are very largely developed, and the elements of the lateral arches are brought into connection with them, so as to form the inclosure of the visceral cavity (Fig. 274, B). From the pleurapophyses are occasionally developed a pair

¹ See his “Archetype Skeleton,” his “Lectures on Comparative Anatomy,” vol. ii., and his “Discourse on the Nature of Limbs.”

of "diverging appendages" (*a, a*), which are well seen in the ribs of Birds; and these are considered by Prof. Owen to be the fundamental elements of the bones of the "extremities" or "limbs," those of the anterior extremity being the diverging appendages of the occipital vertebra (§ 1011), and those of the posterior extremity standing in the same relation to one of the sacral vertebrae.¹—The extremities themselves are developed, in all Vertebrata, as leaflike elevations from the parietes of the trunk (Fig. 269, *q, q, r, r*); those peculiarities of form by which they are adapted to specialities of function being determined by subsequent processes of development. Thus in the Human foetus, the fingers are at first united by the primitive blastema, as if webbed for swimming; but this, as Prof. Müller justly remarks, is less to be regarded as an approximation to the form of the extremity characteristic of aquatic animals, than as the primitive and most general form of the hand, the individual parts of which subsequently become more completely isolated in such animals as require to use them separately.

1011. It is in the *cranial* segments that the vertebral elements undergo their most remarkable transformations, the departure from the "archetype" being more complete in Man than in any other animal; so that it is only by tracing them through their simplest to their most complicated forms and arrangements, that the true nature of the latter can be elucidated.²—The number of the segments entering into the skull has been a subject of much discussion among those who adopt the "vertebral theory" of its composition; but Prof. Owen agrees with Oken (the original propounder of the theory) in fixing the number at *four*, which corresponds with that of the primary divisions succeeding each other in a linear series, that are distinctly marked in the early development of the Encephalon, namely (proceeding from behind forwards), the Epencephalon, the Mesencephalon, the Prosencephalon, and the Rhinencephalon;³ and also corresponding with the number of the nerves of special sense, the Auditory, Gustative, Optic, and Olfactory, which issue from this part of the neural axis with the same segmental regularity that the ordinary sensori-motor nerves do elsewhere.⁴

¹ The beautiful chain of reasoning by which this position is, in the Author's opinion, irrefutably established, is contained in the works of Prof. Owen already referred to; a sketch of it, and of the whole "Vertebral Theory," will be found in the Author's "Princ. of Phys., Gen. and Comp.," § 320 *et seq.*, *Am. Ed.*

² See especially Prof. Owen's "Archetype Skeleton," and the sketch contained in the Author's "Princ. of Phys., Gen. and Comp.," §§ 320 *i*, 320 *l*, *Am. Ed.*

³ The Rhinencephalon (consisting of the Olfactive ganglia) is seldom distinctly marked out in the early stage of development of the higher Vertebrata, but is obvious enough in Fishes (Fig. 171, *A*).

⁴ Under the guidance of the unerring light of Comparative Anatomy and Development, the composition of the Cranial portion of the skull—consisting of the *bodies* and *neural arches* of the four cranial vertebrae—has been determined by Prof. Owen as follows, each of the "elements" enumerated being marked as distinct, by the separateness of its centre of ossification.

TABLE I.

Composition of the Neural Arches of the Cranial Vertebrae, in Man.

I. EPENCEPHALIC OR OCCIPITAL VERTEBRA.

Centrum; Basi-occipital portion of the Occipital bone.

Parapophyses; } Coalesced into the lateral or condyloid portions of the Occipital
Neuropophyses; } bone, the parapophyses being marked by the scabrous ridge
giving attachment to the rectus lateralis muscle.

Neural Spine; Proper Occipital bone.

II. MESENCEPHALIC OR PARIETAL VERTEBRA.

Centrum; Basi-sphenoid, or body of the posterior or sphenotemporal part of the Sphenoid bone.

1012. Within the Cranio-spinal canal thus formed, the rudiment of the Cerebro-spinal axis is found, at first under a very different aspect from that which

Parapophyses; Mastoid portion of the Temporal bones.

Neurapophyses; Great wings of Sphenoid bone, or Ali-sphenoids.

Neural Spine; Parietal bones.

III. PROSENCEPHALIC OR FRONTAL VERTEBRA.

Centrum; Pre-sphenoid, or body of the anterior or sphenoid part of the Sphenoid bone.

Parapophyses; External angular processes of Frontal bone (the post-frontals of Fishes).

Neurapophyses; Small wings of Sphenoid bone, or Orbito-sphenoids.

Neural Spine; Frontal bone.

IV. RHINENCEPHALIC OR NASAL VERTEBRA.

Centrum; Vomer.

Neurapophyses; Ossa plana of Ethmoid bone.

Neural Spine; Nasal bones.

In connection with the foregoing, we have two ossified "sense-capsules;" the Auditory formed by the petrosal portion of the Temporal bone; and the Nasal formed by the principal part of the Ethmoid bone, with the turbinate bones.

The *hæmal arches* of the cranial vertebræ form the bones of the Face and of some other parts, as will be seen from the following table:—

TABLE II.

Composition of the Hæmal Arches of the Cranial Vertebræ, in Man.

I. EPENCEPHALIC OR OCCIPITAL VERTEBRA.

Pleurapophyses; Scapulæ.

Diverging Appendages; Bones of Arm, Forearm, and Hand.

Hæmapophyses; Coracoid processes of Scapulæ (Coracoid bones of Oviparous Vertebrata).

Hæmal Spine; Deficient.

[The Clavicles and first segment of the Sternum, which complete the Scapular arch in the Mammalia, are regarded by Prof. Owen as the hæmapophyses and hæmal spine of the atlas, or highest vertebra of the trunk.]

II. MESENCEPHALIC OR PARIETAL VERTEBRA.

Pleurapophyses; Styloid processes of Temporal bone.

Diverging Appendages; Greater cornua of Hyoid bone, or Thyro-hyals.

Hæmapophyses; Lesser cornua of Hyoid bone, or Cerato-hyals.

Hæmal Spine; Body of Hyoid bone.

III. PROSENCEPHALIC OR FRONTAL VERTEBRA.

Pleurapophyses; Tympanic portion of Temporal bone.

Diverging Appendages; Deficient.

Hæmapophyses; Articular portion of Inferior Maxilla.

Hæmal Spine; Dental portion of Inferior Maxilla.

IV. RHINENCEPHALIC OR NASAL VERTEBRA.

Pleurapophyses; Palatine bones.

Diverging Appendages; Pterygoid and Malar bones, with squamosal and zygomatic portions of Temporal bones.

Hæmapophyses; Superior Maxillary bones.

Hæmal Spine; Intermaxillary bones.

Thus we see that, in the anterior segment, we have the highest development of the visceral portion, coexisting with the lowest development of the neural; this last being obviously related to the comparatively low development of the ganglionic mass which it is destined to protect.—The development of the soft parts of the face takes place in conformity with that of the vertebral segments; these being formed by "visceral arches" which meet on the median line (Fig. 270, c, d d); and the knowledge of this fact enables us to explain those congenital malformations which result from want of union of the two halves on the median plane, such as cleft palate and harelip.

it subsequently presents, especially as regards the relative proportions of its different segments. The encephalon, at about the sixth week, is seen as a series of vesicles arranged in a line with each other (Fig. 275); of which those that represent the Cerebrum (*b*) are the smallest, whilst that which represents the Cerebellum (*d*) is the largest. The latter (or *Epencephalon*), as in Fishes, is single, covering the fourth ventricle on the dorsal surface of the Medulla Oblongata. Anterior to this is the single vesicle (*a*) of the Corpora Quadrigemina (or *Mesencephalon*), from which the optic nerve chiefly arises; this has in its interior a cavity, the ventricle of Sylvius, which is persistent in the adult Bird, though obliterated in the adult Mammal. In front of this is the vesicle (*c*) of the Third Ventricle (or *Deutencephalon*), which contains also the Thalami Optici; as development proceeds, this, like the preceding, is covered by the enlarged hemispheres; whilst its roof becomes cleft anteriorly on the median line, so as to communicate with the cavities which they include. Still more anteriorly (*b*) is the double vesicle (or *Prosencephalon*) which represents the hemispheres of the Cerebrum; this has a cavity on either side, the floor of which is formed by the Corpora Striata, and which has at first no opening except into the third ventricle; the "fissure of Sylvius" (which enables the membranes of the brain to be reflected into the lateral ventricles) being formed at a later period. In the small proportion which the Cerebral Hemispheres bear to the other parts, the absence of convolutions, the deficiency of commissures, and the general simplicity of structure of the whole, there is a certain correspondence between the brain of the Human embryo at this period, and that of a Fish; but the resemblance is much stronger between the *fœtal* brain of the Fish and that of the Mammal; indeed, at this early period of their formation, the two could scarcely be distinguished; and it is the large amount of change which the latter undergoes, as compared with the former, that causes the wide dissimilarity of their adult forms.—At about the 12th week we find the Cerebral Hemispheres much increased in size, and arching back over the Thalami and Corpora Quadrigemina (Fig. 276); still, however, they are destitute of convolutions, and imperfectly connected by commissures; and there is a large cavity still existing in the Corpora Quadrigemina, which freely communicates with the Third Ventricle. In all these particulars there is a strong analogy between the condition of the brain of the Human embryo at this period, and that of the Bird.—Up to the end of the 3d month, the Cerebral Hemispheres present only the rudiments of *anterior* lobes, and do not pass beyond that grade of development which is permanently characteristic of the Marsupial Mammalia, the Thalami being still but incompletely covered in by them. During the 4th and part of the 5th months, however, the middle lobes are developed from their posterior aspect, and cover the Corpora Quadrigemina; and the posterior lobes, of which there was no previous rudiment, subsequently begin to sprout from the back of the middle lobes, remaining separated from them, however, by a distinct furrow, even in the brain of the mature fœtus, and sometimes in that of older persons. In these and other particulars, there is a very close corre-

Fig. 275.

Human Embryo of sixth week, enlarged about three times: *a*, vesicle of corpora quadrigemina; *b*, vesicle of cerebral hemispheres; *c*, vesicle of third ventricle; *d*, vesicle for cerebellum and medulla oblongata; *e*, auditory vesicle; *f*, olfactory fossa; *h*, liver; ** caudal extremity.

spondence between the progressive stages of development of the Human Cerebrum, and those which we encounter in the ascending scale of Mammalia.¹

Fig. 276.

Brain of Human Embryo at twelfth week: A, seen from behind; B, side view; C, sectional view; a, corpora quadrigemina; b, b, hemispheres; d, cerebellum; e, medulla oblongata; f, optic thalamus; g, floor of third ventricle; i, olfactory nerve.

1013. The development of the two principal Organs of Sense, the Eye and the Ear, has been made the subject of careful study (in the Chick) by Mr. H. Gray.²—The development of the Eye commences by a protrusion from the posterior part of the anterior cerebral vesicle, representing the “vesicle of the thalami optici,” which is at that time hollow; and the cavity of the protrusion is continuous with that of the vesicle itself, which remains as the “third ventricle.” This protrusion is lined, like the cerebral vesicle, with granular matter, which gradually becomes distinctly cellular, forming a layer of a truly ganglionic character; and whilst this change is taking place, the protrusion increases, becomes pear-shaped, and is at last connected only by a narrow pedicle with the vesicle from which it sprang. This pedicle closes up, so as completely to separate the two cavities; and the one which has been thus budded forth constitutes the rudiment of the eye, whilst the other goes on to form the ganglionic bodies at the base of the cerebrum, the connecting pedicle becoming the optic nerve, which connects the retina with its ganglionic centre. The spherical extremity of the protrusion is absorbed, and the retina, or vesicular lining, becomes attached to the margin of the lens, which is in the mean time developed in the interior of the cavity, and is at first completely surrounded by the retina. The formation of the coats of the Eye takes place subsequently; the development even of the “fibrous lamina” and of the “membrana Jacobi” of the retina itself, not taking place until after its cellular layer has been very distinctly formed. It is a curious circumstance, and one not very easy to account for, that the development of the Eye should take place from the Deutencephalic and not from the Mesencephalic vesicle; as it is in the latter that the proper “optic ganglia” originate, with which the optic nerves come at last to have their principal connection, their connection with the “thalami optici” being much less close.—The Auditory apparatus takes its origin in a portion of the Epencephalic vesicle, which protrudes on either side, its cavity at first communicating with that of the vesicle, which remains permanent as the “fourth ventricle.” As its protrusion increases, it becomes elongated and pear-shaped, and is only connected with the central mass by a pedicle whose canal gradually closes up; the sac thus cut off becomes the vestibular cavity, and the pedicle the auditory nerve. At first there is no vestige either of cochlea, semicircular canals, or tympanic apparatus; but the sac presents the simple character which it permanently retains in the Cephalopoda and the lower Fishes. Gradually, however, the semicircular

¹ See an account of the observations of Prof. Retzius on the Development of the Cerebrum, in the “Archives d'Anatomie Générale et de Physiologie,” 1846.

² “Philosophical Transactions,” 1850.

canals are developed, by a contraction and folding in of the walls of the vestibular sac; and the cochlea is probably formed as an offset from it. At the same time, the formation of cartilage, and subsequently of bone, takes place around the auditory sac and its prolongations, forming the "sense-capsule," which, in the higher Vertebrata, coalesces with the vertebral elements to form the temporal bone.—It is very interesting to remark, that the membranous labyrinth, between the eighth and thirteenth days in the Chick, has a structure almost precisely similar to that of the retinal expansion of the same period; consisting, like it, of a distinct but very delicate fibrous mesh, in the spaces between which are deposited a quantity of granular matter and numerous nucleated cells, whilst its exterior is composed of a dense mass of nuclei, almost precisely analogous to the granular particles which form a large part of the entire substance of the retina.

1014. There can be no reasonable doubt, that the developmental process must be greatly influenced by the *quality* of the nutriment supplied by the maternal blood. "We have demonstrative evidence," says Dr. A. Combe,¹ "that a fit of passion in a nurse vitiates the quality of the milk to such a degree as to cause colic and indigestion (or even death) in the suckling infant. If, in the child already born, and in so far independent of its parent, the relation between the two is thus strong, is it unreasonable to suppose that it should be yet stronger, when the infant lies in its mother's womb, is nourished indirectly by its mother's blood, and is, to all intents and purposes, a part of her own body? If a sudden and powerful emotion of her own mind exerts such an influence upon her stomach as to excite immediate vomiting, and upon her heart as almost to arrest its motion and induce fainting, can we believe that it will have no effect on her womb and the fragile being contained within it? Facts and reason, then, alike demonstrate the reality of the influence: and much practical advantage would result to both parent and child, were the conditions and extent of its operations better understood." Among facts of this class, there is, perhaps, none more striking than that quoted by the same author from Baron Percy, as having occurred after the siege of Landau in 1793. In addition to a violent cannonading, which kept the women for some time in a constant state of alarm, the arsenal blew up with a terrific explosion, which few could hear with unshaken nerves. Out of 92 children born in that district within a few months afterwards, Baron Percy states that 16 died at the instant of birth; 33 languished for from 8 to 10 months, and then died; 8 became idiotic, and died before the age of 5 years; and 2 came into the world with numerous fractures of the bones of the limbs, caused by the cannonading and explosion. Here, then, is a total of 59 children out of 92, or within a trifle of 2 out of every 3, actually killed through the medium of the Mother's alarm and the natural consequences upon her own organization; an experiment (for such it is to the Physiologist) upon too large a scale for its results to be set down as mere "coincidences."—No soundly judging Physiologist of the present day is likely to fall into the popular error of supposing that "marks" upon the Infant are to be referred to some *transient* though strong impression upon the imagination of the Mother; but there appear to be a sufficient number of facts on record, to prove that *habitual* mental conditions on the part of the Mother *may* have influence enough, at an early period of gestation, to produce evident bodily deformity, or peculiar tendencies of the mind. That the mental state of the Mother can produce important alterations in her own blood, seems demonstrated by the considerations previously adduced (CHAP. XVIII.) in regard to its effect upon the processes of Nutrition and Secretion; and that such alterations are

¹ "On the Management of Infancy," p. 76.

sufficient to determine important modifications in the developmental processes of the Embryo, to which her blood furnishes the materials, can scarcely admit of a question, when we recollect what an influence the presence or absence of particular substances has in modifying the growth of parts in the adult (§ 203). The error of the vulgar notion on this subject, lies in supposing that a *sudden fright, speedily forgotten*, can exert such a continual influence on the nutrition of the Embryo, as to occasion any personal peculiarity.¹ The view here stated is one which ought to have great weight; in making manifest the importance of careful management of the health of the Mother, both corporeal and mental, during the period of pregnancy; since the constitution of the offspring so much depends upon the impressions then made upon its most impressible structure.

1015. It is frequently of great importance, both to the Practitioner and to the Medical Jurist, to be able to determine the *age* of a Fœtus, from the physical characters which it presents; and the following table has been framed by Devergie² in order to facilitate such determination. It is to be remarked, however, that the *absolute length* and *weight* of the Embryo are much less safe criteria, than its *degree of development*, as indicated by the relative evolution of the several parts which make their appearance successively. Thus it is very possible for one child, born at the full time, to weigh less than another born at eight or even at seven months; its length, too, may be no greater: but the position of the middle point of the body will usually afford sufficient ground for the determination; since, during the two latter months of pregnancy, the increasing development of the lower extremities brings it lower down.

Embryo 3 to 4 weeks.—It has the form of a serpent; its length from 3 to 5 lines; its head indicated by a swelling; its caudal extremity (in which is seen a white line, indicating the continuation of the medulla spinalis), slender, and terminating in the umbilical cord; the mouth indicated by a cleft, the eyes by two black points; the members begin to appear as nipple-like protuberances; the liver occupies the whole abdomen; the bladder is very large. The chorion is villous, but its villosities are still diffused over the whole surface.

Embryo of 6 weeks.—Its length from 7 to 10 lines; its weight from 40 to 75 grains; face distinct from cranium; aperture of nose, mouth, eyes, and ears perceptible; head distinct from thorax; hands and forearms in the middle of the length, fingers distinct; legs and feet situated near the anus; clavicle and maxillary bone present a point of ossification; distinct umbilicus for attachment of cord, which at that time consists of the omphalo-mesenteric vessels, of a portion of the urachus, of a part of the intestinal tube, and of filaments which represent the umbilical vessels. The placenta begins to be formed; the chorion still separated from the amnion; the umbilical vesicle very large.

Embryo of 2 months.—Length from 16 to 19 lines; weight from 150 to 300 grains; elbows and arms detached from the trunk; heels and knees also isolated; rudiments of the nose and of the lips; palpebral circle beginning to show itself; clitoris or penis apparent; anus marked by a dark spot; rudiments of lungs, spleen, and suprarenal capsules; cæcum placed behind the umbilicus; digestive canal withdrawn into the abdomen; urachus visible; osseous points in the frontal bone and in the ribs. Chorion commencing to touch the amnion at the point opposite the insertion of the placenta; placenta begins to assume its regular form; umbilical vessels commence twisting.

Embryo of 3 months.—Length from 2 to 2½ inches; weight from 1 oz. to 1½ oz. (Troy); head voluminous; eyelids in contact by their free margin; membrana pupillaris visible; mouth closed; fingers completely separated; inferior extremities of greater length than

¹ For some valuable observations on this subject, see Montgomery "On the Signs of Pregnancy."—Numerous cases have been recorded, during the last few years (especially in the "Lancet" and "Provincial Medical Journal"), in which malformations in the Infant appeared distinctly traceable to strong impressions made on the mind of the Mother some months previously to parturition; these impressions having been persistent during the remaining period of pregnancy, and giving rise to a full expectation on the part of the Mother that the child would be affected in the particular manner which actually occurred.

² "Médecine Légale," Sième edit. tom. i. p. 279.

rudimentary tail; clitoris and penis very long; thymus as well as suprarenal capsules present; cæcum placed below the umbilicus; cerebrum 5 lines, cerebellum 4 lines, medulla oblongata $1\frac{1}{2}$ line, and medulla spinalis $\frac{3}{4}$ of a line, in diameter; two ventricles of heart distinct. The decidua reflexa and decidua uterina in contact; funis contains umbilical vessels and a little of the gelatine of Warthon; placenta completely isolated; umbilical vesicle, allantois, and omphalo-meseraic vessels have disappeared.

Fœtus of 4 months.—Length 5 to 6 inches; weight $2\frac{1}{2}$ to 3 oz.; skin rosy, tolerably dense; mouth very large and open; membrana pupillaris very evident; nails begin to appear; genital organs and sex distinct; cæcum placed near the right kidney; gall-bladder appearing; meconium in duodenum; cæcal valve visible; umbilicus placed near pubis; ossicula auditoria ossified; points of ossification in superior part of sacrum; membrane forming at point of insertion of placenta on uterus; complete contact of chorion with amnion.

Fœtus of 5 months.—Length 6 to 7 inches; weight 5 to 7 oz.; volume of head still comparatively great; nails very distinct; hair beginning to appear; skin without sebaceous covering; white substance in cerebellum; heart and kidneys very voluminous; cæcum situated at inferior part of right kidney; gall-bladder distinct; germs of permanent teeth appear; points of ossification in pubis and calcaneum; meconium has a yellowish-green tint, and occupies commencement of large intestine.

Fœtus of 6 months.—Length 9 to 10 inches; weight 1 lb.; skin presents some appearance of fibrous structure; eyelids still agglutinated, and membrana pupillaris remains; sacculi begin to appear in colon; funis inserted a little above pubis; face of a purplish red; hair white or silvery; sebaceous covering begins to present itself; meconium in large intestine; liver of dark red; gall-bladder contains serous fluid destitute of bitterness; testes near kidneys; points of ossification in four divisions of sternum; middle point at lower end of sternum.

Fœtus of 7 months.—Length 13 to 15 inches; weight 3 to 4 lbs.; skin of rosy hue, thick and fibrous; sebaceous covering begins to appear; nails do not yet reach extremities of fingers; eyelids no longer adherent; membrana pupillaris disappearing; a point of ossification in the astragalus; meconium occupies nearly the whole of large intestine; valvula conniventes begin to appear; cæcum placed in right iliac fossa; left lobe of liver almost as large as right; gall-bladder contains bile; brain possesses more consistency; testicles more distant from kidneys; middle point at a little below end of sternum.

Fœtus of 8 months.—Length 14 to 16 inches; weight 4 or 5 lbs.; skin covered with well-marked sebaceous envelop; nails reach extremities of fingers; membrana pupillaris becomes invisible during this month; a point of ossification in last vertebra of sacrum; cartilage of inferior extremity of femur presents no centre of ossification; brain has some indications of convolutions; testicles descend into internal ring; middle point nearer the umbilicus than the sternum.

Fœtus of 9 months, the full term.—Length from 17 to 21 inches; weight from 5 to 9 lbs., the average probably about $6\frac{1}{2}$ lbs.; head covered with hair in greater or less quantity, of from 9 to 12 lines in length; skin covered with sebaceous matter, especially at bends of joints; membrana pupillaris no longer exists; external auditory meatus still cartilaginous; four portions of occipital bone remain distinct; os hyoides not yet ossified; point of ossification in the centre of cartilage at lower extremity of femur; white and gray substances of brain become distinct; liver descends to umbilicus; testes have passed inguinal ring, and are frequently found in the scrotum; meconium at termination of large intestine; middle point of body at umbilicus, or a little below it.

1016. Even at birth, there is a manifest difference in the physical conditions of infants of different sexes; for, in the average of a large number, there is a decided preponderance on the side of the Males both as to the length and the weight of the body.

a. The length of the body in fifty new-born infants of each sex, as ascertained by Que-telet,¹ was as follows:—

¹ "Sur L'Homme," tom. ii. p. 8.

	Males.	Females.	Total.
From 16 to 17 inches ¹ (French)	2	4	6
" 17 to 18	8	19	27
" 18 to 19	28	18	46
" 19 to 20	12	8	20
" 20 to 21	0	1	1

From these observations, the mean and the extremes of the Lengths of the Male and Female respectively were calculated to be—

	Males.	Females.
Minimum	16 inches, 2 lines	16 inches, 2 lines
Mean	18 6	18 1½
Maximum	19 8	20 6

Notwithstanding that the *maximum* is here on the side of the Female (this being an accidental result, which would probably have been otherwise, had a larger number been examined) the *average* shows a difference of 4½ lines in favor of the Male.

b. The inequality in the Weight of the two is even more remarkable; the observations of M. Quetelet² were made upon 63 male and 56 female infants.

Infants weighing from	Males.	Females.	Total.
1 to 1½ kilog. ³	0	1	1
1½ to 2	0	1	1
2 to 2½	3	7	10
2½ to 3	13	14	27
3 to 3½	28	23	51
3½ to 4	14	7	21
4 to 4½	5	3	8

The extremes and means were as follows:—

	Males.	Females.
Minimum	2.34 kilog.	1.12
Mean	3.20	2.91
Maximum	4.50	4.25

c. The average weight of infants of both sexes, as determined by these inquiries, is 3.05 kilog. or 6.7 lbs.; and this corresponds almost exactly with the statement of Chaussier, whose observations were made upon more than 20,000 infants. The mean obtained by him, without reference to distinction of sex, was 6.75 lbs.; the maximum being 11.3 lbs., and the minimum 3.2 lbs.⁴ The average in this country is probably rather higher; according to Dr. Joseph Clarke,⁵ whose inquiries were made on 60 males and 60 females, the average of Male children is 7½ lbs.: and that of Females 6¾ lbs. He adds that children which at the full time weigh less than 5 lbs. rarely thrive; being generally feeble in their actions, and dying within a short time. Several instances are on record, of infants whose weight at birth exceeded 15 lbs. It appears that healthy females, living in the country, and engaged in active but not over-fatiguing occupations, have generally the largest children; and this is what might be expected *a priori*, from the superior energy of their nutritive functions.

1017. Notwithstanding that, in any ordinary population, there is a decided preponderance in the number of Females, the number of Male *births* is considerably greater than that of females. Taking the average of the whole of Europe, the proportion is about 106 Males to 100 Females. It is curious, however, that this proportion is considerably different for legitimate and for illegitimate births; the average of the latter being only 102½ to 100, in the places where that of the former was 105¼ to 100. This is probably to be ac-

¹ The French inch is about one-fifteenth more than the English.

² Op. cit. tom. ii. p. 35.

³ The kilogramme is equal to 2½ lbs. avoirdupois.

⁴ These numbers have been erroneously stated in many Physiological works; owing to the difference between the French and English pound not having been allowed for.

⁵ "Philosophical Transactions," vol. lxxvi.

counted for by the fact, which is one of the most remarkable contributions that have yet been made by Statistics to Physiology, that the Sex of the offspring is influenced by the relative *ages* of the parents. The following table expresses the average results obtained by M. Hofacker¹ in Germany, and by Mr. Sadler² in Britain; between which it will be seen that there is a manifest correspondence, although both were drawn from a too limited series of observations. The numbers indicate the proportion of Male births to 100 Females, under the several conditions mentioned in the first column.

	Hofacker.		Sadler.
Father younger than Mother . . .	90.6	Father younger than Mother . . .	86.5
Father and Mother of equal age . .	90.0	Father and Mother of equal age . .	94.8
Father older by 1 to 6 years . . .	103.4	Father older by 1 to 6 years . . .	103.7
“ “ 6 to 9 . . .	124.7	“ “ 6 to 11 . . .	126.7
“ “ 9 to 18 . . .	143.7	“ “ 11 to 16 . . .	147.7
“ “ 18 and more . . .	200.0	“ “ 16 and more . . .	163.2

From this it appears, that the more advanced age of the Male parent has a very decided influence in occasioning a preponderance in the number of Male infants; and, as the state of society generally involves a condition of this kind in regard to marriages, whilst in the case of illegitimate children the same does not hold good, the difference in the proportional number of male births is accounted for. We are not likely to obtain data equally satisfactory in regard to the influence of more advanced age on the part of the Female parent; as a difference of 10 or 15 years on that side is not so common. If it exist to the same extent, it is probable that the same law would be found to prevail in regard to Female children born under such circumstances, as has been stated with respect to the Male;—namely, that the mortality is greater during embryonic life and early infancy, so that the preponderance is reduced.

1018. There appears to be, from the first, a difference in the *Viability* (or probability of life) of Male and Female children; for, out of the total number born dead, there are 3 Males to 2 Females: this proportion gradually lessens, however, during early infancy; being about 4 to 3 during the first two months, and about 4 to 5 during the next three months; after which time the deaths are nearly in proportion to the numbers of the two sexes respectively, until the age of puberty. The viability of the two sexes continues to increase during childhood; and attains its maximum between the 13th and 14th years. For a short time after this epoch has been passed, the rate of mortality is higher in Females than in Males; but from about the age of 18 to 28, the mortality is much greater in Males, being at its maximum at 25, when the viability is only half what it is at puberty. This fact is a very striking one; and shows most forcibly that the indulgence of the passions not only weakens the health, but in a great number of instances is the cause of a very premature death. From the age of 28 to that of 50, the mortality is greater and the viability less on the side of the Female; this is what would be anticipated from the increased risk to which she is liable during the parturient period. After the age of 50, the mortality is nearly the same for both.

a. These facts have been expressed by Quetelet (Op. cit.) in a form which brings them prominently before the eye (Fig. 277). The relative viability of the male at different ages is represented by a curved line; the elevation of which indicates its degree at the respective periods marked along the base line. The dotted line, which follows a different curve, represents the viability of the Female. Starting from *a*, the period of birth, we arrive at the maximum of viability for both at *b*; from this point, the Female curve steadily descends towards *n*, at first very rapidly, but afterwards more gradually; whilst the Male curve does not quite descend so soon, but afterwards falls much lower, its minimum being *c*, which

¹ “Annales d’Hygiène,” Oct. 1829.

² “Law of Population,” vol. ii. p. 343.

corresponds with the age of 25 years. It afterwards ascends to *d*, which is the maximum of viability subsequently to the age of puberty; this point is attained at the age of 30

Fig. 277.

Diagram representing the Comparative Viability of the Male and Female at different Ages.

years, from which period, up to 50, the probability of life is greater in the Male than in the Female. In the decline of life there seems little difference for the two sexes.

1019. Similar diagrams have been constructed by Quetelet, to indicate the relative *Heights* and *Weights* of the two sexes at different ages (Fig. 278).

a. In regard to Height, it may be observed that the increase is most rapid in the first year, and that it afterwards diminishes gradually; between the ages of 5 and 16 years, the annual increase is very regular. The difference between the Height of the male and Female, which has been already stated to present itself at birth, continues to increase during infancy and youth; it is not very decided, however, until about the 15th year, after which the growth of the Female proceeds at a much diminished rate, whilst that of the Male continues in nearly the same degree, until about the age of 19 years. It appears, then, that the Female comes to her full development, in regard to Height, earlier than does the Male. It seems probable, from the observations of Quetelet, that the full Height of the Male is not generally attained until the age of 25 years. At about the age of 50, both Male and Female undergo a diminution of their stature, which continues during the latter part of life.

b. The proportional Weight of the two sexes at different periods corresponds pretty closely with their height. Starting from birth, the predominance then exhibited by the Male gradually increases during the first few years; but towards the period of puberty, the proportional weight of the Female increases; and at the age of 12 years, there is no difference between the two sexes in this respect. The weight of the Male, however, then increases much more rapidly than that of the Female, especially between the ages of 15 and 20 years; after the latter period, there is no considerable increase on the side of the Male, though his maximum is not attained until the age of 40; and there is an absolute diminution on the part of the Female, whose weight remains less during nearly the whole

period of child-bearing. After the termination of the parturient period, the weight of the Female again undergoes an increase, and its maximum is attained about 50. In old age, the weight of both sexes undergoes a diminution in nearly the same degree. The average

Fig. 278.

Diagram representing the Comparative Heights and Weights of the Male and Female at different Ages.

Weights of the Male and Female, that have attained their full development, are twenty times those of the new-born Infants of the two sexes respectively. The Heights, on the other hand, are about $3\frac{1}{4}$ times as great.

1020. The chief differences in the *Constitution* of the two sexes manifest themselves during the period when the Generative function of each is in the greatest vigor. Many of these distinctions have been already alluded to; but there are others of too great importance to be overlooked; and these chiefly relate to the Nervous System and its functions. There is no obvious structural difference in the Nervous System of the two sexes (putting aside the local peculiarities of its distribution to the organs of generation), save the inferior size of the Cerebral Hemispheres in the Female. This difference, which is not observed in other parts of the Encephalon, is readily accounted for on the principles formerly stated (§§ 782, 783), when we compare the psychical character of Woman with that of Man; for there can be no doubt that—putting aside the exceptional cases which now and then occur—the *intellectual* powers of Woman are inferior to those of Man. Although her perceptive faculties are more acute, her capability of sustained mental exertion is much less; and though her views are often peculiarly distinguished by clearness and decision, they are generally deficient in that comprehensiveness which is necessary for their stability. With less of the *volitional* powers than Man possesses, she has the *emotional* and *instinctive* in a much stronger degree. The emotions, therefore, predominate; and more frequently become the leading springs of action, than they are in Man. By their direct influence upon the bodily frame, they produce changes in the organic functions, which far surpass in degree anything of the same kind that we ordinarily witness in Man; and they thus not unfrequently occasion symptoms of an anomalous kind, which are very perplexing to the Medical practitioner, though very interesting to the Physiological observer. But they also act as powerful motives to the Will; and, when strongly called forth, produce a degree of vigor and determination, which is very surprising to those who

have usually seen the individual under a different aspect. But this vigor, being due to the strong excitement of the Feelings, and not to any inherent strength of Intellect, is only sustained during the persistence of the motive, and fails as soon as this subsides. The feelings of Woman, being frequently called forth by the occurrences she witnesses around her, are naturally more disinterested than those of Man; *his* energy is more concentrated upon one object; and to this his intellect is directed with an earnestness that too frequently either blunts his feelings, or carries them along in the same channel, thus rendering them selfish. The *intuitive* powers of Woman are certainly greater than those of Man. Her perceptions are more acute, her apprehension quicker; and she has a remarkable power of interpreting the feelings of others, which gives to her, not only a much more ready sympathy with these, but that power of guiding her actions so as to be in accordance with them, which we call *tact*. This tact bears a close correspondence with the *adaptiveness* to particular ends, which we see in Instinctive actions.—In regard to the inferior development of her Intellectual powers, therefore, and in the predominance of the Instinctive, Woman must be considered as ranking below Man; but in the superior purity and elevation of her Feelings, she is as highly raised above him. Her whole character, Psychical as well as Corporeal, is beautifully adapted to supply what is deficient in Man; and to elevate and refine those powers, which might otherwise be directed to low and selfish objects.

5.—Of Lactation.

1021. The new-born Infant in the Human species, as in the class of Mammalia generally, is supplied with nourishment by a secretion elaborated from the blood

Fig. 279.

The Mammary Gland after the removal of the skin, as taken from the subject three days after delivery: 1, the surface of the chest; 2, subcutaneous fat; 3, the skin covering the gland; 4, circumference of the gland; 5, its lobules separated by fat; 6, the lactiferous ducts converging to unite in the nipple; 7, the nipple slightly raised, and showing the openings of the tubes at its extremity.

Fig. 280.

of its maternal parent, by certain glandular organs known as the *Mammary*. The structure of these, which has been thoroughly investigated by Sir A. Cooper¹

¹ "On the Anatomy of the Breast," 1840, *Am. Ed.* 1845.

and Mr. Birket,¹ is extremely simple. Each gland is composed of a number of separate glandules, which are connected together by fibrous or fascial tissue, in such a manner as to allow a certain degree of mobility of its parts, one upon another, which may accommodate them to the actions of the pectoralis muscle whereon they are bound down; and the glandules are also connected by the ramifications of the lactiferous tubes, which intermingle with one another in such a manner as to destroy the simplicity and uniformity of their divisions, although they rarely inosculate. The *mamillary tubes*, or terminal ducts contained in the nipple, are usually about ten or twelve in number; they are straight, but of somewhat variable size; and their orifices, which are situated in the centre of the nipple, and are usually concealed by the overlapping of its sides, are narrower than the tubes themselves. At the base of the nipple, these

Fig. 281.

Distribution of the Milk-ducts in the Mamma of the Human Female, during lactation; the ducts injected with wax.

tubes dilate into reservoirs, which extend beneath the areola and to some distance into the gland, when the breast is in a state of lactation. These are much larger in many of the lower Mammalia than they are in the Human female; their use is to supply the immediate wants of the child when it is first applied to the breast, so that it shall not be disappointed, but shall be induced to proceed with sucking until the "draught" be occasioned (§ 948). From each of these reservoirs commence five or six branches of the *lactiferous tubes*, each of which speedily subdivides into smaller ones; and these again divaricate, until

¹ "The Diseases of the Breast, and their Treatment," 1850.

their size is very much reduced, and their extent greatly increased (Fig. 281). These, like the reservoirs and mamillary tubes, are composed of a fibrous coat lined by a mucous membrane; the latter is highly vascular, and forms a secretion of its own, which sometimes collects in considerable quantity when the milk ceases to be produced. The smaller subdivisions of the lactiferous tubes proceed to distinct lobuli in each glandule; so that when a branch of a mammary tube has been filled with injection, its attached lobules, if separated from each other by long maceration, are like a bunch of fruits clustered upon a stalk (Fig. 282). When the lactiferous tubes are pursued to their ultimate distribution, they are found to terminate in follicles, whose size, in full lactation, is that of a hole pricked in paper by the point of a very fine pin, so that when distended with quicksilver or milk, they are just visible to the naked eye; at other times, however, the follicles do not admit of being injected, though the lactiferous

Fig. 282.

Fig. 283.

Ultimate follicles of Mammary Gland, with their secreting cells, *a, a*; *b, b*, the nuclei.

tubes may have been completely filled. They are lined by a continuation of the same membrane with that which lines the ducts; and this possesses a high vascularity. The arteries which supply the glandules with blood become very large during lactation; and their divisions spread themselves minutely on the follicles. From the blood which they convey, the milk is secreted and poured into the follicles, whence it flows into the ducts. The inner surface of the milk-follicles, in common with other glandular structures, is covered with a layer of epithelium-cells (Fig. 283), as was first observed by Prof. Goodsir; and these, being seen to contain milk-globules, may without doubt be regarded as the real agents in the secreting process. Absorbent vessels are seen to arise in large numbers in the neighborhood of the follicles; their function appears to be to absorb the more watery part of the milk contained in the follicles and tubes, so as to render it more nutrient than it is when first secreted; and also to relieve the distension which would occur, during the absence of the child, from the continuance of the secreting process.—The Mammary gland may be detected at an early period of foetal existence; being easily distinguishable from the surrounding parts by the redness of its color and its high vascularity, especially when the whole is injected. At this period, it presents no difference in the male and female; and it is not until near the period of puberty that any striking change manifests itself, the gland continuing to grow, in the one sex as in the other, in proportion to the body at large. At about the age of thirteen years, however, the enlargement of the gland commences in the Female; and by sixteen, it is greatly evolved, and some of the lactiferous tubes can be injected. At about the age of twenty, the gland attains its full size previous to lactation; but the milk-follicles cannot even then be injected from the tubes. During pregnancy, the mammæ receive a greatly increased quantity of blood. This determination often commences very early, and produces a feeling of tenderness and distension, which is a valuable sign (where it exists in connection with

others) of the commencement of gestation. The Areola at this time becomes darker in its color, and thicker in substance, and also more extended; its papillæ become more developed, and the secretion from its follicles increases. A true lacteal secretion usually commences about the third or fourth month of pregnancy, and may be obtained by pressure properly applied. This fact may be usefully applied in diagnosing cases of concealed or doubtful pregnancy from cases of simple suppression of the catamenia; but it will not serve to distinguish true pregnancy from spurious, or from the distension of the uterus by tumors.¹ The vascularity of the gland continues to increase during pregnancy; and at the time of parturition, its lobulated character can be distinctly felt. The follicles are not, however, developed sufficiently for injection, until lactation has commenced. After the cessation of the catamenia from age, so that pregnancy is no longer possible, the lactiferous ducts continue open, but the milk-follicles are incapable of receiving injection. The substance of the glandules gradually disappears, so that in old age only portions of the ducts remain, which are usually loaded with mucus; but the place of the glandules is commonly filled up by adipose tissue, so that the form of the breast is preserved. Sir A. Cooper notices a curious change, which he states to be almost invariable with age; namely, the ossification of the arteries of the breast, the large trunks as well as the branches, so that their calibre is greatly diminished or even obliterated.—The Mammary gland of the Male is a sort of miniature picture of that of the Female. It varies extremely in its magnitude, being in some persons of the size of a large pea; whilst in others it is an inch, or even two inches, in diameter. In its structure it corresponds exactly with that of the female, but is altogether on a smaller scale. It is composed of lobules containing follicles from which ducts arise; and these follicles and ducts are not too minute to be injected, although with difficulty. The evolution of the gland goes on *pari passu* with that of the body, not undergoing an increase at any particular period; it is sometimes of considerable size in old age. A fluid, which is probably mucus, may be pressed from the nipple in many persons; and this in the dead body with even more facility than in the living. That the essential character of the gland is the same in the male as in the female, is shown by the instances, of which there are now several on record, in which infants have been suckled by men (§ 1022).

1022. Although the state of functional activity in the Mammary gland is usually limited to the epoch succeeding Parturition, yet this is not invariably the case; for numerous instances are on record, in which young women who have never borne children, and even old women long past the period of child-bearing, have had such a copious flow of milk as to be able to act as efficient nurses.² In these cases, the strong desire to furnish milk, and continued irritation of the nipple by the infant's mouth seem to have furnished the stimulus requisite for the formation of the secretion; and it has been found that this is usually adequate to *restore* the secretion, after it has been intermitted for some months during the ordinary period of lactation, in consequence of disorder or debility on the part of the mother, or any other cause; so that where her condition renders it advisable that she should discontinue nursing for a time, the child may be withdrawn and the milk "dried-up" with a confident expectation that the secretion may be reproduced subsequently.³ Dr. M'William mentions, in his Report of the Niger Expedition,⁴ that the inhabitants of Bona Vista (Cape

¹ See the valuable paper by Dr. Peddie, "On the Mammary Secretion," in the "Edinb. Monthly Journ.," Aug. 1848.

² A collection of such cases is given in Dr. Dunglison's "Human Physiology," 7th edit. vol. ii. p. 513.

³ See an account of M. Trousseau's experience on this point, in "L'Union Médicale," 1852, No. 7; and a paper by Dr. Ballou in the "Amer. Journ. of Med. Sci.," Jan. 1852.

⁴ "Medical Gazette," Jan. 1847.

de Verde Islands) are accustomed to provide a wet-nurse in cases of emergency, in the person of any woman who has once borne a child and is still within the age of child-bearing, by continued fomentation of the mammæ with a decoction of the leaves of the *jatropha curcas*, and by suction of the nipple. The most curious fact, however, is that even *Men* should occasionally be able to perform the duties of nurses, and should afford an adequate supply of infantile nutriment. Several cases of this kind are upon record;¹ but one of the most recent and authentic is that given by Dr. Dunglison.² "Professor Hall, of the University of Maryland, exhibited to his Obstetrical class, in the year 1837, a colored man, fifty-five years of age, who had large, soft, well-formed mammæ, rather more conical than those of the female, and projecting fully seven inches from the chest; with perfect and large nipples. The glandular structure seemed to the touch to be exactly like that of the female. This man had officiated as wet-nurse, for several years, in the family of his mistress; and he represented that the secretion of milk was induced by applying the children intrusted to his care to the breasts during the night. When the milk was no longer required, great difficulty was experienced in arresting the secretion. His genital organs were fully developed."—Corresponding facts are also recorded of the male of several of the lower animals.

1023. The secretion of *Milk* consists of Water holding in solution Sugar, various Saline ingredients, and the peculiar albuminous substance termed Casein; and having Oleaginous particles suspended in it. The constitution of this fluid is made evident by the ordinary processes to which it is subjected in domestic economy. If it be allowed to stand for some time, exposed to the air, a large part of the oleaginous globules come to the surface, being of less specific gravity than the fluid through which they are diffused. At the same time, there is reason to believe that they undergo a change, which will be presently described. The *cream* thus formed does not, however, consist of oily particles alone; but includes a considerable amount of casein, with the sugar and salts of the milk. These are further separated by the continued agitation of the cream; which, by rupturing the envelopes of the oil-globules, separates it into *butter*, formed by their aggregation, and *buttermilk*, containing the casein, sugar, &c. A considerable quantity of casein, however, is entangled with the oleaginous matter, and this has a tendency to decompose so as to render the butter rancid; it may be separated by keeping the butter melted at the temperature of 180°, when the casein will fall to the bottom, leaving the butter pure, and much less liable to change.—The milk, after the cream has been removed, still contains the greatest part of its casein and sugar. If it be kept long enough, a spontaneous change takes place in its composition; the sugar is converted into lactic acid, and this coagulates the casein, precipitating it in small flakes. The same precipitation may be accomplished at any time by the addition of an acid; all the acids, however, which act upon albumen, do not precipitate casein, as will presently be pointed out in detail; the most effectual is that contained in the dried stomach of a calf, known as *rennet*. The whey left after the curd has been separated contains a large proportion of the saccharine and saline matter

¹ See the case described by the Bishop of Cork, in the "Philosophical Transactions," vol. xli. p. 813; one mentioned by Captain Franklin ("Narrative of a Journey to the Polar Sea," p. 157); and one which fell under the notice of the celebrated traveller Humboldt ("Personal Narrative," vol. iii. p. 58).

² "Human Physiology," 7th edit. vol. ii. p. 514.—Dr. Dunglison also mentions that in the winter of 1849–50, an athletic man, twenty-two years of age, presented himself at the Jefferson Medical College at Philadelphia, whose left mamma, *without any assignable cause*, became greatly developed, and secreted milk copiously. [Reported in "Philada. Medical Examiner," Aug. 1850.—ED.]—It may be added that a lactescent fluid, apparently presenting the characters of true milk, may frequently be expressed from the mammary glands of infants. (See "Dublin Medical Press," April 17, 1850.)

that entered into the original composition of the milk; this may be readily separated by evaporation.—When Milk is examined with the Microscope, it is seen to contain a large number of particles of irregular size and form, suspended in a somewhat turbid fluid; these particles vary in size from about the 1-12,700th to the 1-3040th of an inch; and they are termed “milk-globules.” They are not affected by the mere contact of ether or alkalis; but if these reagents are shaken with them, an immediate solution is the result. The same effect happens if they are first treated with acetic acid. Hence it is evident that the globules consist of oily matter, inclosed in an envelop of some kind: and an extremely delicate pellicle may in fact be distinguished, after the removal of the oily matter by ether, or after the globules have been ruptured and their contents pressed out by rubbing a drop of milk between two plates of glass. No proof of the organization of this pellicle has, however, been detected; and it is probably to be regarded as the simple result of the contact of oil with albuminous matter (§ 42).—Besides these milk-globules, other globules of much smaller size are seen in milk; and these present the peculiar movement which is exhibited by molecules in general. Most of them seem to consist of oily matter not inclosed in an envelop, as they are at once dissolved when the fluid is treated with ether; but, according to the statements of Donné, it would seem that a portion of them are composed of casein, suspended, not dissolved, in the fluid. In addition to the foregoing particles, there are found in the *Colostrum*, or milk first secreted after delivery, large yellow granulated corpuscles, which seem to be composed of a multitude of small grains aggregated together; these appear to be chiefly of a fatty nature, being for the most part soluble in ether; but traces of some adhesive matter, probably mucus, holding together the particles, are then seen. They are considered by some as “exudation-corpuscles,” to which they certainly bear a close resemblance; according to Reinhardt, they are transformations of the epithelial cells of the mammary ducts, the result of a sort of fatty degeneration or regressive metamorphosis consequent upon the peculiar activity of the mammary gland during pregnancy.¹ Lamellæ of epithelium are also found in the milk.—All the larger globules may be removed by repeated filtration; and the fluid is then nearly transparent. This, in fact, is the simplest way of separating the oleaginous from the other constituents of the milk; as but little casein then adheres to the former. That the transparent fluid which has passed through the filter contains nearly the whole amount of the casein of the milk, appears a sufficient proof that this is, for the most part, truly dissolved in the fluid.

1024. We shall now consider the chemical characters of each of the foregoing ingredients.—The *Oleaginous* matter of milk principally consists of the ordinary components of fat (§ 37); but it also contains another substance peculiar to it, designated as *butyrin*, to which the peculiar smell and taste of butter are due; this yields in saponification three volatile acids, of strong animal odor, to which Chevreul has given the names of butyric, caproic, and capric acids. These peculiar acids are not only formed when the butyrin is treated with alkalis, but are produced by the ordinary decomposition of this principle, which is favored by time and moderate warmth.—The *Casein* of Human milk, however, is usually said to be much less precipitable by acids than is that of the Cow; very commonly resisting the action of the mineral acids, and even that of the acetic, but being always coagulated by rennet, though the curd is long in collecting. On this point, however, there has been much discrepancy of statement, on which the recent experiments of Mr. Moore² throw some light. It appears, from the results obtained by him, that Human Milk forms with most acids two

¹ See an abstract of his views in the “Edinb. Monthly Journal” for Feb. 1848.

² “Dublin Quarterly Journal of Medical Science,” vol. vii. p. 280.

sets of compounds, one of them soluble in water, the other insoluble; the latter being formed only when the quantity of acid is large in proportion to the casein. Thus, when two fluid ounces of Cow's milk were boiled with a single drop of nitric acid, complete coagulation of the casein at once took place: but when two fluid drachms of Human milk were treated in the same manner, no coagulation occurred, though the casein was at once thrown down by a solution of ferrocyanide of potassium; the same quantity of milk, with five drops of the acid, formed a coagulum which was not very manifest until after the lapse of five hours, but was very complete, the serous fluid not being found to contain any casein by testing it with ferrocyanide of potassium; and it required ten drops of nitric acid to produce immediate coagulation.—The quantity of acid necessary to produce coagulation sufficiently rapid to be immediately visible will vary with the amount of casein present in the particular specimen of milk, 5 drops in some instances producing a coagulation as rapid as that produced by 10 drops in others. In no specimen did Mr. Moore fail to produce coagulation by adding a sufficiency of acid. Acetic acid without heat produces in Human milk a slow separation of soft flaky coagula; but, when heat is employed, a more perfect coagulation is produced by small than by large quantities of this acid. Rennet does not seem to act upon the casein of Human milk, unless an acid be also present. In several of these particulars, as well as in its small proportional amount, the Casein of Ass's milk bears a closer resemblance to that of Human milk than does that of the Cow.—The *Sugar of Milk*, which may be obtained by evaporating whey to the consistence of a syrup, and then setting it aside to crystallize, forms opaque prisms or rhombohedra, whose composition is $10C, 8H, 8O + 2HO$. In many of its properties it bears a close resemblance to Glucose (§ 45), into which it is readily converted by the agency of dilute sulphuric or hydrochloric acid, or by the acetic or citric acids. It is readily made to pass into the lactic and butyric fermentation, by the appropriate ferments; but is with difficulty brought to undergo the vinous fermentation.—The *Saline* matter contained in milk appears to be nearly identical with that of the blood; with a larger proportion of the phosphates of lime and magnesia, which amount to 2 or $2\frac{1}{2}$ parts in 1000. These phosphates are held in solution chiefly by the casein, which seems to have a power of combining with them, even greater than that of albumen: the presence of a minute proportion of free alkali, also, assists their solution. A small portion of iron in the state of phosphate, together with the chlorides of potassium and sodium, may also be detected in milk.¹

1025. The proportion of these different constituents is liable to great variation, from several causes. Thus, the whole amount of the solid constituents may vary from 86 to 138.6 parts in 1000; the difference being partly due to individual constitution, but in great part, also, to the amount and character of the ingesta. The average seems to be between 100 and 120 parts. The following are the results of the analyses of Simon; the first column being the average of fourteen observations upon the same woman; the second giving the maximum of each ingredient; and the third the minimum:—

	I.	II.	III.
Water	883.6	914.0	861.4
Butter	25.3	54.0	8.0
Casein	34.3	45.2	19.6
Sugar of Milk and extractive matters . . .	48.2	62.4	39.2
Fixed salts	2.3	2.7	1.6

It also appears, from the analyses of Simon, that the proportion of the different ingredients is liable to variation, according to the time which has elapsed since parturition. The quantity of Casein is at its minimum at the commencement of

¹ Haidlen in "Annalen der Chemie und Pharmacie," band xlv. p. 263.

lactation, and then gradually rises until it attains a nearly fixed proportion. The quantity of Sugar, on the contrary, is at its maximum at first, and gradually diminishes. The amount of Butter (as appears from the wide extremes shown in the above tables) is more variable than that of any other constituent.—That some of the variations are due, moreover, to the character of the ingesta, and others to the external temperature, amount of exercise, and other circumstances affecting the individual, is proved by the inquiries of Dr. Playfair upon the Milk of the Cow. He has shown that the amount of butter depends in part upon the quantity of oily matter in the food, and in part upon the amount of exercise which the animal takes, and the warmth of the atmosphere in which it is kept: exercise and cold, by increasing the respiration, eliminate part of the oily matter in the form of carbonic acid and water; whilst rest and warmth, by diminishing this drain, favor its passage into the milk. The proportion of Casein, on the other hand, is increased by exercise. Dr. Playfair's experience on this head seems to correspond with the results of common observation in Switzerland; for where the cattle pasture in very exposed situations, and are obliged to use a great deal of muscular exertion, the quantity of butter yielded by them is very small, whilst the cheese is in unusually large proportion; but these very cattle, when stall-fed, give a large quantity of butter and very little cheese.

1026. The change which naturally takes place, from the condition of Colostrum to that of true Milk, during the first week of lactation, is a very important one. The Colostrum has a purgative effect upon the child, which is very useful in clearing its bowels of the meconium that loads them at birth; and thus the necessity of any other purgative is generally superseded. Occasionally, however, the *colostric* character is retained by the milk, during an abnormally long period; and the health of the infant is then severely affected. It is important to know that this may occur, even though the milk may present all the usual appearance of the healthy secretion; but the microscope at once detects the difference.¹ The return to the character of the early milk, which has been stated to take place after the expiration of about twelve months, seems to indicate that Nature designs the secretion no longer to be encouraged. The mother's milk cannot then be so nutritious to the child as other food;² and every medical man is familiar with the injurious consequences to which she renders herself liable, by unduly prolonging lactation.³ Cases are not unfrequent, however, in which the secretion continues as long as there is a demand for it; and sometimes quite independently of this. It is the habit, among some nations, to suckle the children until they are three or four years old, and to continue doing so even though another pregnancy should supervene;⁴ so that the older child is only displaced by the arrival of another infant. And it seems to be chiefly among those who have thus forced the mammary gland into a state of unnaturally persistent activity, that the spontaneous and irrepressible flow continues, after the demand for it has ceased.⁵

¹ See Donné, "Du Lait, et en particulier celui des Nourrices," and "Brit. and For. Med. Review," vol. vi. p. 181.

² On the whole subject of Infant Nutrition, the Author would strongly recommend the excellent little work of Dr. A. Combe, formerly referred to.

³ One of these, which has particularly fallen under the Author's notice, is debility of the retina, sometimes proceeding to complete amaurosis: this, if treated in time, is most commonly relieved by discontinuance of lactation, generous diet, and quinine.

⁴ See Erman's "Travels in Siberia" (translated by Cooley), vol. ii. p. 527; and the "Narrative of the United States' Exploring Expedition," vol. ii. p. 138.

⁵ Thus Dr. Green has published ("New York Journ. of Med. and Surg.," Sept. 1844) the case of a lady, æt. 47, the mother of four children, who had an abundant supply of milk for *twenty-seven years* previously. A period of exactly four years and a half occurred

1027. It is very interesting to observe that Milk contains the three classes of principles which are required for human food—the Albuminous, the Oleaginous, and the Saccharine; and it is the only secreted fluid in which these all exist to any considerable amount. It is, therefore, the food most perfectly adapted for the young animal; and is the only single article supplied by nature in which such a combination exists. Our artificial combinations will be suitable to replace it, just in proportion as they imitate its character; but in none of them can we advantageously dispense with milk, under some form or other. It should be remembered that the Saline ingredients of milk, especially the phosphates of lime, magnesia, and iron, have a very important function in the nutrition of the infant, affording the material for the consolidation of its bones and for the production of its red blood-corpuscles; and any fluid substituted for milk, which does not contain these, is deficient in essential constituents. It is very justly remarked by Dr. Rees,¹ that, of all the secreted fluids, Milk is most nearly allied in its composition to Blood.

1028. The proportion of the different ingredients in the Milk of different animals, is subject to considerable variation; and this fact is of much practical importance in guiding our selection, when good Human milk cannot be conveniently obtained for the nourishment of an infant. The first point to be inquired into, is the quantity of solid matter contained in each kind; this may be determined either by evaporation, or by the specific gravity of the fluid. The Specific Gravity of Human milk is stated by Dr. Rees (*loc. cit.*) to vary between 1030 and 1035; others, however, have estimated it much lower. That of the Cow appears to be usually about the same; that of the cream, however, being 1024, and that of the skimmed milk about 1035. The variation will in part depend (as in the case of the urine) upon the quantity of fluid ingested, and in part, it is probable, upon the manner in which the milk is drawn; for it is well known to milkers, that the last milk they obtain is much richer than that with which the udder is distended at the commencement. The quantity of solid matter obtainable from Human and from Cow's Milk by evaporation, seems, like the specific gravities of the fluids, to be nearly the same. In the relative proportion of the ingredients, however, there is a considerable difference; there being much more sugar and less casein in Human Milk, than in that of the Cow. The following table exhibits the relative proportions of the different ingredients, in the Milk of various animals, from which that fluid is commonly obtained:—

	Cow.	Goat.	Sheep.	Ass.	Mare.
Water	861.0	868.0	856.2	907.0	896.3
Butter	38.0	33.2	42.0	12.10	traces
Casein	68.0	40.2	45.0	16.74	16.2
Sugar of Milk and extractive matters .	29.0	52.8	50.0	62.31	87.5
Fixed salts	6.1	5.8	6.8		

It appears from this, that, whilst the milks of the Cow, Goat, and Sheep do not differ from each other in any very prominent degree, that of the Ass and Mare is a fluid of very dissimilar character, containing a comparatively small proportion of casein, and scarcely any butter, but abounding in sugar. Hence it is, that it is much more disposed to ferment than other milk; indeed the sugar of mare's milk is so abundant, that the Tartars prepare from it a spirituous liquor, to which they give the name of *koumiss*. It would further appear that no milk more nearly approaches that of the Human female, in the proportion of its ingredients, than that of the Sheep and Goat; these both possess, however, a

between each birth, and the children were permitted to take the breast until they were running about at play. At the time when Dr. G. wrote, she had been nine years a widow, and was obliged to have her breasts drawn daily, the secretion of milk being so copious.

¹ "Cyclopædia of Anatomy and Physiology," Art. "Milk."

larger amount of casein, which forms a peculiarly dense curd; and the milk of the goat is tainted with the peculiar odor of the animal, which is more intense if the individual be dark colored. The milk of the Ass, though differing in the proportion of its ingredients, seems to bear a closer approximation in properties (§ 1024). The milk of the Cow will usually answer very well for the food of the infant; care being taken to dilute it properly, according to the age of the child, and to add a little sugar. Where there is an apprehension of an early failure in the supply of Milk, the Author has found it advantageous to commence feeding the infant once a day with this mixture, soon after the first month; and the number of its meals may be progressively increased, until it becomes entirely independent of its parent, without any abrupt transition.

1029. From what has been stated of the close correspondence between the elements of the Blood and those of the Milk, it is evident that we can scarcely expect to trace the existence of the latter, as such, in the circulating fluid. To what degree the change in which their elaboration consists is accomplished in the Mammary gland, or during the course of the circulation, there is no certain means of ascertaining. It is evident that this secretion cannot serve as the channel for the deportation of any element the accumulation of which would be injurious to the system; since it does not occur in the male at all, and is present in the female at particular times only. Yet there is reason to believe that if, whilst the process is going on, it be suddenly checked, the retention of the material in the blood, or the reabsorption of the secreted fluid, is attended with injurious consequences. Thus if, when the milk is first secreted, the child be not put to the breast, an accumulation takes place, which, if not relieved, occasions great general disturbance of the system. The narrowness of the orifices of the milk-tubes obstructs the spontaneous exit of the fluid, especially in *primiparæ*; the reservoirs and ducts become loaded; further secretion is prevented; and a state of congestion of the vessels of the gland, tending to inflammation, is induced. The accompanying fever is partly due, no doubt, to the local disturbance; but in part, also, there seems reason to believe, to the reabsorption of the milk into the blood; this cannot but be injurious, since, although but little altered, the constitution of milk is essentially different, especially in regard to the quantity of crystallizable matter (sugar) which it contains.—The instances of the vicarious secretion of milk are not numerous; and in no instance is there any proof that the elements of the fluid were pre-existent in the blood. Some of the most curious are those in which it has been poured out from a gland in the groin; but it is probable that this was in consequence of the existence of a real repetition, in that place, of the true mammary structure; this being the situation of the mammæ of many of the inferior animals, of which the homologues in Man are usually undeveloped.¹

¹ The following is a more unequivocal case of vicarious secretion; and it is peculiarly interesting as exhibiting the injurious effects of the reabsorption of the secretion, and the relief which the system experienced when it was separated from the blood by the new channel. "A lady of delicate constitution (with a predisposition to pneumonia) was prevented from suckling her child, as she desired, by the following circumstance: Soon after her delivery she had a severe fever, during which her breasts became very large, and hard; the nipples were swollen and firm; and there was evidently an abundant secretion of milk; but neither the sucking of the infant, nor any artificial means, could draw a single drop of fluid from the swollen glands. It was clear that the milk-tubes were closed; and as the breasts continued to grow larger and more painful, purgatives and other means were employed to check the secretion of milk. After three days the fever somewhat diminished, and was replaced by a constant cough, which was at first dry, but soon after was followed by the expectoration of simple mucus. After this, the cough diminished in severity, and the expectoration became easy; but the sputa were no longer mucous, but were composed of a liquid, which had all the physical characters of genuine milk. This continued for fifteen days; the quantity of milk expectorated amounting to

1030. Of the quantity of Milk ordinarily secreted by a good Nurse, it is difficult to form a correct estimate;¹ since the amount which can be artificially drawn affords no criterion of that which is secreted at the time of the "draught" (§ 948). The quantity which can be squeezed from either breast at any one time, and which, therefore, must have been contained in its tubes and reservoirs, is about two ounces. The amount secreted is greatly influenced by the mental and physical condition of the female, and also by the quantity and character of the ingesta. In regard to the influence of the mental state upon this secretion, ample details have already been given (CHAP. XVIII.). With respect to the physical state most favorable to the production of an ample supply of this important fluid, it may be stated generally that sound health, a vigorous but not plethoric constitution, regular habits, moderate but not fatiguing exercise, and an adequate but not excessive amount of nutritious food, furnish the conditions most required. It is seldom that stimulating liquors, which are so commonly indulged in, are anything but prejudicial; but the unmeasured condemnation of them in which some writers have indulged is certainly injudicious; as experience amply demonstrates the improvement in the condition both of mother and infant, which occasionally results from the moderate employment of them. Their *modus operandi*, when they are really beneficial, seems to lie in promoting the digestive process, and in thus aiding in the appropriation of those nutritive materials which constitute the real source of the solid constituents of the milk.—The influence of various Medicines upon the Milk is another important question which has not yet been sufficiently investigated. As a general rule, it appears that the most soluble saline compounds pass into the milk as into other secretions; but there are many exceptions. Common salt, the sesquicarbonate of soda, sulphate of soda, iodide of potassium, oxide of zinc, trisnitrate of bismuth, and sesquioxide of iron, have been readily detected in the milk, when these substances were experimentally administered to an Ass; and ordinary experience shows that the Human infant is affected by many of these, when they are administered to the mother. The influence of mercurial medicines taken by the mother in removing from the infant a syphilitic taint possessed by both, is also well known. The vegetable purgatives, especially castor-oil, senna, and colocynth, have little effect upon the milk; hence they are to be preferred to the saline aperients, when it is not desired to act upon the bowels of the child.

three ounces or more in the twenty-four hours. The breasts gradually diminished in size: and by the time that the expectoration ceased, they had regained their natural dimensions. The same complete obstacle to the flow of milk from the nipples recurred after the births of four children successively with the same sequelæ. After the sixth, she had the same symptoms of fever, but this time they were not followed by bronchitis or the expectoration of milk; she had in their stead copious sweatings, which, with other severe symptoms, reduced her to a cachectic state, and terminated fatally in a fortnight." ("Bulletino delle Scienze Mediche," Apr. 1839; and "Brit. and For. Med. Review," Jan. 1840.)

¹ For an estimate by M. Guillot, founded on the comparative weight of the Infant before and after lactation, see "L'Union Médicale," 1852, No. 16. The total amount considered by Mons. G. to be usually drawn in the twenty-four hours, varies from 32 oz. to 64 oz. (Apoth.); but his estimates are vitiated by the extraordinary frequency of the lactations observed, the infant being put to the breast from 25 to 30 times in the twenty-four hours.

CHAPTER XX.

OF THE DIFFERENT BRANCHES OF THE HUMAN FAMILY,
AND THEIR MUTUAL RELATIONS.1.—*General Considerations.*

1031. AMONGST the various tribes of Men which people the surface of the globe, and which are separated from all other animals by the characters formerly described (CHAP. I.), there are differences of a very striking and important nature. They are distinguishable from each other, not merely by their language, dress, manners and customs, religious belief, and other acquired peculiarities, but in the physical conformation of their bodies; and the difference lies, not merely in the color of the skin, the nature of the hair, the form of the soft parts (such as the nose, lips, &c.), but in the shape of the skull, and of other parts of the bony skeleton, which might be supposed to be less liable to variation. It is a question of great scientific interest, as well as one that considerably affects the mode in which we regard the races that differ from our own, whether they are all of *one species*, that is, descended from the *same* or from *similar* parentage—or whether they are to be considered as *distinct species*, the first parents of the several races having had the same differences among themselves as those which are now exhibited by their descendants.

1032. In order to arrive at a just conclusion on this subject, it is necessary to take a very extensive survey of the evidence furnished by a number of different lines of inquiry. Thus, in the first place, it is right to investigate what are the discriminating structural marks by which *species* are distinguished among other tribes of animals.—Secondly, it should be ascertained to what extent *variation* may proceed among races which are historically known to have a common parentage, and what are the circumstances which most favor such variations.—Thirdly, the extreme variations which present themselves among the different races of Men should be compared with those which occur among tribes of animals known to be of the same parentage; and it should be questioned, at the same time, whether the circumstances which favor the production of varieties in the latter case are in operation in the former.—Fourthly, where it is impossible to trace back distinct races to their origin, it is to be inquired how far agreement in physiological and psychological peculiarities may be regarded as indicating specific identity, even where a considerable difference exists in bodily conformation; and this test, if it can be determined on, has to be applied to Man.—Fifthly, it must be attempted, by a detailed examination of the varieties of the Human race themselves, to ascertain whether their differences in conformation are constant; or whether there are not occasional manifestations, in each race, of a tendency to assume the characters of others; so as to prevent any definite lines being drawn between the several tribes, which together make up the (supposed) distinct species.—An investigation so comprehensive could not be followed out, even in the most cursory manner that would be consistent with utility, within the limits of the present work; and no more will be attempted, therefore, than an indication of the principal points of difference among the several Races of Men, and a

statement of the results of inquiry into their degree of constancy in each group which they can be used to separate.¹

1033. The differential characters on which those have relied who have sought to establish the existence of a *plurality of species* among Mankind, are both Anatomico-Physiological, and Psychological. Under the former head rank the Color of the Skin, the texture of the Hair, and the conformation of the bony Skeleton, especially the Skull. The latter consist in the superiority claimed for some races over others in intellectual power, and in moral and religious capacity. The former group will be the one first considered.

1034. The *Color* of the skin exists in the Epidermis only; and it depends upon the admixture of *pigment-cells* with the ordinary epidermic cells (§ 242); all the varied hues presented by the different races of men being due to the relative amount of these cells, and to the particular tint of the pigment which they form. It would be easy, by selecting well-marked specimens of each race, to make it appear that color affords a character sufficiently distinctive for their separation; thus, for example, the fair and ruddy Saxon, the jet-black Negro, the olive Mongolian, and the copper-colored North American, might be considered to be positively separated from each other by this character—propagated as it seems to be, with little or no perceptible change, from generation to generation. But, although such might appear to be the clear and obvious result of a comparison of this kind, yet a more profound and comprehensive survey tends to break down the barrier that would be thus established. For, on tracing this character through the entire family of Man, we find the isolated specimens, just noticed, to be connected by such a series of links, and the transition from one to the other to be so very gradual, that it is impossible to say where the line is to be drawn. There is nothing here, then, which at all approaches to those fixed and definite marks that are always held to be requisite for the establishment of specific distinctions among other tribes of animals.

1035. But, further, there is abundant evidence that these distinctions are far from being constantly maintained, even in any one race. For among all the principal subdivisions, *albinoism*, or the absence of pigment-cells, occasionally presents itself; so that the fair skin of the European may present itself in the offspring of the Negro or of the Red Man.² On the other hand, instances are by no means rare, of the unusual development of pigment-cells in individuals

¹ The whole of this investigation has been most elaborately, and in the Author's opinion most successfully, worked out by Dr. Prichard in his profound and philosophical Treatise on the "Physical History of Man." For a more concise view of Dr. Prichard's argument, with some additional considerations not embraced in it, the Author may refer to his own article on the "Varieties of the Human Species," in the "Cyclop. of Anat. and Phys.," vol. iv.

² A very curious example of *change of color* in a Negro has been recently recorded, on unquestionable authority.—The subject of it is a negro slave in Kentucky, æt. 45, who was born of black parents, and was, himself, perfectly black until 12 years of age. At that time a portion of the skin, an inch wide, encircling the cranium just within the edge of the hair, gradually changed to white; also the hair occupying that locality. A white spot next appeared near the inner canthus of the left eye; and from this the white color gradually extended over the face, trunk, and extremities, until it covered the entire surface. The complete change from black to white occupied about ten years; and, but for his hair, which was crisped or woolly, no one would have supposed at this time that his progenitors had offered any of the characteristics of the Negro, his skin presenting the healthy vascular appearance of that of a *fair-complexioned* European. When he was about 22 years of age; however, dark *copper-colored*, or brown spots began to appear on the face and hands; but these have remained limited to the portions of the surface exposed to light.—About the time that the black color of his skin began to disappear, he completely lost his sense of smell; and since he has become white, he has had measles and hooping-cough a second time. (See Dr. Hutchison's account of this case in the "Amer. Journ. of Med. Sci.," Jan. 1852.)

of the fair-skinned races; so that parts of the body are of a dark red, or brown hue, or are even quite black. Such modifications may seem of little importance to the argument; since they are confined to individuals, and may be put aside as accidental. But there is ample evidence that analogous changes may take place in the course of time, which tend to produce a great variety of shades of color, in the descendants of any one stock. Thus, in the great Indo-European family (part of the *Caucasian* race of Blumenbach), which may be unquestionably regarded as having had a common origin, we find races with fair complexion, yellow hair, and blue eyes—others presenting the xanthous or olive hue—and others decidedly black. A similar diversity may be seen among the American races, which are equally referable to one common stock; and it exists to nearly the same extent among the African nations, which are similarly related to each other. It may be freely admitted, that among European colonists settled in hot climates, such changes do not present themselves within a few generations; but in many well-known instances of earlier colonization, they are very clearly manifested. Thus, the wide dispersion of the Jewish nation, and their remarkable isolation (maintained by their religious observances) from the people among whom they live, render them peculiarly appropriate subjects for such observations; and we accordingly find that the brunette complexion and dark hair, which are usually regarded as characteristic of that race, are frequently superseded, in the Jews of Northern Europe, by red or brown hair, and fair complexion; whilst the Jews who settled in India some centuries ago, have become as dark as the Hindoos around them.

1036. The relation of the complexions of the different races of Men to the climates they respectively inhabit, is clearly established by an extended comparative survey of both. From such a survey the conclusion is inevitable, that the intertropical region of the earth is the principal seat of the darkest races of Men; whilst the region remote from the tropics is that of the fairer races; and that the climates approaching the tropics are generally inhabited by nations which are of an intermediate complexion. To this observation, it may be added that high mountains, and countries of great elevation, are generally inhabited by people of a lighter color than are those of which the level is low, such as swampy or sandy plains upon the sea-coast. These distinctions are particularly well seen in Africa, where the tropics almost exactly mark out the limits of the black complexion of the inhabitants; and where the deepest hue is to be seen among the Negroes of the Guinea Coast, whose residence unites both the conditions just mentioned; whilst the mountainous regions in their immediate vicinity are inhabited by tribes of a much lighter aspect.

1037. The nature of the *Hair* is, perhaps, one of the most permanent characteristics of different races. In regard to its color, the same statements apply as those just made with respect to the color of the skin; the variety of hue being given by pigment-cells, which may be more or less developed under different circumstances. But it has been thought that its *texture* afforded a more valid ground of distinction; and it is commonly said, that the substance which grows on the head of the African races, and of some other dark-colored tribes (chiefly inhabiting tropical climates), is *wool*, and not hair. This, however, is altogether a mistake; for microscopic examination clearly demonstrates that the hair of the Negro¹ has exactly the same structure with that of the European; and that it does not bear any resemblance to wool, save in its crispness and

¹ It is a very common mistake, especially in the United States, to consider *Negro* as synonymous with *African*. So far is this from being the fact, that, as Dr. Latham justly remarks, "the true Negro area, the area occupied by men of the black skin, thick lips, and woolly hair, is exceedingly small; as small in proportion to the rest of the continent, as the area of the district of the stunted Hyperboreans is in Asia, or that of the Lapps in Europe." ("Natural History of the Varieties of Man," p. 471.)

tendency to curl. Moreover, even this character is far from being a constant one; for, whilst Europeans are not unfrequently to be met with, whose hair is nearly as crisp as that of the Negro, there is a great variety amongst the Negro races themselves, which present every gradation from a completely crisp (or what is termed woolly) hair, to merely curled or even flowing locks. A similar observation holds good in regard to the natives of the islands of the great Southern Ocean, where some individuals possess crisp hair, whilst others, of the same race, have it merely curled. It is evident, then, that no characters can be drawn from the color or texture of the hair in Man, sufficiently fixed and definite to serve for the distinction of races; and this view is borne out by the evident influence of climate, in producing changes in the hairy covering of almost every race of domestic animals; such changes often manifesting themselves in the very individuals that have been transported from one country to another, and yet more distinctly in succeeding generations.

1038. It has been supposed that varieties in the configuration of the *Skeleton* would afford characters for the separation of the Human races, more fixed and definite than those derived from differences in the form, color, or texture of the soft parts which clothe it. And attention has been particularly directed to the *skull* and the *pelvis*, as affording such characters. It has been generally laid down as a fundamental principle, that all those nations which are found to resemble each other in the shape of their heads must needs be more nearly related to each other than they are to tribes of Men which differ from them in this particular. But if this principle be rigorously carried out, it will tend to bring together races which inhabit parts of the globe very remote from each other, and which have no other mark of affinity whatever; whilst, on the other hand, it will often tend to separate races which every other character would lead us to bring together. It is to be remembered, moreover, that the varieties in the conformation of the skeleton, presented by the breeds of domesticated animals, are at least equal to those which are manifested in the conformation and color of their soft parts; and we might reasonably expect, therefore, to meet with similar variations among the Human races. It is probable, however, that climate has not so much influence in producing such changes in the configuration of the body, as is exerted by the peculiar habits and mode of life of the different races; and Dr. Prichard has pointed out a very remarkable relation of this kind, in regard to the three principal types of form presented by the Skull.

1039. Among the rudest tribes of Men, hunters and savage inhabitants of forests, dependent for their supply of food on the accidental produce of the soil or on the chase—among whom are the most degraded of the African nations, and the Australian savages—a form of head is prevalent, which is most aptly distinguished by the term *prognathous*, indicating a prolongation or forward-extension of the jaws (Fig. 284). This character is most strongly marked in the Negroes of the Gold Coast, whose skulls are usually so formed as to give the idea of lateral compression. The temporal muscles have a great extent, rising high on the parietal bones; the cheek-bones project forward, and not outward; the upper jaw is lengthened and projects forwards, giving a similar projection to the alveolar ridge and to the teeth; and the lower jaw has somewhat of the same oblique projection, so that the upper and lower incisor teeth are set at an obtuse angle to each other, instead of being nearly in parallel planes, as in the European. From the shape of the upper jaw alone, would result a marked diminution in the facial angle, measured according to the method of Camper; but this diminution is far from being sufficient to approximate the Ethiopian races to the higher Apes, as some have supposed it to be (§ 8). Independently of the diminution of the facial angle, resulting from the projection of the upper jaw, it is quite certain that, in the typical prognathous skull, there is a want of

elevation of the forehead; but it does not appear that there is a corresponding diminution in the capacity of the cranial cavity, the retreating form of the fore-

Fig. 284.

Profile and basal views of the Prognathous Skull of a Negro.

head being partly due to the general elongation of the skull in the antero-posterior direction. Nor is it true, as stated by some, that the position of the foramen magnum in the Negro is decidedly behind that which it holds in the European, in this respect approaching that of the Apes (§ 2): since, if due allowance be made for the projection of the upper jaw, this aperture is found to have the same position in the prognathous skull as in the oval one, namely, exactly behind the transverse line bisecting the antero-posterior diameter of the base of the cranium. The prognathous skull is further remarkable for the large development of the parts connected with the organs of sense, especially those of smell and hearing. The aperture of the nostrils is very wide; and the internal space allowed for the expansion of the Schneiderian membrane, and for the distribution of the olfactory nerve, is much larger than in most European heads. The posterior openings of the nasal cavity are not less remarkable for their width, than the anterior. The external auditory meatus is also peculiarly wide and spacious; and the orbital cavities have been thought to be of more than ordinary capacity—but this last is by no means a constant character.

1040. A second type of cranial conformation, very different from the preceding, belongs principally to the Nomadic races, who wander with their herds and flocks over vast plains; and to the tribes who creep along the shores of the Icy Sea, and live partly by fishing, and in part on the flesh of their reindeer. This form, designated by Dr. Prichard as the *pyramidal* (Fig. 285), is typically exhibited by various nations of Northern and Central Asia; and is seen, in an exaggerated degree, in the Esquimaux. Its most striking character is the lateral or outward projection of the zygoma, which is due to the form of the malar bones. These do not project forwards and downwards under the eyes, as in the prognathous skull; but take a direction laterally or outwards, forming, with the zygomatic process of the temporal bone, a large rounded sweep or segment of a circle. From this, in connection with the narrowness of the forehead, it results, that lines drawn from the zygomatic arches, touching the temples on either side, instead of being parallel (as in Europeans) meet over the forehead, so as to form with the basis a triangular figure. The upper part of the face being remarkably flat, the nose also being flat, and the nasal bones, as well as the space between the eyebrows, being nearly on the same plane with the cheek-bones,

the triangular space bounded by these lines may be compared to one of the faces of a pyramid. The orbits are large and deep; and the peculiar conforma-

Fig. 285.

Front and basal views of the Pyramidal Skull of an Esquimaux.

tion of the bones which surround it, gives to the aperture of the lids an appearance of obliquity—the inner angle seeming to be directed downwards. The whole face, instead of presenting an oval form, as in most Europeans and Africans, is of a lozenge-shape. The greater relative development of the zygomatic bones, and of the bones of the face altogether, when compared with the capacity of the cranium, indicates in the pyramidal skull a more ample extension of the organs subservient to sensation; the same effect being thus produced by lateral expansion, as by the forward extension of the facial bones in the prognathous skulls.

1041. The most civilized races—those which live by agriculture and the arts of cultivated life—all the most intellectually improved nations of Europe and Asia—have a shape of the head which differs from both the preceding forms, and which may be termed *oval* or *elliptical* (Fig. 286). This at once approves itself as a more symmetrical form; no part having an excessive prominence; whilst, on the other hand, there is nowhere an appearance of undue flattening or compression. The head is altogether of a rounder shape than in other varieties, and the forehead is more expanded; while the maxillary bones and the zygomatic arches are so formed as to give the face an oval shape, nearly on a plane with the forehead and cheek-bones, and not projecting towards the lower part. Owing to the more perpendicular direction of the alveolar processes, the front teeth are fixed in planes which are nearly or quite parallel to each other. The principal features in this form of cranium are thus of a negative character; the chief positive distinction is the large development of the cranial cavity, and

Fig. 286.

Oval Skull of an European.

especially the fulness and elevation of the forehead, in proportion to the size of

the face;—indicating the predominance of the intellectual powers over those merely instinctive propensities which are more directly connected with sensations. Among European nations, the Greeks have probably displayed the greatest symmetry and perfection in the form of the head; but various departures may be traced towards the preceding forms, when we compare the crania of different races, and even of individuals, belonging to the same stock—some approaching the pyramidal form of the Northern Asiatics, whilst others approximate to the prognathous type of the Negro.

1042. The influence of habits of life, continued from generation to generation, upon the form of the head, is remarkably evinced by the transition from one type to another, which may be observed in nations that have undergone a change in their manners and customs, and have made an advance in civilization. Thus, to mention but one instance, the Turks at present inhabiting the Ottoman and Persian empires are undoubtedly descended from the same stock with the nomadic races which are still spread through Central Asia (§ 1053). The former, however, having conquered the countries which they now inhabit, eight centuries since, have gradually settled down to the fixed and regular habits of the Indo-European race, and have made corresponding advances in civilization; whilst the latter have continued their wandering mode of life, and can scarcely be said to have made any decided advance during the same interval. Now the long since civilized Turks have undergone a complete transformation into the likeness of Europeans; whilst their nomadic relatives retain the pyramidal configuration of the skull in a very marked degree. Some have attributed this change in the physical structure of the Turkish race to the introduction of Circassian slaves into the harems of the Turks; but this could only affect the opulent and powerful amongst the race; and the great mass of the Turkish population have always intermarried among themselves. The difference of religion and manners must have kept them separate from those Greeks whom they subdued in the new Ottoman countries; and in Persia, the Tajiks, or real Persians, still remain quite distinct from their Turkish rulers, belonging to a different sect among the Mussulmans, and commonly living apart from them.—In like manner, even the Negro head and face may become assimilated to the European, by long subjection to similar influences; thus, in some of our older West Indian Colonies, it is not uncommon to meet with Negroes, the descendants of those first introduced there, who exhibit a very European physiognomy; and it has even been asserted that a Negro belonging to the Dutch portion of Guiana may be distinguished from another belonging to the British settlements, by the similarity of the features and expression of each, to those which peculiarly characterize his masters. The effect could not be here produced by the intermixture of bloods, since this would be made apparent by alteration of color.—But not only may the pyramidal and prognathous types be elevated towards the elliptical; the elliptical may be degraded towards either of these. Want, squalor, and ignorance have a special tendency to induce that diminution of the cranial portion of the skull, and that increase of the facial, which characterize the prognathous type; as cannot but be observed by any one who takes an accurate and candid survey of the condition of the most degraded part of the population of the great towns of this country, but as is seen to be pre-eminently the case with regard to the lowest classes of Irish immigrants.¹ A certain degree of retrogression to the pyramidal type is also to be noticed among the nomadic tribes which are to be found in every civilized community. Among these, as has been remarked by a very acute observer,² “According as they partake more or less of the purely vagabond nature, doing nothing whatsoever for their living, but moving from

¹ See the “Dublin University Magazine,” No. xlviii.

² Mr. Henry Mayhew, in “London Labor and the London Poor,” p. 2.

place to place, preying on the earnings of the more industrious portion of the community, so will the attributes of the nomade races be found more or less marked in them; and they are all more or less distinguished for their high cheek-bones and protruding jaws;" thus showing that kind of mixture of the pyramidal with the prognathous type which is to be seen among the lowest of the Indian and Malayo-Polynesian races.

1043. Next to the characters derived from the form of the head, those which are founded upon the form of the *pelvis* seem entitled to rank. These have been particularly examined by Professors Vrolik and Weber. The former was led, by his examinations of this part of the skeleton, to consider that the pelvis of the Negress, and still more that of the female Hottentot, approximates to that of the Simiæ in its general configuration; especially in its length and narrowness—the iliac bones having a more vertical position, so that the anterior spines approach one another much more closely than they do in the European; and the sacrum also being longer and narrower. On the other hand, Prof. Weber¹ concludes, from a more comprehensive survey, that no particular figure is a permanent characteristic of any one race. He groups the principal varieties which he has met with, according to the form of the upper opening—whether oval, round, four-sided, or wedge-shaped. The first of these is most frequent in the European races; the second, among the American races; the third, most common among the Mongolian nations, corresponds remarkably with the form of their heads; whilst the last chiefly occurs among the races of Africa, and is in like manner conformable with the oblong compressed form usually presented by their cranium. But though there are particular shapes which are most prevalent in each race, yet there are numerous individual deviations, of such a nature that every variety of form presents itself occasionally in any given race.

1044. Other variations have been observed by anatomists, in the relative length of the bones, and in the shape of the limbs, between the different races of Man; but these also seem to have reference to the degree of civilization, and to the regularity of the supply of wholesome nutriment. It is generally to be observed that the races least improved by civilization, like the uncultivated breeds of animals, have slender, lean, and elongated limbs; this may be especially remarked in the natives of Australia. In nearly all the less civilized races of Men, the limbs are more crooked and badly formed than the average of those of Europeans; and this is particularly the case in the Negro, the bones of whose legs bow outwards, and whose feet are remarkably flat. It has been generally believed that the length of the forearm in the Negro is so much greater than in the European, as to constitute a real character of approximation to the Apes. The difference, however, is in reality extremely slight; and is not at all comparable with that which exists between the most uncultivated races of Men and the highest Apes (§ 5). And in regard to all the peculiarities here alluded to, it is to be observed that they can only be discovered by the comparison of large numbers of one race with corresponding numbers of another; for individuals are found in every tribe possessing the characters which distinguish the majority of the other race. Such peculiarities, therefore, are totally useless as the foundation of *specific* characters; being simply variations from the ordinary type, resulting from causes which might affect the entire race, as well as individuals.—The connection between the general form of the body, on the one hand, and the degree of civilization (involving the regular supply of nutriment) on the other, is made apparent, not merely by the improvement which we perceive in the form, development, and vigor of the frame, as we advance from the lowest to the most cultivated of the Human races; but also by the

¹ "Die Lehre von den Ur- und Racenformen der Schaedel und Becken des Menschen;" Dusseldorf, 1830.

degradation that is occasionally to be met with in particular groups of the higher tribes which have been subjected for several generations to the influence of depressing causes. Of such degradation, occurring under circumstances that permit its successive steps to be traced, we have a remarkable example in the conversion of certain tribes of the Hottentot race into Bushmen (§ 1058); and there is very strong ground for the belief that similar influences have operated, at a more remote period, in the production of the peculiar characters of the Guinea Coast Negroes and Australian Bushmen.

1045. Independently, however, of the obvious modifying influence of external circumstances, much allowance must be made for that tendency to variation, which presents itself, more or less, in all those races of animals which possess such a constitutional capability of adaptation to changes in climate, habits of life, &c., as enables them to live and flourish under a variety of conditions. Thus we find that the offspring of any one pair of domesticated animals do not all precisely agree among themselves, or with their parents, either in bodily conformation or in psychical character; but that *individual* differences, as they are termed, exist among them. Now, as this tendency to variation cannot be clearly traced to any influence of external circumstances, it is commonly distinguished by the term "spontaneous;" but there is no effect without a cause; and as the widest differences of this kind present themselves in those races which are most obviously amenable to the influence of external conditions, we seem justified in attributing them to agencies operating unostensibly upon the parents, either previously to their intercourse, or at the time of coition (§ 975), or in the female during the period of utero-gestation (§ 1014). The difference between wild and domesticated animals in regard to *color* affords a very good illustration of this general fact; for the uniformity among the former is no less remarkable than the want of constancy among the latter; and whilst variety of color soon gives place to uniformity, when domesticated races return in any considerable degree towards their primitive state,¹ it very speedily develops itself in races which are undergoing the converse process.²—Now it is by taking advantage of those "spontaneous" departures from the ordinary type which present features of value to the breeders of domesticated animals, that *new races* are developed from time to time among these; any strongly marked peculiarity which thus appears in only a single individual being usually transmitted to some of its offspring, and being almost certainly perpetuated when *both* parents are distinguished by it, as happens when the products of the first procreation become capable of breeding with each other.³—Now there can be no hesitation in admitting that the tendency to the so-called "spontaneous" variation prevails in the Human race to a greater degree than in any other; since we find most remarkable diversities in features, complexion, hair, and general conformation,

¹ This has been especially noticed in the horses, cattle, sheep, hogs, and dogs, introduced by the Spaniards into South America.

² Thus Mr. T. Bell informs us ("British Quadrupeds," 2d edit. p. 203) that an Australian bitch, or dingo, in the Zoological Gardens, had a litter of puppies, the father of which was also of that breed; both parents had been taken in the wild state; both were of the uniform reddish-brown color which belongs to the race, and the mother had never bred before; but the young, bred in confinement, and in a half domesticated state, were all more or less spotted.

³ See the history of the introduction of the *ancon* breed of sheep, characterized by a peculiar conformation of its limbs, in Massachusetts, given by Col. Hutchinson in the "Phil. Trans." for 1813. A very similar account has been recently given by Prof. Owen (in a Lecture delivered before the Society of Arts, Dec. 10, 1851), respecting the recent introduction of a new breed of merino sheep, distinguished for the long, smooth, straight, and silky character of the wool, and now known as the Mauchamp breed.—In both instances, the breed originated in the spontaneous appearance of a male lamb possessing the peculiarities in question; and from its offspring such a selection was made by the breeder as enabled him to bring together males and females both of which were distinguished by them.

among the offspring of the same parentage; whilst more special modifications of the ordinary type, such as the possession of six fingers on each hand and of six toes on each foot, are of no unfrequent occurrence. Under ordinary circumstances, these modifications tend to disappear as often as they occur; the free intermixture of those members of the race which possess them, with those which depart less from the ordinary type, tending to merge them in the general average. But there can be no reasonable doubt that, if the same kind of segregation were practised among mankind which is adopted by the breeders of animals for the purpose of perpetuating a particular variety—if, for example, the members of a six-fingered family were to intermarry exclusively with one another—any such variety would be permanently established as a new race. Now if it be borne in mind, that the influence of a scanty population, in the early ages of the human race, by isolating different families from each other, and causing intermarriages among even the nearest relatives, would have been precisely the same with that which is now exercised by the breeders of animals, we see one reason why the varieties which *then* arose should have a much greater tendency to self-perpetuation than those which *now* occasionally present themselves. And when, too, it is borne in mind, that the change in external conditions induced by migration would thus operate not only upon the parents, but upon the offspring, and would have a continual influence in so modifying the constitution of the latter that the peculiarities thus acquired by them would be transmitted in yet greater intensity to their progeny, there is no real difficulty in accounting, upon the strictest physiological principles, for the widest departures from one common type of conformation which we encounter in our survey of the different Races of Mankind.¹

1046. Hence we are led to conclude, that, so far as regards their Anatomical structure, there is no such difference among them as would justify to the Zoologist the assertion of their distinct origin. But, further, it can be shown that, although the comparison of the structural characters of the Human races does not furnish any positive evidence of their descent from a common stock, it proves that even if their stocks *were* originally distinct, there could have been no essential difference between them; the descendants of any one such stock being able to assume the characters of another. This, as already remarked, can be proved by historical evidence in regard to a sufficient number of tribes, to justify the same assertion with respect to others, whose languages, customs, habits of thought, &c., have an affinity strong enough to warrant us in regarding them as descendants of the same stock, whilst their physical conformation is widely different. Each principal geographical area, that is so isolated from others as to render it probable, *a priori*, that its population has extended from one centre—such as the Continent of Africa or America—contains races of very diversified physical characters, whose linguistic affinities make it almost certain that they must have had a common descent; and thus, in whatever mode the types of the principal varieties are selected, they are found to be connected by so gradual a series of intermediate or transitional forms, that it is impossible to draw any such line of demarcation between them, as would be required by a soundly-judging Naturalist for the boundary of distinct species.

1047. A very important confirmation of this view is afforded by the essential agreement which exists among the different Races of Men in regard to their Physiological history; the variations which they present not being greater than

¹ For a masterly digest of the analogical evidence furnished by the changes known to have been thus produced among domesticated animals, and of the modifications which particular tribes of Men can be shown to have undergone within the historic period, see Dr. Prichard's "Physical History of Mankind," and his "Natural History of Man;" see, also, the summary given by the Author in the "Cyclop. of Anat. and Physiol.," vol. iv. pp. 1301-1339.

those which we meet with between the different individuals of any one race. Thus, we not only find the average duration of life to be the same (making allowance for circumstances which are likely to induce disease), but the various epochs of life—such as the times of the first and second dentition, the period of puberty, the duration of pregnancy, the intervals of the catamenia, and the time of their final cessation—present a marked general uniformity, such as does not exist among similar epochs in the lives of species that are nearly allied, but yet unquestionably distinct. Further, the different races of Man are all subject to the same diseases, both sporadic, endemic, and epidemic; the only exceptions being those in which the constitution of a race has *grown to* a certain set of influences (as that of the Negro to the malaria which produces certain pernicious fevers in the European), producing an hereditary immunity in the race, which is capable of being acquired by individuals of other races, by a process of acclimatization commenced sufficiently early.¹—The most important physiological test, however, of specific unity or diversity is that furnished by the Generative process. It may be considered as a fundamental fact, alike in the Vegetable and in the Animal kingdom, that *hybrid* races, originating in the sexual connection of individuals of two different *species*, do not tend to self-perpetuation; the hybrids being nearly sterile with each other, although they may propagate with either of their parent races, in which the hybrid race will soon merge; whilst, on the other hand, if the parents be themselves *varieties* of the same species, the hybrid constitutes but another variety, and its powers of reproduction are rather increased than diminished, so that it may continue to propagate its own race, or may be used for the production of other varieties, almost *ad infinitum*. It appears that, among Plants, hybrids originating between undoubtedly distinct species, sometimes reproduce themselves for two or three generations, but do not continue beyond the fourth. Amongst Animals, the limits of hybridity between parents of distinct species are more narrow, since the hybrid is totally unable to continue its race with one of its own kind;² and although it may propagate with one of its parent-species, the progeny will of course approach in character to the pure breed, and the race will speedily merge into it. In Animals, as among Plants, the mixed offsprings, originating from different races within the limits of the same species, generally *exceed* in vigor, and in the tendency to multiply, the parent-races from which they are produced, so as to gain ground upon the older varieties, and gradually to supersede them. In this manner, by the *crossing* of the breeds of our domesticated animals, many new and superior varieties have been produced. The general principle is, then, that beings of distinct *species*, or descendants from stocks

¹ This view of the immunity of the Negro race from certain forms of Fever which are very fatal to Europeans, is justified, the Author believes, by all the facts known upon the subject. Much may be set down, as he is assured by Dr. Daniell, to the better adaptation of the Negro habits of life to their climate; and Europeans who exercise due caution (especially in regard to the functions of the skin) may preserve an immunity scarcely less complete. Dr. D. himself, having been taken prisoner by one of the Negro tribes at an early age, and having spent two years among them, seems to have been thoroughly acclimatized; and has subsequently passed many years on the most unhealthy parts of the coast, without experiencing any severe attacks of illness, and in the enjoyment of very good general health. It is sometimes maintained that the Negro race possesses such a complete exemption from the Yellow Fever of the United States, as marks its specific difference; such, however, is not constantly the case, since Negroes occasionally suffer from it; and their *comparative* immunity seems fairly attributable to the constitutional peculiarity *acquired* by their African progenitors, and capable of being acquired by Europeans also.

² One or two instances have been stated to occur, in which a Mule has produced offspring from union with a similar animal; but this is certainly the extreme limit, since no one has ever maintained that the race can be continued further than the second generation, without admixture with one of the parent-species.

originally different, cannot produce a mixed race which shall possess the capability of perpetuating itself; whilst the union of *varieties* has a tendency to produce a race superior in energy and fertility to its parents.—The application of this principle to the Human races leaves no doubt with respect to their specific unity; for, as is well known, not only do all the races of Men breed freely with each other; but the mixed race is generally superior in physical development, and in tendency to rapid multiplication, to either of the parent stocks; so that there is much reason to believe that, in many countries, the mixed race between the Aborigines and European colonizers will ultimately become the dominant power in the community. This is especially the case in India, South America, and Polynesia.

1048. The question of *Psychical* conformity or difference among the Races of Mankind is one which has a most direct bearing upon the question of their specific unity or diversity; but it has an importance of its own, even greater than that which it derives from this source. For, as has been recently argued with great justice and power,¹ the real Unity of Mankind does not lie in the consanguinity of a common descent, but has its basis in the participation of every race in the same moral nature, and in the community of moral rights which hence becomes the privilege of all. "This is a bond which every man feels more and more, the farther he advances in his intellectual and moral culture, and which in this development is continually placed upon higher and higher ground; so much so, that the physical relation arising from a common descent is finally lost sight of, in the consciousness of the higher moral obligations." It is in these obligations that the moral *rights of men* have their foundation; and thus, "while Africans have the hearts and consciences of human beings, it could never be right to treat them as domestic cattle or as wild-fowl, if it were ever so abundantly demonstrated that their race was but an improved species of ape, and ours a degenerate kind of god."—The *Psychical* comparison of the various Races of Mankind is really, therefore, in a practical point of view, the most important part of the whole investigation; but it has been, nevertheless, the one most imperfectly pursued, until the inquiry was taken up by Dr. Prichard. The mass of evidence which he has accumulated on this subject, however, leaves no reasonable doubt that no more "impassable barrier" really exists between the different races with respect to this, than in regard to any of those points of ostensible diversity which have been already considered; the variations in the positive and relative development of their respective *psychical* powers and tendencies, not being greater, either in kind or degree, than those which present themselves between individuals of our own or of any other race, by some members of which a high intellectual and moral standard has been attained. The tests by which we recognize the claims of the outcast and degraded of our own or of any other "highly-civilized" community, to a common humanity, are the same as those by which we should estimate the true relation of the Negro, the Bushman, or the Australian, to the cultivated European. If, on the one hand, we admit the influence of want, ignorance, and neglect, in accounting for the debasement of the savages of our own great cities—and if we witness the same effects occurring under the same conditions among the Bushmen of Southern Africa (§ 1058)—we can scarcely hesitate in admitting that the long-continued operation of the same agencies has had much to do with the *psychical* as well as the physical deterioration of the Negro, Australian, and other degraded savages. So, on the other hand, if we cherish the hope that the former, so far from being irreclaimable, may at least be brought up to the standard from which they have degenerated, by means adapted to develop

¹ See the "New Quarterly Review," No. xv., p. 131; and an Article by Prof. Agassiz in the "Christian Examiner," Boston (N. E.), 1850.

their intellectual faculties and to call forth the higher parts of their moral nature, no adequate reason can be assigned why the same method should not succeed with the latter, if employed with sufficient perseverance. It will be only when the effect of education, intellectual, moral, and religious, shall have been fairly tested by the experience of *many generations*, in conjunction with the influence of a perfect equality in civilization and social position, that we shall be entitled to speak of any essential and constant psychical difference between ourselves and the most degraded beings clothed in a human form. All the evidence which we at present possess leads to the belief that, under a vast diversity in degree and in modes of manifestation, the same intellectual, moral, and religious *capabilities* exist in all the Races of Mankind; so that, whilst we may derive from this conformity a powerful argument for their zoological Unity as a species, we are also directly led to recognize their community of moral nature with ourselves, and to admit them to a participation in our own rights.

1049. Most important assistance is afforded in the determination of the real affinities of different Races, by the study of their *Languages*. This, however, is a department of the inquiry so far beyond the limits of Physiological science, that it must be here dismissed with a bare mention of the results, to which the zealous pursuit of it by a large number of philosophic philologists seems undoubtedly to tend.—There can be no reasonable doubt that, as a general principle, the affinities of races are more surely indicated by their languages, than by their physical features; and the experienced philologist is generally able to discriminate those resemblances which may have arisen out of the introduction of words or of modes of construction from the one into the other, by conquest, commercial intercourse, or absolute intermixture, from those which are the result of a community of origin. And thus are supplied those means of tracing the past history of races, which are seldom afforded by historical records, or even (at least with any degree of certainty) by traditional information. It is to be borne in mind, that the affinities of languages are indicated, not merely by verbal resemblance, but by the similarity of their modes of grammatical construction, or the methods by which the relation between different words that constitute sentences is indicated. The most positive evidence is of course afforded, when a conformity exists both in the *vocabularies* and in the *types of construction* of two languages; but it frequently happens that although the conformity exists in regard to one of these alone, yet the evidence which it affords is perfectly satisfactory. Thus, there are many cases in which these vocabularies are so continually undergoing important changes (the want of written records not permitting them to acquire more than a traditional permanence), that their divergence becomes so great, even in the course of a few generations, as to prevent tribes which are by no means remotely descended from a common ancestry, from understanding one another; whilst yet the system of grammatical construction, which depends more upon the grade of mental development and upon habits of thought, exhibits a remarkable permanence. Such appears to be true of the whole group of American languages, which seem, as a whole, to be legitimately referable to a common stock, notwithstanding their complete verbal diversity. On the other hand, when two languages or groups of languages differ greatly in construction, but present that kind of verbal correspondence on which the philologist feels justified in placing most reliance (namely, an essential conformity in those “primary words,” which serve to represent the universal ideas of a people in the most simple state of existence), that correspondence may be held to indicate a community of origin, if it can be proved that it has not been the result of intercourse between the two families of nations subsequently to their first divergence, and if it seems probable on other grounds that their separation took place at a period when as yet the grammatical development of both languages was in its infancy. Such appears to have been the case with

certain of those groups of languages whose distinctness can be traced back historically for the longest period.—It is evident, then, that philological inquiry must be looked to as one of the chief means of determining the question of radiation from a *single* centre or from *multiple* centres; and it is a remarkable fact, that the linguistic affinity and the conformity in physical characters frequently stand in a sort of complemental relation to each other, each being the strongest where the other is weakest; so that by one or other of these links of connection, a close relationship is indicated between all these families of nations, under which the several races appear to be most naturally grouped.

2.—General Survey of the Principal Families of Mankind.

1050. The distribution of the Races of Mankind under five primary varieties, according to their respective types of cranial conformation, as first proposed by Blumenbach, is still so commonly received, notwithstanding the distinct proof which has been given of the fallacious nature of its basis, that it will be desirable to explain his terms, and at the same time to show how far the information subsequently acquired has tended to modify his arrangement.—The first of these varieties, which is considered to be distinguished by the possession of the *oval* or *elliptical* type of cranial conformation, was designated *Caucasian* by Blumenbach, on two grounds; first, because he considered the Caucasian people (Georgians and Circassians) as presenting its physical characters in the greatest perfection; and second, because it was supposed that the Caucasian range of mountains might be regarded as the centre or focus of the races belonging to it. Neither of these ideas, however, is correct: for whilst the oval form of cranium is presented with fully as great beauty and symmetry by the Greeks, it seems now to be almost certainly determinable by the evidence of language, that the Georgian and Circassian nations are really of Mongolian origin, and consequently have no direct relation of affinity with the other nations usually ranked as belonging to this variety; and the evidence of history and tradition, so far from pointing to the Caucasian range as the original centre of radiation of the race, accords with that of language in assigning its locality much nearer to Central Asia. It would be most desirable, therefore, that some other designation should be substituted for that given by Blumenbach; were it not that the present state of our knowledge requires the entire abandonment of his doctrine, that the races agreeing in this type of conformation are mutually connected by community of descent. For, even within the limits of Europe, we find at least two nations—the Turks, and the Magyars or true Hungarians—whose crania are characteristically oval, and which are yet undoubtedly of Mongolian descent; and although some allowance must be made, in regard to the change which has taken place among the former, for the influence of intermixture with other races, yet there is no reason to believe that any such influence has operated among the Magyars, whose blood seems to have been transmitted with remarkable purity from the time when they settled in Hungary about ten centuries since. In Asia, we find this type presented not merely by the Indo-European races, but also by the Syro-Arabian, and by the larger proportion of the inhabitants of Hindostan; yet the Syro-Arabian races are more nearly related to the African stock (§ 1052), than to that from which most of the present inhabitants of Europe have sprung; and there is good reason to believe that the great mass, if not the whole, of the existing inhabitants of India, are of Mongolian descent (§ 1054). It will be necessary, therefore, to consider the nations which present the so-called Caucasian type of cranial conformation, under several distinct heads. No uniformity exists among them in regard to *color*; for this character presents every intermediate gradation between the fair and florid hue, with light, red, or auburn hair, of the Northern European, to the jet-black of many tribes in Northern

Africa and the Indian Peninsula. The hair is generally long and flexible, with a tendency to curl; but considerable variety presents itself with regard to this particular. The conformation of the features approaches more or less closely to that which we are accustomed to regard as the type of beauty.

1051. The first place, in a more natural distribution of the Human Races, must undoubtedly be given to that which is designated by Dr. Prichard as the *Arian*, and which is often termed the *Indo-European*; including the collective body of European nations, with the Persians, Affghans, and certain other nations of the south-western portion of the Asiatic continent, near to which their original focus appears to have been. The great bond of connection between these nations lies in their languages; which, in spite of great diversities, present a certain community of character that is recognized by every philologist. The family which is most dissimilar to the rest is that which is formed by the Celtic nations; these are undoubtedly, like the others, of eastern origin, as was first shown by Dr. Prichard;¹ but they appear to have detached themselves from the common stock at an earlier period in the development of its language; and both in their physical conformation and in their psychical character, the typical Celt contrasts remarkably with the Germanic group of nations. The languages of the whole Indo-Germanic group are united alike by community in many of the most important "primary words," and by general similarity in grammatical construction; being obviously all formed upon the same base with the ancient Sanskrit, if not upon the Sanskrit itself. The existing Lettish or Lithuanian dialect presents a very near approach to that type; and the Old Prussian, a dialect spoken as late as the sixteenth century, had a still closer alliance to the ancient Zend or Median, which seems to have been a very early derivation from the Sanskrit, and which is the basis of the language now spoken in Persia. But there is evidence that, notwithstanding the mutual affinities of the Indo-Germanic languages, every one of them has been modified by the introduction of extraneous elements: thus, in those of Western Europe, there is a considerable admixture of Celtic; whilst in others there are traces of more barbaric tongues. In fact, there can be little doubt that Europe had an indigenous population before the immigration of the Indo-German or even of the Celtic tribes; and of this population it seems most probable that the Lapps and Finns of Scandinavia, and the Euskarians (or Basques) of the Biscayan provinces, are but the remnant. The former of these tribes, which is undoubtedly of Mongolian origin, once extended much further south than at present; and with regard to the latter, whose nearest linguistic affinities are also with the tongues of High Asia, there is ample historical proof that they had formerly a very extensive distribution through Southern Europe. It would not seem improbable, then, that the advance of the Indo-European tribes from the south-east corner into central Europe, separated that portion of the aboriginal (Mongolian) population which they did not absorb or destroy, into two great divisions; of which one was gradually pressed northward and eastward, so as to be restricted to Finland and Lapland; and the other southward and westward, so as to be confined at the earliest historic period to a part of the peninsula of Spain and the south of France, gradually to be driven before the successive irruptions of the Celts, Romans, Arabians, and other nations, until their scanty remnant found an enduring refuge in the fastnesses of the Pyrenees.²—The Indo-Germanic race is unquestionably that which has exercised the greatest influence on the civiliza-

¹ "On the Eastern Origin of the Celtic Nations," 1831.

² This view, which was suggested by the Author in the "Brit. and For. Med. Rev.," Oct., 1847, without the knowledge that it had been elsewhere propounded, has been put forth with considerable confidence by Dr. Latham ("Varieties of Man," 1850), as having originated with Arndt and been adopted by Rask, distinguished Scandinavian ethnologists.

tion of the Old World; and it seems indubitably destined to acquire a similar influence in those newly-found lands which have been discovered by its enterprise. With scarcely an exception, as Dr. Latham has justly remarked, the nations belonging to it present an *encroaching* frontier: there being no instance of its permanent displacement by any other race, save in the case of the Arab dominion in Spain, which has long since ceased: in that of the Turkish dominion in Turkey and Asia Minor, which is evidently destined to expire at no distant period, being upheld for merely political purposes by extraneous influence; and in that of the Magyars in Hungary, who only maintain their ground through their complete assimilation to the Indo-Germanic character. It is a remarkable fact that in most cases in which this race extends itself into countries previously tenanted by people of an entirely different type, the latter progressively decline and at last disappear before it, provided the climate be such as enables it to maintain a vigorous existence; this is pre-eminently the case in North and South America, in Australia, in New Zealand, and in many of the smaller Polynesian islands. And where the climate is less favorable to the perpetuation of the race in its purity, an intermixture with the native blood frequently gives rise to a mixed race, which possesses the developed intellect of the one, and the climatic adaptiveness of the other, and which appears likely ultimately to take the place of both.

1052. The *Syro-Arabian* or *Semitic* nations, agree with the preceding in general physical characters, but differ entirely in the structure of their language, and for the most part in vocabulary also, though recent researches seem to indicate that certain *roots* of the Semitic and Indo-Germanic languages have a decided affinity. It seems quite certain, however, that the linguistic affinities of the Semitic nations are rather with the *African* than with the Indo-European races; and so strong is the link of connection thus established, that by Dr. Latham they are ranked with the former under the general designation *Atlantidæ*,¹ whilst Mr. Norris, whose authority upon all such subjects is deservedly great, is strongly disposed (as he has himself informed the Author) to consider them an essentially African people.—The original centre of this race, however, is commonly reputed to have been that region of Asia which is intermediate between the countries of the Indo-European and of the Egyptian races; having as its centre the region watered by the great rivers of Mesopotamia. Several of the nations originally constituting this group have become extinct, or nearly so; and the *Arabs*, which originally formed but one subdivision of it, have now become the dominant race, not only throughout the ancient domain of the Syro-Arabian nations, but also in Northern Africa. In the opinion of Baron Larrey, who had ample opportunities for observation, the skulls of the Arabian race furnish, at present, the most complete type of the human head; and he considered the remainder of the physical frame as equally distinguished by its superiority to that of other races of men. The different tribes of Arabs present very great diversities of color, which are generally found to coincide with variations in climate. Thus the *Shegya* Arabs, and others living on the low countries bordering on the Nile, are of a dark-brown or even black hue; but even when quite jetty, they are distinguished from the Negro races by the brightness of their complexions, by the length and straightness of their hair, and by the regularity of their features. The same may be said of the wandering Arabs of Northern Africa; but the influence of climate and circumstances is still more strongly marked in some of the tribes long settled in that region, whose descent may be traced to a distinct branch of the Syro-Arabian stock, namely, the *Berber*, to which belong the Kabyles of Algiers and Tunis, the Tuaryks of Sahara, and the Guanches or ancient population of the Canary Isles. Amongst

¹ See his "Varieties of Man," 1850, p. 469.

these tribes, whose affinity is indisputably traceable through their very remarkable language, every gradation may be seen, from the intense blackness of the Negro skin, to the more swarthy hue of the inhabitants of the South of Europe. It is remarkable that some of the Tuaryk inhabitants of particular Oases in the great desert, who are almost as insulated from communication with other races as are the inhabitants of islands in a wide ocean, have hair and features that approach those of the Negroes; although they speak the Berber language with such purity, as to forbid the idea of the introduction of these characters by an intermixture of races. The *Jews*, who are the only remnants now existing of the once powerful Phœnician tribe, and who are now dispersed through nearly every country on the face of the earth, present a similar diversity; having gradually assimilated in physical characters to the nations among which they have so long resided (§ 1035).

1053. The second primary division of the Human family, according to the arrangement of Blumenbach, is that commonly termed *Mongolian*. The real Mongols, however, constitute but a single and not very considerable member of the group of nations associated under this designation; which is, therefore, by no means an appropriate one. The original seat of these races appears to have been the great central elevated plain of Asia, in which all the great rivers of that continent have their sources, whatever may be their subsequent direction. Taken as a whole, this division is characterized by the pyramidal form of the skull, whose antero-posterior diameter scarcely exceeds the parietal, and by the broad flat face and prominent cheek-bones; by the flattening of the nose, which is neither arched nor aquiline; by the eyes being drawn upwards at their outer angle; by the xanthous or olive complexion, which sometimes becomes fair, but frequently swarthy; by the scantiness and straightness of the hair, and by deficiency of beard; and by lowness of stature. These characters, however, are exhibited in a prominent degree only in the more typical members of the group; and may become so greatly modified as to cease altogether to be recognizable. Such a modification has been remarkably effected in the case of the *Turkish* people, now so extensively distributed. All the most learned writers on Asiatic history are agreed in opinion, that the Turkish races are of one common stock; although at present they vary in physical characters to such a degree that, in some, the original type has been altogether changed. Those which still inhabit the ancient abodes of the race, and preserve their pastoral nomadic life, present the physiognomy and general characteristics which appear to have belonged to the original Turkomans; and these are decidedly referable to the so-called Mongolian type. Before the Mohammedan era, however, the Western Turks or Osmanlis had adopted more settled habits, and had made considerable progress in civilization; and their adoption of the religion of Islam incited them to still wider extension, and developed that spirit of conquest which, during the Middle Ages, displayed itself with such remarkable vigor. The branches of the race, which, from their long settlement in Europe, have made the greatest progress in civilization, now exhibit in all essential particulars the physical characters of the European model; and these are particularly apparent in the conformation of the skull.—In like manner we find that the Ugrian division, which migrated towards the north-west at a very early period, planted a colony in Europe, which still tenants the northern Baltic countries, forming the races of *Finns* and *Lapps*. In the time of Tacitus, the Finns were as savage as the Lapps; but the former, during the succeeding ages, became so far civilized, as to exchange a nomadic life for one of agricultural pursuits, and have gradually assimilated with the surrounding people; whilst the Lapps, like the Siberian tribes of the same race, have ever since continued to be barbarous nomades, and have undergone no elevation in physical characters. The same division gave origin to the *Magyars* or Hungarians; a warlike and energetic

people, unlike their kindred in the North; in whom a long abode in the centre of Europe has, in like manner, developed the more elevated characters, physical and mental, of the European nations.

1054. The nations inhabiting the South-eastern and Southern portion of Asia, also, appear to have had their origin in the Mongolian or Central Asiatic stock; although their features and form of skull by no means exhibit its characteristic marks, but present such departures from it as are elsewhere observable in races that are making advances in civilization. The conformity to the Mongolian type is most decidedly shown by the nations (collectively termed *Seriform* by Dr. Latham) which inhabit China, Thibet, the Indo-Chinese peninsula, and the base of the Himalayan range; these are associated by certain linguistic peculiarities which distinguish them from all other races; that primitive condition of human speech, in which there is a total absence of inflections indicative of the relation of the principal words to one another, being apparently preserved with less change in the tongues of these people than in those of any other. The Chinese may be physically characterized as Mongolians softened down; and in passing from China towards India, through the Burmese empire, there is so gradual a transition towards the ordinary Hindoo type, that no definite line of demarcation can be anywhere drawn.—The inhabitants of the great peninsula of Hindostan have been commonly ranked (as already remarked) under the Caucasian race; both on account of their physical conformity to that type, and also because it has been considered that the basis of their languages is Sanskritic. It is certain, however, that this conclusion is incorrect with regard to a very large proportion of the existing population of India; and there is strong reason to believe that no part of it bears any real relation of affinity to the Indo-European group of nations, except such as may be derived from a slight intermixture. Thus, the *Tamulian*, which is the dominant language of *Southern* India, is undoubtedly not Sanskritic in its origin (although containing an infusion of Sanskritic words), but more closely approximates to the *Seriform* type; and many of the hill tribes, in different parts of India, speak peculiar dialects, which, though mutually unintelligible, appear referable to the same stock. Now it is among this portion of the population of India that the greatest departure presents itself from the Caucasian type of cranial conformation, and the closest conformity to the Mongolian; the cheek-bones being more prominent, the hair coarse, scanty, and straight, and the nose flattened; sometimes, also, the lips are very thick, and the jaws project, showing an approximation to the prognathous type. Now in the opinion of Dr. Latham and Mr. Norris, the various dialects of *Northern* India (of which the *Hindustani* is the most extensively spoken) are to be regarded as belonging, in virtue of their fundamental nature, to the same group with those of High Asia, notwithstanding the large infusion of Sanskritic words which they contain; this infusion having been introduced at an early period by an invading branch of the Arian stock, of whose advent there is historical evidence, and whose descendants the ordinary Hindoo population have been supposed to be. According to this view, then, the influence of the Arian invasion upon the language and population of Northern India was very much akin to that of the Norman invasion upon those of England; the number of individuals of the invading race being so small in proportion to that of the indigenous population, as to be speedily merged in it, not, however, without contributing to an elevation of its physical characters; and a large number of new words having been in like manner introduced, without any essential change in the type of the original language. And thus the only distinct traces of the Arian stock are to be found in the Brahminical caste, which preserves (though with great corruption) the original Brahminical religion, and which keeps up the Sanskrit as its classical language; it is certain, however, that this race is far from being of pure descent, having intermingled

to a considerable extent with the ordinary Hindoo population. There is but little to remind us of the Mongolian type in the countenances of the Hindoos, which are often remarkable for a symmetrical beauty that only wants a more intellectual expression to render them extremely striking; some traces of it, however, may perhaps be found in the rather prominent zygomatic arches which are common amongst them; but the cranial portion of the skull presents no approach to the pyramidal type, being often very regularly elliptical. There is a remarkable difference in the color of the different Hindoo tribes; some being nearly as dark as Negroes, others more of a copper color, others but little darker than the inhabitants of Southern Europe, whilst others, who can be shown to have migrated at a remote period into one of the hilly districts of Northern India, have a fair complexion with blue eyes and auburn or even red hair.—Another marked departure from the ordinary Mongolian type is presented by the Hyperborean tribes inhabiting the borders of the Icy Sea; these have for the most part a pyramidal skull, but their complexion is swarthy and their growth is peculiarly stunted; and they form the link that connects ordinary Mongolids with the Lapps and Finns of Europe on one side, and with the Esquimaux of North America on the other.

1055. According to the usual mode of dividing the Human family, the *Ethiopian* or *Negro* stock is made to include all the nations of Africa, to the southward of the Atlas range. But, on the one hand, there is good reason for separating the Hottentots and Bushmen of the southern extremity as a distinct race; so, again, the region north of the Great Desert is mostly occupied by *Semitic* tribes; the scattered population of the Great Desert itself is far from being Negro in many of its features; the valley of the Nile, at least in its middle and lower portions, including Egypt, Nubia, and even Abyssinia, is inhabited by a group of nations which may be designated as Nilotic, and which presents a series of gradational transitions between the Negroes and Kaffres and the Semitic races; a large portion of the area south of the Equator is occupied by the Kaffre tribes and their allies, which cannot be truly designated as Negroes; so that the true Negro area is limited to the western portion of the African continent, including the alluvial valleys of the Senegal, the Gambia, and the Niger, with a narrow strip of central Africa, passing eastward to the alluvial regions of the Upper Nile. Even within this area, the true Negro type of conformation, such as we see in the races which inhabit the low countries near the Slave Coast—consisting in the combination of the prognathous form of skull with receding forehead and depressed nose, thick lips, black woolly hair, jet-black unctuous skin, and crooked legs—is by no means universally prevalent; for many of the nations which inhabit it must be ranked as *sub-typical* Negroes; and from these the gradation in physical characters is by no means abrupt to those African nations which possess, in a considerable degree, the attributes which we are accustomed to exclude altogether from our idea of the African race. Thus the race of Jolofs near the Senegal, and the Guber in the interior of Sudan, have woolly hair and deep black complexions, but fine forms and regular features of a European cast; and nearly the same may be said of the darkest of the Kaffres of Southern Africa. The Bechuana Kaffres present a still nearer approach to the European type; the complexion being of a light brown, the hair often not woolly but merely curled, or even in long flowing ringlets, and the figure and features having much of the European character.—There is no group, in fact, which presents a more constant correspondence between external conditions and physical conformation than that composed of the African nations. As we find the complexion becoming gradually darker, in passing from northern to southern Europe, thence to North Africa, thence to the borders of the Great Desert, and thence to the intertropical region where alone the dullest black is to be met with—so do we find, on passing southwards from

this, that the hue becomes gradually lighter in proportion as we proceed further from the equator, until we meet with races of comparatively fair complexions among the nations of Southern Africa. Even in the intertropical region, high elevations of the surface have the same effect as we have seen them to produce elsewhere, in lightening the complexion. Thus, the high parts of Senegambia, where the temperature is moderate and even cool at times, are inhabited by Fulahs of a light copper color; whilst the nations inhabiting the lower regions around them are of true Negro blackness: and nearly on the same parallel, but at the opposite side of Africa, are the high plains of Enarea and Kaffa, where the inhabitants are said to be fairer than the natives of Southern Europe.

1056. The languages of the Negro nations, so far as they are known, seem to belong to one group; for although there is a considerable diversity in their vocabularies (arising in great part from the want of written records which would give fixity to their tongues), yet they seem to present the same grade of development and the same grammatical forms; and various proofs of their affinity with the Semitic languages have been developed, these being afforded by similarity alike of roots and of grammatical construction. The Semitic affinity of the Negro nations is further indicated in a very remarkable manner by the existence of a variety of superstitions and usages among the Negroes of the Western coast, closely resembling those which prevail also among the Nilotic races whose Semitic relations are most clear, as well as among branches of the Semitic stock itself; and thus we seem to have adequate proof of the absence of any definite line of demarcation, in regard either to *physiological* or to *linguistic* characters, between the Negro race and one of those which has always been considered to rank as among the most elevated forms of the Caucasian variety.—Nor is there anything in the *psychical* character of the Negro which gives us a right to separate him from other Races of Mankind. It is true that those races which have the Negro character in an exaggerated degree are uniformly in the lowest stage of society, being either ferocious savages, or stupid, sensual, and indolent; such are most of the tribes along the Slave Coast. But, on the other hand, there are many Negro states, the inhabitants of which have attained a considerable degree of improvement in their social condition; such are the Ashanti, the Sulima, and the Dahomans of Western Africa, also the Guber of Central Sudan, among which a considerable degree of civilization has long existed; the physical characters of all these nations deviate considerably from the strongly marked or exaggerated type of the Negro; and the last are perhaps the finest race of genuine Negroes on the whole continent, and present in their language the most distinct traces of original relationship to the Syro-Arabian nations. The highest civilization, and the greatest improvement in physical characters, are to be found in those African nations which have adopted the Mohammedan religion; this was introduced, three or four centuries since, into the eastern portion of Central Africa; and it appears that the same people, which were then existing in the savage condition still exhibited by the pagan nations further south, have now adopted many of the arts and institutions of civilized society, subjecting themselves to governments, practising agriculture, and dwelling in towns of considerable extent, many of which contain 10,000 and some even 30,000 inhabitants; a circumstance which implies a considerable advancement in industry, and in the resources of subsistence. This last fact affords most striking evidence of the *improvability* of the Negro races; and, taken in connection with the many instances that have presented themselves, of the advance of individuals, under favorable circumstances, to at least the average degree of mental development among the European nations, it affords clear proof that the line of demarcation, which has been supposed to separate them intellectually and morally from the races that have attained the greatest elevation, has no more *real* existence than that which has been sup-

posed to be justified by a difference in physical characters, and of which the fallacy has been previously demonstrated.

1057. The southern portion of the African continent is inhabited by a group of nations which, as already mentioned, recede, more or less decidedly, from the Negro type in physical characters, and which seem connected together by essential community of language, as branches of the stock of which the Kaffres may be considered the stem. In this warlike nomadic people, which inhabit the eastern parts of South Africa, to the northward of the Hottentot country, so great a departure from the ordinary Negro type presents itself, that many travellers have assigned to them a different origin. The degree of this departure, however, varies greatly in the different Kaffre tribes; for, whilst some of them are black, woolly-headed, and decidedly prognathous, so as obviously to approach the modified Negroes of Congo in general aspect, others recede considerably from the typical prognathous races, both in complexion, features, and form of head, presenting a light-brown color, high forehead, prominent nose, and a tall, robust, well-shaped figure. The thick lips and black frizzled hair are generally retained, however; but the hair is sometimes of a reddish color, and becomes flowing; and the features may present a European cast. Even among the tribes which depart most widely from the Negro type, however, individuals are found who present a return to it; and it is interesting to remark that the people of Delagoa Bay, though of the Kaffre race (as indicated by their language), having been degraded by subjugation, approach the people of the Guinea Coast in their physical characters. In fact, between the most elevated Kaffre and the most degraded Negro, every possible gradation of physical and psychical characters is presented to us, as we pass northwards and westwards from Kaf-fraria towards the Guinea Coast; and we meet with a similar transition, although not carried to so great an extent, as we pass up the eastern coast.—The languages of the Kaffres and other allied tribes are distinguished by a set of remarkable characters, which have been considered as isolating them from other African tongues. According to Dr. Latham, however, these peculiarities are not so far without precedent elsewhere, as to establish the very decided line of demarcation which some have attempted to draw; and may be regarded, in fact, as resulting from the fuller development of tendencies which manifest themselves in other African languages.

1058. The *Bushman* or *Bosjesmen* of South Africa are generally regarded as presenting the most degraded and miserable condition of which the human race is capable; and they have been supposed to present resemblances in physical characters to the higher Quadrumana. Yet there is distinct evidence, that this degraded race is but a branch or subdivision of the once extensive nation of Hottentots; and that its present condition is in great part due to the hardships to which it has been subjected, partly in consequence of European colonization. The Hottentot race differs from all other South African nations, both in language and in physical conformation. The language cannot be shown to possess distinct affinities with any other stock;¹ but in bodily structure there is a remarkable

¹ It is considered by some, that the Hottentot language is a degraded Kaffre, as the Bushman language is a degraded Hottentot; but the Author is informed by Mr. Norris that he sees no valid ground for this assumption, the affinities of the Hottentot language being rather, in his opinion, with the languages of High Asia, although the connecting links are extremely slight. Such as they are, however, they tend to confirm an idea suggested to the Author, some years since, by the marked reproduction of so many Mongolian characters in the Hottentot race—that it is the remnant of a migration from Asia earlier than that in which the great bulk of the African nations have their origin; and that it has been driven down to the remotest corner of the continent, just as the aboriginal (Mongolian) population of south-western Europe seems to have been driven back by the Indo-European immigration (§ 1050).

admixture of the characters of the Mongolian with those of the Negro. Thus the face presents the very wide and high cheek-bones, with the oblique eyes and flat nose, of the Northern Asiatics; at the same time that, in the somewhat prominent muzzle and thick lips, it resembles the countenance of the Negro. The complexion is of a tawny buff or fawn color, like the black of the Negroes diluted with the olive of the Mongols. The hair is woolly, like that of the Negroes, but it grows in small tufts scattered over the surface of the scalp (like a scrubbing-brush), instead of covering it uniformly; thus resembling in its comparative scantiness that of the Northern Asiatics. It is most interesting to observe this remarkable resemblance in physical characters, between the Hottentots and the Mongolian races, in connection with the similarity that exists between the circumstances under which they respectively live; and it is not a little curious that the Hottentot, as the Mongol, should be distinguished by the extraordinary acuteness of his vision. No two countries can be more similar than the vast steppes of Central Asia, and the karroos of Southern Africa; and the proper inhabitants of each are nomadic races, wandering through deserts remarkable for the wide expansion of their surface, their scanty herbage, and the dryness of their atmosphere, and feeding upon the milk and flesh of their horses and cattle. Of the original pastoral Hottentots, however, very few now remain. They have been gradually driven, by the encroachments of European colonists and by internal wars with each other, to seek refuge among the inaccessible rocks and deserts of the interior; and they have thus been converted from a mild, unenterprising race of shepherds, into wandering hordes of fierce, suspicious, and vindictive savages, treated as wild beasts by their fellow-men, until they have become really assimilated to wild beasts in their habits and dispositions. This transformation has taken place, under the observation of eye-witnesses, in the Koranas, a tribe of Hottentots well known to have been previously the most advanced in all the improvements which belong to pastoral life; for having been plundered by their neighbors, and driven out into the wilderness to subsist upon wild fruits, they have adopted the habits of the Bushmen, and have become assimilated in every essential particular to that miserable tribe. It appears, however, from the inquiries of Dr. Andrew Smith, that this process of degradation has been in operation quite independently of external agencies; nearly all the South African tribes who have made any advances in civilization, being surrounded by more barbarous hordes, whose abodes are in the wildernesses of mountains and forests, and who constantly recruit their numbers by such fugitives as crime and destitution may have driven from their own more honest and more thriving communities; and these people vary their mode of speech designedly, and even adopt new words, in order to make their meaning unintelligible to all but the members of their own community. All this has its complete parallel in the very midst of our own or any other highly civilized community; all our large towns containing spots nearly as inaccessible to those unacquainted with them as are the rude caves or clefts of hills, or the burrows scooped out of the level karroo, in which the wretched Bushman lies in wait for his prey; and these being tenanted by a people that have been well characterized as *les classes dangereuses*, which, as often as the arm of the law is paralyzed, issue forth from the unknown deserts within which they lurk, and rival in their fierce indulgence of the most degrading passions, and in their excesses of wanton cruelty, the most terrible exhibitions of barbarian inhumanity. Such outcasts, in all nations, purposely adopt, like the Bushmen, "a flash" language; and in their general character and usages, there is a most striking parallel.¹

1059. The *American* nations, taken collectively, form a group which appears

¹ See "London Labor and London Poor," p. 2.

to have existed as a separate family of nations from a very early period in the world's history. They do not form, however, so distinct a variety, in regard to physical characters, as some anatomists have endeavored to prove; for, although certain peculiarities have been stated to exist in the skulls of the aboriginal Americans, yet it is found, on a more extensive examination, that these peculiarities are very limited in their extent—the several nations spread over this vast continent differing from each other in physical peculiarities as much as they do from those of the Old World, so that no typical form can be made out among them. In regard to complexion, again, it may be remarked that, although the native Americans have been commonly characterized as “red men,” they are by no means invariably of a red or coppery hue, some being as fair as many European nations, others being yellow or brown, and others nearly, if not quite, as black as the Negroes of Africa; whilst, on the other hand, there are tribes equally red, and perhaps more deserving that epithet, in Africa and Polynesia.—In spite of all this diversity of conformation, it is believed that the structure of their languages affords a decided and clearly marked evidence of relationship between them. The words, and even the roots, may differ entirely in the different groups of American nations; but there is a remarkable similarity in grammatical construction amongst them all, which is of a kind not only to demonstrate their mutual affinity, but to separate them completely from all known languages of the Old Continent. Notwithstanding their diversities in mode of life, too, there are peculiarities of mental character, as well as a number of ideas and customs derived from tradition, which seem to be common to them all, and which, for the most part, indicate a former elevation in the scale of civilization, that has left its traces among them even in their present degraded condition, and that still distinguishes them from the sensual, volatile, and almost animalized savages that are to be met with in many parts of the Old Continent.—The Esquimaux constitute an exception to all general accounts of the physical characters of the American nations; for in the configuration of their skulls, as also in their complexion and general physiognomy, they conform to the Mongolian type, even presenting it in an exaggerated degree. Their wide extension along the whole northern coast of America, and the near proximity of this coast to Kamschatka, certainly lend weight to the idea that they derive their origin from the Northern Asiatic stock; but, on the other hand, they have a marked affinity, in regard to language, to the other American nations. The Athapascan Indians, various tribes of which inhabit the country south of the Esquimaux country, seem intermediate in physical characters, as they are in geographical position, between the Esquimaux and the ordinary Americans. They have a tradition which seems to indicate that they are derived from the North-Eastern Asiatics, with whom they have many points of accordance in dress and manners.

1060. It now remains for us to notice the *Oceanic* races, which inhabit the vast series of islands scattered through the great ocean, that stretches from Madagascar to Easter Island. There is no part of the world which affords a greater variety of local conditions than this, or which more evidently exhibits the effects of physical agencies on the organization of the human body. Moreover, it affords a case for the recognition of affinities by means of language, that possesses unusual stability; since the insulated position of the various tribes that people the remote spots of this extensive tract prevents them from exercising that influence upon each other's forms of speech which is to be observed in the case of nations united by local proximity or by frequent intercourse. Tried by this test, it is found that the different groups of people, inhabiting the greater part of these insular tracts, are more nearly connected together, although so widely scattered, and so diverse in physical characters, than most of the families of men occupying continuous tracts of land on the great continents of the globe. The inhabitants of Oceania seem divisible into two principal groups, which are

probably to be regarded as having constituted distinct races from a very early period; these are the Malayo-Polynesian race, and the Pelagian Negroes or Negritos.

1061. The *Malayo-Polynesian* group is by far the more extensive of the two; and comprehends the inhabitants of the greater part of the Indian and Polynesian Archipelagoes, with the peninsula of Malacca (which is the centre of the Malays proper), and the inhabitants of Madagascar. These are all closely united by affinities of language. The proper Malays bear a strong general resemblance to the Mongolian races, and this resemblance is shared, in a greater or less degree, by most of the inhabitants of the Indian Archipelago. They are of a darker complexion, as might be expected from their proximity to the equator; but in this complexion, yellow is still a large ingredient. The Polynesian branch of the group presents a much wider diversity; and if it were not for the community of language, it might be thought to consist of several races, as distinct from each other as from the Malayan branch. Thus the Tahitians and Marquesans are tall and well made; their figures combine grace and vigor; their skulls are usually remarkably symmetrical; and their physiognomy presents much of the European cast, with a very slight admixture of the features of the Negro. The complexion, especially in the females of the higher classes, who are sheltered from the wind and sun, is of a clear olive or brunette, such as is common among the natives of Central and Southern Europe; and the hair, though generally black, is sometimes brown or auburn, or even red or flaxen. Among other tribes, as the New Zealanders, and the Tonga and Friendly Islanders, there are greater diversities of conformation and hue; some being finely proportioned and vigorous, others comparatively small and feeble; some being of a copper-brown color, others nearly black, others olive, and others almost white. In fact, if we once admit a strongly marked difference in complexion, features, hair, and general configuration, as establishing a claim to original distinctness of origin, we must admit the application of this hypothesis to almost every group of islands in the Pacific;—an idea of which the essential community of language seems to afford a sufficient refutation. Among the inhabitants of Madagascar, too, all of which speak dialects of the same language, some bear a strong resemblance to the Malayan type, whilst others present approaches to that of the Negro.

1062. The *Pelagian-Negro* races must be regarded as a group altogether distinct from the preceding; having a marked diversity of language; and presenting more decidedly than any of the Malayo-Polynesians the characters of the Negro type. They form the predominating population of New Britain, New Ireland, the Louisiade and Solomon Isles, of several of the New Hebrides, and of New Caledonia; and they seem to extend westwards into the mountainous interior of the Malayan Peninsula, and into the Andaman Islands in the Bay of Bengal. The Tasmanians, or aborigines of Van Dieman's Land, which are now almost completely exterminated, undoubtedly belong to this group. Very little is known of them, except through the reports of the people of Malayo-Polynesian race inhabiting the same islands; but it appears that, generally speaking, they have a very inferior physical development, and lead a savage and degraded life. There is considerable diversity of physical characters among them; some approximating closely in hair, complexion, and features, to the Guinea Coast Negroes; whilst others are of yellower tint, straight hair, and better general development. The *Papuans*, who inhabit the northern coast of New Guinea and some adjacent islands, and who are remarkable for their large bushy masses of half-woolly hair, have been supposed to constitute a distinct race; but there is little doubt that they are of hybrid descent, between the Malays and the Pelagian Negroes.—To this group we are probably to refer the *Alfourous*, or *Alforian* race, which are considered by some to be the earliest inhabitants of the greater part of the Malayan Archipelago, and to have been supplanted by

the more powerful people of the preceding races, who have either extirpated them altogether, or have driven them from the coasts into the mountainous and desert parts of the interior. They are yet to be found in the central parts of the Moluccas and Philippines; and they seem to occupy most of the interior and southern portions of New Guinea, where they are termed Endamenes. They are of very dark complexion; but their hair, though black and thick, is lank. They have a peculiarly repulsive physiognomy; the nose is flattened, so as to give the nostrils an almost transverse position; the cheek-bones project; the eyes are large, the teeth prominent, the lips thick, and the mouth wide. The limbs are long, slender, and misshapen. From the close resemblance in physical characters between the Endamenes of New Guinea and the aborigines of New Holland, and from the proximity between the adjacent coasts of these two islands, it may be surmised that the latter belong to the Alforian race; but too little is known of the language of either to give this inference a sufficient stability. In the degradation of their condition and manner of life, the savages of New Holland fully equal the Bushmen of South Africa; and it is scarcely possible to imagine human beings existing in a condition more nearly resembling that of brutes. But there is reason to believe that the tribes in closest contact with European settlers are more miserable and savage than those of the interior; and even with respect to these, increasing acquaintance with their language, and a consequent improved insight into their modes of thought, tend to raise the very low estimate which had been formed and long maintained in regard to their extreme mental degradation. The latest and most authentic statements enable us to recognize among them the same principles of a moral and intellectual nature, which, in more cultivated tribes, constitute the highest endowments of humanity; and thus to show that they are not separated, by any impassable barrier, from the most civilized and elevated nations of the globe. There are many indications, indeed, that the Negrito race is not so radically distinct from the Malayo-Polynesian, as the marked physical dissimilarity of their respective types, and the apparent want of conformity between their languages, would make it appear. For as, on the one hand, some of the subdivisions of the latter present a decided tendency towards that prognathous character and depth of complexion which are typical of the former, so among the former do we not unfrequently meet with a lighter shade of skin, a greater symmetry of skull, and a considerable improvement in form and feature. And although no very close relationship can be discovered between the Negrito and Malayo-Polynesian languages, yet it has been pointed out by Mr. Norris that a much more decided relationship exists between the Australian and Tamulian (§ 1054); and remote as this connection seems, the circumstance adds weight to the idea that the native Australians (with other Negrito tribes) are an offset from that southern branch of the great nomadic stock of Central Asia which seems early to have spread itself through the Indo-Chinese and the Indian Peninsulas, and to have even there shown an approximation to the prognathous type.

1063. Looking, then, to the great diversity which exists among the subordinate groups of which both these divisions consist, and their tendency to mutual approximation, it cannot be shown that any sufficient reason exists for isolating them from each other; and, as already remarked, there seems no medium between the supposition that each island had its aboriginal pair or pairs, and the doctrine that the whole of Oceania has been peopled from a common stock. Looking, again, to the very marked approximation which is presented by certain Oceanic tribes to the Mongolian type, and this in a locality which, on other grounds, might be regarded as having received the first stream of migration, the possibility, to say the least, can scarcely be denied, that the mainland furnished the original stock, which has undergone various transformations subsequently to its first dispersion; these having been the result of climatic influence

and mode of life, and having been chiefly influenced as to degree by the length of time during which the transforming causes have been in operation. At any rate, it may be safely affirmed that there is no physical peculiarity which entitles the Oceanic races to rank as a group which must have necessarily had an original stock distinct from that of the continental nations.

CHAPTER XXI.

OF DEATH.

1064. It seems inherent in the very nature of Vital Action, that it can only be sustained during a *limited period* by any Organized body; for although the duration of certain structures may be prolonged, and their vital properties retained, almost indefinitely, yet this is only when the withdrawal of all extraneous agencies has reduced them to a condition of complete inactivity (§ 114). The Organized fabric, in fact, is at the same time the *instrument* whereby Vital Force is exercised, and the *subject* of its operation; and of this operation, as we have seen (§ 114), *decline* is no less a constituent part than *development*, and *Death* is its necessary sequence. Hence, in the performance of each one of those Functions whose aggregate makes up the Life of Man, the particular organ which ministers to that function undergoes a certain loss by the decline and death of its component tissues; and this the more rapidly, in proportion to the activity of the changes which are effected by their instrumentality. But if the regenerative processes be also performed with due vigor, no deterioration of the organ is manifested, since every loss of substance is compensated by the production of an equivalent amount of new and similar tissue. This regenerative power, however, gradually diminishes with the advance of years; and thus it happens that the entire organism progressively deteriorates (§ 133), and that Death at last supervenes from a general failure of the vital powers, rather than from the perversion or cessation of any one class of actions in particular.

1065. But Death may occur at any period of Life, from some local interruption produced by disease or injury in the regular sequence of vital actions; such interruption extending itself from the part in which it commences to the organism in general, in virtue of that intimate mutual dependence of one function upon another which is characteristic of all the higher orders of living beings. The death of the body, as a whole, which may be appropriately designated *Somatic*¹ death, becomes a necessary consequence of the death of a certain part of it, or *Molecular* death, only when the cessation of activity in the latter interferes with the elaboration, the circulation, or the depuration of the Blood, which supplies not merely the nutritive *pabulum* to every part of the organism, but also the oxygen which is essential to the activity of the nervo-muscular apparatus. Thus, even in the higher animals, the death or removal of the limbs, although they may constitute (as in Man) a large proportion of the fabric, is not necessarily fatal; because it involves no interruption, either in the nutritive operations of the viscera, or in the sensorial functions of the brain.² On the other hand, the destruction of

¹ This term was first suggested by Dr. Prichard in place of the less accurate term "systemic," which was previously in use. (See "Cyclop. of Anat. and Physiol.," vol. x. p. 791.)

² The Author has been informed by Dr. Daniell that it is not at all uncommon, in Negroes who are in the last stage of the adynamic fevers of the African coast, for death and decomposition to extend gradually upwards from the extremities to the trunk; so that the

a certain minute portion of the nervous centres, or such a lesion of the heart's structure as would be trivial in almost any other organ, may be the occasion of immediate death; because these changes arrest the respiratory movements, or interfere directly with the action of the heart, so as to bring the flow of blood to a stand. It sometimes happens, however, that life may be prolonged, after the death or removal of some important organ, in consequence of the power which some other possesses of discharging its function; thus we find that, in Man, the kidneys seem occasionally to take upon themselves the elimination of the constituents of bile from the blood (§ 622); and in the Frog, the skin can perform part of the office of the Lungs, so as to effect the aeration of the blood in a sufficient degree to prolong life for some time, unless the temperature be elevated.¹—But although the vital activity of every part of the body is dependent upon a due supply of circulating fluid, yet this dependence is usually not so close as to involve the *immediate* suspension of vital activity in every part, whenever the general Circulation shall have been brought to a stand. For we have distinct evidence of the persistence of vital changes in various organs and tissues of the body, after the death of the body at large; as is manifested in the performance of ciliary and of muscular movements (§§ 231, 328), in acts of secretion (§ 945) and perhaps even of nutrition, in the maintenance of the local circulation (§ 522), and in the generation of animal heat (§ 652); and the fact is even yet more remarkably manifested in the reunion (even after the lapse of some hours) of parts that have been entirely severed, such as fingers or toes, noses or ears, by adhesion between the cut surfaces when brought into apposition, which could not take place if the severed part were dead.

1066. The permanent and complete cessation of the Circulating current, which essentially constitutes *Somatic Death*, may be directly or indirectly consequent upon several distinct causes.—In the *first* place, it may be due to failure in the propulsive power of the Heart, which constitutes *Syncope*. This failure may occur either (*a*) in consequence of a loss of the proper irritability of the Muscular tissue, or (*b*) through the supervention of a “tonic spasm,” the organ remaining rigidly contracted without its usual alternation of relaxation. The phenomena attending death in the two cases are not dissimilar, when the loss of irritability is sudden and immediate (as when it arises from violent impressions on the nervous system); for the individual suddenly turns pale, falls back or drops down, and expires with one gasp. But under the former condition, the heart is found *flabby*, sometimes empty, sometimes distended with blood, both cavities being equally filled; whilst in the latter, the heart is contracted and hard, containing little or no blood, as when in the state of *rigor mortis* (§ 335).—The cause of the loss of irritability, when sudden, usually lies in the influence of a “shock” transmitted through the Nervous system, and originating either in some severe lesion of its central organs or of its peripheral expansion (§ 321), or in a deficiency of its supply of blood or diminution of its usual pressure (such as is produced by rapid detraction of blood, especially in the erect posture, by the rapid removal of the fluid in ascites without the substitution of artificial pressure, or by suddenly rising into the erect posture after prolonged recumbency,² still more, after long stooping), or in some powerful mental

former may be in a state of absolute putrescence, before the respiration and circulation have been brought to a stand; and he learns from his friend Prof. Jackson, of Philadelphia, that he has more than once witnessed the same occurrence.

¹ That such cannot take place in Man, is due not merely to the far less complete adaptation of his skin for the aeration of the blood, but also to the difference in the type of his circulation, which causes the arrest of blood in the pulmonary vessels to produce a stagnation of the entire current.

² Hence it is that great caution should be exercised, in allowing patients who are convalescent from acute diseases to rise into the erect position; many cases of fatal syncope

emotion, either exciting or depressing. A more gradual effect of the same kind is produced by lesions of the internal organs (such as rupture of the uterus), which often prove fatal by the general "collapse" thus induced, rather than by the disturbance which takes place in their own proper functions; and this seems to be the usual *modus operandi* of corrosive poisons, whose effect upon the heart's action resembles that produced by severe burns of the surface in children. The influence of the proper *sedative* poisons, however—such as digitalis, tobacco, aconite, and opium—seems to be directly exerted, through the Blood, upon the tissue of the heart itself; and the same is probably the case with some of those "morbid poisons" whose introduction into the system gives rise to diseases of the most intensely adynamic type, such as Malignant Cholera, in which the "collapse" is out of all proportion to any local lesion. But again, the loss of the Heart's irritability may be a gradual process, resulting from the deterioration of its tissue by fatty degeneration or by simple atrophy; and this last condition may be due to deficiency of blood, as happens in chronic starvation and diseases of exhaustion, in which the failure of the circulation seems due to the weakening of the heart's power and to the lowering of the quantity and quality of the blood, as concurrent causes, the condition thus induced being appropriately designated *Asthenia*. In all cases it is to be observed, that when the Vital powers have been previously depressed, a much slighter impression on the Nervous system is adequate to produce Syncope, than would be required when it is in a state of full vigor.—The causes of the tonic spasm of the heart have not been clearly made out, but it seems producible, like the more common form of Syncope, by agencies operating through the Nervous system; thus it has supervened upon the ingestion of a large quantity of cold water into the stomach.

1067. Somatic Death may be occasioned, secondly, by an obstruction to the flow of blood through the capillaries of the lungs, constituting *Asphyxia* (§ 574); and this may be consequent upon a disordered state of the lungs themselves, or upon suspension of the respiratory movements through affections of the Nervous centres. It is in this mode that most fatal disorders of the Nervous System produce death, except when a sudden and violent impression occasions a cessation of the heart's power; thus in Apoplexy, Narcotic Poisoning, &c., death results from the paralyzed condition of the Medulla Oblongata; whilst in Convulsive diseases, the fatal result ensues upon a spasmodic fixation of the respiratory muscles.—*Thirdly*, Somatic death may be occasioned by a disordered condition of the *Blood* itself (§ 178), which at the same time weakens the power of the Heart, impairs the activity of the Nervous system, and prevents the performance of those changes in the systemic capillaries which afford a powerful auxiliary to the circulation. This is Death by *Necræmia*.¹—*Fourthly*, Somatic death may result directly from the agency of *Cold*, which stagnates all the vital operations of the system. Where the cooling is due to the agency of an extremely low external temperature, which acts first upon the superficial parts, there is reason to think that the congestion of the internal vessels thereby induced occasions a torpid condition of the nervous centres, and that the cessation of the Circulation is immediately due to Asphyxia. But when the cooling is gradual, and the loss of heat is almost equally rapid throughout, it is obvious that the stagnation must be universal, and that no cessation of activity in any one part is the occasion of the torpor in the functions of the remainder. It is in this manner that death results from Starvation; and not by the weakening of the heart's action, as commonly supposed. The proofs of this have been already stated (§ 658). And as a general rule we find, that the more active the changes which normally take place in any

having been thus induced. The state of general debility, and the continued recumbency, both favor this result, especially in persons advanced in life.

¹ See Dr. C. J. B. Williams's "Principles of Medicine," 3d Am. Ed. p. 484.

tissue during life, the more speedily does its Molecular Death follow Somatic Death, the requisite conditions of its vital action being no longer supplied to it. Thus we observe that, in Cold-blooded animals, the supervention of Molecular upon Somatic death is much less speedy than it is in Birds and Mammals. This seems due to two causes. In the first place, the tissues of the former, being at all times possessed of a lower degree of vital activity than those of the latter, are disposed to retain it for a longer time; according to the principle already laid down. And, secondly, as the maintenance of a high temperature is an essential condition of the vital activity of the tissues of warm-blooded animals, the rapid cooling of the body after Somatic death is calculated to extinguish it speedily; and that this cause has a real operation is evinced by the influence of artificial warmth in sustaining the vital properties of separated parts.—The rapidity with which Molecular death follows the cessation of the general circulation will be influenced by a variety of causes; but especially by the degree in which the condition of the solids and fluids of the body has been impaired by the mode of death. Thus in *Necræmia*, *Asthenia*, and Death by gradual cooling, Molecular and Somatic death may be said to be simultaneous; and the same appears to be true of death by sudden and violent impressions on the Nervous system (§ 321). But in many cases of death by causes which operate by producing a more gradual Syncope or Asphyxia, the tissues and blood having been previously in a healthy condition, Molecular death may be long postponed; and we cannot be quite certain that it has supervened until signs of actual decomposition present themselves. When Molecular death takes place in an isolated part, it must result from some condition peculiar to that part, and not primarily affecting the body in general. Thus we may have Gangrene or Mortification of a limb as adirect result of the application of severe cold, or of an agent capable of producing chemical changes in its substance, or of violent contusions occasioning mechanical injury; or, again, from an interruption to the current of nutritive fluid; or, further, from some ill understood stagnation of the nutritive process, which manifests itself in the spontaneous death of the tissues without any assignable cause, as in some cases of senile gangrene. Sometimes we are enabled to trace this stagnation to a disordered condition of the circulating fluid; as in the gangrene resulting from the continued use of the ergot of rye or wheat; but we can give no other account of the almost invariable commencement of such gangrene in the extremities, than we can of the selection of lead, introduced into the blood, by the extensors of the forearm.—When Mortification or Molecular Death is once established in any part, it tends to spread, both to contiguous and to distant portions of the body. Thus we have continually to witness the extension of gangrene of the lower extremities, resulting from severe injury or from the use of the ergot, from the small part first affected, until the whole limb is involved; and this extension is easily accounted for by our knowledge of the tendency of organic substances, in the act of decomposition, to produce a similar change in other organic substances subjected to the influence of proximity to them. And the propagation of the gangrenous tendency to remoter parts is obviously due to the perversion of the qualities of the Blood, which results from a similar cause.¹

1068. It is quite certain that an *apparent* cessation of *all* the vital functions may take place, without that entire loss of vitality which would leave the organism in the condition of a *dead* body, liable to be speedily disintegrated by the operation of chemical and physical agencies (§ 115). The state of Syncope is some-

¹ On the proximate causes of Death, see especially the Art. "Death," by Dr. Symonds, in the "Cyclop. of Anat. and Phys.," vol. i.; the first chapter of Prof. Alison's "Outlines of Pathology and Practice of Medicine," and Dr. C. J. B. Williams's "Principles of Medicine," pp. 376, 387, *Am. ed.*

times so complete that the heart's action cannot be perceived, nor any respiratory movements be observed, all consciousness and power of movement being at the same time abolished; and yet recovery has spontaneously taken place, which could scarcely be the case, however, if *all* vital action had been suspended. It is not a little remarkable that certain individuals have possessed the power of *voluntarily* inducing this condition. The best authenticated case of this kind is that of Col. Townsend, which was described by Dr. George Cheyne,¹ who was himself the witness of the fact. But statements have been recently made respecting the performances of certain Indian Fakeers, which are far more extraordinary; it being demonstrated, if these assertions are to be credited,² that the Human organism may not only be voluntarily reduced to a state resembling profound collapse, in which there appear to be a nearly complete suspension of all its vital operations, but may continue in that condition for some days or even weeks—until, in fact, means are taken to produce resuscitation.—Another form of Apparent Death, the existence of which appears to be well authenticated, is that sometimes designated as “Trance” or “Cataplexy,” in which there is a reduction of all the Organic Functions to an extremely low ebb, but in which Consciousness is still preserved, whilst the power of voluntary movement is suspended; so that the patient, though fully aware of all that is being said and done around, is unable to make the least visible or audible sign of life.³ It is impossible, in the present state of our knowledge, to give any satisfactory account of these states; but some light appears to be thrown upon them by certain phenomena of Artificial Somnambulism, “hypnotic” or “mesmeric” (§ 827); for in this condition there is sometimes an extraordinary retardation of the respiratory movements and of the pulsations of the heart, which, if carried further, would produce a state of complete collapse; and its self-induction is suspected by Mr. Braid to be the secret of the performance of the Indian Fakeers just referred to.

1069. The signs by which *real* is certainly distinguishable from *apparent* Death are not numerous, a large proportion of those commonly relied on being fallacious; but they are conclusive.—In the first place, it is to be remarked that no reliance is to be placed, for the reasons already mentioned, upon the apparent cessation of the heart's action, and of the respiratory movements; since the reduction of these

¹ See his “Treatise on Nervous Diseases,” p. 307.

² See a collection of these cases, directly obtained from British officers who had been eye-witnesses of them in India, by Mr. Braid, in his “Observations on Trance, or Human Hybernation,” 1850.—In one of these, vouched for by Sir Claude M. Wade, formerly political agent at the Court of Runjeet Singh, the Fakeer was buried in an underground cell, under strict guardianship, for *six weeks*; the body had been twice dug up by Runjeet Singh during the period of interment, and had been found in the same position as when first buried.—In another case, narrated by Lieut. A. Boileau, in his “Narrative of a Journey in Rajwarra, in 1835,” the man had been buried for ten days in a grave lined with masonry and covered with large slabs of stone, and strictly guarded; and he assured Lieut. B. that he was ready to submit to an interment of a twelve months' duration, if desired.—In a third case, narrated by Mr. Braid, the trial was made under the direct superintendence of a British Officer, a period of nine days having been stipulated for on the part of the devotee; but this was shortened to three at the desire of the Officer, who feared lest he should incur blame if the result was fatal.—The appearance of the body when first disinterred is described in all instances as having been quite corpse-like, and no pulsation could be detected at the heart or in the arteries; the means of restoration employed were chiefly warmth to the vertex and friction to the body and limbs.—It may be remarked that the possibility of the protraction of such a state (supposing that no deception vitiates the authenticity of the narratives referred to) can be much better comprehended as occurring in India, than as taking place in this country; since the warmth of the tropical atmosphere and soil would prevent any serious loss of heat, such as must soon occur in a colder climate when the processes whereby it is generated are brought to a stand.

³ Several such cases are recorded in Dr. H. Mayo's “Letters on the Truths contained in Popular Superstitions,” and also by Mr. Braid, *Op. cit.*

to so low a condition that they are no longer distinguishable, is by no means incompatible with the persistence of vitality. A surer test, however, is afforded by the condition of the *Muscular* substance; for this gradually loses its irritability after real Death, so that it can no longer be excited to contraction by electrical or any other kind of stimulation; and the loss of irritability is succeeded by the appearance of cadaveric rigidity (§ 333). So long, then, as the muscle retains its irritability, and remains free from rigidity, so long we may say with certainty that it is not dead; and the persistence of its vitality for an unusual period affords a presumption in favor of the continuance of some degree of vital action in the body generally; whilst, on the other hand, the entire loss of irritability, and the supervention of rigidity, afford conclusive evidence that Death has occurred. The most satisfactory proof, however, is given by the occurrence of Putrefaction; this usually first manifests itself in the blue-green coloration of the cutaneous surface, especially the abdominal; but it speedily becomes apparent in other parts, its rate being usually in some degree of accordance with the external temperature, though also much influenced by the previous condition of the solids and fluids of the body, these having been sometimes left by diseased actions in a state that renders them peculiarly prone to disintegration (§ 418).

1070. With the final restoration of the components of the Human Organism to the Inorganic Universe, in those very forms, or nearly so, in which they were first withdrawn from it, the Corporeal Life of Man, of which it has been the object of the foregoing Treatise to sketch the leading features, comes to a final close; but the Death of this Body is but the commencement of a new Life of the Soul, in which (as the religious physiologist delights to believe) all that is pure and noble in Man's nature will be refined, elevated, and progressively advanced towards perfection, whilst all that is carnal, selfish, and degrading, will be eliminated by the purifying processes to which each individual must be subjected before Sin can be entirely subjugated, and Death can be completely "swallowed up of Victory."

INDEX OF AUTHORS.

A.

- ABERCROMBIE, Dr., on dreaming, 802 *note*, 803 *note*.
 Addison, Mr., on fibrillation of liquor sanguinis, 138; on colorless corpuscles, 163, 205, 206 *note*.
 Agassiz, Prof., on psychical conformity of human races, 1040 *note*.
 Alcock, Dr., on nerves of taste, 687.
 Alison, Prof., on buffy coat, 199; on muscular irritability, 326; on asphyxia, referred to, 537 *note*; on jaundice from suppression of hepatic excretion, 592; on guiding sensations, 722; on rapidity of muscular actions, 919; on Death, referred to, 1057 *note*.
 Allen and Pepys, their experiments on respiration, 524.
 Ansell, Mr., on red corpuscles of the blood, referred to, 158 *note*; on coagulation of the blood, 195 *note*.
 Andral, M., on temperature in disease, 618; on pathology of Corpora Striata and Thalami Optici, 710; on pathology of Cerebellum, 734.
 Andral and Gavarret, MM., on composition of blood in health, 171; on composition of blood in disease, 184-189; on buffy coat, 200; on expiration of carbonic acid, 526, 527.
 Arnott, Dr., on the venous circulation, 499; on stammering, 940.
 Atkinson, Mr. H. G., on materialism, 771 *note*.
 Ascherson, M., on uses of fat, 73.

B.

- Babington, Dr., on mucus, 233.
 Baillarger, M., on gray matter of Cerebrum, 742.
 Bain, Mr. Alex., on laws of Association, 780 *note*.
 Ballou, Dr., on suspended lactation, 1021.
 Baly, Dr., on glandulæ solitariae, 435; on mechanical excitement of olfactive and gustative sensations, 853, 864; on Corpus Luteum, 966.
 Barker, Dr., his case of early viability, 984.
 Barlow, Mr. F., on spontaneous movements after death from Cholera, 327.
 — Rev. J., on self-control, 809, 810 *note*.

- Barral, M., on amount of carbon excreted, 530; on excretion of nitrogen, 532; on excretion of hydrogen, 533; on statistics of excretion, 576, 577.
 Barruel, on odorous principles of blood, 173.
 Barry, Dr. Martin, on ovisac, 958, 959; on changes in germinal vesicle, 969.
 Baxter, Mr., on disturbance of electric equilibrium in secretion, 633.
 Beau, M., on growth of nail, 250.
 Beau and Maissiat, MM., on mechanism of respiration, 521 *note*.
 Beaumont, Dr., on sense of satiety, 384; on movements of stomach, 405, 406; on secretion of gastric juice, 420; on disordered states of the stomach, 421, 422; on gastric digestion, 424-426.
 Beck, Dr., on superfætation, 985.
 Béclard, M., on blood of mesenteric vein, 182; on blood of splenic vein, 183.
 Becquerel, M., on development of electricity by capillary action, 117.
 Becquerel and Breschet, MM., on development of heat by muscular contraction, 329; on cutaneous asphyxia, 625.
 Becquerel and Rodier, MM., on composition of blood in health, 171, 172, 175, 176; on effect of loss of blood, 178; on composition of blood in disease, 184-190; on increase of cholesterin in blood of old persons, 213.
 Belfield-Lefevre, M., on tactile sensibility, 859 *note*.
 Bell, Sir C., on the hand, 41; on paralysis of respiratory muscles, 515; on distinct functions of anterior and posterior roots of spinal nerves, 651, 847 *note*; on cephalic nerves, 654; on columns of Spinal Cord, 668; on decussation of posterior pyramids, 680; on motor and sensory tracts of Medulla Oblongata, 681-682; on fifth pair, 683; on spinal accessory, 691; on guiding sensations, 722; on partial paralysis, 764.
 Bell, Mr. T., on secretion of serpent-poison after death, 941; on Australian Dingo, 1037 *note*.
 Bellingieri, on columns of Spinal Cord, 670.
 Bement, Mr., his cases of protracted gestation, 983.
 Bennett, Prof., on uses of fat, 74; on cyto-genesis, 128; on leucocythæmia, 189; on colorless corpuscles, 205; on epithelium-cells of intestinal villi, 441; on production of blood-corpuscles in ductless glands, 462; on aggregations of disintegrating blood-

- corpuscles, 464; on cells of absorbent glands, 451; his cases of production of sensations by ideas, 857.
- Bensch, on milk of carnivora, 114.
- Berger and Delaroche, MM., their experiments on endurance of heat, 620, 621.
- Bernard, M. Claude, on production of fat in the liver, 71; on passage of cane-sugar into the urine, 75; on presence of sugar in blood, 76; on production of sugar by liver, 76-78; on blood of hepatic vein, 183; on state of gastric follicles in intervals between digestion, 392; on salivary secretion, 413; on composition of gastric juice, 418; on secretion of gastric juice, 420; influence of nervous system on, 422; on gastric digestion, 427; on pancreatic fluid, 429; on influence of bile on digestion, 430, 431; on intestinal digestion, 432; on reflux of blood to the kidneys, 442 *note*; on assimilating power of liver, 450, 594; on influence of lesion of Sympathetic on animal heat, 627; on motor roots of pneumogastric, 690; on spinal accessory, 691; on chorda tympani, 718.
- Berzelius, on lactic acid, 79; on coloring matter of bile, 96, 97; on fluorine, 104; his analysis of muscle, 311.
- Bibra, Von, on phosphate of lime, 102; on carbonate of lime, 103; on composition of bone, 271, 272; on composition of teeth, 286.
- Bidder, on Sympathetic nerve-fibres, 338 *note*; on amount of lymph and chyle, 454; on structure of kidney, referred to, 595 *note*.
- Bidder and Schmidt, on quantity of bile secreted, 431.
- Bird, Dr. Golding, on lateritious sediments, 85; on efflorescence of uric acid, 85; on hippuric acid, 88; on inosic acid, 90; on purpurine, 92; on xanthine, 93; on cystine, 93, 94; on phosphates in urine, 356; on coloring matters of urine, 604 *note*; on oxalates in urine, 607; on base of uric acid deposits, 608 *note*; on action of diuretics, 608.
- Birkett, Mr., on anatomy of breast, 1019.
- Bischof, Prof., on excretion of urea, 602.
- Bischoff, Prof., on transfusion of blood, 202; on excretion of carbonic acid, 529; on evolution of ovum, 958; on formation of chchion, 971, 972; on embryonic development of Mammalia, 987 *note*.
- Bishop, Mr., on physiology of Voice, 932-935; on stammering, 940 *note*.
- Bizot, M., on thickness of heart's parietes, 475.
- Blagden, Dr., on endurance of heat, 621.
- Blake, Prof., his estimate of amount of blood, 156; on the rate of circulation, 479.
- Blane, Sir G., on reflex action, 672.
- Blondlot, M., on secretion of gastric juice, 420; on gastric digestion, 427; on action of bile in digestion, 431; on quantity of bile secreted, 431; on acid of cæcum, 433.
- Blumenbach, Prof., on Races of Mankind, 1042.
- Böckmann, on comparative composition of muscle and blood, 311.
- Boileau, Lieut., his case of Trance, 1058 *note*.
- Boileau-Castelnau, M., on Maison Centrale of Nismes, 396.
- Bois-Reymond, M. Du, on electric disturbance by organic processes, 615 *note*; by muscular contraction, 329, 636-637; on muscular current, 634-636; on nervous current, 637-640.
- Bouchardat and Sandras, MM., on blood of mesenteric veins, 182.
- Bouillaud, M., his experiments on Cerebellum, 733.
- Bourdon, M., on respiratory movements, 516 *note*.
- Boussingault, M., on production of fat in the body, 71, 72 *note*; on decomposition of urea, 81; on influence of salt, 106; on exhalation of nitrogen, 532.
- Boutigny, M. de, on spherical state of vapor, 620 *note*.
- Boyd, Dr. S., on structure of mucous membrane of stomach, 416 *note*.
- Bowman, Mr., on primary membrane, 139; on structure of cornea, 263; on crystalline lens, 265; on vitreous humor, 266; on structure of muscle, 304, 305; on contraction of muscle, 307, 308; on Pacinian corpuscles, 342; on fatty liver, 587; on structure of kidney, 595-598; on functions of Malpighian bodies of kidney, 599; on structure of retina, 879; on peculiar form of double vision, 914 *note* (see *Todd and Bowman*).
- Brachet, M., on sense of hunger, 391; on movements of stomach, 407.
- Braid, Mr., on Hypnotism, 794, 801, 802, 827-829; on influence of attention on organic functions, 947, 948; his cases of Trance, 1058.
- Brewster, Sir D., on crystalline lens, 265; on natural magic, 794 *note*; on the Stereoscope, 885, 886 *note*.
- Brinton, Dr., on serous membranes, 232.
- Brittan, Dr., his observations on cholera at Bridgewater, 388 *note*.
- Brodie, Sir B., on influence of pneumogastric on secretions of stomach, 423; on dependence of animal heat upon nervous system, 626, 627; on morbid sensations, 854.
- Brown-Séguard, M., on spontaneous rhythmic contractions of muscles, 319 *note*; effects of paralysis on irritability and cadaveric rigidity of muscles, 321 *note*; on restoration of irritability by arterial blood, 323; on influence of electricity on duration of muscular irritability, 333; on regeneration of nervous tissue, 347, 348; on hypertrophy of suprarenal capsules, following injury of spinal cord, 459 *note*; disturbance of temperature produced by injuries of nervous system, 627; effects of section of spinal cord, 670; effects of removal of medulla oblongata, 676; phenomena produced by injuries of nervous system, 711.
- Brücke, on termination of Nerves in muscles, 312 *note*; on Peyerian glands, 435.
- Buchanan, Prof., on coagulation of fibrin, 61; on milky serum, 176.
- Budd, Dr. G., on morbid changes in hepatic cells, 590; on abscess of liver, 592; on jaundice from suppression of hepatic excretion, 592; on reabsorption of bile, 592.
- Budd, Dr. W., on symmetrical diseases, 209; on localization of inflammatory action, 568; his cases of paraplegia, 672-674; on para-

lysis of the tongue, 693 ; on continuance of automatic movements, 699.
 Budge, Dr., on columns of Spinal Cord, 670.
 Budge and Waller, Drs., on dilatation of pupil by sympathetic, 831.
 Burdach, on vicarious secretion of urine, 579, 580 ; on pathology of Cerebellum, 738 ; on influence of passion on mammary secretion, 945 *note*.
 Burrows, Dr. G., on blood-clots, 61 ; on the intracranial circulation, 501.
 Bushnell, Rev. H., on unconscious influences, 792 *note*.
 Busk, Mr. G., on blood in Scurvy, 187.

C.

Carpenter, Miss, on Juvenile Reformation, 833 *note*.
 Carlyle, Thomas, on Coleridge, 789 *note*.
 Chatin and Bouvier, MM., on blood in scurvy, 187.
 Chaussier, M. on weight of new-born infants, 1014.
 Cheselden, his case of cataract, 882.
 Chevreul, M., on proportion of water in the body, 100 ; on rhythmical oscillations, 921 *note*.
 Cheyne, Dr. G., on case of Col. Townsend, 1058.
 Chossat, M., his experiments on starvation, 207, 259, 393, 396, 623 ; on diurnal variation of temperature, 617 ; on dependence of animal heat upon nervous system, 627.
 Christison, Dr., on blood in albuminuria, 189 ; on milky serum, 190.
 Clark, Mr. A., on fat in feces, 208.
 Clarke, Mr. J. L., on structure of Spinal Cord, 661-662 ; on roots of spinal accessory, 690.
 Clarke, Dr. Joseph, on weight of new-born infants, 1014.
 Coathupe, Mr., on amount of air respired, 523 ; on products of combustion of charcoal, 534, 535 *note*.
 Collard de Martigny, M., on respiration in nitrogen, 531 ; on pulmonary exhalation, 533.
 Collins, Dr., on infantile mortality, 545.
 Combe, Dr. A., on digestion, 422 ; on influence of passion on mammary secretion, 945 ; on influence of mother on fœtus, 1011 ; on infant nutrition, 1025.
 Combe, Mr. G., on result of sexual intercourse in a state of intoxication, 670.
 Combetti, his case of destruction of Cerebellum, 734.
 Cooper, Sir A., his experiments on the cerebral circulation, 352 ; on influence of emotions on mammary secretion, 944 ; on structure of mammary gland, 1018-1021.
 Copland, Dr., on antiphlogistic regimen, 396, 397.
 Corfe, Mr., on water at Wolverton, 389 *note*.
 Cork, Bishop of, his case of lactation by male, 1022 *note*.
 Corti, Marquis, on cochlear nerve, 895, 896.
 Coste, M., on decidua reflexa, 974.
 Cowan, Dr., his case of consensual movements, 720 ; of apoplexy of cerebellum, 734 *note*.
 Cruveilhier, M., his case of Ectopia Cordis, 473.

Curling, Mr., his cases of hypertrophy of the fingers, 555 *note* ; on atrophy of bone, 559.
 Currie, Dr., on cutaneous absorption, 446.
 Cuvier, on the hand, 41.
 Czermak, Prof., on motion of particles within cells, 130 ; on structure and development of dentine, 288.

D.

Dalrymple, Mr., on vasa lutea of Bird's egg, 992 *note*.
 Dalton, Dr., on statistics of excretion, 576.
 Dalton, Dr. J. C., on difference in corpora lutea of menstruation and pregnancy, 966.
 Daniell, Dr., on adynamic fevers, 221, 614 ; on immunity from African fevers, 1039 *note* ; on gradual death of fever patients, 1054, 1055 *note*.
 Davaine, M., on changes of form of colorless corpuscles, 164.
 Davis, Dr. N. S., on central lobe of cerebellum, 740.
 Davy, Dr. J., on venous hue of arterial blood, 156 ; on effect of loss of blood, 178 ; on non-coagulation of blood, 194-196 ; on temperature of human body, 616-618.
 Delaroche and Berger, MM., their experiments on endurance of heat, 620, 621.
 Deleau, M., on vocal sounds, 936.
 Dennis, M., on reduction of fibrin to state of albumen, 60 ; on composition of blood, 175, 176.
 Desaguliers, Dr., his examples of muscular power, 918.
 Devergie, M., on presence of lead in muscle, 214 ; on characters of embryo at different periods, 1012, 1013.
 Dieffenbach, Prof., on transfusion of blood, 202.
 Dill, Dr., his case of absorption in diabetes, 447.
 Dittrich, on ciliary movement, 237.
 Dobson, Mr., his experiments on the spleen, 463.
 Dodd, Mr., his case of early viability, 984.
 Donders, Prof., on structure of nail, 250 ; on absorption of solid particles, 445.
 Donné, M., on temperature in disease, 619 ; on human milk, 1025.
 Donovan, Dr., on Irish starvation, 395 ; on evolution of light, 632.
 Dowler, Dr. Bennet, on spontaneous movements after death from yellow fever, 327 ; on blood's movement after death, 492 ; on *post-mortem* elevation of temperature, 619.
 Doyère, M., on desiccation of Tardigrada, 55 *note*.
 Draper, Prof., on influence of Light on Plants, 143 ; on the capillary circulation, 496.
 Dugès, M., on function of cerebellum, 734 ; on function of cochlea, 905.
 Dulong, M., on calorification, 626.
 Dumas, on production of fat in the body, 71 ; on decomposition of urea, 81 ; on milk of carnivora, 114.
 Dunglison, Prof., on gastric juice, 418 ; on cutaneous absorption, 448 ; on temperature in disease, 618 ; heat of uterus in parturition, 623 *note* ; on temperature of paralyzed

limbs, 627; his cases of peculiar secretion of milk, 1022.
 Dunn, Mr., his cases of apoplexy of cerebellum, 734 *note*, 739; of suspended cerebral action, 838-840 *note*.
 Dupuy, M., on injection of cerebral substance into veins, 197.
 Dupuytren, M., on provisional callus, 282.
 Duval, M., on pulsations of heart after death, 472 *note*.
 Dzondl, on deglutition, 401.

E.

Earle, Mr. H., on temperature of paralyzed limbs, 627.
 Eberhard, on absorption of solid particles, 445.
 Ecker, Prof., on suprarenal bodies, 458.
 Edwards, Dr. W., on respiration in hydrogen, 531; on temperature of infants, 616 *note*; on seasonal variation of calorific power, 618; on influence of moist air, 621; on inferior calorifying power of young animals, 629, 630.
 Edwards, Prof. Milne, on infantile mortality, 630.
 Egerton, Sir Philip, on effect of castration on buck, 212.
 Ehrenberg, Prof., on limits of vision, 879.
 Elliotson, Dr., his case of rapid respiration, 513.
 Emerson, Dr., on infantile mortality, 630 *note*.
 Enderlin, on ashes of blood and flesh, 106; on gastric juice, 418; on ash of feces, 437.
 Engelhardt, on columns of Spinal Cord, 670.
 Erichsen, Prof., on duration of muscular irritability, 324; his experiments on rate of absorption, 442; on Asphyxia, 495, 537, 538 *note*.
 Erman, on protracted lactation, 1025.
 Evanson, Dr., his case of abolition of sexual desire, 739 *note*.

F.

Fenwick, Mr., his experiments on absorption by lacteals, 440.
 Figuier, M., on analysis of the blood, 172.
 Fletcher, Dr., on fattening influence of despair, 943.
 Flourens, M., on removal of Cerebrum, 706, 753 *note*; on functions of Corpora Quadrigemina, 707, 708; on auditory nerve, 708; on Cerebellum, 732.
 Ford, Mr., his case of absorption in ovarian dropsy, 447.
 Fordyce and Blagden, Drs., their experiments on endurance of heat, 621.
 Fourcault, Dr., on cutaneous asphyxia, 613.
 Foville, M., on function of Cerebellum, 734; on pathology of Insanity, 754.
 Franklin, Sir J., his case of lactation by male, 1022 *note*.
 Fremy, M., on chemical composition of nervous matter, 344.
 Frerichs, Prof., on metamorphosis of uric acid, 84; on increase of urea after ingestion of gelatin, 412; on composition of saliva, 412; on gastric juice, 417; on pancreatic fluid, 429-430; on succus entericus, 429, 432; on

meconium, 590, 591; on structure of kidney, referred to, 595 *note*; on uræmia, 600.
 Frey, Prof., on bloodvessels of Peyerian glands, 435; on suprarenal bodies, 458.
 Funke, on colorless corpuscles in blood of splenic vein, 462; on blood of splenic vein, 464-465.

G.

Gairdner, Dr. W., on production of fibrin, 179-180.
 Gairdner, Dr. W. T., on formation of capillaries, 301; on contractility of bronchial tubes, 510; on structure of kidney, referred to, 595 *note*.
 Gall, on amative function of Cerebellum, 735-737; on comparative development of Cerebrum, 751.
 Garreau, M., on production of heat by Arum, 621 *note*.
 Garrod, Dr., on urea in blood, 82; on uric acid in blood, 86; on proximate cause of scurvy, 109 *note*; on salines of blood in cholera, 190.
 Gelatin-Commission, report of, 377.
 Gerber, Prof., on progressive alteration of chyle, 453.
 Gerlach, on ciliary movement, 237; on structure of kidney, referred to, 595 *note*, 597.
 Gilchrist, Dr., on water-dressing, 564.
 Girdwood, Mr., on periodical discharge of ova, 961, 968 *note*.
 Goodfellow, Dr., on muscular fibrilla, 306 *note*.
 Goodsir, Prof., on primary membrane, 139, 140; on germinal spots of epithelium, 238; on development of teeth, 290-295; on absorption by intestinal villi, 441; on structure of absorbent glands, 451; on structure of kidney, referred to, 595 *note*; on structure of decidua, 972-974; on villi of chorion, 974; on formation of placenta, 975; on cells of milk-follicles, 1020.
 Goodsir, Mr. H. D. S., on spermatic cells of Crustacea, 124.
 Gorup-Besanez, on guanine, 93; on silica in hair and feathers, 105; on composition of blood, 170, 172.
 Gosselin, M., on ciliary movement, 237.
 Graham, Prof., on iron in blood of crab, 204; on gastric juice, 418; his law of mutual diffusion of gases, 525.
 Grainger, Mr., on act of sucking, 398; on structure of Spinal Cord, 667.
 Granville, Dr., on heat of uterus in parturition, 623.
 Gray, Mr. H., on development of spleen, 458; of suprarenal bodies, 458, 459; of thyroid body, 461; of retina, 879 *note*; of eye and ear, 1010, 1011.
 Green, Dr., on protracted lactation, 1025 *note*.
 Greenhow, Dr., on treatment of burns, 564.
 Gregory, Dr., his case of suggested dreaming, 802.
 Gregory, Prof., on creatine, 89.
 Grove, Prof., on correlation of physical forces, 120, 142, 357.
 Gruby and Delafond, MM., on rhythmical movements of intestinal villi, 440; on epithelium-cells of villi, 441.
 Guckelberger, on oxidation of azotized histogenetic substances, 88.

- Guillot, M., on structure of liver, 586; on amount of milk secreted, 1028 *note*.
- Gull, Dr., on uses of plexuses of nerves, 652; on paralysis, 841 *note*, 847.
- Gulliver, Mr., on molecular base of chyle, 72; on red corpuscles of blood, 158 *note*, 159; on colorless corpuscles, 163, 165; on production of red corpuscles, 168; on coagulation of blood, 193-196; on buffy coat, 199, 200; on reunion of fractures, 282; on rigor mortis of muscles, 333; on molecular base of chyle, 452; on gorged state of hepatic cells, 590.
- Gunther and Schön, on degeneration of nerve-fibres after section, 346.
- Guy, Dr., on the rate of the pulse, 481, 482; on relative weights of liver and lungs, 591.
- Guyot, M., on treatment of wounds by hot air, 564.
- H.
- Haidlen, on composition of milk, 1024.
- Hales, on the force of heart's contraction, 479, 480; on rate of blood's movement in capillaries, 497.
- Hall, Dr. C. Radclyffe, on contractility of bronchial tubes, 510; on vital capacity of lungs, 522; on decussation of posterior pyramids, 680; on ciliary ganglion, 685 *note*.
- Hall, Dr. J. C., on protracted gestation, 982.
- Hall, Dr. M., on muscular irritability, 324, 325; on deglutition, 402; on vomiting, 408; on defecation and urination, 410; on action of sphincters, 411; on circulation in acardiac fœtus, 493; on stimulus to respiratory movement, 514, 515; on structure of Spinal Cord, 667; on reflex action of spinal cord, 672, 695-697, 847 *note*; on muscular tension, 700; on action of cantharides on spinal cord, 702; on emotional actions, 764; on stammering, 939.
- Haller, on quantity of blood in the body, 155; on muscular irritability, 326; on respiratory pulse, 498; on vicarious secretion of urine, 579.
- Hamernjk, on sounds of heart, 478.
- Hamilton, Sir W., on perception, 758 *note*; on unconscious action of Cerebrum, 791 *note*.
- Harless, on columns of Spinal Cord, 670; on muscular irritability, 321.
- Harvey, Dr. Alex., on influence of fœtal blood on maternal, 970.
- Haygarth, Dr., on metallic tractors, 948 *note*.
- Heller, on urine-pigments, 91, 92.

- Schreger, on absorption by cutaneous lymphatics, 448.
- Schröder Van der Kolk, on coagulation of blood, 196.
- Schultze, on reaction of oleine, 95.
- Schwann, Prof., on force of muscular contraction, 328, 329; on peripheral terminations of nerve-fibres, 342; on division of bile-duct, 431.
- Seebeck and Wartmann, on Daltonism, 893.
- Serres, M., on comparative anatomy of Cerebellum, 729; on pathology of Cerebellum, 738.
- Sharpey, Prof., on motion of particles within cells, 130; on mucous membranes, 232; on cartilage, 260; on structure of animal basis of bone, 270; on intra-membranous ossification, 272; on formation of lacunæ and canaliculi of bone, 277; on structure of fibrillæ of muscle, 305, 306; on development of muscle, 313; on sympathetic nerve-fibres, 338 *note*; on peripheral terminations of nerve-fibres, 342; on formation of decidua, 972.
- Sibson, Dr., on mechanism of respiration, 521 *note*.
- Simpson, Dr., on pathology of Cerebellum, 739.
- Simpson, Prof., on analogy between puerperal and surgical fever, 217; on regeneration of limbs, 561; on parturition, 982 *note*; on hermaphroditism, referred to, 1005 *note*.
- Simon, Dr., on action of bile, &c. on blood-corpuscles, 162; on blood of renal vessels, 184; on blood in typhus, 187; on meconium, 590; on variations in urine, 601; on variations in milk, 1024.
- Simon, Mr., on nature of fibrin, 63 *note*; on free nuclei, 137; on cancer-cells, 141; on coagulation of blood in the vessels, 197; on thymus gland, 461; on cancerous cachexia, 574 *note*.
- Simon, on mechanism of respiration, 521 *note*.
- Sion, Dr., his case of fat in the blood, 190.
- Sloan, Dr., his case of protracted abstinence, 397.
- Smith, Dr. Andrew, on Bushmen, 1050.
- Smith, Dr. Southwood, on cutaneous absorption, 446; on cutaneous transpiration, 612.
- Smith, Dr. Tyler, on *post-mortem* contraction of uterus, 334; on cause of parturition, 982 *note*.
- Smith, Mr. R. A., on pulmonary exhalation, 533.
- Smith, Mr. Richard, his case of blunted sensibility, 850 *note*; on metallic tractors, 948 *note*.
- Smith, Rev. Sydney, on emotions, 763.
- Snow, Dr., his experiments on respiration, 524.
- Solly, Mr. S., on Medulla Oblongata, 679; on the brain, 694, 704 *note*; on optic chiasma, 716.
- Spallanzani, on fertilizing power of spermatozoa, 955 *note*.
- Spencer, Earl, his cases of protracted gestation, 982, 983.
- Städeler, on carbonaceous acids of urinary extractive, 539 *note*, 604.
- Stanley, Mr., his case of softening of Spinal Cord, 669.
- Stark, Dr., on composition of bone, 271.
- Stilling, on structure of Spinal Cord, 662, 665; on columns of Spinal Cord, 669.
- Stokes, Dr., on muscular contractions in phthisis, &c., 328; on evolution of light, 632.
- Strecker, on constitution of hippuric acid, 87; on biliary acids, 94-96.
- Symonds, Dr., on volitional actions, 768 *note*; on death, referred to, 1057 *note*.

T.

- Thackrah, Mr., on coagulation of blood, 196, 198.
- Taylor, Dr. A., on precipitation of gelatin, 68; on poisonous change in meat, 387; on protracted gestation, referred to, 983 *note*.
- Taylor, Mr., on Duverney's glands, 962 *note*.
- Tessier, M., his cases of protracted gestation, 983.
- Theile, Prof., on hypospadias, 1005 *note*.
- Thomson, Prof. A., on proportion of water in the tissues, 100; on intestinal glandulæ, 240, 434, 435; on contraction of muscle, 307; on Peyerian glands, 434, 435; on double monstrosity, 557 *note*, 949.
- Thompson, Dr. R. D., on presence of sugar in blood, 76; on milky serum, 176; on gastric juice, 418.
- Tiedemann and Gmelin, MM., on action of bile in digestion, 431; their experiments on absorption, 444.
- Tilanus, on saliva, 414 *note*.
- Tod, Mr., on duration of irritability of heart, 468.
- Todd, Dr., on structure of mucous membrane of stomach, 415; on artificial epilepsy, 711; on Commissures of Cerebrum, 746; on delirium, 805; on chorea, 836; on epilepsy, 842; on general physiology of Nervous System, referred to, 847 *note* (see Todd and Bowman).
- Todd and Bowman, on areolar tissue, 226 *note*; on structure of cuticle, 248; on ossification, 277; on enamel-pulp, 289; on fibres of olfactory nerve, 337; on conducting power of nerves for electricity, 357; on polar character of nerve-force, 358; on muscular

- layer of bronchial tube, 506; on structure of Spinal Cord, 665; on muscular tension, 700; on peculiar excitability of frog, 701 *note*; on corpora striata and thalami optici, 705; on papillæ of tongue, 865, 866; on olfactory nerve, 871, 872; on adaptation of eye to distances, 876; on cochlear nerve, 896.
- Tomes, Mr., on granular structure of bone, 270; on ossification, 277; on ununited fracture, 282; on structure of dentine, 284, 285; on calcification of dentine, 287, 288; on formation of enamel, 289.
- Toynbee, Mr., on nutrition of cartilage, 261; on vessels of cornea, 264; on structure of kidney, referred to, 595 *note*; on membrana tympani, 899.
- Trall, Dr., on fat in the blood, 190.
- Travers, Mr., on formation of capillaries, 302.
- Treviranus, on complementary nutrition, 210.
- Trommer, M., on absorption of sugar into lacteals, 76.
- Trousseau, M., on suspended lactation, 1021.
- Turck, Dr., on pathological changes in Spinal Cord, 836.
- Turley, Mr., his case of excessive sexual desire, 739 *note*.
- U.
- Unzer, Prof., on reflex action, 672; his general Physiology of the Nervous System, referred to, 847 *note*.
- V.
- Valentin, Prof., his estimate of amount of blood, 155; on filtration of albuminous fluids, 231; on development of muscle, 313; on *post-mortem* contraction of intestinal tube, 334; on degeneration of optic nerve and retina from disuse, 345; on sense of hunger, 391, 392 *note*; on movements of stomach, 407; on movements of intestinal canal, 409; on excitement of heart's action by irritation of the pneumogastric, 469; on sounds of heart, 477; on amount of blood discharged from heart, 478; on rate of blood's movement in capillaries, 497; on excitability of mucous surface of trachea and bronchi, 518; on quantity of air respired, 523; on interchange of gases in respiration, 525; on columns of spinal cord, 670; on roots of pneumogastric, 688; on spinal accessory, 691; on hypoglossal, 692; on cephalic nerves generally, 695; on olfactory nerves, 714; on motor actions of sympathetic nerves, 830; on tactile sensibility, 859; on evolution of ovum, 958; on discharge of ovum from ovisac, 963.
- Van Deen, on columns of Spinal Cord, 669.
- Vanner, his estimation of the quantity of blood, 155.
- Verdeil, on creatine and creatinine in blood, 174; on composition of ashes of blood, 174.
- Vierordt, on quantity of air respired, 523; on percentage of carbonic acid in expired air, 524; on circumstances affecting this, 526-529.
- Villermé, M., on infantile mortality, 630.
- Virchow, on hæmatoidin, 66; on fatty degeneration of uterus after parturition, 553.
- Vogt, his cases of paralysis of fifth pair, 688; on changes in germinal vesicle, 969.
- Volkman, Prof., on muscular contraction, 319; on sympathetic nerve-fibres, 338; on glossopharyngeal nerve, 403; on sounds of heart, 476; on amount of blood discharged from heart, 478; on force of heart's contraction, 481; on rate of pulse in the aged, 481; on the influence of stature on the pulse, 481; on pressure of liquids within rigid tubes, 487; on dilatation of arteries by pulse-wave, 487; on transmission of pulse-wave, 487; on rate of movement of blood in arteries, 488; on hæmodrometer, 488-489; on lateral pressure of blood within arteries, 490; on rate of blood's movement in capillaries, 497; on contractility of bronchial tubes, 509; on discrimination of sensory impressions, 653; on structure of Spinal Cord, 665-667; on motor roots of pneumogastric, 688; on refractive power of eye, 883.
- Von Ammon, Dr., on influence of passion on mammary secretion, 944, 945.
- Vrolik, Prof., on double monstrosity, 557 *note*, 949; on varieties in form of plevis, 1036.
- W.
- Wade, Sir Claude, his case of Trance, 1058 *note*.
- Wagner, Prof., on termination of nerves in muscle, 312 *note*; on motor roots of pneumogastric, 688; on tactile papillæ, 858; on spermatozoa, 954, 955; on changes in germinal vesicle, 969.
- Wallace, Dr. Clay, on adaptation of eye to distances, 876.
- Waller, Dr., on papillæ of tongue, 238, 866 *note*; on degeneration of nerve-fibres after section, 346; on influence of sympathetic over movements of pupil, 831.
- Wallis, Mr., his case of deficient encephalic power, 363, 400 *note*.
- Walshe, Dr., on cancerous cachexia, 574 *note*.
- Ward, Mr., on movements after death from cholera, 327.
- Wardrop, Mr., on influence of passion on mammary secretion, 945 *note*.
- Wartmann and Seebeck, on Daltonism, 893.
- Wasmann, on pepsin, 419, 420.
- Watson, Dr., on absorption of vapor, 447.
- Weber, Profrs., on development of blood-corpuscles in liver, 167, 450; on muscular contraction, 308, 318; on epithelium-cells of intestinal villi, 441; on arrestment of heart's action by electro-magnetic current, 470; on effects of electro-magnetic current on small arteries, 484; on capillaries, 494; on acceleration of blood by contraction of arteries, 487; on rate of blood's movements in capillaries, 497; on size of pulmonary air-cells, 507; on tactile sensibility, 859-861; on sensibility of tongue, 864; on sounds of vibrating reeds, 930; on formation of decidua, 972, 974; on vesicula prostatica, 1003, 1005 *note*; on varieties of form of pelvis, 1036.
- Webster, Dr., his case of softening of Spinal Cord, 669.

- Wheatstone, Prof., on Stereoscope, 885-888 ;
on falsetto voice, 933.
- White, Mr., his case of reproduction of super-
numary thumb, 561.
- Whitehead, Mr., on menstrual fluid, 960.
- Williams, Dr. C. J. B., on destruction of blood-
corpuscles, 188 ; on colorless corpuscles,
205 ; on ulceration of Peyerian glandulæ,
221, 435 *note* ; on elimination of morbid
poisons, 222 ; on force required to propel
the blood, 467 ; his experiments on the toni-
city of bloodvessels, 485, 488, 499 ; on con-
tractility of bronchial tubes, 509, 510 ; on
maintenance of animal heat by artificial re-
spiration, 626 ; on death, 1057 *note* ; from
necræmia, 1056.
- Wilson, Dr. G., on fluorine, 104.
- Williams, Dr. Robert, on morbid poisons, 222.
- Williams, Dr. T., on hepatic follicles, 582 ; on
disintegration of hepatic cells, 590.
- Wilson, Mr. E., on follicular parasite, 244 ; on
growth of nails, 250, 251 ; on diameter of
hair, 251 ; on muscular fibrilla, 305, 306
note ; on congestion of liver, 588 *note* ; on
sudoriparous glandulæ, 611.
- Willis, Mr., on the voice, 935 ; his artificial
glottis, 931 ; on vowel sounds, 937.
- Wollaston, Dr., on development of sound by
muscular contraction, 330 ; on optic chiasma,
717 *note*.
- Wright, Dr., on composition of saliva, 412.
- Wrisberg, on loss of blood, 155.
- Wohler, on urea in humors of eye, 82 ; on
metamorphosis of uric acid, 84 ; on action
of soluble salts on kidneys, 609.

Y.

- Yarrell, Mr., on assumption of male plumage
by female, 212.

Z.

- Zanarelli, on fat in the blood, 190.
- Zander, on succus entericus, 432.
- Zimmermann, Dr., on effect of saline solutions
on fibrin, 60 ; on nature of fibrin 63 *note* ;
on effects of loss of blood, 178.
- Zwicky, on organization of blood-clot, 194.

INDEX OF SUBJECTS.

A.

- ABERRATION**, spherical and chromatic, 874.
- Abnormal forms of Nutritive process**, 566-574; inflammation, 566-572; tuberculosis, 572-574; heterologous growths, 573.
- Abortion**, 981.
- Abscesses, formation of**, 567-572.
- Absence of Mind**, 797.
- Absorbent Cells**, 439, 441.
- **System**, 438, 439, 451; movement of fluids through, 454, 455.
- **Vessels, structure and development of**, 298; see *Lacteals*, and *Lymphatics*.
- ABSORPTION**, general nature of the function, 365, 438, 439; by bloodvessels of intestinal surface, 439, 440, 443-445; by lacteals, 439-442; by lymphatics, 445, 449, 451, 452; by general sanguiferous system, 449-452.
- Of vapors by lungs, 534, 535.
- Of effete tissues, 448, 449.
- Abstinence, entire**, 397.
- Abstraction, mental**, 793; voluntary, 795, 796; involuntary, 797-799.
- Activity, varying, of nutritive processes**, 554-566.
- , **Vital, conditions of**, 140-148; variations of, with age, 149-153; relation of to duration of organism, 134, 554; to amount of heat supplied, 143-146.
- Acardiac fœtus, movement of blood in**, 493.
- Acidity of the urine**, 608-609.
- Adaptiveness of movements no proof of sensation**, 674.
- Adhesion between cut surfaces**, 562; secondary, 565.
- Adipocere**, 71.
- Adipose Tissue, structure of**, 256, 257; development of, 258, 259; uses of, 259.
- Adult age, peculiar attributes of**, 152.
- Aeration, see Respiration**.
- Afferent nerve-fibres**, 651, 653.
- Affinities, Chemical, operation of, in the living body**, 112.
- Age, influence of, on nutritive activity**, 149-153; on rate of pulse, 481; on excretion of carbonic acid, 530; on excretion of urea, 602; on power of calorification, 629-631.
- of *Fœtus*, means of determining, 1012, 1013.
- Air, amount of, used in respiration**, 522-523; changes in proportions of oxygen and carbonic acid, 524-525; amount of carbonic acid imparted to, 526-531; changes in proportion of nitrogen, 531, 532; watery vapor imparted to, 533, 535.
- Air-cells of lungs, structure of**, 504, 505.
- Albinoism**, 1030.
- Albumen, composition and properties of**, 54, 55; its presence in the solids and fluids of the body generally, 56; conversion of, into fibrine, 60-64, 157, 161, 453; normal proportion of, in blood, 161-170; variations in amount of, in disease, 184; its uses, 54, 63, 205, 206.
- Albuminose**, 182, 427.
- Albuminous Compounds**, 53, 91.
- **principles of Food**, 376-385.
- Albuminuria, blood in**, 189.
- Alcohol, rapid absorption of**, 443.
- Alcoholic drinks, their effects on the system**, 389-390; uses of, in *Fever*, 624.
- Alfourous**, 1052.
- Aliment, sources of demand for**, 363, 364; see *Food*.
- Alimentary canal, development of**, 999.
- Alkaline Carbonates, uses of, in the system**, 103, 107.
- **Phosphates, uses of, in the system**, 108; presence of, in urine, 606; amount of, proportional to waste of nervous matter, 355.
- **Sulphates, presence of, in the system**, 110; in urine, 605.
- Alkalinity of the urine**, 607, 608.
- Allantoin**, 84.
- Allantois, development of**, 993, 994; formation of urinary bladder from, 1002.
- Alloxan**, 84.
- American races**, 1050, 1051.
- Ammonia, a product of decomposition**, 109.
- Amnion, formation of**, 990, 991.
- Amphibia, spinal cord of**, 663.
- Amphioxus, nervous system of**, 646, 706.
- Anæmia, state of blood in**, 186.
- Analysis of Blood, different methods of**, 170-172; in disease, 185.
- Ancon breed of sheep**, 1037 *note*.
- Animal Functions**, 371; their relations to the *Organic*, 372-374.
- **Heat**; see *Heat*, *Animal*.
- **Magnetism**; see *Mesmerism*.
- Anterior Columns of Spinal Cord, structure of**, 659-661; functions of, 668-671.
- **Commissure**, 742.
- **Pyramids of Medulla Oblongata**, 677-681.
- Anthropomorphism**, 794-795.

- Aorta, development of, 992; contraction of, produced by irritation of Sympathetic, 470.
 Aplastic exudations, 569, 570.
 Aponeuroses, structure of, 224.
 Apoplexy, state of blood in, 187.
 Apparent Death, 1057.
 Arab races, 1044.
 Arciform fibres, 677.
 Area germinativa, 989.
 — pellucida, 989.
 — vasculosa, 991.
Areolar Tissue, structure and composition of, 226; development of, 227.
 Arian race, 1043-1046.
 Arrest of Development, 548; of circulating apparatus, 999; of sexual organs, 1004; of visceral arches of face, 1008 *note*.
 Arsenic, occasional presence of, in the body, 110; elimination of, 111, 215.
 Arterial and Venous blood, differences of, 181-185.
 — system, first development of, 995, 996; subsequent changes in, 997-998.
Arteries, movement of Blood in, 482-490; diameters of, 482; properties of coats of, 226, 483; irritability of, 483; influence of nerves upon, 483; influence of electrical and other stimuli on, 484; tonicity of, 485; regulation of diameter of, 486; elasticity of, 486, 487; pulsation of, 487, 488; rate of movement of blood in, 488, 489; lateral pressure of blood in, 490.
 Articulate sounds, production of, 935-940; vowels, 935-937; consonants, 937.
 Articulation, movements of, guided by sensations, 722, 723, 934.
 Artificial Respiration, partial sustenance of heat by, 626.
 Arum, liberation of heat by flowers of, 621.
 Arytenoid cartilages, movements of, 925-927.
 — muscles, actions of, 927, 928.
 Asphyxia, pathology of, 535-537; in relation to capillary circulation, 493, 494; death by, 535, 1056.
Assimilation, general nature of the function, 365, 366.
 Association of Ideas, laws of, 775-780.
 Asthenia, death by, 1056.
 Asthma, spasmodic, pathology of, 846.
 Atlantidæ, 1044.
 Atrophy, 547; conditions of, 558-560.
 Attention, state of, 780, 781; its share in perception, 759; in higher intellectual processes, 788; voluntary, 795, 796; influence of, on intensity of sensations, 849, 850, 855, 856; in producing muscular movements, 920-924; on organic changes, 947, 948.
 Auditory Ganglia, 680, 702; functions of, 708.
 — Nerves, endowments of, 717; ultimate distribution of, 894-896.
 Auricles of Heart, action of, 472-474; capacity of, 475.
 Australian race, 1053.
Automatic actions, of Spinal Axis, 695-699; of Sensory Ganglia, 719-722; their instrumentality in voluntary movement, 722-728; of Cerebrum, 774, 775, 788, 789; sleep prevented by them, 819, 820; of Nervous System in general, 831; their subordination to the Will, 831.
 Axioms, fundamental, of human thought, 785-788.
 Azote; see Nitrogen.
- B.
 Barclay, Capt., case of, 822.
 Barrackpore, mortality in barracks at, 544.
 Basement-membrane, 139.
 Basque race, 1043, 1044.
 Beauty, elementary notion of, 785.
 Bee, manifestations of instinct in, 643, 749; modification of development by food in, 212; development of heat in, 622.
 Berber races, 1044.
 Bellary, cholera at, 541.
 Benzoic Acid, 87.
Bile, secretion of, from venous blood, 591; excrementitious nature of, 592, 594; partly formed from products of disintegration, 98, 591, 592; in part from newly-absorbed materials, 592; effects of suspension of, 592, 593; reabsorption of, 592; general composition of, 593; individual components of, 94-98; quantity of, secreted, 431; uses of, in digestion, 430, 431.
 Bile-Pigment, 96, 97.
 Biliary cells, 587; fatty degeneration of, 589, 590.
 — secretion, metastasis of, 579, 580.
 Bilifulvin, 97.
 Bilin, 95.
 Biliphæin, 96.
 Biliverdin, 97.
 Biological state, phenomena of, 797-799.
 Birds, temperature of, 622; effects of starvation on, 623, 624; spinal cord of, 663; sensory ganglia of, 706-709; cerebellum of, 729; cerebrum of, 746, 747, 1009; intelligence and educability of, 749, 750.
 Binocide of protein, 64, 65.
 Bladder, contraction of, 318, 410.
 Blastema, formative, 127, 128; fibrillation of, 228.
 Blastodermic vesicle, 989.
 Blind persons, acuteness of touch in, 862.
 Broom, general purposes of, in the economy, 153, 154; quantity of, in Man, 154, 155; physical characters of, 156, 157.
 Chemical Composition of, 170-174; modification of, by age, 174, 175; by sex, 175; by food and drink, 176, 177; by loss of blood, 178; differences of Arterial and Venous, 178-181; peculiarities of portal blood, 181, 182; of splenic blood, 182, 183; of hepatic vein, 183, 184; of renal vein, 184.
 Pathological Conditions of, 184-191; increase of fibrin, 185, 186; diminution of fibrin, 186, 187; increase of red corpuscles, 187; diminution of red corpuscles, 188; increase of colorless corpuscles, 188; diminution of albumen, 189; increase of fatty matter, 189, 190; altered proportion of salts, 190; increase and diminution of water, 190; presence of poisons in, 191; alterations of, in inflammation, 185-190, 567-569; buffy coat of, 198-200; inflammatory effusions from, 569-572.
 Vital Properties of, 191, 192; coagulation of, 193-198 (see Coagulation); uses of fibrin of, 201-202; uses of corpuscles of, 203-206; uses of albumen of, 207; uses of fatty matters of, 207; uses of inorganic components of, 208; purification of, by excretory processes, 209, 210; composi-

- tion of, determines nutritive operations, 211, 212; life of, 212, 221; self-maintaining power of, 213; elimination of poisons from, 214-215; contamination of, by morbid poisons, 215-222.
- Blood of Mother, influence of state of, on embryonic development, 969, 970, 1011, 1012.
- Blood-Corpuscles*, Red, form, size, and aspect of, 157-159; composition of, 160, 161; influence of reagents on, 162; tendency to aggregation of, 163; production of, 165; development of, in embryo, 165, 166; subsequent development from lymph-corpuscles, 167-170; change of color in, by respiration, 180, 181; their uses, 203, 204; variations in amount of, in disease, 187, 188; destruction of, 188; mutual attraction of, in coagulation, 193, 199; adhesion of, to walls of vessels, 494.
- Colorless, form, size, and aspect of, 163, 164; changes of form of, 164; numerical proportion of to red, 164, 165; development of, into red, 167-170; their uses, 204-206; variations in amount of, in disease, 188, 189.
- Bloodvessels, development of, in vascular area, 165, 300, 991 (see *Arteries*, *Veins*, and *Capillaries*).
- Bone*, structure of, 267-269; composition of, 270-272; development of, 272-277; growth of, 279, 280; irregular production of, 280, 281; regeneration of, 281, 282.
- Brain; see *Cerebrum*, *Cerebellum*, and *Sensory Ganglia*.
- Branchial arches, 992.
- Breeds of animals, origination of new, 1037.
- Bronchial tubes, contractility of, 509, 510.
- Brunner's Glands, 240, 428.
- Buffy coat of blood, 198-200.
- Bulbus arteriosus, 992.
- Bushmen of Southern Africa, 1040, 1049, 1050.
- Butyrin, 1023.
- C.
- Caco-plastic deposits, 572.
- Calcium, fluoride of, its presence in the body, 104.
- Calcutta, Black Hole of, 538.
- Callus, formation of, 282.
- Calorification, theory of, 628, 629 (see *Heat*, *Animal*).
- Canaliculi of Bone, 269; formation of, 276, 277.
- Cancelli of Bone, 267.
- Cancerous growths, 558, 573.
- Capacity, germinal, 149; gradual diminution of, with advance of life, 150-153.
- vital, of Respiration, 521-522.
- Capillarity, influence of, on chemical reaction, 116.
- Capillary Bloodvessels*, structure of, 298, 299; offices of, 299, 300; development of, 300-302.
- Circulation of blood in, 491-497; continuous flow through, 500; independent of heart's propulsion, 492, 493; variations in movement, not influenced by heart, 493; influence of alterations in diameter on, 494, 495; general doctrine of, 495, 496; effect of shock on, 496, 497; rate of movement in, 497.
- Carbolic acid, 539 *note*.
- Carbonate of Lime, uses of, in the body, 103.
- Magnesia, its presence in the body, 110.
- Carbonic Acid*, in Blood, 179; absorption of, by serum, 108; by red corpuscles, 162; sources of production of, in System, 502-504; its exchange for oxygen in respiration, 524-525; quantity of, generated, 525-530; extrication of, by skin, 529, 530; elimination of, by atmosphere of nitrogen or hydrogen, 531.
- Cartilage*, simple cellular, 259, 260; duplication of cells of, 126; nutrition of, 261-263; ulceration and reparation of, 261; fibrous, 260.
- Casein*, chemical composition and properties of, 56, 57.
- of human milk, peculiarities of, 1023, 1024.
- Catalepsy, state of, 1058; rigidity in, 828.
- Catamenial flow, see Menstruation.
- Caucasian race, 1042; color of, 1031.
- Cause, proper meaning of the term, 35.
- Cell-Force, manifestations of, 129, 130, 133.
- Cells*, the types of Organization, 358; independent life of, 124, 358; general history of, 120-136; form of, 121; wall of, 121; contents of, 122; nuclei of, 123; multiplication of, by duplication, 125, 126; endogenous development of, 126, 127; development of, in blastema, 127, 128; evolution of, from granules, 128.
- Vital operations of, 129; changes of form of, 129-131; movement of particles within, 130; motility of, 130, 131; ciliary movement of, 131; development of nerve-force by, 132, 133; reciprocity of actions of, 133, 134; duration of, 134, 135; influence of physical and chemical forces on, 135-137.
- Cellular tissues, albuminous composition of, 63, 112.
- Celtic race, 1043.
- Cementum, structure of, 286, 287; composition of, 286; development of, 290.
- Cephalic Ganglia of Invertebrata, 706.
- Nerves, general character and relations of, 693, 695.
- Cerebellum*, general structure and relations of, 947; particular account of, 728-740; relative development of, in different animals, 729-732; results of experiments on, 732, 733; pathological phenomena of, 733, 734; its instrumentality in co-ordinating movements, 728-734; supposed by some to be seat of sensation, 734, 735; by others to be organ of sexual instinct, 735; facts in opposition to this view, 736-738; probably contains centre of sexual sensation, 739, 740; but not the seat of desires and emotions prompted by this, 740.
- Cerebration, unconscious, 784, 790-792.
- Cerebric Acid, 75.
- Cerebro-spinal fluid, 747.
- Cerebrum*, general structure and physiological relations of, 374, 647, 741, 832; pathological relations of, 833-836; its relative inferiority to sensory ganglia in lower animals, 705, 706.
- Leading features of its structure, 741-746; comparative weight of, in different animals,

- 746, 747; peculiarity of its circulation, 501; immediate dependence of its activity on supply of blood, 353.
- Its functional relation to Intelligence, as contrasted with Instinct, 748-754; its operations excited by reception of Sensations, 754, 755; but not themselves necessarily attended with Consciousness, 755-757, 784, 790-792; formation of Ideas, 755, 756; first stage consists in Perception, 758-761; connection of Emotional states with ideas, 761-769; uniformities of mental action exhibited by, 770; general relation of its functional changes to psychical activity, 770-774; these changes conformable to law of reflex action, 773, 775, 788, 789; influence of the Will upon their succession, 775, 788-790, 795-796, 810-814, 817-818; growth of, in accordance with its habitual action, 776, 783, 792, 810, 812.
- State of, in Sleep, 819, 820; cases of suspended activity of, 837, 838; development of, 1009, 1010.
- Ceruminous Glands, 245.
- Chaetodon rostratus, instinct of, 761.
- Chemical Forces, operation of, in the living body, 116-118.
- Chiasma of Optic nerves, 714-716.
- Childhood, peculiar attributes of, 151, 152.
- Chimpanzee, comparison of, with Man, 41-49.
- Chloride of Sodium, a constituent of the body, 105; its uses in the economy, 105, 106; its presence in the urine, 607.
- Chlorosis, state of blood in, 188; buffy coat in, 200.
- Choleic Acid, 95.
- Cholepyrrhin, 96.
- Cholera, influence of putrescent Food in developing, 388; influence of imperfect Respiration in developing, 539-541; movements after death from, 326, 327.
- Cholesterin, its composition and properties, 74.
- Cholic Acid, 94.
- Choloidic Acid, 95.
- Chondrin, chemical composition and properties of, 67, 68.
- Chorda dorsalis, 990; transformation of, 1005.
- tympani, participation of, in sense of taste, 718.
- Chordæ vocales, 925; structure of, 226; length of, 919; alterations in tension of, by muscular action, 926, 928; compared with vibrating strings, 929, 930; with flute-pipes, 929, 930; with reed instruments, 931-932; their mode of vibration in falsetto voice, 933, 934.
- Chorea, pathology of, 767, 836.
- Chorion, formation of, 971; villi of, 974, 975.
- Chromatic aberration, 874.
- Chyle, composition and properties of, 451-453; corpuscles of, 453; absorption of, 441, 442; changes effected in, during passage to thoracic duct, 453, 454; milky aspect of, due to fat, 72; molecular base of, 452, 453.
- Chyme, formation of, by digestive process, 424-428.
- Ciliary Ganglion, 684.
- Movement, 131, 236, 237.
- Cineritious substance of brain, 339.
- CIRCULATION, general plan of, 383, 466-467; action of Heart in, 468-482 (see *Heart*); action of Arteries in, 482-490 (see *Arteries*); action of Capillaries in, 491-497 (see *Capillaries*); action of Veins in, 497-500 (see *Veins*); peculiarity of, in cranium, 500, 747, 748; in erectile tissues, 501.
- Circulation, in Fœtus, early type of, 992-995; changes in plan of, 995-996; plan of, in mature fœtus, 996, 997.
- of fluid within cells, 130.
- Cirrhosis of liver, 589.
- Civilization, influence of, on form of skull, 1034, 1035; on body in general, 1036.
- Classification, mental tendency to, 777.
- Clitoris, development of, 1004.
- Cloaca, of Human embryo, 1002, 1003.
- Coagulable lymph, 570; see *Lymph*.
- Coagulation of Albumen, 55.
- of Casein, 56, 57.
- of Fibrin, 60; circumstances affecting it, 61; its vital nature, 62.
- of *Blood*, 193-202; essentially due to solidification of fibrin, 193; an act of vitality, 194; occasional deficiency of, 194; retardation of, 194-196; effect of external influences on, 194-197; influence of rest, 195; influence of warmth, 195; effect of neutral salts, 195; non-effect of surrounding atmosphere, 195; influence of depressed vitality or death of vessels, 196; influence of admixture of dead matter, 197; varying proportions of serum and clot, 198.
- Cochlea, functions of, 905.
- Cochlear nerve, distribution of, 896.
- Cod, brain of, 647.
- Cod-liver oil, rationale of its use, 73, 74.
- Codrington, Sir E., case of, 823.
- Coition, act of, in male, 956; in female, 962, 963.
- Cold, influence of, on muscular tonicity, 331; power of enduring, 619; production of, by cutaneous exhalation, 631; death by, 623, 624, 1056.
- Coldbath-fields prison, cholera at, 542.
- Coleridge, automatic action of his intellectual powers, 780 *note*.
- Colostrum, 1025.
- Color, variation of, in Man, 1030-1031.
- Coloring matters of Bile, 96, 97.
- of Urine, 92.
- of Red Corpuscles, influence of reagents on, 180, 181.
- Colorless Corpuscles, see *Blood-Corpuscles*, *Colorless*.
- Colors, complementary, 891; modifications in, by proximity, 892; want of power of discrimination for, 892.
- Commissural fibres of Cerebrum, 741-746.
- Commissure, transverse, of Spinal Cord, 661-662.
- Commissures, case of deficiency of, 746 *note*.
- Comparison, mental tendency to, 777; intentional exercise of, 788, 789.
- Complemental Nutrition, 211, 212.
- Complementary Colors, 891, 892.
- Compound Association, law of, 779.
- Complexion, variation of, in Man, 1030-1031.
- Conception, act of, 979.
- Concussion of Brain, 313, 314.
- Conduct, determination of, by the will, 811; influence of motives on, 812-813.
- Conduction of sounds, 897, 898.
- Conjugated Acids, 87 *note*.
- Conjugation, among simple cellular Plants, 949, 950.
- Conscience, nature of, 814-816.

- Consciousness, seat of, in the Sensory Ganglia, 706, 707; probably not in the Cerebrum, 755-757; perceptive, 757-761; emotional, 761-769; intellectual, 769-790.
- Consensual Actions, 350, 374, 398; performed by instrumentality of Sensory Ganglia, 648, 719-722.
- Consonants, articulation of, 937-940.
- Constructive Association, law of, 779.
- Contiguous Association, law of, 776.
- Contractility of Muscle, 317; see *Muscular Fibre*.
- Contraction of Muscle, state of fibres in, 306-308; see *Muscular Fibre*.
- Contractions, Muscular, after death, 326, 327; rhythmical, 319 *note*.
- Convergence of optic axes, 916.
- Convulsions of Brain, 742.
- Convulsive diseases, pathology of, 843-846.
- Copper, occasional presence of, in body, 111.
- Copulation, act of, in male, 956, 957; in female, 962.
- Corium, structure of, 241, 242; nutrition of, 246.
- Cornea, structure of, 263, 264; nutrition of, 264, 265.
- Corpora Malpighiana of Spleen, 456; of Kidney, 594-598; uses of, 599.
- Olivaria, 677-682.
- Pyramidalia, 677-682.
- Quadrigemina, 702; functions of, 707, 708.
- Restiformia, 677-682.
- Striata, 703, 705; functions of, 708-710.
- Wolfiana, 1001, 1002.
- Corpus Callosum, 744; deficiency of, 746.
- Dentatum, 678.
- Luteum, structure and formation of, 863-966.
- Corpuscles of Blood (see *Blood-Corpuscles*); of Chyle, 453; of Lymph, 454.
- Corpuscular lymph, 570, 571.
- Correlation of Vital and Physical Forces, 141-146; of Nervous and Electrical Forces, 356-358; of Nervous and Mental Forces, 772-775.
- Cortical substance of Brain, 339; of Kidney, 610, 611.
- Coughing, act of, 519.
- Cranio-spinal Axis, 645, 646, 659.
- Cranium, circulation within, 500, 747.
- Crassamentum of Blood, 157, 193; proportion of, to Serum, 198.
- Creatine*, composition and properties of, 89, 90; sources of, in the body, 89, 90; its presence in the Blood, 174 *note*; in the Urine, 604.
- Creatinine*, composition and properties of, 89, 90; sources of, in the body, 89, 90; its presence in the Blood, 174 *note*; an important component of Urine, 603.
- Croup-like Convulsion, 846.
- Croupous exudation, 570.
- Crura Cerebri, effects of division of, 710, 711.
- Crusta petrosa, structure and composition of, 286, 287; development of, 290.
- Crustacea, decapodous, independent vitality of their spermatic cells, 102.
- Crying, act of, 518.
- Cryptogamia, generation in, 949, 950.
- Crystalline Lens, structure and nutrition of, 265.
- Cutaneous Asphyxia, 613, 633, 634.
- Glandulæ, 242-245, 611.
- Cutaneous Transpiration, 611-614; composition of, 612; quantity of, 612, 613; excrementitious nature of, 613, 614.
- Cuticle, see *Epidermis*.
- Cutis, structure of, 241, 242; nutrition of, 246.
- Cyclostome Fishes, chorda dorsalis of, 1005; sympathetic system of, 659.
- Cystine, 93, 94.
- Cysts, piliferous and dentigerous, 558.
- Cytogenesis, different modes of, 125-127.
- D.
- Deaf and dumb, their want of command over muscles of vocalization, 722, 723; their sign-language, 759 *note*.
- Death*, the necessary consummation of Life, 134, 135, 1054; different modes of, 1055-1056; somatic, 1055, 1056; molecular, 1054-1057; apparent and real, 1057, 1058; signs of, 1058, 1059.
- Decidua, formation of, 972-974.
- Decline of life, 152, 153.
- Decussation of Optic Nerves, 716.
- Defecation, act of, 410, 411.
- Degeneration* of tissues, 549, 550; of muscular substance, 553, 559; increased tendency to, in inflammation, 567, 568; of lymph and its products, 571, 572 (see *Fatty Degeneration*).
- Deglutition, 401-404.
- Deity, notions respecting, 786-788.
- Dental groove, 290-295.
- Dentine, structure of, 283-285; composition of, 287; development of, 287, 288.
- Dentition, first, 290-295; second, 296, 297.
- Desires, formation of, dependent on ideas, 740, 761.
- Development, a source of demand for nutrition, 548; its difference from growth, 548; arrest of, 548, 995, 1004, 1008 *note*.
- Development of Embryo*, 985-1018; general plan of, 985-987; earliest stages of, 987-989; segmentation of yolk, 987-989; formation of blastodermic vesicle, 989; foundation of vertebral column, 990; development of amnion, 991, 994; vascular area, 991; vitelline vessels, 991; heart and arterial system, 992, 995-998; allantois, 993; umbilical vessels and placental villi, 994; venous system, 995, 996; alimentary canal, 999; liver, 999, 1000; lungs, 1000-1001; urinary organs, 1001, 1002; generative apparatus, 1002-1005; skeleton, 1005, 1006; cranium, 1007, 1008; nervous centres, 1008-1010; cephalic nerves, 693, 695; eye, 1010; ear, 1010, 1011; spleen, 458; suprarenal bodies, 459, 460; thymus gland, 460, 461; thyroid gland, 461.
- Influence of mother on, 1011, 1012.
- General progress of, 1012-1017.
- Development of Tissues*, 120; fibrous, 138, 139, 227, 228; epithelium, 237; glandular follicles, 239, 240; sebaceous glandulæ, 244; epidermis, 248; nails, 250, 251; hair, 254-256; fat-cells, 256; cartilage, 261; bone, 272-277; dentine, 287, 288; enamel, 288, 289; cementum, 290; milk-teeth, 291-295; permanent teeth, 295-297; capillary blood-vessels, 300-302; absorbents, 302; muscular fibres, 313-315; nervous tissue, 346.
- Deutencephalon, 1009.

Diabetic sugar, 77 *note*.
 Diaphragm, movements of, 511.
 Diarrhœa, eliminative agency of, 437, 438.
 Dichrotous pulse, 487.
 Diet, animal and vegetable, 379-381; influence of, on composition of blood, 177, 178; of urine, 602-605.
 Diet-scales, 384, 386.
 Dietetics, general principles of, 381-383.
 Digestion, general nature of, 364, 365.
 Gastric, 424-427; a process of chemical solution, 424; influence of various conditions on, 425, 427; limited to azotized substances, 426.
 Intestinal, 428-433; influence of pancreatic fluid in, 428, 429; influence of bile in, 430, 431; influence of succus entericus in, 429, 432, 433.
 Direction, visual appreciation of, 883; auditory appreciation of, 908.
 Discus proligerus, 958, 963, 971, 972.
 Disintegration of tissues, continual during life, 134, 361, 546, 549, 550, 552-554.
 Distance, visual appreciation of, 888, 889; auditory appreciation of, 908.
 Diuretic medicines, influence of, 609-611.
 Diverging Appendages of vertebra, 1006.
 Divining-rod, rationale of, 922, 923.
 Dominant ideas, influence of, in determining the course of thought, 796, 798, 800, 811.
 Double Monsters, 557, 949.
 Draught in mammary gland, 943.
 Dreaming, phenomena of, 802-804, 811.
 Dublin Lying-in Hospital, high rate of mortality in, 545.
 Ductless Glands, 456; see *Spleen, Suprarenal, Thymus, and Thyroid bodies*.
 Ductus Arteriosus, 995, 998.
 — Cuvieri, 996.
 — Venosus, 995-998.
 Duplicative subdivision of Cells, 125, 126.
 Duration of Cell-life, 134, 135; varying, of different parts of the fabric, 549, 550; inverse ratio of, to vital activity, 134.
 Duty, idea of, 814-816.
 Duverney's glands, 962.
 Dyslysin, 95.

E.

Ear, general action of, 894; comparative structure of, 894-899; distribution of auditory nerve in, 894-896; acoustic principles of, 896-899; uses of, middle, 899-901; internal, 901, 902; external, 906; development of, 1010, 1011; (see *Hearing*).
 Earthy Phosphates in Urine, 606, 607.
 Ectopia Cordis, case of, 478.
 Efferent nerve-fibres, 651, 654.
 Egg-shell, fibrous tissue of, 62.
 Eighth Pair of Nerves; see *Pneumogastric*.
 Ejaculatio Seminis, 956; its independence of sensation, 695, 696, 698.
 Elastic Fibrous tissue, 224-226.
 Elasticity of Arteries, 486.
 Electricity, relation of, to nerve-force, 356-358; influence of currents of, on muscles, 318, 319; on rigor mortis, 333; on movements of heart, 469; on contraction of arteries, 484; connection of, with nutritive and secretory operations, 634.

Evolution of, in living body, 633, 634, 640; disturbance of, in muscular contraction, 329, 636-637; muscular current of, 634-637; nervous current of, 637-639; peculiar cases of, 640.
 Electro-biological state, 797-799.
 Electro-tonic state of nerves, 638, 639.
 Elliptical skull, 1034, 1035.
 Embryo-cell, 988.
 Embryo, general development of, at different ages, 1012, 1013 (see *Development of Embryo*).
 Embryonic life, peculiar condition of, 148, 149.
 Emotions, composite nature of, 761, 762; their direct action on the automatic apparatus, 763-764; their influence on the intellectual processes, 765; their expenditure in bodily change, 765, 766; their perverted action in hysteria, 767, 845, 846; in insanity, 766 *note*, 806-809; their influence on volitional movements, 768, 769; their unconscious action, 791, 792; influence of, on stammering, 940; on heart's action, 474.
 Emulsification of fat in duodenum, 429.
 Enamel, structure of, 285; composition of, 286; development of, 288-290.
 Encysted embryos, 558.
 Encephalon, 990, 1009.
 Encephalon of Man, its proportion to Spinal Cord, 746; supply of blood to, 747 (see *Cerebrum, Cerebellum, and Medulla Oblongata*).
 Epidermis, structure of, 246-248; development of, 248; pigment-cells in, 248-250; appendages to, 250-256.
 Epilepsy, pathology of, 841, 842; artificial, induced by irritation of mesocephale, 710.
 Epithelium, forms of, 235, 236; ciliated, 236-237; renewal of, 244.
 Erectile tissues, peculiar structure of, 501.
 Erect vision, 883.
 Ethiopian Nations, 1047-1050.
 European Nations, 1042-1046.
 Euskarian language, 1043, 1044.
 Eustachian Tube, uses of, 901.
 — Valve, uses of, 997, 998.
 Exanthemata, state of blood in, 187, 567, 568.
 Excito-motor actions, 349, 373, 398, 671-676.
 Excrementitious substances, 80.
 EXCRETION, general nature of, 367-368, 575; sources of demand for, 367, 577, 578; statistics of, 576, 577; complementary relation of different modes of, 578; vicarious forms of, 579, 580.
 Exhalation from Lungs, 532, 533; from Skin, see *Cutaneous Transpiration*.
 Exhausting diseases, death by, causes of, 624, 1055, 1056.
 Expectant Attention, production of movements by, 920-924; production of organic changes by, 947, 948.
 Experiments on Nerves, value of, 655-657.
 Expiratory movements, 511; force required for, 512.
 External Ear, 905, 906.
 Externality, elementary notion of, 757, 758.
 Extra-uterine fixation, 968.
 Extractive Matters of Blood, 173.
 — of Urine, 91, 92, 603, 605.
 Exudations, inflammatory, 569-572.
 Exuviation of effete tissues, 552.
 Eye, optical structure of, 874-877; adaptation of, to distances, 876; defects in refractive

power of, 877; nervous organization of, 878, 879; development of, 1010 (see *Vision*).
 Eyes, convergence of, 876, 888; consensual movements of, 912-917.

F.

Facial Angle of Man and Quadrumana, 47.
 — Nerve, 685; its connection with sense of taste, 718.

Fæces, composition of, 435-438; expulsion of, 410, 411.

Faith, curative powers of, 947.

Fakeurs, Indian, simulated death of, 1058.

Fallopian Tubes, passage of spermatozoa through, 962, 963; passage of ova through, 968; formation of chorion in, 971.

False Joints, 232.

Falsetto voice, 933-934.

Faroe Islanders, food of, 388.

Fat; see *Adipose Tissue*.

Fat-Cells, 256, 257.

Fats, saponifiable, 71; their production in the body, 71, 72; their presence in its tissues and fluids, 72, 73; their calorifying power, 73, 74; their use in assimilation and histogenesis, 73, 74.

— non-saponifiable, 74-75.

Fatty Components of the Human body, 69.

— Degeneration, 71, 559; of uterus, after parturition, 553, 980; of biliary cells, 589, 590.

— Matters of Blood, 173; variations in amount of, in disease, 189, 190; uses of, 207, 208.

Fecundation, nature of, 968, 969; seat of, 967, 968.

Female, peculiarities of constitution of, 1017, 1018; pulse of, 481; respiration of, 526, 527; relative viability of, 1015; relative height and weight of, 1016, 1017; function of, in generation, see *GENERATION*.

Fenestra ovalis and rotunda, 901, 902.

Ferment of saliva, 412; of gastric fluid, 427.

Fermented liquors, influence of, on the system, 389, 390.

Ferments, operation of, in the body, 54, 116, 136, 191 (see *Zymotic Poisons*).

Fever, state of blood in, 186, 187; mortality from, 542, 543.

Fibre, Muscular, striated, 303-309; non-striated, 309, 310 (see *Muscular Fibre*).

—, Nervous, tubular, 336, 337; gelatinous, 337.

Fibres, simple, their formation, 138, 139.

Fibrillæ of Muscle, ultimate structure of, 205, 206.

Fibrillation of Fibrin, 60; circumstances affecting it, 61.

Fibrin, distinctive characters of, 58; chemical composition of, 59; reduction of, to albuminous condition, 60; fibrillation of, 60; circumstances affecting it, 61; vital nature of the process, 62; probable use of, in the economy, 63; increase of, by oxygenation, 179.

— of Blood, variations of in disease, 185-187; its share in producing coagulation, 193; its uses, 201-202; larger proportion of, in arterial blood, 178; increase of, in passing through liver, 183.

— of Chyle, 451, 452; increase of, in transit towards sanguiferous system, 453, 454.

Fibrin of Lymph, 451, 454.

Fibro-Cartilage, 260, 261.

Fibro-Cellular Membranes, 229, 230.

Fibrous tissues, 224; white, 224; yellow, 225; areolar, 226; development and reparation of, 227-229; gelatinous composition of, 63, 113.

Fibrous Membranes, structure of, 224.

Fifth Pair of Nerves, general functions of, 683-685; lingual branch of, 687, 688; its action in mastication, 400; influence of, on smell, 872.

Fins, race of, 1045.

Fishes, brain of, 647; spinal cord of, 663.

Flowering Plants, generation in, 950.

Fluids, absorption of, from stomach, 442, 443; from intestinal walls, 438-445; from general surface, 445-448; by lacteals, 439-442; by lymphatics, 448; by bloodvessels, 442-445, 447, 448.

Fluoride of Calcium, its presence in the body, 104.

Flute-pipes, action of, 929.

Flying-fish, spinal cord of, 663.

Fætus, circulation in, 992-999; development of organs in (see *Development of Embryo*); general condition of, at different ages, 1012, 1013; size and weight of, at birth, 1013, 1014.

Follicles of Glands, 239-241; of Mucous membranes, 232, 239; of Lieberkühn, 239.

Food, classification of components of, 375; saccharine and oleaginous constituents of, 376, 381, 382; albuminous constituents, 376, 381; gelatinous constituents of, 377; proportions of carbon and nitrogen in different articles of, 378, 379; most economical combinations of, 379, 380; relative value of animal and vegetable, 379-381; general conclusions regarding its composition, 381-383; quantity of, needed by Man, 384-386; importance of purity of, 387, 388; prehension and ingestion of, 397; relative digestibility of different kinds of, 424, 426.

Force, to be considered as an expression of Will, 37, 773, 787; relation of, to mental action, 772-775.

—, Vital, 119; its manifestations, 141; its relations to Physical forces, 142, 146; variations in degree of, with age, 148-153.

Form, mode of acquiring a knowledge of, by touch, 859; by sight, 882-887.

Formative power of individual parts, 546, 551; excess of, in hypertrophy, 555-558; deficiency of, in atrophy, 559, 560; manifestation of, in reparative process, 560-566; greater energy of, in lower animals and in early stage of higher, 149, 151, 560, 561; deficiency of, in inflammation, 566-568.

Fornix, 746.

Fourth Pair of Nerves, functions of, 685.

Freckles, 249.

Free-will, 775; belief in our own, 785.

Frigorifying process, 631.

Functions, Vital, 359; Organic, 359, 360; Animal, 360, 361; their mutual relations, 361-363.

Fungous growths, 573, 574.

G.

Gall-bladder, contraction of, 432.

Ganglia, nervous structure of, 334, 335.

- Ganglia, Sensory; see *Sensory Ganglia*.
 Gangrene, nature of, 567; spread of, 572.
 Gases of Blood, 179.
 Gastric Follicles, 414, 416.
Gastric Juice, composition of, 417-420; conditions of its secretion, 420-424; uses of in digestion, 424-427; amount of, secreted, 426.
Gelatin; see *Glutin*.
Gelatinous Compounds, 66.
 Gelatinous nerve-fibres, 337.
 Gelatin sugar, 67.
 Geldings, Cerebellum of, 737, 738.
 GENERATION, general nature of, 370, 948; mode of its performance in Plants, 949-951; general mode of its performance in Animals, 952; essentially consists in union of contents of sperm-cell and germ-cell, 949.
 Action of Male in, 951-957; structure of testes, 951, 952; characters of seminal fluid, 954; nature and evolution of Spermatozoa, 954-955; essential importance of Spermatozoa, 954, 955, 969; share of, in coition, 956.
 Action of Female in, 957-985; structure of ovum, 957; evolution of ovum, 958; maturation and discharge of ovum, 959; period of puberty, 959, 960; menstrual discharge, 960-962; share of, in coition, 962, 963; expulsion of ova from Graafian vesicle, 963; formation of corpus luteum, 963-966; discharge of ova independent of coitus, 967, 968; fecundation of ovum, 968, 969; changes in germinal vesicle and germinal spot, 969; nature of fecundating process, 969-971; formation of chorion, 971, 972; of decidua, 972-974; of villi of chorion, 974, 975; of placenta, 974-978; placental murmur, 978; changes in mammae, 978; quickening, 979; parturition, act of, 979, 980; period of, 980-985; superfœtation, 985 (see Lactation).
 Embryonic Development; see *Development of Embryo*.
 Generative apparatus, of Male, 951, 952; of Female, 957-959; development of, 1002-1005; see Testes, Ovaria, and Uterus.
 Germ-Cell, of Plants, 949, 950; of Man, 958.
 Germinal Capacity, of embryo, 148, 149; progressive reduction of, with advance of life, 150-153.
 — Membrane, 989, 990.
 — Vesicle and Spot, 958; changes in, at maturation of ova, 969.
 Gestation; see *Pregnancy*.
Glands, elementary structure of, 239-241.
 — of Absorbent System, 450, 451.
 — Vascular or Ductless, 456.
Globules, of Blood; see *Blood-Corpuscles*.
 — of Chyle, 457.
Globulin, chemical composition and properties of, 58.
 Glosso-Pharyngeal Nerve, functions of, 686, 687; its instrumentality in deglutition, 402, 403; in sense of taste, 687, 688.
 Glottis, regulation of aperture of, 928, 929.
 Glucose, 75, 76.
Glutin, chemical composition and properties of, 66, 67; uses of, in the body, 68; presence of, in bone, 270, 271.
 Gluttony, feats of, 386.
 Glycerine, 70, 71.
 Glycine, 67, 87, 95.
 Glycocholic Acid, 95.
 Gough, case of, 862.
 Graafian vesicle; see *Ovisac*.
 Granulation, process of, 564-566.
 Granules, development of, into cells, 128.
 Gray Fibres of Nervous System, 337.
 — Matter of Nervous System, 338, 339; distribution of, in Spinal Cord, 661, 662; in Cerebrum, 741, 742.
 Growth, a source of demand for food, 547; excess and deficiency of, 547; its difference from development, 548, 549.
 Guanine, 86 *note*, 93.
 Guiding sensations, necessity of, in so-called "oddylic" movements, 921, 922; essential to voluntary movements, 722-728.
 Gustative Sense; see *Taste*.
 Gustatory Ganglia, 703.
 — Nerves, 687, 688, 718, 719.
- ## H.
- Habits, influence of, in determining muscular movements, 699, 721; in determining succession of thoughts, 769, 788, 812-814; in producing access of sleep, 822; in terminating sleep, 823; in modifying intensity of sensations, 850, 851.
 Hachisch, delirium of, 803-805.
 Hæmadynamometer, 479.
Hæmatin, chemical composition and properties of, 65.
Hæmatococcus, multiplication of cells of, 125.
Hæmatoidin, 66.
Hair, structure of, 251-254; development of, 254-256; production of, in cysts, 558; variation of, in different races, 1031.
 Hallucinations of insanity, 809, 810.
 Hamilton, Dr. R., case of, 797 *note*.
 Hand, peculiar to Man, 41.
 Harmony of movements of eyeballs, 914.
 Haversian Canals of Bone, 267-269.
 Healing of wounds, 561-566; see *Reparation of injuries*.
Hearing, physical conditions of, 894-899.
 Organ of, essential structure of, 894, 896; its adaptation to laws of propagation of sound, 897-899; structure and functions of membrana tympani, 899, 901; uses of tympanic cavity, and Eustachian tube, 901; chain of bones, and fenestra ovalis, 901, 902; labyrinth, 903; external ear and meatus, 905, 906; transmission of vibrations through bones of head, 906.
 Sense of, 907-909; tones produced by succession of impulses, 907; estimate of intensity, direction, and distance of sounds, 907, 908; rapidity of perception by, compared with vision, 908; uses of, in regulating voice, 726, 727, 908.
Heart, muscular fibre of, 310; concentric hypertrophy of, 334; irritability of, 468.
 Rhythmical movements of, 468-472; influence of Nervous system on, 470, 471; disturbance of, by attention to them, 920.
 Successive actions of, 472, 473; course of blood through, 474; difference of two sides of, 475, 476; sounds of, 476-477; rate of propulsion of blood by, 478, 479; force of propulsion of, 479, 480; number of pulsations of, 481, 482.

- First development of, 992; subsequent changes in, 995-999.
- Heat*, Influence of, on Vital action, 143-145, 614, 615.
- Animal, sources of its production, 73, 80, 145, 146, 621-629; standard of, in Man, 616; in infants, 616; in aged subjects, 616; diurnal variation of, 617; development of, in muscular contraction, 329; increase of, by exercise, 617; in inflammation, 568; by ingestion of food, 617; influence of external temperature on, 618; influence of disease on, 618, 619; liberation of, after death, 619; dependence of, on oxidation of hydrocarbon, 621-625; loss of, the cause of death by starvation and exhausting diseases, 624; partial dependence of, on cutaneous respiration, 625; influence of nervous system on, 626-629; inferior power of generating in infants, 629-631; reduction of, by evaporation from cutaneous surface, 631.
- External, power of enduring, 619-621; influence of, on muscular tonicity, 331; on temperature of body, 618; effect of, on transpiration, 612, 613.
- Sexual, of lower animals, analogous to menstruation, 960, 961.
- Height at different ages, 1016, 1017.
- Hemorrhage, influence of, on composition of Blood, 178.
- Hemorrhagic diathesis, state of blood in, 187.
- Hepatic Artery, distribution of, in liver, 583, 584.
- Cells, 589; fatty degeneration of, 589.
- Ducts, distribution of, in liver, 585-587.
- Vein, blood of, 183, 184; distribution of, in liver, 583, 585.
- Hereditary transmission of psychical powers, 817; of psychical peculiarities, 1037.
- Hermaphroditism, 1004, 1005.
- Heterologous growths, 573.
- Hiccup, act of, 518.
- Hindustan, languages and people of, 1046, 1047.
- Hippuric Acid*, composition and properties of, 87, 88; sources of its production in the living body, 87, 88; its presence in human urine, 603.
- Histogenetic Compounds, 51, 112; appropriation of, by the tissues, 140, 153, 154.
- Homicidal Insanity, cases of, 808 *note*, 809 *note*.
- Hooping-cough, 546.
- Horny matter, composition of, 248.
- Horses, cerebellum of, 737-738; experiments on spinal cord of, 665.
- Hottentot race, 1049, 1050.
- Hull, cholera at, 542; fever at, 542.
- Humblebee, heat evolved by, 622.
- Hunger, indicates necessity for aliment, 364, 382; sources of sense of, 391, 392.
- Hunting, effects of, on rigor mortis, 333.
- Hybrid races, 970; fertility of, 1039.
- Hybridity between species, limits of, 1039.
- Hydrochloric acid, its presence in the body, 105; the principal acid of gastric juice, 418, 419.
- Hydrogen, elimination of, by respiratory process, 532, 533.
- , respiration of, 531.
- Hydrophobia, pathology of, 727, 844; excitement of its paroxysm by sensations, 720.
- Hypertrophy, 547, 555; conditions of, 555-556; shown in production of tumors, 556; in supernumerary parts, 557, 558; modification of, in malignant tumors, 558.
- Hypnotism, phenomena of, 801, 802.
- Hypochondriasis, state of, 947.
- Hypoglossal Nerve, functions of, 691, 692.
- Hypoxanthine, 87.
- Hysteria, emotional perversion in, 767, 768; pathology of, 844-846; remarkable case of, 844 *note*.
- Hysterical ischuria, 579.
- I.
- Iago, character of, 818.
- Iceland, high rate of mortality in, 544, 545.
- Ideas*, formation of, by the instrumentality of the Cerebrum, 755, 756; sensational, 785; intellectual, 785.
- Ideational consciousness, 757; actions prompted by, 799, 833, 922.
- Identification, mental tendency to, 777.
- Ideo-motor actions, 799, 922.
- Idiocy, predominance of instinct in, 752; remarkable cases of, 363 *note*, 766 *note*, 813 *note*; causes of, 817, 970, 971.
- Imagination, faculty of, 792.
- Imitation, tendency to, 809 *note*.
- Impressions on Nervous Centres, ordinary action of, 648; reflex movements excited by, 648, 649.
- Impulsive insanity, 808, 809.
- Inanition, M. Chossat's experiments on, 393, 394, 623-624.
- Incontinence of Urine, 702, 846.
- India, languages and population of, 1046, 1047.
- Indo-European race, 1043-1046.
- Induction, mental tendency to, 777.
- Infancy, peculiar attributes of, 150.
- Infants, temperature of, 616; imperfect heat-producing power of, 629-630; size and weight of, 1013, 1014; early viability of, 984, 985; relative viability of, in male and female, 1015, 1016.
- Inflammation, essential nature of, 566-568; relations of, to hypertrophy and atrophy, 566; causes of, 567, 568; phenomena of, 568-569; state of the blood in, 185-190, 569; characteristic effusions in, 569-572; unhealthy forms of, 571; effects of, in tubercular subjects, 572, 573.
- Ingestion of food, 397.
- Inorganic Constituents of Blood, 174; their uses, 208, 209.
- Inosic Acid, 90.
- Inosite, or Muscle-Sugar, 77.
- Insalivation, 412-414.
- Insanity, phenomena of, 806-810; from intellectual perversion or deficiency, 806, 807; emotional disorder or moral insanity, 807, 808; impulsive, 808, 809; delusions of, 809, 810; pathology of, 754, 834, 835.
- Insects, heat evolved by, 622; instinctive actions of, 642, 643, 748-749.
- Inspiration, causes of first, 515.
- Inspiratory movements, 511; force required for, 512.
- Instinctive actions, 642, 643; relations of, to Intellectual, 748-749.
- Intellectual operations, 775-793; their subordination to the Will, 793-796.

Intelligence, nature of, as opposed to Instinct, 749, 750; degree of, conformable to size and development of Cerebrum, 750-754.
 Interlobular veins of liver, 584.
 Internal senses, nerves of, 728, 756.
 Intestinal Digestion; see *Digestion*.
 — Fluid, 428, 429, 432, 433.
 Intestines, peristaltic movements of, 409-410; small, passage of food through, 428-435; large, passage of food through, 435; glandulæ of, 239-241, 432-435; secretions of, 429-435; villi of, 239, 439-442.
 Intralobular veins of liver, 584.
 Intuitive Perceptions, 758-761.
 Invertebrata, their nervous system, automatic character of, 642, 644.
 Iris, movements of; see *Pupil*.
 Iron, a constituent of the human body, 109; presence of, in red corpuscles, 160; administration of, in chlorosis, 188.
 Irritability of Arteries, 483, 484.
 — of Heart, 468; see *Heart*.
 — of Muscles, 317; see *Muscular Fibre*.

J.

Jacob, membrane of, 878.
 Jails, Indian, high rate of mortality in, 544; English, cholera in, 539-541.
 Jaundice, passage of biliary coloring matter into the tissues and secretions in, 580; different forms of, 592, 593.
 Jewish Females, period of conception in, 968 *note*.
 — Nation, 1045; varied hues of, 1031.
 Juice of Flesh, 79, 89, 90.

K.

Kaffre race, 1049.
 Kidney, structure of, 594-599; tubuli uriniferi of, 595-597; circulation in, 597-599; Corpora Malpighiana of, 595-599; secreting cells of, 595; development of, 1001, 1002; elimination of water by, 598, 599; secreting action of, 599-609; excretory function of, 609-611 (see *Urine*).
 Kurrachee, cholera at, 540, 541.
 Kymographion, 490.

L.

Labyrinth of Ear, functions of, 903.
 Lachrymal secretion, influence of nervous system on, 942.
 Lactation, 1021, 1025; see *Mammary Gland* and *Milk*.
 Lacteals, origin of, in villi, 439-441; absorption of by, 442-445.
 Lactic Acid, its composition and properties, 78, 79; its presence in the fluids of the body, 79, 80; its origin and destination, 80; its occasional presence in urine, 603, 604.
 Lacunæ of Bone, 269; formation of, 276, 277.
 Lamina spiralis, 896.
 Lamina dorsales, 990.
 Languages of different races, essential conformity in, 1041, 1042; Indo-Germanic, 1043; Celtic, 1043; Euskarian, 1043; Syro-

Arabian, 1044, 1047, 1048; Mongolian, 1045; Seriform, 1046; Tamulian, 1046; Hindoo, 1046; Sanskritic, 1043, 1046; Negro, 1048; Kaffre, 1049; Hottentot, 1049; Bushman, 1050; American, 1051; Malayo-Polynesian, 1052; Negrito, 1053.

Landau, effects of siege of, 1011.

Langugo of fœtus, 255.

Lapps, race of, 1045.

Laryngeal nerves, their respective actions, 517, 518.

Larynx, structure of, 924, 925; actions of, 517, 518, 927-929; their instrumentality in the production of sounds, 929-932; theory of the voice, 932, 933; falsetto voice, 933, 934; automatic nature of movements of, 934, 935; their dependence on guiding sensations, 722, 723, 908; spasmodic closure of, 846.

Laughing, act of, 518.

Law of Nature, meaning of the term, 33.

Lead, occasional presence of, in the body, 111; toxic action of, 214.

Length of Fœtus at different ages, 1012-1013.

Leucine, derived from protein compounds, 54; from gelatin, 67.

Leucocythæmia, 188.

LIFE, or Vital Activity, dependent on material conditions and dynamical agency, 119, 120; relation of, to chemical and physical forces, 116-118, 126-137, 140-146; varying duration of, in individual parts, see *Duration*.

Life of a Cell, history of, 124-135.

— of Man, characters of principal epochs of, 148-153.

Ligaments, structure of, 224; elastic, 226.

Light, Influence of, on Vital action, 143; on pigment-cells, 249, 250.

— Evolution of, in human subject, 632, 633; from urine, sweat, and semen, 633.

Limbs, nature and development of, 1007.

Line, Carbonate of, its uses in the body, 103; proportion of, in bone, 271, 272; in teeth, 286, 287.

— Phosphate of, its uses in the body, 101; proportion of, in bone, 271, 272; in teeth, 286, 287.

Limits of vision, 880.

Lingual branch of Fifth pair, its participation in sense of Taste, 684, 687, 688.

Liquor Sanguinis, 157.

Liver, structure of, 581-590; general plan of, in lower animals, 581, 582; in man, 583; arrangement of bloodvessels in, 583-585; biliary ducts in, 585-587; secreting cells in, 586, 587, 588, 590; development of, 999, 1000; alterations of, in disease, 587-590.

Excretory function of, 590, 592, 594; in fœtus, 996, 999; formation of bile by, 591-594 (see *Bile*).

Assimilating action of, 183, 184, 449, 450, 594; production of fat by, 71, 113, 594; of sugar by, 76, 77, 113, 594; of fibrin by, 183, 184; of red corpuscles by, 167 *note*.

Fœtal, depurating action of, 996, 997, 999; development of, 999, 1000.

Liver-sugar, 77.

Locomotion, movements of, automatic character of, 698-699.

Loss of Blood, influence of, on Composition of Blood, 178.

Luminosity in Human subject, 632, 633.

Lungs, structure of, 504-508; contractility of bronchial tubes, 510; elasticity of, 510; force required for their distension, 510; changes in, from section of pneumogastric nerves, 519-521; development of, 999-1001.

Lymph, composition and properties of, 451, 452; corpuscles of, 453, 454.

—, coagulable, 61; effusion of, in inflammation, 570; conservative nature of, 572; fibrinous and corpuscular forms of, 571; degenerations of, 571, 572.

Lymphatics, absorption by, 445, 446, 448, 449.

Lymphatic Glands, structure of, 450, 451.

M.

Madder, effect of, on bones, 280; on teeth, 285.

Magnesia, Carbonate of, its presence in the body, 110.

—, Phosphate of, its uses in the body, 103.

Magnetism, Animal; see *Mesmerism*.

Magnetometer, 922 *note*.

Magyars, 1045; assimilation of, to Europeans, 1042, 1044.

Maintenance, a form of nutrition, 551.

Malayo-Polynesian races, 1052-1054.

Male, rudimentary uterus in, 1003; rudimentary mammary gland in, 1021; lactation by, 1022; action of, in generation, see *GENERATION*.

Malignant growths, 558, 574.

Malpighian Bodies, of Kidney, 595-599; of Spleen, 456, 457.

Malting, liberation of heat in, 621.

Mammalia, spinal cord of, 663; cerebellum of, 731; cerebrum of, 750, 751.

Mammary Gland, structure of, 1018-1021; functional activity of, 1021; secretion of, influence of mental emotions on, 944-945; of expectant attention on, 947 (see *Milk*).

MAN, distinctive characteristics of, 41; hand of, 41; cranium of, 42, 46; position of face of, 42; vertebral column of, 43; lower extremities of, 44; facial angle of, 47; myology of, 47; visceral apparatus of, 48; brain of, 48; subordination of senses to intelligence of, 48; peculiar adaptability of, 49; slow growth of, 49; mental endowments of, 49, 50; articulate speech of, 50; capacity for progress in, 50.

—, General Survey of Life of, 148-153; embryonic life of, 149; childhood of, 150-151; adult age of, 152; decline of life in, 152, 153.

—, Varieties of, 1029-1054; see *Color, Hair, Languages, Pelvis, Races, Skull, and Varieties*.

Mania, phenomena of, 806.

Mara, Mad., range of voice of, 920 *note*.

Mares, Cerebellum of, 737, 738.

Margaric Acid, 70.

Margarin, 69.

Mastication, 398-400.

Materialist doctrine, its truths and its errors, 770-772.

Matter and Mind, their differences and relations, 770-775.

Mauchamp breed of sheep, 1037 *note*.

Meatus auditorius, 905, 906.

Meconium, composition of, 590, 591.

Medulla Oblongata, general structure and relations of, 645, 646; particular account of, 676-683; the centre of nerves of respiration and deglutition, 646, 678, 695 (see *Spinal Axis*).

Medulla Spinalis; see *Spinal Cord*.

Membrana Granulosa, 957, 964.

— Tympani, structure and functions of, 899, 900.

Membrane, simple primary, 139, 140; serous, 230-232; synovial, 230-232; mucous, 232-235; fibrous, 224; development of bone in, 272, 273, 280.

Memory, connection of, with Association, 776; nature of, 781; persistence of, 782; dislocation of, 782 (see *Recollection*).

Menstruation, period of, 959, 960; nature of, 960-962; persistence of, 961, 962.

Mental action, its relation to Nervous action, 770-775.

Mesencephalon, 990, 1007.

Mesmerism, examination of reputed phenomena of, 826-829 *note*; coma, 826; somnambulism, 801, 826; exaltation of senses, 827; cataleptic rigidity of muscles, 828; involuntary movements in, 924; affection of organic functions, 828, 947; excitement of phrenological organs, 828; clairvoyance, 828; nature of mesmeric agency, 828.

Mesocephale, effects of division of, 710, 711; effects of electric irritation of, 711.

Metamorphosis, retrograde, of tissues, 113, 114.

Metastasis of secretion, 578-580.

Milk, secretory apparatus of, 1018-1021; supply of, 1021; constituents of, 1022-1024; variation in their proportions, 1024, 1025; influence of mental states upon, 942, 944-946; varieties of, in different animals, 1026, 1027; reabsorption of, 1027; vicarious secretion of, 1027; amount of, 1028; passage of medicines, &c., into, 1028.

—, sugar of, 1024.

Milk-teeth, development of, 290-294; order of, 295; exuviation of, 296, 297.

Milky serum of Blood, 73.

Milbank Penitentiary, scurvy at, 395, 396; cholera at, 539.

Mind and Matter, their differences and relations, 770-775.

Mitchell, James, case of, 872.

Model Lodging-houses, low mortality in, 543.

Modelling-process, 563-564.

Molecular base of chyle, 452.

— death, 1054-1056.

Mongolian races, 1045, 1046.

Monomania, phenomena of, 809.

Monotony, influence of, in producing sleep, 821, 828 *note*.

Monstrosities by excess, 556, 557; by inclusion, 557; by arrest of development, 548, 995, 996, 1004, 1008 *note*.

Moral insanity, 807, 808.

Morbid poisons, 216-221.

Mother, influence of state of, on development of fetus, 970, 971, 1011, 1012; on mammary secretion, 944-946.

Motility, an attribute of Cells, 130, 131; spontaneous, of muscles, 319 *note*; of heart, 471-472; of uterus, 979-981.

Motive Powers to Human action, 812, 814.

- Motor Linguae, 691, 692.
 Motor Nerves, laws of transmission through, 653, 654.
 — of Orbit, 685, 695.
 Motor Tract of Medulla Oblongata, 681.
 Movements, Ciliary, see 130, 236, 237.
 — Muscular, nature of, 131, 132; relation of, to organism at large, 909, 910; voluntary and involuntary, 910; combination of, 910; symmetry and harmony of, 911, 912; of eye, 913-917; energy and rapidity of, 917-920; influence of expectant attention on, 920-923 (see *Muscular Fibre*).
 Mozart, automatic action of his creative powers, 789 *note*.
 Mucous follicles, 233.
 — layer of germinal membrane, 989.
 Mucous Membranes, structure of, 232, 233; secretion of, 233; general functions of, 234, 235.
 Mucus, 233.
 Multiplication of Cells, 125-128.
 Murexide, 85.
 Muscle-Sugar, 77.
 Muscular Contraction, different modes of, 317-320; spontaneous, 319 *note*; after death, 327; force of, 328, 329; heat evolved in, 329; electrical disturbance produced by, 329, 634-637 (see *Movements*, Muscular).
 Muscular Current of electricity, 634-637.
 Muscular Fibre, composition of, 56, 59, 311; structure of, 303-310; striated, 303-309; non-striated, 309, 310; supply of vessels and nerves to, 312, 313; development of, 313, 314; nutrition of, 315; disintegration of, 315-316; effects of disuse of, 316, 317.
 Vital endowments of, 317-334; irritability of, 317-320; its gradual departure after death, 320; its diminution by sedatives, 321; influence of shock on, 321, 322; dependence of, upon arterial blood, 322, 323; their independence of nervous system, 324-326; peculiar *post-mortem* manifestations of, 326, 327; Tonicity of, 330, 331; rigor mortis of, 332-334; influence of electricity upon, 333; spontaneous motility of, 471-472.
 Muscular Sense, importance of, in voluntary movements, 722-724; extraordinary exaltation of, in somnambulism, &c., 724; suggestion of ideas by, 801, 802.
 Muscular Tension, influence of spinal cord on, 699.
 Myopia, 877.

N.

- Nails, structure of, 250; rate of growth of, 250, 251.
 Necramia, death by, 1056.
 Negritoes, or Pelagian Negroes, 1052, 1053.
 Negro races, color of, 1031; hair of, 1032; skull of, 1032, 1033; pelvis of, 1036; modification of, 1035; geographical range, and varieties of, 1047-1049.
 Nerve-Force, generation of, by cells, 132, 133; transmission of, 349-351, 652-654; its relations to physical forces, 351, 352; to electricity, 356, 357; to animal heat, 628, 629; to mental activity, 770-775 (see *Nervous Tissue*).
 Nerve-Trunks, structure of, 335-337; plexuses

formed by, 651, 652; central terminations of, 339, 340; peripheral terminations of, 312, 313, 341-343 (see *Eye*, *Ear*, *Papillæ*, &c.).

Endowments of, 349, 651-657; afferent and efferent, 651; use of plexuses of, 651, 652; laws of transmission in, 652-654; modes of determining their functions, 654-657; by peripheral distribution, 654, 655; by central connections, 655, 656; by experiment, 656-657.

Nervous Centres, structure of, 338, 339; connection of, with nerve-trunks, 339, 340; functional relations of, to system in general, 348-350; principal organs of, in Man, 645; Cranio-Spinal axis, 645, 646; Spinal Cord, 645; Medulla Oblongata, 645, 646; Sensory Ganglia, 646; Cerebrum, 647; Cerebellum, 647; general course of action of, 648-650; reflex operations of the several parts, 648-649; subordination of these to the Will, 649, 650.

Development of, 999, 1008-1010.

See *Spinal Cord*, *Medulla Oblongata*, *Sensory Ganglia*, *Cerebellum*, *Cerebrum*, and *Sympathetic*.

Nervous Current of electricity, 637-639.

NERVOUS SYSTEM, general structure and endowments of, 334 (see *Nervous Tissue*); general functions of, 371, 372; internuncial character of, 349; connection of, with organs of sense, 372, 373; principal divisions of, 374, 375.

General arrangement of, 641-642; automatic character of, in Invertebrata, 642, 643; distinguished, in Vertebrata, by Cerebrum, and ministering to Intelligence, 644; subservience of general organism to, 645.

Influence of, on Animal Heat, 625-629; on Organic Functions, 941-948; shown in effects of Emotion on Secretions, 942-946; influence of, on Nutrition, 946, 947; marked effect of expectant attention, 947-948.

Nervous Tissue, structure of, 334-343; fibrous, 335-337; vesicular, 338, 339; connection of cells and fibres, 339, 340; peripheral terminations of nerve-fibres, 341-343; composition of, 343; vascular supply of, 344, 345; nutrition of, 345; effects of disuse on, 345, 346; development of, 346; disintegration of, 354-356; regeneration of, 347, 348.

—, functions of, 348-357; transmitting power of nerve-trunks, 349; psychical relations of centres, 349, 350; relations of nerve-force to other vital forces, 350, 351; to physical forces, 351, 352; to electricity, 356, 357; to mental force, 773-775; conditions of its development, 353-356; necessity for oxygenated blood, 352; influence of contaminated blood on, 353; disintegration resulting from its activity, 354-356.

Nîmes, prison at, 396.

Nitric acid of urine, 607.

Nitrogen, proportion of, in different articles of food, 378; changes of, in respiration, 531, 532; respiration in, 530, 531.

Nomadic races, peculiarities of, 1033, 1035.

Nuclear fibres, 228.

Nucleated blastema, organization of, 138, 219, 287.

Nuclei, of cells, 123; their subdivision, 125-

127; free, 137; their development into nuclear fibres, 228.
NUTRITION, general nature of, 366, 367, 546, 547; dependent on pabulum in blood, 140, 211; sources of demand for, 547-551; condition of its performance, 551-554; interstitial and superficial, 552, 553; varying activity of, 554-560; peculiar phases of, in reparation of injuries, 562-566; abnormal forms of, 566-574; inflammation and its results, 566-572; tubercular formations, 572-574; malignant growths, 574; influence of nervous system on, 350, 351, 367, 946-948.

O.

Oblique muscles of eyeball, function of, 913, 914.
 Oceanic races, 1051-1054.
 Odoriferous glandulæ, 242, 243.
 Odorous matter in blood, 173.
 Odors, sensibility to, 871.
 Odylie movements, rationale of, 921-923.
 Oesophagus, action of, in deglutition, 404; in vomiting, 404.
Oleaginous Compounds, 69.
 Oleic Acid, 70.
 Olein, 69.
 Oleo-phosphoric acid, 75.
 Olfactory Ganglia, 702.
 — Nerve, endowments of, 714; distribution of, 871, 872.
 Olivary Bodies, 677-682.
 — Ganglia, 678.
 Omphalo-mesenteric vessels, 992, 994, 995.
 Ophthalmic ganglion, 684.
 Optic Ganglia, 702; functions of, 707, 708.
 — Nerves, peculiar arrangement of, 716, 717; endowments of, 714-716; distribution of, 878; deficient sensibility at entrance of, 893.
 — Thalami, 703-705; functions of, 708-711.
 Orang-Outan, comparison of, with Man, 41-49.
 Orbicularis muscle, reflex action of, 696, 716.
 Orbit, motor nerves of, 685.
 Order of Nature, 33, 34; belief in, 785.
 Organic Functions, 359, 360; their relations to the Animal, 361-363.
 Organization, its relation to Life, 119, 120.
 Oscillations produced by expectant attention, 921.
Osseous Tissue; see *Bone*.
 Ossification, intra-membranous, 272, 273; intra-cartilaginous, 273-276; in osseous tumors, 280.
 Outness, elementary notion of, 757, 758.
 Oval skull, 1034, 1035.
 Ovary, human, structure of, 957; development of, 1002, 1003; evolution of ovisacs within, 959; discharge of ova from, 963-968.
 Overcrowding, a powerful predisposing cause of zymotic disease, 539.
 Ovisac, structure and functions of, 957-959; formation of corpus luteum within, 963-968.
Ovum, structure of, 957, 958; evolution of, 958, 959; maturation and discharge of, 963-968; fecundation of, 968, 969; first changes in, 969; subsequent changes in, see *Development of Embryo*.
 Oxalic acid of urine, 607.
 Oxygen, respiration of, 535; influence of, on production of fibrin, 180.

P.

Pacinian corpuscles, 342, 343.
Pancreatic fluid, composition of, 428; uses of, in digestion, 429; amount of, secreted, 430.
 Pantheism, 786-788.
 Papillæ, dental, 287; development of, in fœtus, 290-293.
 — of Mucous Membranes, 238; of Skin, 242, 858, 859; of Tongue, 864-868.
 Papuans, 1096.
 Par Vagum; see *Pneumogastric*.
 Paralysis, pathology of, 841, 846; peculiar cases of, 673-674.
 Paraplegia, pathology of, 668, 847; peculiar cases of, 672-674.
 Parents, influence of state of, on offspring, 969, 970.
 Parturition, act of, 979, 980; regular period and causes of, 980-982; retarded, 982-983; premature, 984, 985.
 Passion, influence of, on secretion of milk, 944, 945.
 Pathology, relation of, to Physiology, 38.
 Pelagian-Negro Races, 1096.
 Pelvis, variations in form of, 1036.
 Penis, erectile tissue of, 501; function of, in coition, 956; development of, 1004.
 Pepsin, 419.
 Peptones, 427.
 Perception, nature of, 758-761.
 Perceptions, visual, 882, 883.
 Periodical phenomena, relation of, to Heat, 615, 980.
 Periodicity of sleep, 819.
 Peristaltic movements of intestines, 309, 409; influence of sympathetic nerve on, 409, 410; influence of mental states on, 920.
 Persistence of sensory impressions, gustative, 870; olfactive, 873; visual, 890, 891; auditory, 908.
 Personal identity, consciousness of, 785.
Perspiration; see *Cutaneous Transpiration*.
 Peyer's Glands, 433, 434.
 Pharynx, action of, in deglutition, 401-404.
 Phosphate of Lime, uses of, in the body, 101; its importance in bones, 271, 272; in teeth, 286, 287.
 Phosphate of Magnesia, uses of, in the body, 103.
 Phosphates, alkaline, in Urine, 355.
 Phosphorescence, cases of, in human subject, 533, 632, 633.
 Phosphorized Fats, 75; their presence in red corpuscles of blood, 161; in nervous tissue, 344.
 Phosphorus, a constituent of albumen, 55, 56; of fats of brain, 75; its oxidation in the body, 355, 606; its elimination from lungs as luminous vapor, 533, 632, 633; its presence in the urine, sweat, and semen, 92, 632, 633.
 Phosphorus-extractive of Urine, 92.
 Photophobia, 716.
 Phrenological doctrine of Cerebellum, 733 *note*, 735-740; of Cerebrum, 750, 780.
 Phthisis, state of blood in, 186.
 Physical Forces, correlation of, 142; their relations to Vital, 135-137, 142-144.
 Physiology, object of the Science of, 33; relation of, to Pathology, 38.
 Pigment-cells, 248, 249; influence of light on, 249, 250; variations of, in different races, 1030.

- Pigmentum nigrum, 249.
 Pigmentary matter of Urine, 604.
 Pitch of voice, regulation of, 928.
 Pituitary membrane, distribution of nerves in, 871, 872.
 Placenta, formation of maternal portion of, 974-978; formation of fœtal portion of, 994.
 Placental sound, 978.
 Plexuses, nervous, uses of, 651, 652.
 Plica Polonica, alteration of hair in, 254.
Pneumogastric Nerve, general distribution and endowments of, 688-690; its instrumentality in deglutition, 403, 404; its influence on secretion of gastric fluid, 422-423; on movements of stomach, 407; on movements of heart, 469; its action as an excitor of respiration, 514; its motor powers, 516-517; effects of section of, 519-520; influence of, on larynx, 689, 690.
Poisons, influence of, on the living body, 136; elimination of, from the blood, 214-216; influence of, on the Nervous System; see *Toxic Influence*.
 —, morbid, their substantive existence, 216, 217; zymotic conditions of their activity, 216, 217; course of phenomena in, 219, 220; alteration of blood by, 220, 221; recovery of blood from, 221, 222; *materies morborum* generated within the system, 218, 219.
 Polynesian races, 1052-1054.
 Pons Tarini, 745.
 — Varolii, effects of division of, 710, 711.
 Portal blood, peculiarities of, 182.
 Portio Dura of Seventh Pair, 685 (see *Facial Nerve*).
 Posterior Columns of Spinal Cord, structure of, 660-662; functions of, 667-671.
 — Pyramids of Medulla Oblongata, 679-683.
 Potash, its presence in the body, 109; its predominance in red corpuscles and in muscles, 161.
 Potteries (Kensington), mortality at, 542, 543.
 Pregnancy, state of blood in, 186; signs of, 978; usual term of, 980-982; protracted, 982-983; abbreviated, 984, 985.
 Presbyopia, 877.
 Pressure of blood, in heart, 479; in arteries, 490.
 Primitive trace, 990.
 Prognathous skull, 1032, 1033.
 Projection, idea of, 758, 885-887.
 Proencephalon, 990, 1009.
 Protective agency of Spinal Cord, 696, 697.
Protein Compounds, general properties and reactions of, 53, 54.
 Protein, binoxide and tritoxide of, 64, 65.
 Psychical endowments of different races, essential conformity in, 1040-1041.
 Ptyalin, 412.
 Puberty, usual epoch of, in female, 959, 960; in male, 955.
 Puerperal fever, predisposing causes of, 217.
 Pulp, dentinal, 287; enamel, 288, 289; cemental, 290.
 Pulsations of Heart, causes of, 468-472.
Pulse, Arterial, 487, 488; rate of, at different ages, 481; variations of, under different circumstances, 481-482; proportion of, to respiratory movements, 513.
 —, Respiratory, 498, 499.
 —, Venous, 475.
 Pupil, movements of, 697, 716, 877, 880; relation of, to Third pair, 685 *note*; to Sympathetic, 830, 831.
 Purkinje, experiment of, 893.
 Purpuric acid, 85.
 Purpurine, 92.
 Pus, formation and characters of, 571, 572; influence of, on coagulation of Blood, 198.
 Putrefaction, the result of chemical agencies, 135; may take place even during life, 395, 1054; evolution of light in, 632; final destruction of body by, 1059.
 Pyin, 64.
 Pyramidal bodies of Medulla Oblongata, 677-683; anterior, their structure and connections, 677, 681, 683; posterior, their structure and connections, 679-683.
 — skull, 1033, 1034.
- Q.
- Quadrumana, comparison of, with Man, 41-49.
 Quagga, transmission of marks of, 970.
 Quickening, 979.
- R.
- Races of Mankind*, Caucasian, 1042-1046; Arian, or Indo-European, 1043, 1044; Syro-Arabian, 1044, 1045; Mongolian, 1045, 1046; Seriform, 1046; Hindostanic, 1046, 1047; Negro, 1047-1049; Kaffre, 1049; Bushman, 1049, 1050; American, 1050, 1051; Oceanic, 1051; Malayo-Polynesian, 1052; Pelagian-Negro, 1052, 1053.
 Radiating fibres of Cerebrum, 742.
 Radiation of Sensations, 854.
 Rapidity of muscular movements, 919.
 Rattlesnake, secretion of poison of, continued after death, 941.
 Reasoning Power, nature of, 780.
 Reciprocation of sounds, 896-898.
 Reciprocity of manifestations of Cell-force, 133.
 Recollection, power of, dependent on Association, 776; mode in which it is exerted, 783-785.
 Recti muscles of eyeball, function of, 913.
 Red Corpuscles, see *Blood-Corpuscles*, Red.
 Reeds, vibrating, action of, 930-932.
 Refraction, laws of, 873, 874.
Reflex actions of Nervous System, 349; of Spinal Axis, 671-676; of Sensory Ganglia, 719-722; of Cerebrum, 774, 775, 816, 832.
Regeneration of Tissues—of fibrous tissues, 228, 229; of serous and synovial membranes, 231; of mucous membranes, 234; of epithelium, 237; of skin, 246; of epidermis, 248; of nails, 251; of hairs, 256; of crystalline lens, 265; of bones, 281-282; of teeth, 284; of capillary vessels, 301, 302; of nervous tissue, 347, 348.
 Regeneration of lost parts, 560, 561; see *Reparation*.
 Regimen, influence of, on composition of Blood, 177; on system generally, 380-386.
 Renal vein, blood of, 184.
Reparation of injuries, 560; completeness of, in lower animals, 560; limitations of, in higher, 560, 561; more energetic and complete in embryonic state and in childhood,

- 149, 150, 151, 560; not dependent on inflammation, 561, 562; by immediate union, 561; by adhesion, 562; by modelling process, 563-564; by suppurative granulation, 564-566.
- Reproduction*, general nature of the function, 370 (see *REGENERATION*).
- of lost parts, 560, 561 (see *Regeneration and Reparation*).
- Resinous dressing for wounds, 564.
- Resistance, sense of, most generally diffused, 852, 859.
- Resonance of sounds, 896-898.
- RESPIRATION*, general nature of the function, 367, 368; provisions for, 502; sources of demand for, 502-504.
- Structure of apparatus for, 504-511 (see *Lungs*).
- Movements of, 511; muscular force required for, 512; rate and extent of, 513; dependence of, on nervous system, 514-521; incapable of voluntary restraint, 516; disturbance of, by attention to them, 920.
- Effects of, on Air, 521-538 (see *Air*); on Blood, 178-181.
- Consequences of Suspension of, 535-537; effects of deficiency of, 538-546.
- of hydrogen, 531; of nitrogen, 531; of oxygen, 179, 535.
- artificial, partial sustenance of heat by, 626.
- Respiratory Circulation, peculiarity of, 504, 505.
- Pulse, 498, 499.
- Restiform Bodies, 677-683.
- Ganglia, 678.
- Rete Mucosum, 247.
- Retina, structure of, 879; deficient sensibility of, at entrance of optic nerve, 893; visual perception of, 893; development of, 1049.
- Rhythmical movements of heart, 468-472.
- Rigor mortis, 332-334; influence of electricity upon, 333.
- of heart, 478.
- Right, elementary notion of, 786.
- Roots of spinal nerves, peculiar endowments of, 651, 655, 656; connections of, with Spinal Cord, 660-662.
- S.
- Saccharine Compounds*, 75.
- Matter in blood, 177.
- Principles of Food, 376, 381, 382.
- St. Kilda, high rate of infantile mortality in, 545.
- St. Martin, case of, 405, 420, 422, 424-426.
- Saliva*, composition of, 412-414; uses of, 413, 414; influence of nervous system on flow of, 942, 943.
- Salivary glands, 412.
- Salt, common; see *Chloride of Sodium*.
- Salts of Blood, 174; alteration of, in disease, 190.
- Sanguification*, process of, 449-464; share of Liver in, 450; share of Absorbent system in, 450, 455; share of Ductless Glands in, 461-464.
- Sanskritic languages, 1043, 1046.
- Sarcous elements of muscle, 304.
- Saunderson, case of, 862.
- Schneiderian membrane, distribution of nerves in, 871, 872.
- Scrofulous constitution, 572.
- Scurvy, state of blood in, 187, 188.
- at Milbank Penitentiary, 395.
- Sebaceous Glands, 243, 244.
- Secondarily automatic actions, 721, 722.
- SECRETION*, general nature of, 368, 574, 575; effected by the agency of cells, 122, 133, 240; continuance of, after death, 941; influence of nervous system on, 350, 360, 361, 942-948; its relations to excretion, 574, 575 (see *Excretion*); metastasis of, 578-580 (see *Liver, Kidney, Bile, Urine, &c.*).
- Secunderabad, mortality in barracks at, 543.
- Segmentation of vitellus, 988, 989.
- Selecting power of individual parts, 210.
- Self-control, power of, 648, 649; gradual acquirement of, 817; loss of, in Insanity, 806-810 (see *Will*).
- Semicircular canals, 903.
- Seminal Animalcules; see *Spermatozoa*.
- Fluid, characters of, 954; secretion of, influenced by state of feeling, 943 note.
- Semitic races, 1044, 1045, 1047, 1048.
- Sensation*, definition of, 848; dependence of, on nervous distribution, 848; on capillary circulation, 849; connection of, with pain and pleasure, 849-851; influence of habit on, 850, 851; different forms of, 851-853; general and special, 851-853; subjective and objective, 853, 854; reference of, to seat of impressions, 855; influence of attention on, 855-856; modification of, by previous beliefs, 857, 858.
- Sensations*, not essential to reflex actions of Spinal Cord, 671-674; but usually associated with them, 697, 698; instrumental in reflex actions of Sensory Ganglia, 719-722; essential to voluntary movements, 722-728; the stimuli to higher intellectual operations, 754, 755.
- Senses, exaltation of, in Somnambulism, 827.
- Sensori-motor actions, 350, 374, 398, 648, 720-722.
- Sensorium, its special seat in the sensory ganglia, 706.
- Sensory Ganglia*, general structure and relations of, 646, 836-837; particular account of, 702-706; their relative predominance in the descending series, 705; constitute the whole Encephalon of lowest Fishes and Invertebrata, 709; the probable seat of sensation, 706, 707; reflex actions of, 719-720; independent functions of, 720-722, 837-840; their participation in voluntary actions, 722-728; pathological relations of, 837-842; suspended action of, 840-842.
- Sensory Nerves, laws of transmission through, 652, 653.
- Sensory Tract of Medulla Oblongata, 680, 681.
- Seriform races, 1046.
- Serolin, 74.
- Serous Effusions of inflammation, 569.
- Serous Layer of germinal membrane, 989.
- Serous Membranes*, 230-232.
- Serpents, spinal cord of, 663; sympathetic system of, 659.
- Serum of Blood, 157, 193; proportion of, to Crassamentum, 198; milky, 176, 177.
- of Serous Membranes, 231.
- Seventh Pair of Nerves, portio dura of, 685 (see *Facial Nerves*).
- Sexes, proportional number of, 1014; differences in general development of, 1014,

- 1017; in viability of, 1015; in constitution of, 1017, 1018.
- Sexual Instinct, supposed location of, in Cerebellum, 735-739.
- Organs; see Generative Apparatus, Testes, Ovaria, and Uterus.
- Secretions, influence of nervous system on, 943.
- sense, situation of ganglionic centre of, 739, 740.
- Sheep, new breeds of, 1037 *note*.
- Shock, influence of, on muscular irritability, 321, 322; on heart, 470.
- Sighing, act of, 518.
- Sign-language of deaf and dumb, 759 *note*.
- Signs of Death, 1058, 1059.
- of Pregnancy, 978, 979.
- Silica, its presence in the body, 105.
- Similarity, law of, 777-779.
- Single vision with two eyes, 884-887.
- Sinus pularis, 1003.
- urogenitalis, 1002, 1003.
- Six-fingered races, 1038.
- Sixth Pair of Nerves, functions of, 685, 686.
- Size, visual appreciation of, 888, 889.
- Skeleton of Invertebrata, structure of, 266.
- Vertebrata, general structure of, 266; development of, 1005; varieties in conformation of, 1032-1037.
- Skin*, structure of, 241-250; Cutis vera, 241, 242; glandulæ of, 243-245; papillæ of, 858, 859; nutrition of, 245, 246; Epidermis, 246-248; pigment-cells, 248-250; transpiration from, 611-614.
- Skull of Man, distinctive peculiarities of, 42, 46; varieties in form of, 1032-1035; induced modifications of, 1035, 1036.
- Sleep*, definition of, 819; necessity for, 819, 820; periodicity of, 819; predisposing influences to, 820; intermediate stages between sleep and waking, 821, 822; influence of habit in inducing, 822, 823; influence of impressions on the sleeper, 823, 824; amount of, required by man, 824-825; cases of absence and deficiency of, 825; undue protraction of, 826.
- Smell*, sense of, 871-873; peculiar objects of, 871; nervous apparatus of, 872; influence of Fifth pair on, 872; uses of, 872; improvement of, 873; special exaltation of, 873 *note*; modification of, by habit, 873.
- Smoke, peculiar acid of, 539 *note*.
- Smooth Muscular fibre, 309, 310.
- Sneezing, act of, 519.
- Sobbing, act of, 518.
- Soda, carbonate and phosphate of, their presence and uses in the body, 107-109.
- Sodium, chloride of; see Chloride of Sodium.
- Solidity, perception of, 885-887.
- Somatic death, 1054-1056.
- Somnambulism, peculiarity of state of, 800-802, 811; exaltation of Muscular sense in, 724; exaltation of sense of smell in, 873 *note*.
- Sound, laws of propagation of, 896-899.
- Sounds, Articulate, 935-940.
- of heart, 476-478; of placenta, 978.
- Specific distinction between Human races, no adequate grounds for, 1038-1042.
- Spermatic cells, independent life of, 124.
- Spermatozoa, characters of, 954; evolution of, 954; the essential fertilizing agents, 955.
- Sperm-cell of Plants, 949, 950; of Man, 955.
- Spherical aberration, 874.
- Sphincters, action of, 410, 695.
- Spinal Accessory Nerve, functions of, 690, 691; inosculation of its roots with Pneumogastric, 688.
- Spinal Axis*, functions of, 695-702, 842, 843; its control over the orifices of the body, 695; its relation to the Organic functions, 695, 696; its protective agency, 696, 697; morbid excitability of, 701, 702; pathological relations of, 842-848.
- *Cord*, general structure and relations of, 645; comparative anatomy of, 663; particular account of, 659-676; anatomy of, 660-667; external conformation, and connection of with nerves, 660; internal structure of, 661-667; different views respecting, 664, 665; functions of, 667-676; conducting power of, 667-671; reflex actions of, 671-676; their independence of sensation, 671-674; their adaptive character, 674, 676; cases of injury of, 672-674; experimental researches on, 671, 672, 676 (see *Spinal Axis*).
- Spinal Nerves, connections of, with *Cord*, 660-662, 683; general endowments of, 650-656.
- Spleen*, structure of, 456-458; development of, 458; functions of, 461-464.
- Spiritualist doctrine, its truths and its errors, 770-772.
- Spitalfields Workhouse, fever, &c., at, 543.
- Spontaneous amputation, reproduction of limbs after, 561.
- Splenic vein, blood of, 182, 183, 463.
- Stallions, Cerebellum of, 737, 738.
- Stammering, pathology and treatment of, 939-940; influence of emotions on, 767, 768.
- Starvation, effects of, 393, 394; symptoms of, 394, 395; prolonged, 395, 396; death by, 393-397; consequent upon loss of heat, 623-624.
- Steam, application of, to wounds, 564.
- Stearic Acid, 70.
- Stearin, 69.
- Stereoscope, 886-887.
- Stomach*, movements of, 404-408; secreting apparatus of, 414, 415; villi of, 416, 417; gastric secretion of, 417-424 (see *Gastric Juice*); its operation in Digestion, 424-427; effects of blows on, 321.
- Strabismus, pathology and treatment of, 916, 917.
- Strangury, convulsive action in, 846.
- Stratum Malpighii, 247.
- Strength, feats of, 918, 919.
- Striated Muscular fibre, 303 (see *Muscular Fibre*).
- Strings, vibrating, action of, 929.
- Strumous constitution, 572.
- Strychnia, artificial tetanus of, 702, 844.
- Subcutaneous Wounds, reparation of, 228, 229.
- Subjective Sensations, 853-858.
- Substantia gelatinosa of Spinal Cord, 661, 662.
- spongiosa, 661.
- Succession of Mental states, 816, 817 (see *Trains of Thought*).
- Succus entericus, 428, 429, 432, 433.
- Suction, act of, 398, 698.
- Sudoriparous excretion, composition of, 612; amount of, 612, 613; vicarious with urinary, 613, 614.

Sudoriparous glandulæ, structure of, 245; number of, 611; excretory action of, 612-614.
Sugar, its composition and properties, 75; its transformation in the body, 76; its production in the body, 76, 77.
Sugar of Milk, 1024.
 Suggestion, influence of, in determining succession of thought, 788, 796-810.
 Sulphates, Alkaline, their presence in the body, 110; in the urine, 605, 606.
 Sulphocyanide of potassium, its presence in the body, 110; in the saliva, 412
 Sulphur, an element of protein-compounds, 53; presence of, in urine, 92; large proportion of, in cystine, 93, 94; in taurine, 96; oxidation of, in body, 110.
 Superfætation, 985.
 Supernumerary parts, development of, 557, 558.
 Suppuration, 571, 572; of granulation surface, 564, 565.
Suprarenal bodies, structure of, 458, 459; development of, 459, 460; functions of, 461, 462.
 Surgical fever, predisposing causes of, 217.
 Symmetrical diseases, 210.
Sympathetic System, general structure of, 657, 658; arrangement of, 829.
 Cerebro-Spinal fibres in, 829, 830; their instrumentality in sensation and muscular contraction, 830, 831; their influence on movements of intestines, 409, 920; on heart's action, 469, 470; on calibre of bloodvessels, 483, 830; on dilatation of pupil, 831.
 Proper Fibres of, 337; their probable functions, 831; influence of, on animal heat, 627.
 Syncope, state of Nervous Centres in, 701; death by, 1055.
 Synovia, 230.
Synovial Membranes, 230-232.
 Syro-Arabian races, 1044, 1045.
 Systole of ventricles, 472, 473; sound produced by, 476, 477; quantity of blood discharged by, 478, 479; force of, 479, 480; frequency of, 481, 482.
 Swallowing, act of, 401-404.

T.

Taliacotian operation, regeneration of nerve-tissue in, 347.
 Tamulian language, 1046.
Taste, sense of, 862-870; peculiar objects of, 862; special conditions of, 863; papillæ of, 864, 865; nerves of, 866, 867, 862; varying acuteness of, 869; participation of smell in, 869; uses of, 870; improvement of, by habit, 870; cases of loss of, 688, 869.
 Taunton, cholera at, 539.
 Taurine, 96.
 Taurocholic Acid, 95.
Teeth, structure of, 283-287; composition of, 286; development of tissues of, 287-290; evolution of, 290-295; exuviation and replacement of, 296, 297; degeneration and death of, 554; production of, in cysts, 558.
 Temperature, Animal; see *Heat*.
 — sense of, 860-861.
 Tendencies to thought, 769.

Tendons, structure of, 224; reparation of, 228; attachment of, to muscle, 309.
 Tenesmus, convulsive action in, 846.
 Tension, muscular, influence of Spinal Cord on, 699, 700.
 Testes, structure and secretion of, 952, 953; development of, 1002, 1003.
 Tetanus, pathology of, 702, 843, 844.
 Thalami Optici, 703, 704; functions of, 708-710.
 Thaumatrope, 891.
 Third Pair of Nerves, functions of, 685; its influence on the movements of the pupil, 685 note, 697, 880.
 Third Ventricle of Brain, 1009.
 Thirst, sense of, 392, 393.
 Thorax, movements of, in respiration, 511-513.
Thymus Gland, structure of, 460; development of, 461; functions of, 461, 462.
 Thyroid cartilage, 925; movements of, 926, 927.
Thyroid Gland, structure of, 461; development of, 461; functions of, 461, 462.
Tissues, primary, general classification of, 222-223.
 Tongue, papillæ of, 864-868; sensory nerves of, 684, 687, 688; motor nerves of, 691, 693; partial paralysis of, 688, 693.
 Tonicity of Muscles, 330, 331; of Arteries, 485.
Touch, Ganglia of, 705; Nerves of, 718; Sense of, 858-862; papillæ of, 858, 859; varying acuteness of, 859; knowledge acquired by, 859-861; improvement of, 861, 862.
 Townsend, Col., case of, 1058.
 Toxic diseases, general pathology and therapeutics of, 215-222.
Toxic Influence on the Nervous System, production of delirium by, 803-805; its relation to Insanity, 834; to chorea, 835; to coma, 840; to paralysis, 841, 846; to epilepsy, 841; to tetanus, 843; to hysteria, 844; to convulsive diseases generally, 846.
 Trainers' Diet, 387.
Trains of Thought, 785; intuitional nature of some of these, 785-788; influence of Suggestion in exciting them, 788, 796-810; influence of the Will in directing and controlling them, 788, 789, 793-796, 817-819.
 Trance, state of, 1158.
 Transmission of nerve-force, laws of, 652-654; of electricity, 653.
 Transudation of water by Kidneys, 598.
 Trigeminal or Trifacial Nerve, functions of, 683-686; lingual branch of, 687, 688.
 Trismus nascentium, mortality from, 545.
 Tritoxide of Protein, 64, 65.
 Troglodytes gorilla, skull of, 46.
 Truth, elementary notion of, 785.
 Tuber Annulare, effects of division of, 710, 711.
 — Cinereum, 745.
 Tubercle, nature of, 572-574.
 Tubercula Quadrigemina, 702; functions of, 707, 708.
 Tubuli seminiferi, 952.
 — uriniferi, 595-597.
 Tumors, their relation to hypertrophies, 556; malignant, 558, 574.
 Turkish nation, modification of, 1035, 1045.
 Tympanum, structure and functions of membrane of, 899, 900; cavity of, 901.

Typhoid fever, state of blood in, 186, 191.
Tyrosine, derived from protein-compounds, 54.

U.

Ulceration, nature of, 567.
Umbilical Cord, structure of, 994, 995.
— Vesicle, 991, 994.
— Vessels, 995-999.
Unconscious activity of the Cerebrum, 784, 790-792.
Union of cut surfaces, immediate, 561; by adhesion, 562.
Unity, Specific, of Human Races, 1038-1042.
Uræmia, 599, 600.
Urea, its chemical composition and properties, 81; sources of its production in the living body, 82-83; amount of, ordinarily excreted, 601, 602; variations in quantity of, 602-605; presence of, in sweat, 612.
Uric Acid, its chemical composition and properties, 83-86; sources of its production in the living body, 86, 87; amount of, ordinarily excreted, 601, 602; variations in quantity of, 86, 602, 605; circumstances affecting solubility of, 85, 86, 607, 608.
Uric Oxide, 92, 93.
Urinary Bladder, contraction of, 410, 411; development of, 1002, 1004.
— Excretion, general purposes of, 80, 113, 599; metastasis of, 578, 579; see *Urine*.
— Organs, development of, 1001-1003.
Urination, act of, 410, 411, 695.
Urine, secretion of, 599; excrementitious character of, 599, 600; physical properties of, 600; quantity of, 601; specific gravity of, 601; composition and properties of, 601, 602; differences of, with age, 602; individual components of, 80-93, 602-604; influence of diet upon, 604, 605; inorganic constituents of, 605-607; acid reaction of, 607-608; alkaline reaction of, 608, 609; eliminating agency of, 609, 610; influence of diuretics on, 609, 610; incontinence of, 702, 846.
Urine-Pigment, 92.
Uro-erythrine, 92.
Uro-glaucin, 92.
Uroxanthin, 91.
Uterus, muscular substance of, 310, 318; development of, during pregnancy, 978; embryonic development of, 1003; inherent motility of, 130-132; action of, in parturition, 979, 980; reflex action of, 979; subsequent fatty degeneration of, 553, 980 *note*; rudimentary, of male, 1003.

V.

Vagus Nerve; see *Pneumogastric*.
Valves of Heart, 475; sounds produced by tension of, 476, 477.
Vapor, aqueous absorption of, 446, 447, 534; exhalation of, 532, 533.
Variation, individual, 1029, 1030, 1036.
—, spontaneous, tendency to, 1036, 1037.
Varieties of Man, their essential conformity in structure, 1030-1038; in physiological history, 1038, 1040; in psychical endowments,

1040-1041; in languages, 1041, 1042 (see *Races*).
Vasa lutea, 992 *note*.
Vascular Area, 991; formation of vessels in, 165, 299.
— Layer of Germinal membrane, 990, 991.
— Glands, 455; see *Spleen*, *Suprarenal*, *Thymus*, and *Thyroid* bodies.
Vegetable substances adapted for Human food, 375-381; their dietetic uses, 381-383.
Vegetables, movements of, 130.
Veins, movement of Blood in, 497-500; structure and properties of, 497, 498; causes of motion of blood in, 498, 499; influence of gravity on, 499, 500; effects of deficient tonicity on, 499.
Vena Porta, distribution of, in liver, 583, 584; blood of, 181, 182.
Venæ Azygos, 996.
Venous and Arterial Blood, differences of, 178-181.
Ventilation, effects of deficient, 538-546.
Ventricles of Heart, movements of, 472, 473; relative thickness of, 474, 475; capacity of, 475; sounds produced by, 476-477; quantity of blood propelled by, 478, 479; force of propulsion by, 479, 480.
Vertebra, typical, 1006-1007.
Vertebræ, cranial, 1007, 1008.
Vertebral Column, first indications of, 990; subsequent development of, 1005.
Vertebrata, distinguished by Intelligence, and by possession of Cerebrum, 644; subsergency of entire organism to Nervous System in, 645.
Vesicles of evolution of Spermatozoa, 954.
Vesicula prostatica, 1003.
Vesicular nervous substance, 338-340.
Vessels, Sanguiferous; see *Arteries*, *Capillaries*, and *Veins*.
— Absorbent; see *Lacteals* and *Lymphatics*.
Vestibular cavity of ear, 894, 904.
Viability of Fœtus, 984; relative, of Male and Female, at different ages, 1015, 1016.
Villi, Intestinal, 232, 239; structure and action of, 439-442; rhythmical movements of, 440.
— of Chorion, 974; of placenta, 975, 976.
Virility, protracted, 956.
Visceral system; see *Sympathetic System*.
Vision, sense of, 873-893; special use of, in guiding locomotive actions, 723, 724; optical conditions of, 873-877; defective, 877; nervous apparatus of, 878-880; limits of, 882; mental participation in, 882, 890; connection of, with touch, 882; erect, 883, 884; single, with two eyes, 884, 885; appreciation of solid forms by, 885-887; of distance, 887, 888; of size, 888, 889; persistence of impressions, 890, 891; complementary colors, 891; other modifications of color, 892; want of power to distinguish colors, 892; vanishing of images, 893; representation of retina itself, 893.
Vital Capacity of lungs, 521-522
— Force, its agency in the living body, 119; conditions of its exercise, 140-144; its relations to Physical Forces, 143-146.
Vitellin, 57.
Vitelline vesicle and duct, 990, 991, 994.
— vessels, 991, 992.
Vitellus of ovum, 958; segmentation of, 988, 989.

Vitreous body, structure and nutrition of, 266.
 Vocalization, automatic action of muscles of, 722, 723.
 Vocal Ligaments; see *Chordæ Vocales*.
 Voice, ordinary mode of production of, 932; falsetto, mode of production of, 933, 934 (see *Larynx*).
 Volition, action of, on the Body, 793-795; on the Mind, 795-796 (see *Will*).
 Volitional actions, 768 *note*; influence of emotions on, 768, 769; dependence of, upon previous idea of success, 769, 793, 794, 798; (see *Will*).
Voluntary Movements, their dependence on guiding sensations, 722-724; performed by the instrumentality of the Sensori-motor apparatus, 724-728; not definitely distinguishable from involuntary movements, 909-910; impulse to them originates in Cerebrum, 754 (see *Volitional Actions*).
 Vomiting, reversed action of œsophagus in, 404; action of stomach in, 407, 408.
 Vowel-sounds, production of, 935-937.

W.

Walking, automatic action of, 698-699.
 Wandsworth, cholera at, 542.
 Waste of Tissues; see *Disintegration and Degeneration*.
Water, proportion of, in different tissues, 100; its uses in the economy, 100, 101; proportion of, in blood, 170; influence of ingestion of fluid on, 177; alterations in, produced by disease, 190; importance of, in diet, 380; effects of impurities of, 389.
 Water-dressing for wounds, 564.
 Weight of Fœtus at different ages, 1012-1014; of male and female at after periods of life, 1016, 1017.
White Corpuscles; see *Blood-Corpuscles*, Colorless.
White Fibrous Tissue, structure and composition of, 224, 225; presence of, in Areolar tissue, 226, 227; development and reparation of, 227-229.
Will, freedom of, 775, 817; its influence on the Organism in general, 793-795; its manifestation in Force, 37, 774, 787; its domination over reflex actions, 648, 649; its operation through automatic apparatus,

725-728; requires guiding sensations for its direction to the muscles, 722-724; influence of emotional states of mind upon its exercise, 768, 769; influence of ideational states, 793, 794.
 Its influence on Psychical action, 649-650, 775, 788-790, 795-796, 810-814; effects of its suspension, in Reverie, 796, 797; in "Biological" state, 797, 798; in Somnambulism, 800, 801; in Dreaming, 802-804; in Delirium and Mania, 804-806; in Insanity, 806-810; government of the conduct by, 811, 812, 817-819.
 Its general control over Automatic actions of nervous system, 831; over Cerebral action, 832-836; over Sensory Ganglia, 836, 837; over Spinal Axis, 842.
 Winking, act of, 697.
 Wounds, healing of, 561-566.

X.

Xanthine, 92.

Y.

Yawning, act of, 518; consensual nature of, 720.
 Yelk, composition of, 958; segmentation of, 988, 989.
 Yellow Fever, muscular actions after death from, 327; continued flow of blood, 492; subsequent production of heat, 619.
Yellow Fibrous Tissue, structure and composition of, 225, 226; presence of, in Areolar tissue, 226, 227; development of, 228.
 Young animals, inferior heat-producing power of, 629-631.

Z.

Zona pellucida, 958.
 Zymotic diseases, favored by previous state of blood, 216-220; by putrescent food, 387, 388; by putrescent water, 389; by starvation, 395; by deficiency of respiration, 538-546.

CATALOGUE

OF

BLANCHARD & LEA'S

MEDICAL AND SURGICAL PUBLICATIONS.

TO THE MEDICAL PROFESSION.

In submitting the following catalogue of our publications in medicine and the collateral sciences, we beg to remark that no exertions are spared to render the issues of our press worthy a continuance of the confidence which they have thus far enjoyed, both as regards the high character of the works themselves, and in respect to every point of typographical accuracy, and mechanical and artistical execution. Gentlemen desirous of adding to their libraries from our list, can in almost all cases procure the works they wish from the nearest bookseller, who can readily order any which may not be on hand; and who, as well as ourselves, will be happy to answer any inquiries as to price, &c.

BLANCHARD & LEA.

PHILADELPHIA, November, 1854.

TWO MEDICAL PERIODICALS, FREE OF POSTAGE, FOR FIVE DOLLARS PER ANNUM.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES, subject to
postage, when not paid for in advance, - - - - - \$5 00
THE MEDICAL NEWS AND LIBRARY, invariably in advance, - - - 1 00
OR, BOTH PERIODICALS furnished, FREE OF POSTAGE, for Five Dollars remitted
in advance.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES, EDITED BY ISAAC HAYS, M. D.,

is published Quarterly, on the first of January, April, July, and October. Each number contains at least two hundred and eighty large octavo pages, appropriately illustrated, wherever necessary, by engravings. It has now been issued regularly for a period of THIRTY-FIVE years, during a quarter of a century of which it has been under the control of the present editor. Throughout this long space of time, it has maintained its position in the highest rank of medical periodicals both at home and abroad, and has received the cordial support of the entire profession in this country. Its list of Collaborators will be found to contain a large number of the most distinguished names of the profession in every section of the United States, rendering the department devoted to

ORIGINAL COMMUNICATIONS

full of varied and important matter, of great interest to all practitioners.

As the aim of the Journal, however, is to combine the advantages presented by all the different varieties of periodicals, in its

REVIEW DEPARTMENT

will be found extended and impartial reviews of all important new works, presenting subjects of novelty and interest, together with very numerous

BIBLIOGRAPHICAL NOTICES,

including nearly all the medical publications of the day, both in this country and Great Britain, with a choice selection of the more important continental works. This is followed by the

QUARTERLY SUMMARY,

being a very full and complete abstract, methodically arranged, of the

IMPROVEMENTS AND DISCOVERIES IN THE MEDICAL SCIENCES.

This department of the Journal, so important to the practising physician, is the object of especial care on the part of the editor. It is classified and arranged under different heads, thus facilitating the researches of the reader in pursuit of particular subjects, and will be found to present a very full and accurate digest of all observations, discoveries, and inventions recorded in every branch of medical science. The very extensive arrangements of the publishers are such as to afford to the editor complete materials for this purpose, as he not only regularly receives

ALL THE AMERICAN MEDICAL AND SCIENTIFIC PERIODICALS,

but also twenty or thirty of the more important Journals issued in Great Britain and on the Continent, thus enabling him to present in a convenient compass a thorough and complete abstract of everything interesting or important to the physician occurring in any part of the civilized world.

An evidence of the success which has attended these efforts may be found in the constant and steady increase in the subscription list, which renders it advisable for gentlemen desiring the Journal, to make known their wishes at an early day, in order to secure a year's set with certainty, the publishers having frequently been unable to supply copies when ordered late in the year. To their old subscribers, many of whom have been on their list for twenty or thirty years, the publishers feel that no promises are necessary; but those who may desire for the first time to subscribe, can rest assured that no exertion will be spared to maintain the Journal in the high position which it has occupied for so long a period.

By reference to the terms it will be seen that, in addition to this large amount of valuable and practical information on every branch of medical science, the subscriber, by paying in advance, becomes entitled, without further charge, to

THE MEDICAL NEWS AND LIBRARY,

a monthly periodical of thirty-two large octavo pages. Its "NEWS DEPARTMENT" presents the current information of the day, while the "LIBRARY DEPARTMENT" is devoted to presenting standard works on various branches of medicine. Within a few years, subscribers have thus received, without expense, the following works which have passed through its columns:—

WATSON'S LECTURES ON THE PRACTICE OF PHYSIC.

BRODIE'S CLINICAL LECTURES ON SURGERY.

TODD AND BOWMAN'S PHYSIOLOGICAL ANATOMY AND PHYSIOLOGY OF MAN.

724 pages, with numerous wood-cuts, being all that has yet appeared in England.

WEST'S LECTURES ON THE DISEASES OF INFANCY AND CHILDHOOD.

MALGAIGNE'S OPERATIVE SURGERY, with wood-cuts, and

SIMON'S LECTURES ON GENERAL PATHOLOGY.

While the year 1854, presents

BENNETT ON PULMONARY TUBERCULOSIS,

BEAUTIFULLY ILLUSTRATED ON WOOD.

AND

WEST ON ULCERATION OF THE OS UTERI.

To be followed in 1855 by

A VALUABLE WORK ON A PRACTICAL DEPARTMENT OF MEDICAL SCIENCE.

It will thus be seen that for the small sum of FIVE DOLLARS, paid in advance, the subscriber will obtain a Quarterly and a Monthly periodical,

EMBRACING ABOUT FIFTEEN HUNDRED LARGE OCTAVO PAGES.

mailed to any part of the United States, free of postage.

These very favorable terms are now presented by the publishers with the view of removing all difficulties and objections to a full and extended circulation of the Medical Journal to the office of every member of the profession throughout the United States. The rapid extension of mail facilities, will now place the numbers before subscribers with a certainty and dispatch not heretofore attainable; while by the system now proposed, every subscriber throughout the Union is placed upon an equal footing, at the very reasonable price of Five Dollars for two periodicals, without further expense.

Those subscribers who do not pay in advance will bear in mind that their subscription of Five Dollars will entitle them to the Journal only, without the News, and that they will be at the expense of their own postage on the receipt of each number. The advantage of a remittance when ordering the Journal will thus be apparent.

As the Medical News and Library is in no case sent without advance payment, its subscribers will always receive it free of postage.

It should also be borne in mind that the publishers will now take the risk of remittances by mail, only requiring, in cases of loss, a certificate from the subscriber's Postmaster, that the money was duly mailed and forwarded.

Funds at par at the subscriber's place of residence received in payment of subscriptions.

Address, BLANCHARD & LEA, PHILADELPHIA.

ANALYTICAL COMPENDIUM

OF MEDICAL SCIENCE, containing Anatomy, Physiology, Surgery, Midwifery, Chemistry, Materia Medica, Therapeutics, and Practice of Medicine. By JOHN NEILL, M. D., and F. G. SMITH, M. D. Second and enlarged edition, one thick volume royal 12mo. of over 1000 pages, with 350 illustrations. See NEILL.

ABEL (F. A.), F. C. S.

Professor of Chemistry in the Royal Military Academy, Woolwich.

AND

C. L. BLOXAM,

Formerly First Assistant at the Royal College of Chemistry.

HANDBOOK OF CHEMISTRY, Theoretical, Practical, and Technical, with a Recommendatory Preface by Dr. HOFMANN. In one large octavo volume of 662 pages, with illustrations. (*Now Ready.*)

There was still wanting some book which should aid the young analytical chemist through all the phases of the science. The "Handbook" of Messrs. Abel and Bloxam appears to supply that want. As Dr. Hofmann says in his brief Preface, "The present volume is a synopsis of their (the authors') experience in laboratory teaching; it gives the necessary instruction in chemical manipulation, a concise account of general chemistry as far as it is involved in the operations of the laboratory, and lastly, qualitative and quantitative analysis. It must be understood that this is a work fitted for the earnest student,

who resolves to pursue for himself a steady search into the chemical mysteries of creation. For such a student the 'Handbook' will prove an excellent guide, since he will find in it, not merely the most approved modes of analytical investigation, but descriptions of the apparatus necessary, with such manipulatory details as rendered Faraday's 'Chemical Manipulations' so valuable at the time of its publication. Beyond this, the importance of the work is increased by the introduction of much of the technical chemistry of the manufactory."—*Athenæum*.

ASHWELL (SAMUEL), M. D.

A PRACTICAL TREATISE ON THE DISEASES PECULIAR TO WOMEN.

Illustrated by Cases derived from Hospital and Private Practice. With Additions by PAUL BECK GODDARD, M. D. Second American edition. In one octavo volume, of 520 pages.

ARNOTT (NEILL), M. D.

ELEMENTS OF PHYSICS; or Natural Philosophy, General and Medical.

Written for universal use, in plain or non-technical language. A new edition, by ISAAC HAYS, M. D. Complete in one octavo volume, of 484 pages, with about two hundred illustrations.

BENNETT (J. HUGHES), M. D., F. R. S. E.,

Professor of Clinical Medicine in the University of Edinburgh, &c.

THE PATHOLOGY AND TREATMENT OF PULMONARY TUBERCULOSIS, and on the Local Medication of Pharyngeal and Laryngeal Diseases frequently mistaken for or associated with, Phthisis. In one handsome octavo volume, with beautiful wood-cuts.

(*Now Ready.*)

How it may be most effectually carried into practice, our readers will learn from Dr. Bennett's pages, especially from the histories of the valuable and interesting cases which he records. Indeed, if the author had only reported these cases he would have benefited his profession, and deserved our thanks. As it is, however, his whole volume is so replete with valuable matter, that we feel bound to recommend our readers, one and all, to peruse it.—*Lond. Lancet*.

The elegant little treatise before us shows how faithfully and intelligently these investigations have been pursued, and how successfully the author's studies have resulted in clearing up some of the most doubtful points and conflicting doctrines hitherto entertained in reference to the history and treatment of pulmonary tuberculosis.—*N. Y. Journal of Medical and Collateral Science*, March, 1854.

BENNETT (HENRY), M. D.

A PRACTICAL TREATISE ON INFLAMMATION OF THE UTERUS,

ITS CERVIX AND APPENDAGES, and on its connection with Uterine Disease. Fourth American, from the third and revised London edition. In one neat octavo volume, of 430 pages, with wood-cuts. (*Now Ready.*)

This edition will be found materially improved over its predecessors, the author having carefully revised it, and made considerable additions, amounting to about seventy-five pages.

This edition has been carefully revised and altered, and various additions have been made, which render it more complete, and, if possible, more worthy of the high appreciation in which it is held by the medical profession throughout the world. A copy should be in the possession of every physician.—*Charleston Med. Journal and Review*, March, 1854.

We are firmly of opinion that in proportion as a knowledge of uterine diseases becomes more appreciated, this work will be proportionably established as a text-book in the profession.—*The Lancet*.

When, a few years back, the first edition of the present work was published, the subject was one almost entirely unknown to the obstetrical celebrities of the day; and even now we have reason to know

that the bulk of the profession are not fully alive to the importance and frequency of the disease of which it takes cognizance. The present edition is so much enlarged, altered, and improved, that it can scarcely be considered the same work.—*Dr. Ranking's Abstract*.

Few works issue from the medical press which are at once original and sound in doctrine; but such, we feel assured, is the admirable treatise now before us. The important practical precepts which the author inculcates are all rigidly deduced from facts. . . . Every page of the book is good, and eminently practical. . . . So far as we know and believe, it is the best work on the subject of which it treats.—*Monthly Journal of Medical Science*.

BEALE (LIONEL JOHN), M. R. C. S., &c.

THE LAWS OF HEALTH IN RELATION TO MIND AND BODY.

A Series of Letters from an old Practitioner to a Patient. In one handsome volume, royal 12mo., extra cloth.

BILLING (ARCHIBALD), M. D.

THE PRINCIPLES OF MEDICINE. Second American, from the Fifth and Improved London edition. In one handsome octavo volume, extra cloth, 250 pages.

BLAKISTON (PEYTON), M. D., F. R. S., &c.

PRACTICAL OBSERVATIONS ON CERTAIN DISEASES OF THE CHEST, and on the Principles of Auscultation. In one volume, 8vo., pp. 384.

BURROWS (GEORGE), M. D.

ON DISORDERS OF THE CEREBRAL CIRCULATION, and on the Connection between the Affections of the Brain and Diseases of the Heart. In one 8vo. vol., with colored plates, pp. 216.

BUDD (GEORGE), M. D., F. R. S.,

Professor of Medicine in King's College, London.

ON DISEASES OF THE LIVER. Second American, from the second and enlarged London edition. In one very handsome octavo volume, with four beautifully colored plates, and numerous wood-cuts. pp. 468. New edition. (*Just Issued.*)

The reputation which this work has obtained as a full and practical treatise on an important class of diseases will not be diminished by this improved and enlarged edition. It has been carefully and thoroughly revised by the author; the number of plates has been increased, and the style of its mechanical execution will be found materially improved.

The full digest we have given of the new matter introduced into the present volume, is evidence of the value we place on it. The fact that the profession has required a second edition of a monograph such as that before us, bears honorable testimony to its usefulness. For many years, Dr. Budd's

work must be the authority of the great mass of British practitioners on the hepatic diseases; and it is satisfactory that the subject has been taken up by so able and experienced a physician.—*British and Foreign Medico-Chirurgical Review.*

BUSHNAN (J. S.), M. D.

THE PHYSIOLOGY OF ANIMAL AND VEGETABLE LIFE; a Popular Treatise on the Functions and Phenomena of Organic Life. To which is prefixed a Brief Exposition of the great departments of Human Knowledge. In one handsome royal 12mo. volume, with over one hundred illustrations.

Though cast in a popular form and manner, this work is the production of a man of science, and presents its subject in its latest development, based on truly scientific and accurate principles. It may therefore be consulted with interest by those who wish to obtain in a concise form, and at a very low price, a résumé of the present state of animal and vegetable physiology.

BLOOD AND URINE (MANUALS ON).

BY JOHN WILLIAM GRIFFITH, G. OWEN REESE, AND ALFRED MARKWICK. One thick volume, royal 12mo., extra cloth, with plates. pp. 460.

BRODIE (SIR BENJAMIN C.), M. D., &c.

CLINICAL LECTURES ON SURGERY. 1 vol. 8vo., cloth. 350 pp.

BY THE SAME AUTHOR.

SELECT SURGICAL WORKS, 1 vol. 8vo. leather, containing Clinical Lectures on Surgery, Diseases of the Joints, and Diseases of the Urinary Organs.

BIRD (GOLDING), A. M., M. D., &c.

URINARY DEPOSITS: THEIR DIAGNOSIS, PATHOLOGY, AND THERAPEUTICAL INDICATIONS. A new and enlarged American, from the last improved London edition. With over sixty illustrations. In one royal 12mo. volume, extra cloth.

The new edition of Dr. Bird's work, though not increased in size, has been greatly modified, and much of it rewritten. It now presents, in a compendious form, the gist of all that is known and reliable in this department. From its terse style and convenient size, it is particularly applicable to the student, to whom we cordially commend it.—*The Medical Examiner.*

It can scarcely be necessary for us to say anything of the merits of this well-known Treatise, which so admirably brings into practical application the re-

sults of those microscopical and chemical researches regarding the physiology and pathology of the urinary secretion, which have contributed so much to the increase of our diagnostic powers, and to the extension and satisfactory employment of our therapeutic resources. In the preparation of this new edition of his work, it is obvious that Dr. Golding Bird has spared no pains to render it a faithful representation of the present state of scientific knowledge on the subject it embraces.—*The British and Foreign Medico-Chirurgical Review.*

BY THE SAME AUTHOR.

ELEMENTS OF NATURAL PHILOSOPHY; being an Experimental Introduction to the Physical Sciences. Illustrated with nearly four hundred wood-cuts. From the third London edition. In one neat volume, royal 12mo. pp. 402.

BARTLETT (ELISHA), M. D.,

Professor of Materia Medica and Medical Jurisprudence in the College of Physicians and Surgeons, New York.

THE HISTORY, DIAGNOSIS, AND TREATMENT OF THE FEVERS OF THE UNITED STATES. Third edition, revised and improved. In one octavo volume, of six hundred pages, beautifully printed, and strongly bound.

In preparing a new edition of this standard work, the author has availed himself of such observations and investigations as have appeared since the publication of his last revision, and he has endeavored in every way to render it worthy of a continuance of the very marked favor with which it has been hitherto received.

The masterly and elegant treatise, by Dr. Bartlett is invaluable to the American student and practitioner.—*Dr. Holmes's Report to the Nat. Med. Association.*

We regard it, from the examination we have made of it, the best work on fevers extant in our language, and as such cordially recommend it to the medical public.—*St. Louis Medical and Surgical Journal.*

Take it altogether, it is the most complete history of our fevers which has yet been published, and every practitioner should avail himself of its contents.—*The Western Lancet.*

Of the value and importance of such a work, it is needless here to speak; the profession of the United States owe much to the author for the very able volume which he has presented to them, and for the careful and judicious manner in which he has executed his task. No one volume with which we are acquainted contains so complete a history of our fevers as this. To Dr. Bartlett we owe our best thanks for the very able volume he has given us, as embodying certainly the most complete, methodical, and satisfactory account of our fevers anywhere to be met with.—*The Charleston Med. Journal and Review.*

BUCKLER (T. H.), M. D.,

Formerly Physician to the Baltimore Almshouse Infirmary, &c.

ON THE ETIOLOGY, PATHOLOGY, AND TREATMENT OF FIBRO-BRONCHITIS AND RHEUMATIC PNEUMONIA. In one handsome octavo volume, extra cloth. (*Just Issued.*)

BOWMAN (JOHN E.), M. D.

PRACTICAL HANDBOOK OF MEDICAL CHEMISTRY. In one neat volume, royal 12mo., with numerous illustrations. pp. 288.

BY THE SAME AUTHOR.

INTRODUCTION TO PRACTICAL CHEMISTRY, INCLUDING ANALYSIS. With numerous illustrations. In one neat volume, royal 12mo. pp. 350.

BARLOW (GEORGE H.), M. D.

A MANUAL OF THE PRINCIPLES AND PRACTICE OF MEDICINE. In one octavo volume. (*Preparing.*)

CYCLOPÆDIA OF PRACTICAL MEDICINE.

Edited by DUNGLISON, FORBES, TWEEDIE, and CONOLLY, in four large octavo volumes, strongly bound. See DUNGLISON.

COLOMBAT DE L'ISERE.

A TREATISE ON THE DISEASES OF FEMALES, and on the Special Hygiene of their Sex. Translated, with many Notes and Additions, by C. D. MEIGS, M. D. Second edition, revised and improved. In one large volume, octavo, with numerous wood-cuts. pp. 720.

The treatise of M. Colombat is a learned and laborious commentary on these diseases, indicating very considerable research, great accuracy of judgment, and no inconsiderable personal experience. With the copious notes and additions of its experienced and very erudite translator and editor, Dr. Meigs, it presents, probably, one of the most complete and comprehensive works on the subject we possess.—*American Med. Journal.*

M. Colombat De L'Isere has not consecrated ten years of studious toil and research to the frailer sex in vain; and although we regret to hear it is at the expense of health, he has imposed a debt of gratitude as well upon the profession, as upon the mothers and daughters of beautiful France, which that gallant nation knows best how to acknowledge.—*New Orleans Medical Journal.*

COPLAND (JAMES), M. D., F. R. S., &c.

OF THE CAUSES, NATURE, AND TREATMENT OF PALSY AND APOPLEXY, and of the Forms, Seats, Complications, and Morbid Relations of Paralytic and Apoplectic Diseases. In one volume, royal 12mo., extra cloth. pp. 326.

CLYMER (MEREDITH), M. D., &c.

FEVERS; THEIR DIAGNOSIS, PATHOLOGY, AND TREATMENT. Prepared and Edited, with large Additions, from the Essays on Fever in Tweedie's Library of Practical Medicine. In one octavo volume, of 600 pages.

CARSON (JOSEPH), M. D.,

Professor of Materia Medica and Pharmacy in the University of Pennsylvania.

SYNOPSIS OF THE COURSE OF LECTURES ON MATERIA MEDICA AND PHARMACY, delivered in the University of Pennsylvania. In one very neat octavo volume, of 208 pages.

CARPENTER (WILLIAM B.), M. D., F. R. S., &c.,
 Examiner in Physiology and Comparative Anatomy in the University of London.

PRINCIPLES OF HUMAN PHYSIOLOGY; with their chief applications to Psychology, Pathology, Therapeutics, Hygiene, and Forensic Medicine. Fifth American, from the fourth and enlarged London edition. With three hundred and fourteen illustrations. Edited, with additions, by FRANCIS GURNEY SMITH, M. D., Professor of the Institutes of Medicine in the Pennsylvania Medical College, &c. In one very large and beautiful octavo volume, of about 1100 large pages, handsomely printed and strongly bound in leather, with raised bands. New edition. (*Lately Issued.*)

The most complete work on the science in our language.—*Am. Med. Journal.*

The most complete exposition of physiology which any language can at present give.—*Brit. and For. Med.-Chirurg. Review.*

We have thus adverted to some of the leading "additions and alterations," which have been introduced by the author into this edition of his physiology. These will be found, however, very far to exceed the ordinary limits of a new edition, "the old materials having been incorporated with the new, rather than the new with the old." It now certainly presents the most complete treatise on the subject within the reach of the American reader; and while, for availability as a text-book, we may perhaps regret its growth in bulk, we are sure that the student of physiology will feel the impossibility of presenting a thorough digest of the facts of the science within a more limited compass.—*Medical Examiner.*

The greatest, the most reliable, and the best book on the subject which we know of in the English language.—*Stethoscope.*

The most complete work now extant in our language.—*N. O. Med. Register.*

The changes are too numerous to admit of an extended notice in this place. At every point where the recent diligent labors of organic chemists and micrographers have furnished interesting and valuable facts, they have been appropriated, and no pains have been spared, in so incorporating and arranging them that the work may constitute one harmonious system.—*Southern Med. and Surg. Journal.*

BY THE SAME AUTHOR. (*Now Ready.*)

PRINCIPLES OF COMPARATIVE PHYSIOLOGY. New American, from the Fourth and Revised London edition. In one large and handsome octavo volume, with over three hundred beautiful illustrations.

The delay which has existed in the appearance of this work has been caused by the very thorough revision and remodelling which it has undergone at the hands of the author, and the large number of new illustrations which have been prepared for it. It will, therefore, be found almost a new work, and fully up to the day in every department of the subject, rendering it a reliable text-book for all students engaged in this branch of science. Every effort has been made to render its typographical finish and mechanical execution worthy of its exalted reputation, and creditable to the mechanical arts of this country. A few notices of the last edition are appended.

Without pretending to it, it is an Encyclopedia of the subject, accurate and complete in all respects—a truthful reflection of the advanced state at which the science has now arrived.—*Dublin Quarterly Journal of Medical Science.*

A truly magnificent work—in itself a perfect physiological study.—*Ranking's Abstract.*

This work stands without its fellow. It is one few men in Europe could have undertaken; it is one no man, we believe, could have brought to so successful an issue as Dr. Carpenter. It required for its production a physiologist at once deeply read in the labors of others, capable of taking a general,

The best text-book in the language on this extensive subject.—*London Med. Times.*

A complete cyclopædia of this branch of science.—*N. Y. Med. Times.*

The standard of authority on physiological subjects. * * * In the present edition, to particularize the alterations and additions which have been made, would require a review of the whole work, since scarcely a subject has not been revised and altered, added to, or entirely remodelled to adapt it to the present state of the science.—*Charleston Med. Journ.*

Any reader who desires a treatise on physiology may feel himself entirely safe in ordering this.—*Western Med. and Surg. Journal.*

From this hasty and imperfect allusion it will be seen by our readers that the alterations and additions to this edition render it almost a new work—and we can assure our readers that it is one of the best summaries of the existing facts of physiological science within the reach of the English student and physician.—*N. Y. Journal of Medicine.*

The profession of this country, and perhaps also of Europe, have anxiously and for some time awaited the announcement of this new edition of Carpenter's Human Physiology. His former editions have for many years been almost the only text-book on Physiology in all our medical schools, and its circulation among the profession has been unsurpassed by any work in any department of medical science.

It is quite unnecessary for us to speak of this work as its merits would justify. The mere announcement of its appearance will afford the highest pleasure to every student of Physiology, while its perusal will be of infinite service in advancing physiological science.—*Ohio Med. and Surg. Journ.*

critical, and unprejudiced view of those labors, and of combining the varied, heterogeneous materials at his disposal, so as to form an harmonious whole. We feel that this abstract can give the reader a very imperfect idea of the fulness of this work, and no idea of its unity, of the admirable manner in which material has been brought, from the most various sources, to conduce to its completeness, of the lucidity of the reasoning it contains, or of the clearness of language in which the whole is clothed. Not the profession only, but the scientific world at large, must feel deeply indebted to Dr. Carpenter for this great work. It must, indeed, add largely even to his high reputation.—*Medical Times.*

BY THE SAME AUTHOR. (*Preparing.*)

THE MICROSCOPE AND ITS REVELATIONS. In one handsome volume, beautifully illustrated with plates and wood-cuts.

BY THE SAME AUTHOR. (*Preparing.*)

GENERAL PHYSIOLOGY. In one large and very handsome octavo volume, with several hundred illustrations.

The subject of general physiology having been omitted in the last edition of the author's "Comparative Physiology," he has undertaken to prepare a volume which shall present it more thoroughly and fully than has yet been attempted, and which may be regarded as an introduction to his other works.

CARPENTER (WILLIAM B.), M. D., F. R. S.,

Examiner in Physiology and Comparative Anatomy in the University of London.

ELEMENTS (OR MANUAL) OF PHYSIOLOGY, INCLUDING PHYSIOLOGICAL ANATOMY. Second American, from a new and revised London edition. With one hundred and ninety illustrations. In one very handsome octavo volume.

In publishing the first edition of this work, its title was altered from that of the London volume, by the substitution of the word "Elements" for that of "Manual," and with the author's sanction the title of "Elements" is still retained as being more expressive of the scope of the treatise. A comparison of the present edition with the former one will show a material improvement, the author having revised it thoroughly, with a view of rendering it completely on a level with the most advanced state of the science. By condensing the less important portions, these numerous additions have been introduced without materially increasing the bulk of the volume, and while numerous illustrations have been added, and the general execution of the work improved, it has been kept at its former very moderate price.

To say that it is the best manual of Physiology now before the public, would not do sufficient justice to the author.—*Buffalo Medical Journal*.

In his former works it would seem that he had exhausted the subject of Physiology. In the present, he gives the essence, as it were, of the whole.—*N. Y. Journal of Medicine*.

Those who have occasion for an elementary treatise on Physiology, cannot do better than to possess themselves of the manual of Dr. Carpenter.—*Medical Examiner*.

The best and most complete exposé of modern Physiology, in one volume, extant in the English language.—*St. Louis Medical Journal*.

With such an aid in his hand, there is no excuse for the ignorance often displayed respecting the subjects of which it treats. From its unpretending dimensions, it may not be so esteemed by those anxious to make a parade of their erudition; but whoever masters its contents will have reason to be proud of his physiological acquirements. The illustrations are well selected and finely executed.—*Dublin Med. Press*.

BY THE SAME AUTHOR.

A PRIZE ESSAY ON THE USE OF ALCOHOLIC LIQUORS IN HEALTH AND DISEASE. New edition, with a Preface by D. F. CONDIE, M. D., and explanations of scientific words. In one neat 12mo. volume. (*Now Ready*.)

This new edition has been prepared with a view to an extended circulation of this important little work, which is universally recognized as the best exponent of the laws of physiology and pathology applied to the subject of intoxicating liquors, in a form suited both for the profession and the public. To secure a wider dissemination of its doctrines the publishers have done up copies in flexible cloth, suitable for mailing, which will be forwarded through the post-office, free, on receipt of fifty cents. Societies and others supplied in quantities for distribution at a liberal deduction.

CHELIUS (J. M.), M. D.,

Professor of Surgery in the University of Heidelberg, &c.

A SYSTEM OF SURGERY. Translated from the German, and accompanied with additional Notes and References, by JOHN F. SOUTH. Complete in three very large octavo volumes, of nearly 2200 pages, strongly bound, with raised bands and double titles.

We do not hesitate to pronounce it the best and most comprehensive system of modern surgery with which we are acquainted.—*Medico-Chirurgical Review*.

The fullest and ablest digest extant of all that relates to the present advanced state of surgical pathology.—*American Medical Journal*.

As complete as any system of Surgery can well be.—*Southern Medical and Surgical Journal*.

The most learned and complete systematic treatise now extant.—*Edinburgh Medical Journal*.

A complete encyclopædia of surgical science—a very complete surgical library—by far the most complete and scientific system of surgery in the English language.—*N. Y. Journal of Medicine*.

The most extensive and comprehensive account of the art and science of Surgery in our language.—*Lancet*.

CHRISTISON (ROBERT), M. D., V. P. R. S. E., &c.

A DISPENSATORY; or, Commentary on the Pharmacopœias of Great Britain and the United States; comprising the Natural History, Description, Chemistry, Pharmacy, Actions, Uses, and Doses of the Articles of the *Materia Medica*. Second edition, revised and improved, with a Supplement containing the most important New Remedies. With copious Additions, and two hundred and thirteen large wood-engravings. By R. EGLESFELD GRIFFITH, M. D. In one very large and handsome octavo volume, of over 1000 pages.

It is not needful that we should compare it with the other pharmacopœias extant, which enjoy and merit the confidence of the profession: it is enough to say that it appears to us as perfect as a Dispensatory, in the present state of pharmaceutical science, could be made. If it omits any details pertaining to this branch of knowledge which the student has a right to expect in such a work, we confess the omission has escaped our scrutiny. We cordially recommend this work to such of our readers as are in need of a Dispensatory. They cannot make choice of a better.—*Western Journ. of Medicine and Surgery*.

There is not in any language a more complete and perfect Treatise.—*N. Y. Analyst*.

In conclusion, we need scarcely say that we strongly recommend this work to all classes of our readers. As a Dispensatory and commentary on the Pharmacopœias, it is unrivalled in the English or any other language.—*The Dublin Quarterly Journal*.

We earnestly recommend Dr. Christison's Dispensatory to all our readers, as an indispensable companion, not in the Study only, but in the Surgery also.—*British and Foreign Medical Review*.

CONDIE (D. F.), M. D., &c.

A PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. Fourth edition, revised and augmented. In one large volume, 8vo., of nearly 750 pages. (*Just Issued.*)

FROM THE AUTHOR'S PREFACE.

The demand for another edition has afforded the author an opportunity of again subjecting the entire treatise to a careful revision, and of incorporating in it every important observation recorded since the appearance of the last edition, in reference to the pathology and therapeutics of the several diseases of which it treats.

In the preparation of the present edition, as in those which have preceded, while the author has appropriated to his use every important fact that he has found recorded in the works of others, having a direct bearing upon either of the subjects of which he treats, and the numerous valuable observations—pathological as well as practical—dispersed throughout the pages of the medical journals of Europe and America, he has, nevertheless, relied chiefly upon his own observations and experience, acquired during a long and somewhat extensive practice, and under circumstances peculiarly well adapted for the clinical study of the diseases of early life.

Every species of hypothetical reasoning has, as much as possible, been avoided. The author has endeavored throughout the work to confine himself to a simple statement of well-ascertained pathological facts, and plain therapeutical directions—his chief desire being to render it what its title imports it to be, **A PRACTICAL TREATISE ON THE DISEASES OF CHILDREN.**

Dr. Condie's scholarship, acumen, industry, and practical sense are manifested in this, as in all his numerous contributions to science.—*Dr. Holmes's Report to the American Medical Association.*

Taken as a whole, in our judgment, Dr. Condie's Treatise is the one from the perusal of which the practitioner in this country will rise with the greatest satisfaction.—*Western Journal of Medicine and Surgery.*

One of the best works upon the Diseases of Children in the English language.—*Western Lancet.*

Perhaps the most full and complete work now before the profession of the United States; indeed, we may say in the English language. It is vastly superior to most of its predecessors.—*Transylvania Med. Journal.*

We feel assured from actual experience that no physician's library can be complete without a copy of this work.—*N. Y. Journal of Medicine.*

A veritable pædiatric encyclopædia, and an honor to American medical literature.—*Ohio Medical and Surgical Journal.*

We feel persuaded that the American medical profession will soon regard it not only as a very good, but as the **VERY BEST** "Practical Treatise on the Diseases of Children."—*American Medical Journal.*

We pronounced the first edition to be the best work on the diseases of children in the English language, and, notwithstanding all that has been published, we still regard it in that light.—*Medical Examiner.*

COOPER (BRANSBY B.), F. R. S.,

Senior Surgeon to Guy's Hospital, &c.

LECTURES ON THE PRINCIPLES AND PRACTICE OF SURGERY.

In one very large octavo volume, of 750 pages. (*Lately Issued.*)

For twenty-five years Mr. Bransby Cooper has been surgeon to Guy's Hospital; and the volume before us may be said to consist of an account of the results of his surgical experience during that long period. We cordially recommend Mr. Bransby

Cooper's Lectures as a most valuable addition to our surgical literature, and one which cannot fail to be of service both to students and to those who are actively engaged in the practice of their profession.—*The Lancet.*

COOPER (SIR ASTLEY P.), F. R. S., &c.

A TREATISE ON DISLOCATIONS AND FRACTURES OF THE JOINTS.

Edited by BRANSBY B. COOPER, F. R. S., &c. With additional Observations by Prof. J. C. WARREN. A new American edition. In one handsome octavo volume, with numerous illustrations on wood.

BY THE SAME AUTHOR.

ON THE ANATOMY AND TREATMENT OF ABDOMINAL HERNIA.

One large volume, imperial 8vo., with over 130 lithographic figures.

BY THE SAME AUTHOR.

ON THE STRUCTURE AND DISEASES OF THE TESTIS, AND ON THE THYMUS GLAND. One vol. imperial 8vo., with 177 figures, on 29 plates.

BY THE SAME AUTHOR.

ON THE ANATOMY AND DISEASES OF THE BREAST, with twenty-five Miscellaneous and Surgical Papers. One large volume, imperial 8vo., with 252 figures, on 36 plates.

These last three volumes complete the surgical writings of Sir Astley Cooper. They are very handsomely printed, with a large number of lithographic plates, executed in the best style, and are presented at exceedingly low prices.

CHURCHILL (FLEETWOOD), M. D., M. R. I. A.

ON THE THEORY AND PRACTICE OF MIDWIFERY. A new American, from the last and improved English edition. Edited, with Notes and Additions, by D. FRANCIS CONDIE, M. D., author of a "Practical Treatise on the Diseases of Children," &c. With 139 illustrations. In one very handsome octavo volume, pp. 510. (*Lately Issued.*)

To bestow praise on a book that has received such marked approbation would be superfluous. We need only say, therefore, that if the first edition was thought worthy of a favorable reception by the medical public, we can confidently affirm that this will be found much more so. The lecturer, the practitioner, and the student, may all have recourse to its pages, and derive from their perusal much interest and instruction in everything relating to theoretical and practical midwifery.—*Dublin Quarterly Journal of Medical Science.*

A work of very great merit, and such as we can confidently recommend to the study of every obstetric practitioner.—*London Medical Gazette.*

This is certainly the most perfect system extant. It is the best adapted for the purposes of a text-book, and that which he whose necessities confine him to one book, should select in preference to all others.—*Southern Medical and Surgical Journal.*

The most popular work on midwifery ever issued from the American press.—*Charleston Med. Journal.*

Were we reduced to the necessity of having but one work on midwifery, and permitted to choose, we would unhesitatingly take Churchill.—*Western Med. and Surg. Journal.*

It is impossible to conceive a more useful and elegant manual than Dr. Churchill's Practice of Midwifery.—*Provincial Medical Journal.*

Certainly, in our opinion, the very best work on the subject which exists.—*N. Y. Annalist.*

No work holds a higher position, or is more deserving of being placed in the hands of the tyro, the advanced student, or the practitioner.—*Medical Examiner.*

Previous editions, under the editorial supervision of Prof. R. M. Huston, have been received with marked favor, and they deserved it; but this, reprinted from a very late Dublin edition, carefully revised and brought up by the author to the present time, does present an unusually accurate and able exposition of every important particular embraced in the department of midwifery. * * The clearness, directness, and precision of its teachings, together with the great amount of statistical research which its text exhibits, have served to place it already in the foremost rank of works in this department of remedial science.—*N. O. Med. and Surg. Journal.*

In our opinion, it forms one of the best if not the very best text-book and epitome of obstetric science which we at present possess in the English language.—*Monthly Journal of Medical Science.*

The clearness and precision of style in which it is written, and the great amount of statistical research which it contains, have served to place it in the first rank of works in this department of medical science.—*N. Y. Journal of Medicine.*

Few treatises will be found better adapted as a text-book for the student, or as a manual for the frequent consultation of the young practitioner.—*American Medical Journal.*

BY THE SAME AUTHOR.

ON THE DISEASES OF INFANTS AND CHILDREN. In one large and handsome volume of over 600 pages.

We regard this volume as possessing more claims to completeness than any other of the kind with which we are acquainted. Most cordially and earnestly, therefore, do we commend it to our professional brethren, and we feel assured that the stamp of their approbation will in due time be impressed upon it. After an attentive perusal of its contents, we hesitate not to say, that it is one of the most comprehensive ever written upon the diseases of children, and that, for copiousness of reference, extent of research, and perspicuity of detail, it is scarcely to be equalled, and not to be excelled, in any language.—*Dublin Quarterly Journal.*

After this meagre, and we know, very imperfect notice of Dr. Churchill's work, we shall conclude by saying, that it is one that cannot fail from its copiousness, extensive research, and general accuracy, to exalt still higher the reputation of the author in this country. The American reader will be particularly pleased to find that Dr. Churchill has done full justice throughout his work to the various American authors on this subject. The names of Dewees, Eberle, Condie, and Stewart, occur on nearly every page, and these authors are constantly referred to by the author in terms of the highest praise, and with the most liberal courtesy.—*The Medical Examiner.*

The present volume will sustain the reputation acquired by the author from his previous works. The reader will find in it full and judicious directions for the management of infants at birth, and a compendious, but clear account of the diseases to which children are liable, and the most successful mode of treating them. We must not close this notice without calling attention to the author's style, which is perspicuous and polished to a degree, we regret to say, not generally characteristic of medical works. We recommend the work of Dr. Churchill most cordially, both to students and practitioners, as a valuable and reliable guide in the treatment of the diseases of children.—*Am. Journ. of the Med. Sciences.*

We know of no work on this department of Practical Medicine which presents so candid and unprejudiced a statement or posting up of our actual knowledge as this.—*N. Y. Journal of Medicine.*

Its claims to merit both as a scientific and practical work, are of the highest order. Whilst we would not elevate it above every other treatise on the same subject, we certainly believe that very few are equal to it, and none superior.—*Southern Med. and Surgical Journal.*

BY THE SAME AUTHOR.

ESSAYS ON THE PUERPERAL FEVER, AND OTHER DISEASES PECULIAR TO WOMEN. Selected from the writings of British Authors previous to the close of the Eighteenth Century. In one neat octavo volume, of about four hundred and fifty pages.

To these papers Dr. Churchill has appended notes, embodying whatever information has been laid before the profession since their authors' time. He has also prefixed to the Essays on Puerperal Fever, which occupy the larger portion of the volume, an interesting historical sketch of the principal epi-

demies of that disease. The whole forms a very valuable collection of papers, by professional writers of eminence, on some of the most important accidents to which the puerperal female is liable.—*American Journal of Medical Science.*

CHURCHILL (FLEETWOOD), M. D., M. R. I. A., &c.

ON THE DISEASES OF WOMEN; including those of Pregnancy and Child-bed. A new American edition, revised by the Author. With Notes and Additions, by D. FRANCIS CONDIE, M. D., author of "A Practical Treatise on the Diseases of Children." In one large and handsome octavo volume, with wood-cuts, pp. 684. (*Just Issued.*)

From the Author's Preface.

In reviewing this edition, at the request of my American publishers, I have inserted several new sections and chapters, and I have added, I believe, all the information we have derived from recent researches; in addition to which the publishers have been fortunate enough to secure the services of an able and highly esteemed editor in Dr. Condie.

We now regretfully take leave of Dr. Churchill's book. Had our typographical limits permitted, we should gladly have borrowed more from its richly stored pages. In conclusion, we heartily recommend it to the profession, and would at the same time express our firm conviction that it will not only add to the reputation of its author, but will prove a work of great and extensive utility to obstetric practitioners.—*Dublin Medical Press.*

Former editions of this work have been noticed in previous numbers of the Journal. The sentiments of high commendation expressed in those notices, have only to be repeated in this; not from the fact that the profession at large are not aware of the high merits which this work really possesses, but from a desire to see the principles and doctrines therein contained more generally recognized, and more universally carried out in practice.—*N. Y. Journal of Medicine.*

We know of no author who deserves that approbation, on "the diseases of females," to the same extent that Dr. Churchill does. His, indeed, is the only thorough treatise we know of on the subject; and it may be commended to practitioners and students as a masterpiece in its particular department. The former editions of this work have been commended strongly in this journal, and they have won their way to an extended, and a well-deserved popu-

larity. This fifth edition, before us, is well calculated to maintain Dr. Churchill's high reputation. It was revised and enlarged by the author, for his American publishers, and it seems to us that there is scarcely any species of desirable information on its subjects that may not be found in this work.—*The Western Journal of Medicine and Surgery.*

We are gratified to announce a new and revised edition of Dr. Churchill's valuable work on the diseases of females. We have ever regarded it as one of the very best works on the subjects embraced within its scope, in the English language; and the present edition, enlarged and revised by the author, renders it still more entitled to the confidence of the profession. The valuable notes of Prof. Huston have been retained, and contribute, in no small degree, to enhance the value of the work. It is a source of congratulation that the publishers have permitted the author to be, in this instance, his own editor, thus securing all the revision which an author alone is capable of making.—*The Western Lancet.*

As a comprehensive manual for students, or a work of reference for practitioners, we only speak with common justice when we say that it surpasses any other that has ever issued on the same subject from the British press.—*The Dublin Quarterly Journal.*

DEWEES (W. P.), M. D., &c.

A COMPREHENSIVE SYSTEM OF MIDWIFERY. Illustrated by occasional Cases and many Engravings. Twelfth edition, with the Author's last Improvements and Corrections. In one octavo volume, of 600 pages. (*Just Issued.*)

BY THE SAME AUTHOR.

A TREATISE ON THE PHYSICAL AND MEDICAL TREATMENT OF CHILDREN. Tenth edition. In one volume, octavo, 548 pages. (*Just Issued.*)

BY THE SAME AUTHOR.

A TREATISE ON THE DISEASES OF FEMALES. Tenth edition. In one volume, octavo, 532 pages, with plates. (*Just Issued.*)

DICKSON (PROFESSOR S. H.), M. D.

ESSAYS ON LIFE, SLEEP, PAIN, INTELLIGENCE, HYGIENE, AND DEATH. In one very handsome volume, royal 12mo.

DANA (JAMES D).

ZOOPHYTES AND CORALS. In one volume, imperial quarto, extra cloth, with wood-cuts.

ALSO,

AN ATLAS TO THE ABOVE, one volume, imperial folio, with sixty-one magnificent plates, colored after nature. Bound in half morocco.

ALSO,

ON THE STRUCTURE AND CLASSIFICATION OF ZOOPHYTES. Sold separate, one vol., cloth.

DE LA BECHE (SIR HENRY T.), F. R. S., &c.

THE GEOLOGICAL OBSERVER. In one very large and handsome octavo volume, of 700 pages. With over three hundred wood-cuts. (*Lately Issued.*)

DRIITT (ROBERT), M. R. C. S., &c.

THE PRINCIPLES AND PRACTICE OF MODERN SURGERY. A new American, from the improved London edition. Edited by F. W. SARGENT, M. D., author of "Minor Surgery," &c. Illustrated with one hundred and ninety-three wood-engravings. In one very handsomely printed octavo volume, of 576 large pages.

Dr. Druitt's researches into the literature of his subject have been not only extensive, but well directed; the most discordant authors are fairly and impartially quoted, and, while due credit is given to each, their respective merits are weighed with an unprejudiced hand. The grain of wheat is preserved, and the chaff is unmercifully stripped off. The arrangement is simple and philosophical, and the style, though clear and interesting, is so precise, that the book contains more information condensed into a few words than any other surgical work with which we are acquainted.—*London Medical Times and Gazette*, February 18, 1864.

No work, in our opinion, equals it in presenting so much valuable surgical matter in so small a compass.—*St. Louis Med. and Surgical Journal*.

Druitt's Surgery is too well known to the American medical profession to require its announcement anywhere. Probably no work of the kind has ever been more cordially received and extensively circulated than this. The fact that it comprehends in a comparatively small compass, all the essential elements of theoretical and practical Surgery—that it is found to contain reliable and authentic information on the nature and treatment of nearly all surgical affections—is a sufficient reason for the liberal patronage it has obtained. The editor, Dr. F. W. Sargent, has contributed much to enhance the value of the work, by such American improvements as are calculated more perfectly to adapt it to our own views and practice in this country. It abounds everywhere with spirited and life-like illustrations, which to the young surgeon, especially, are of no minor consideration. Every medical man frequently needs just such a work as this, for immediate reference in moments of sudden emergency, when he has not time to consult more elaborate treatises.—*The Ohio Medical and Surgical Journal*.

The author has evidently ransacked every standard treatise of ancient and modern times, and all that

is really practically useful at the bedside will be found in a form at once clear, distinct, and interesting.—*Edinburgh Monthly Medical Journal*.

Druitt's work, condensed, systematic, lucid, and practical as it is, beyond most works on Surgery accessible to the American student, has had much currency in this country, and under its present auspices promises to rise to yet higher favor.—*The Western Journal of Medicine and Surgery*.

The most accurate and ample resumé of the present state of Surgery that we are acquainted with.—*Dublin Medical Journal*.

A better book on the principles and practice of Surgery as now understood in England and America, has not been given to the profession.—*Boston Medical and Surgical Journal*.

An unsurpassable compendium, not only of Surgical, but of Medical Practice.—*London Medical Gazette*.

This work merits our warmest commendations, and we strongly recommend it to young surgeons as an admirable digest of the principles and practice of modern Surgery.—*Medical Gazette*.

It may be said with truth that the work of Mr. Druitt affords a complete, though brief and condensed view, of the entire field of modern surgery. We know of no work on the same subject having the appearance of a manual, which includes so many topics of interest to the surgeon; and the terse manner in which each has been treated evinces a most enviable quality of mind on the part of the author, who seems to have an innate power of searching out and grasping the leading facts and features of the most elaborate productions of the pen. It is a useful handbook for the practitioner, and we should deem a teacher of surgery unpardonable who did not recommend it to his pupils. In our own opinion, it is admirably adapted to the wants of the student.—*Provincial Medical and Surgical Journal*.

DUNGLISON, FORBES, TWEEDIE, AND CONOLLY.

THE CYCLOPÆDIA OF PRACTICAL MEDICINE: comprising Treatises on the Nature and Treatment of Diseases, Materia Medica, and Therapeutics, Diseases of Women and Children, Medical Jurisprudence, &c. &c. In four large super royal octavo volumes, of 3254 double-columned pages, strongly and handsomely bound.

* * * This work contains no less than four hundred and eighteen distinct treatises, contributed by sixty-eight distinguished physicians.

The most complete work on Practical Medicine extant; or, at least, in our language.—*Buffalo Medical and Surgical Journal*.

For reference, it is above all price to every practitioner.—*Western Lancet*.

One of the most valuable medical publications of the day—as a work of reference it is invaluable.—*Western Journal of Medicine and Surgery*.

It has been to us, both as learner and teacher, a work for ready and frequent reference, one in which modern English medicine is exhibited in the most advantageous light.—*Medical Examiner*.

We rejoice that this work is to be placed within the reach of the profession in this country, it being

unquestionably one of very great value to the practitioner. This estimate of it has not been formed from a hasty examination, but after an intimate acquaintance derived from frequent consultation of it during the past nine or ten years. The editors are practitioners of established reputation, and the list of contributors embraces many of the most eminent professors and teachers of London, Edinburgh, Dublin, and Glasgow. It is, indeed, the great merit of this work that the principal articles have been furnished by practitioners who have not only devoted especial attention to the diseases about which they have written, but have also enjoyed opportunities for an extensive practical acquaintance with them, and whose reputation carries the assurance of their competency justly to appreciate the opinions of others, while it stamps their own doctrines with high and just authority.—*American Medical Journ.*

DUNGLISON (ROBLEY), M. D.,

Professor of the Institutes of Medicine in the Jefferson Medical College, Philadelphia.

HUMAN HEALTH; or, the Influence of Atmosphere and Locality, Change of Air and Climate, Seasons, Food, Clothing, Bathing, Exercise, Sleep, &c. &c., on Healthy Man; constituting Elements of Hygiene. Second edition, with many modifications and additions. In one octavo volume, of 464 pages.

DUNGLISON (ROBLEY), M. D.,

Professor of Institutes of Medicine in the Jefferson Medical College, Philadelphia.

MEDICAL LEXICON; a Dictionary of Medical Science, containing a concise Explanation of the various Subjects and Terms of Physiology, Pathology, Hygiene, Therapeutics, Pharmacology, Obstetrics, Medical Jurisprudence, &c. With the French and other Synonyms; Notices of Climate and of celebrated Mineral Waters; Formulæ for various Official, Empirical, and Dietetic Preparations, etc. Eleventh edition, revised. In one very thick octavo volume, of over nine hundred large double-columned pages, strongly bound in leather, with raised bands. (Just Issued.)

Every successive edition of this work bears the marks of the industry of the author, and of his determination to keep it fully on a level with the most advanced state of medical science. Thus nearly FIFTEEN THOUSAND WORDS have been added to it within the last few years. As a complete Medical Dictionary, therefore, embracing over FIFTY THOUSAND DEFINITIONS, in all the branches of the science, it is presented as meriting a continuance of the great favor and popularity which have carried it, within no very long space of time, to an eleventh edition.

Every precaution has been taken in the preparation of the present volume, to render its mechanical execution and typographical accuracy worthy of its extended reputation and universal use. The very extensive additions have been accommodated, without materially increasing the bulk of the volume by the employment of a small but exceedingly clear type, cast for this purpose. The press has been watched with great care, and every effort used to insure the verbal accuracy so necessary to a work of this nature. The whole is printed on fine white paper; and, while thus exhibiting in every respect so great an improvement over former issues, it is presented at the original exceedingly low price.

We welcome it cordially; it is an admirable work, and indispensable to all literary medical men. The labor which has been bestowed upon it is something prodigious. The work, however, has now been done, and we are happy in the thought that no human being will have again to undertake the same gigantic task. Revised and corrected from time to time, Dr. Dunglison's "Medical Lexicon" will last for centuries.—*British and Foreign Med. Chirurg. Review*, July, 1853.

The fact that this excellent and learned work has passed through eight editions, and that a ninth is rendered necessary by the demands of the public, affords a sufficient evidence of the general appreciation of Dr. Dunglison's labors by the medical profession in England and America. It is a book which will be of great service to the student, in teaching him the meaning of all the technical terms used in medicine, and will be of no less use to the practitioner who desires to keep himself on a level with the advance of medical science.—*London Medical Times and Gazette*.

In taking leave of our author, we feel compelled to confess that his work bears evidence of almost incredible labor having been bestowed upon its composition.—*Edinburgh Journal of Med. Sciences*, Sept. 1853.

A miracle of labor and industry in one who has written able and voluminous works on nearly every branch of medical science. There could be no more useful book to the student or practitioner, in the present advancing age, than one in which would be found, in addition to the ordinary meaning and derivation of medical terms—so many of which are of modern introduction—concise descriptions of their explanation and employment; and all this and much more is contained in the volume before us. It is therefore almost as indispensable to the other learned professions as to our own. In fact, to all who may have occasion to ascertain the meaning of any word belonging to the many branches of medicine. From a careful examination of the present edition, we can vouch for its accuracy, and for its being brought quite up to the date of publication; the author states in his preface that he has added to it about four thousand terms, which are not to be found in the preceding one.—*Dublin Quarterly Journal of Medical Sciences*.

On the appearance of the last edition of this

valuable work, we directed the attention of our readers to its peculiar merits; and we need do little more than state, in reference to the present reissue, that, notwithstanding the large additions previously made to it, no fewer than four thousand terms, not to be found in the preceding edition, are contained in the volume before us.—Whilst it is a wonderful monument of its author's erudition and industry, it is also a work of great practical utility, as we can testify from our own experience; for we keep it constantly within our reach, and make very frequent reference to it, nearly always finding in it the information we seek.—*British and Foreign Med.-Chirurg. Review*.

It has the rare merit that it certainly has no rival in the English language for accuracy and extent of references. The terms generally include short physiological and pathological descriptions, so that, as the author justly observes, the reader does not possess in this work a mere dictionary, but a book, which, while it instructs him in medical etymology, furnishes him with a large amount of useful information. The author's labors have been properly appreciated by his own countrymen; and we can only confirm their judgment, by recommending this most useful volume to the notice of our cisatlantic readers. No medical library will be complete without it.—*London Med. Gazette*.

It is certainly more complete and comprehensive than any with which we are acquainted in the English language. Few, in fact, could be found better qualified than Dr. Dunglison for the production of such a work. Learned, industrious, persevering, and accurate, he brings to the task all the peculiar talents necessary for its successful performance; while, at the same time, his familiarity with the writings of the ancient and modern "masters of our art," renders him skilful to note the exact usage of the several terms of science, and the various modifications which medical terminology has undergone with the change of theories or the progress of improvement.—*American Journal of the Medical Sciences*.

One of the most complete and copious known to the cultivators of medical science.—*Boston Med. Journal*.

The most comprehensive and best English Dictionary of medical terms extant.—*Buffalo Medical Journal*.

BY THE SAME AUTHOR.

THE PRACTICE OF MEDICINE. A Treatise on Special Pathology and Therapeutics. Third Edition. In two large octavo volumes, of fifteen hundred pages.

Upon every topic embraced in the work the latest information will be found carefully posted up.—*Medical Examiner*.

The student of medicine will find, in these two elegant volumes, a mine of facts, a gathering of precepts and advice from the world of experience, that will nerve him with courage, and faithfully direct him in his efforts to relieve the physical suf-

ferings of the race.—*Boston Medical and Surgical Journal*.

It is certainly the most complete treatise of which we have any knowledge.—*Western Journal of Medicine and Surgery*.

One of the most elaborate treatises of the kind we have.—*Southern Med. and Surg. Journal*.

DUNGLISON (ROBLEY), M. D.,

Professor of Institutes of Medicine in the Jefferson Medical College, Philadelphia.

HUMAN PHYSIOLOGY. Seventh edition. Thoroughly revised and extensively modified and enlarged, with nearly five hundred illustrations. In two large and handsomely printed octavo volumes, containing nearly 1450 pages.

It has long since taken rank as one of the medical classics of our language. To say that it is by far the best text-book of physiology ever published in this country, is but echoing the general testimony of the profession.—*N. Y. Journal of Medicine.*

There is no single book we would recommend to the student or physician, with greater confidence than the present, because in it will be found a mirror of almost every standard physiological work of the day. We most cordially recommend the work to every member of the profession, and no student should be without it. It is the completest work on

Physiology in the English language, and is highly creditable to the author and publishers.—*Canadian Medical Journal.*

The most complete and satisfactory system of Physiology in the English language.—*Amer. Med. Journal.*

The best work of the kind in the English language.—*Silliman's Journal.*

The most full and complete system of Physiology in our language.—*Western Lancet.*

BY THE SAME AUTHOR. (*Just Issued.*)

GENERAL THERAPEUTICS AND MATERIA MEDICA; adapted for a Medical Text-book. Fifth edition, much improved. With one hundred and eighty-seven illustrations. In two large and handsomely printed octavo vols., of about 1100 pages.

The new editions of the United States Pharmacopœia and those of London and Dublin, have rendered necessary a thorough revision of this work. In accomplishing this the author has spared no pains in rendering it a complete exponent of all that is new and reliable, both in the departments of Therapeutics and Materia Medica. The book has thus been somewhat enlarged, and a like improvement will be found in every department of its mechanical execution. As a convenient text-book for the student, therefore, containing within a moderate compass a satisfactory resumé of its important subject, it is again presented as even more worthy than heretofore of the very great favor which it has received.

In this work of Dr. Dunglison, we recognize the same untiring industry in the collection and embodying of facts on the several subjects of which he treats, that has heretofore distinguished him, and we cheerfully point to these volumes, as two of the most interesting that we know of. In noticing the additions to this, the fourth edition, there is very little in the periodical or annual literature of the profession, published in the interval which has elapsed since the issue of the first, that has escaped the careful search of the author. As a book for reference, it is invaluable.—*Charleston Med. Journal and Review.*

It may be said to be the work now upon the subjects upon which it treats.—*Western Lancet.*

As a text-book for students, for whom it is particularly designed, we know of none superior to it.—*St. Louis Medical and Surgical Journal.*

It purports to be a new edition, but it is rather a new book, so greatly has it been improved, both in the amount and quality of the matter which it contains.—*N. O. Medical and Surgical Journal.*

We bespeak for this edition, from the profession, an increase of patronage over any of its former ones, on account of its increased merit.—*N. Y. Journal of Medicine.*

We consider this work unequalled.—*Boston Med. and Surg. Journal.*

BY THE SAME AUTHOR.

NEW REMEDIES, WITH FORMULÆ FOR THEIR ADMINISTRATION.

Sixth edition, with extensive Additions. In one very large octavo volume, of over 750 pages.

One of the most useful of the author's works.—*Southern Medical and Surgical Journal.*

This well-known and standard book has now reached its sixth edition, and has been enlarged and improved by the introduction of all the recent gifts to therapeutics which the last few years have so richly produced, including the anæsthetic agents, &c. This elaborate and useful volume should be found in every medical library, for as a book of reference, for physicians, it is unsurpassed by any other work in existence, and the double index for

diseases and for remedies, will be found greatly to enhance its value.—*New York Med. Gazette.*

The great learning of the author, and his remarkable industry in pushing his researches into every source whence information is derivable, has enabled him to throw together an extensive mass of facts and statements, accompanied by full reference to authorities; which last feature renders the work practically valuable to investigators who desire to examine the original papers.—*The American Journal of Pharmacy.*

DURLACHER (LEWIS).

A TREATISE ON CORNS, BUNIONS, THE DISEASES OF NAILS, AND THE GENERAL MANAGEMENT OF THE FEET. In one 12mo. volume, cloth. pp. 134.

DE JONGH (L. J.), M. D., &c.

THE THREE KINDS OF COD-LIVER OIL, comparatively considered, with their Chemical and Therapeutic Properties. Translated, with an Appendix and Cases, by EDWARD CAREY, M. D. To which is added an article on the subject from "Dunglison on New Remedies." In one small 12mo. volume, extra cloth.

DAY (GEORGE E.), M. D.

A PRACTICAL TREATISE ON THE DOMESTIC MANAGEMENT AND MORE IMPORTANT DISEASES OF ADVANCED LIFE. With an Appendix on a new and successful mode of treating Lumbago and other forms of Chronic Rheumatism. One volume, octavo, 226 pages.

ELLIS (BENJAMIN), M. D.

THE MEDICAL FORMULARY: being a Collection of Prescriptions, derived from the writings and practice of many of the most eminent physicians of America and Europe. Together with the usual Dietetic Preparations and Antidotes for Poisons. To which is added an Appendix, on the Endermic use of Medicines, and on the use of Ether and Chloroform. The whole accompanied with a few brief Pharmaceutical and Medical Observations. Tenth edition, revised and much extended by ROBERT P. THOMAS, M. D., Professor of Materia Medica in the Philadelphia College of Pharmacy. In one neat octavo volume, of two hundred and ninety-six pages. (*Now Ready. Revised and enlarged to 1854.*)

This work has received a very complete revision at the hands of the editor, who has made whatever alterations and additions the progress of medical and pharmaceutical science has rendered advisable, introducing fully the new remedial agents, and revising the whole by the latest improvements of the Pharmacopœia. To accommodate these additions, the size of the page has been increased, and the volume itself considerably enlarged, while every effort has been made to secure the typographical accuracy which has so long merited the confidence of the profession.

After an examination of the new matter and the alterations, we believe the reputation of the work built up by the author, and the late distinguished editor, will continue to flourish under the auspices of the present editor, who has the industry and accuracy, and, we would say, conscientiousness requisite for the responsible task.—*American Journal of Pharmacy*, March, 1854.

It will prove particularly useful to students and young practitioners, as the most important prescriptions employed in modern practice, which lie scattered through our medical literature, are here collected and conveniently arranged for reference.—*Charleston Med. Journal and Review*.

ERICHSEN (JOHN),

Professor of Surgery in University College, London, &c.

THE SCIENCE AND ART OF SURGERY; BEING A TREATISE ON SURGICAL INJURIES, DISEASES, AND OPERATIONS. Edited by JOHN H. BRINTON, M. D. Illustrated with three hundred and eleven engravings on wood. In one large and handsome octavo volume, of over nine hundred closely printed pages. (*Now Ready.*)

This is a new work, brought up to May, 1854.

It is, in our humble judgment, decidedly the best book of the kind in the English language. Strange that just such books are not oftener produced by public teachers of surgery in this country and Great Britain. Indeed, it is a matter of great astonishment, but no less true than astonishing, that of the many works on surgery republished in this country within the last fifteen or twenty years as text-books for medical students, this is the only one, that even approximates to the fulfilment of the peculiar wants of young men just entering upon the study of this branch of the profession.—*Western Jour. of Med. and Surgery*.

Embracing, as will be perceived, the whole surgical domain, and each division of itself almost complete and perfect, each chapter full and explicit, each subject faithfully exhibited, we can only express our estimate of it in the aggregate. We consider it an excellent contribution to surgery, as probably the best single volume now extant on the subject, and with great pleasure we add it to our text-books.—*Nashville Journal of Medicine and Surgery*.

Its value is greatly enhanced by a very copious well-arranged index. We regard this as one of the most valuable contributions to modern surgery. To one entering his novitiate of practice, we regard it the most serviceable guide which he can consult. He will find a fulness of detail leading him through every step of the operation, and not deserting him until the final issue of the case is decided. For the same reason we recommend it to those whose routine of practice lies in such parts of the country that they must rarely encounter cases requiring surgical management.—*Stethoscope*.

Prof. Erichsen's work, for its size, has not been surpassed; his nine hundred and eight pages, profusely illustrated, are rich in physiological, pathological, and operative suggestions, doctrines, details, and processes; and will prove a reliable resource for information, both to physician and surgeon, in the hour of peril.—*N. O. Med. and Surg. Journal*.

FERGUSON (WILLIAM), F. R. S.,

Professor of Surgery in King's College, London, &c.

A SYSTEM OF PRACTICAL SURGERY. Fourth American, from the third and enlarged London edition. In one large and beautifully printed octavo volume, of about seven hundred pages, with three hundred and ninety-three handsome illustrations. (*Just Issued.*)

The most important subjects in connection with practical surgery which have been more recently brought under the notice of, and discussed by, the surgeons of Great Britain, are fully and dispassionately considered by Mr. Ferguson, and that which was before wanting has now been supplied, so that we can now look upon it as a work on practical surgery instead of one on operative surgery alone. And we think the author has shown a wise discretion in making the additions on surgical disease which are to be found in the present volume, and has very much enhanced its value; for, besides two elaborate chapters on the diseases of bones and joints, which were wanting before, he has headed each chief section of the work by a general description of the surgical disease and injury of that region of the body which is treated of in each, prior to entering into the consideration of the more special morbid conditions and their treatment. There is also, as in former editions, a sketch of the anatomy of particular regions. There was some ground formerly for the complaint before alluded to, that it dwelt too exclu-

sively on operative surgery; but this defect is now removed, and the book is more than ever adapted for the purposes of the practitioner, whether he confines himself more strictly to the operative department, or follows surgery on a more comprehensive scale.—*Medical Times and Gazette*.

No work was ever written which more nearly comprehended the necessities of the student and practitioner, and was more carefully arranged to that single purpose than this.—*N. Y. Med. and Surg. Journal*.

The addition of many new pages makes this work more than ever indispensable to the student and practitioner.—*Ranking's Abstract*.

Among the numerous works upon surgery published of late years, we know of none we value more highly than the one before us. It is perhaps the very best we have for a text-book and for ordinary reference, being concise and eminently practical.—*Southern Med. and Surg. Journal*.

FRICK (CHARLES), M. D.

RENAL AFFECTIONS; their Diagnosis and Pathology. With illustrations. One volume, royal 12mo., extra cloth.

FOWNES (GEORGE), PH. D., &c.

ELEMENTARY CHEMISTRY; Theoretical and Practical. With numerous illustrations. A new American, from the last and revised London edition. Edited, with Additions, by ROBERT BRIDGES, M. D. In one large royal 12mo. volume, of over 550 pages, with 181 wood-cuts, sheep, or extra cloth. (*Now Ready.*)

The lamented death of the author has caused the revision of this edition to pass into the hands of those distinguished chemists, H. Bence Jones and A. W. Hofmann, who have fully sustained its reputation by the additions which they have made, more especially in the portion devoted to Organic Chemistry, considerably increasing the size of the volume. This labor has been so thoroughly performed, that the American Editor has found but little to add, his notes consisting chiefly of such matters as the rapid advance of the science has rendered necessary, or of investigations which had apparently been overlooked by the author's friends.

The volume is therefore again presented as an exponent of the most advanced state of chemical science, and as not unworthy a continuation of the marked favor which it has received as an elementary text-book.

We know of no better text-book, especially in the difficult department of organic chemistry, upon which it is particularly full and satisfactory. We would recommend it to preceptors as a capital "office book" for their students who are beginners in Chemistry. It is copiously illustrated with excellent wood-cuts, and altogether admirably "got up."—*N. J. Medical Reporter*, March, 1851.

A standard manual, which has long enjoyed the reputation of embodying much knowledge in a small space. The author has achieved the difficult task of condensation with masterly tact. His book is concise without being dry, and brief without being too dogmatical or general.—*Virginia Med. and Surgical Journal*.

The work of Dr. Fownes has long been before the public, and its merits have been fully appreciated as the best text-book on chemistry now in existence. We do not, of course, place it in a rank superior to the works of Brande, Graham, Turner, Gregory, or Gmelin, but we say that, as a work for students, it is preferable to any of them.—*London Journal of Medicine*.

A work well adapted to the wants of the student. It is an excellent exposition of the chief doctrines and facts of modern chemistry. The size of the work, and still more the condensed yet perspicuous style in which it is written, absolve it from the charges very properly urged against most manuals termed popular.—*Edinburgh Monthly Journal of Medical Science*.

GRAHAM (THOMAS), F. R. S.,

Professor of Chemistry in University College, London, &c.

THE ELEMENTS OF CHEMISTRY. Including the application of the Science to the Arts. With numerous illustrations. With Notes and Additions, by ROBERT BRIDGES, M. D., &c. &c. Second American, from the second and enlarged London edition

PART I. (*Lately Issued*) large 8vo., 430 pages, 185 illustrations.

PART II. (*Preparing*) to match.

The great changes which the science of chemistry has undergone within the last few years, render a new edition of a treatise like the present, almost a new work. The author has devoted several years to the revision of his treatise, and has endeavored to embody in it every fact and inference of importance which has been observed and recorded by the great body of chemical investigators who are so rapidly changing the face of the science. In this manner the work has been greatly increased in size, and the number of illustrations doubled; while the labors of the editor have been directed towards the introduction of such matters as have escaped the attention of the author, or as have arisen since the publication of the first portion of this edition in London, in 1850. Printed in handsome style, and at a very low price, it is therefore confidently presented to the profession and the student as a very complete and thorough text-book of this important subject.

GROSS (SAMUEL D.), M. D.,

Professor of Surgery in the Louisville Medical Institute, &c.

A PRACTICAL TREATISE ON THE DISEASES AND INJURIES OF THE URINARY ORGANS. In one large and beautifully printed octavo volume, of over seven hundred pages. With numerous illustrations.

A volume replete with truths and principles of the utmost value in the investigation of these diseases.—*American Medical Journal*.

Dr. Gross has brought all his learning, experience, tact, and judgment to the task, and has produced a work worthy of his high reputation. We feel perfectly safe in recommending it to our readers as a monograph unequalled in interest and practical value by any other on the subject in our language.—*Western Journal of Med. and Surg.*

It has remained for an American writer to wipe away this reproach; and so completely has the task been fulfilled, that we venture to predict for Dr. Gross's treatise a permanent place in the literature of surgery, worthy to rank with the best works of the present age. Not merely is the matter good, but the getting up of the volume is most creditable to transatlantic enterprise; the paper and print would do credit to a first-rate London establishment; and the numerous wood-cuts which illustrate it, demonstrate that America is making rapid advances in

this department of art. We have, indeed, unfeigned pleasure in congratulating all concerned in this publication, on the result of their labours; and experience a feeling something like what animates a long-expectant husbandman, who, oftentimes disappointed by the produce of a favorite field, is at last agreeably surprised by a stately crop which may bear comparison with any of its former rivals. The grounds of our high appreciation of the work will be obvious as we proceed; and we doubt not that the present facilities for obtaining American books will induce many of our readers to verify our recommendation by their own perusal of it.—*British and Foreign Medico-Chirurgical Review*.

Whoever will peruse the vast amount of valuable practical information it contains, and which we have been unable even to notice, will, we think, agree with us, that there is no work in the English language which can make any just pretensions to be its equal.—*N. Y. Journal of Medicine*.

BY THE SAME AUTHOR. (*Now Ready.*)

A PRACTICAL TREATISE ON FOREIGN BODIES IN THE AIR-PASSAGES. In one handsome octavo volume, with illustrations.

BY THE SAME AUTHOR. (*Preparing.*)

A SYSTEM OF SURGERY; Diagnostic, Pathological, Therapeutic, and Operative. With very numerous engravings on wood.

GRIFFITH (ROBERT E.), M. D., &c.

A UNIVERSAL FORMULARY, containing the methods of Preparing and Administering Official and other Medicines. The whole adapted to Physicians and Pharmacologists. **SECOND EDITION**, thoroughly revised, with numerous additions, by ROBERT P. THOMAS, M. D., Professor of Materia Medica in the Philadelphia College of Pharmacy. In one large and handsome octavo volume, of over six hundred pages, double columns. (*Just Issued.*)

The speedy exhaustion of a large edition, and the demand for a second, sufficiently show the position which this work has so rapidly attained as an authoritative and convenient work of reference for the physician and pharmacist. The opportunity thus afforded for its improvement has not been neglected. In its revision, Professor Thomas (to whom this task has been confided in consequence of the death of the author), has spared no labor, in the hope of rendering it the most complete and correct work on the subject as yet presented to the profession. All the newly introduced articles of the *Materia Medica* have been inserted, such formulæ as had escaped the attention of the author have been added, and the whole has been most carefully read and examined, to insure the absolute correctness, so indispensable in a work of this nature. The amount of these additions may be estimated from the fact that not only has the page been considerably enlarged, but the volume has also been increased by about fifty pages, while the arrangement of the formulæ and the general typographical execution will be found to have undergone great improvement. To the practitioner, its copious collection of all the forms and combinations of the articles of the *Pharmacopœia* render it an invaluable book of reference, while its very complete embodiment of official preparations of all kinds, derived from all sources, American, English, and Continental, make it an indispensable assistant to the apothecary.

It was a work requiring much perseverance, and when published was looked upon as by far the best work of its kind that had issued from the American press, being free of much of the trashy, and embracing most of the non-official formulæ used or known in American, English, or French practice, arranged under the heads of the several constituent drugs, placing the receipt under its more important constituent. Prof. Thomas has certainly "improved," as well as added to this Formulary, and has rendered it additionally deserving of the confidence of pharmacologists and physicians.—*American Journal of Pharmacy.*

We are happy to announce a new and improved edition of this, one of the most valuable and useful works that have emanated from an American pen. It would do credit to any country, and will be found of daily usefulness to practitioners of medicine; it is better adapted to their purposes than the dispensatories.—*Southern Med. and Surg. Journal.*

A new edition of this well-known work, edited by R. P. Thomas, M. D., affords occasion for renewing our commendation of so useful a handbook, which ought to be universally studied by medical men of every class, and made use of by way of reference by office pupils, as a standard authority. It has been much enlarged, and now condenses a vast amount of useful and necessary knowledge in small compass. The more of such books the better for the profession and the public.—*N. Y. Med. Gazette.*

It is one of the most useful books a country practitioner can possibly have in his possession.—*Medical Chronicle.*

The amount of useful, every-day matter, for a practicing physician, is really immense.—*Boston Med. and Surg. Journal.*

This is a work of six hundred and fifty one pages, embracing all on the subject of preparing and administering medicines that can be desired by the physician and pharmacist.—*Western Lancet.*

In short, it is a full and complete work of the kind, and should be in the hands of every physician and apothecary.—*O. Med. and Surg. Journal.*

We predict a great sale for this work, and we especially recommend it to all medical teachers.—*Richmond Stehoseope.*

This edition of Dr. Griffith's work has been greatly improved by the revision and ample additions of Dr. Thomas, and is now, we believe, one of the most complete works of its kind in any language. The additions amount to about seventy pages, and no effort has been spared to include in them all the recent improvements which have been published in medical journals, and systematic treatises. A work of this kind appears to us indispensable to the physician, and there is none we can more cordially recommend.—*N. Y. Journal of Medicine.*

BY THE SAME AUTHOR.

MEDICAL BOTANY; or, a Description of all the more important Plants used in Medicine, and of their Properties, Uses, and Modes of Administration. In one large octavo volume, of 704 pages, handsomely printed, with nearly 350 illustrations on wood.

GLUGE (GOTTLIEB), M. D.,

Professor of Physiology and Pathological Anatomy in the University of Brussels, &c.

AN ATLAS OF PATHOLOGICAL HISTOLOGY. Translated, with Notes and Additions, by JOSEPH LEIDY, M. D., Professor of Anatomy in the University of Pennsylvania. In one volume, very large imperial quarto, with three hundred and twenty figures, plain and colored, on twelve copperplates.

This being, as far as we know, the only work in which pathological histology is separately treated of in a comprehensive manner, it will, we think, for this reason, be of infinite service to those who desire to investigate the subject systematically, and who have felt the difficulty of arranging in their mind

the unconnected observations of a great number of authors. The development of the morbid tissues, and the formation of abnormal products, may now be followed and studied with the same ease and satisfaction as the best arranged system of physiology.—*American Med. Journal.*

GREGORY (WILLIAM), F. R. S. E.,

Professor of Chemistry in the University of Edinburgh, &c.

LETTERS TO A CANDID INQUIRER ON ANIMAL MAGNETISM. In one neat volume, royal 12mo., extra cloth.

GARDNER (D. PEREIRA), M. D.

MEDICAL CHEMISTRY, for the use of Students and the Profession: being a Manual of the Science, with its Applications to Toxicology, Physiology, Therapeutics, Hygiene, &c. In one handsome royal 12mo. volume, with illustrations.

HASSE (C. E.), M. D.

AN ANATOMICAL DESCRIPTION OF THE DISEASES OF RESPIRATION AND CIRCULATION. Translated and Edited by SWAINE. In one volume, octavo.

HARRISON (JOHN), M. D.

AN ESSAY TOWARDS A CORRECT THEORY OF THE NERVOUS SYSTEM. In one octavo volume, 292 pages.

HUNTER (JOHN).

TREATISE ON THE VENEREAL DISEASE. With copious Additions, by DR. PH. RICORD, Surgeon to the Venereal Hospital of Paris. Edited, with additional Notes, by F. J. BUMSTEAD, M. D. In one octavo volume, with plates (*Now Ready.*) See RICORD. Also, HUNTER'S COMPLETE WORKS, with Memoir, Notes, &c. &c. In four neat octavo volumes, with plates.

HUGHES (H. M.), M. D.,

Assistant Physician to Guy's Hospital, &c.

A CLINICAL INTRODUCTION TO THE PRACTICE OF AUSCULTATION, and other Modes of Physical Diagnosis, in Diseases of the Lungs and Heart. Second American from the Second and Improved London Edition. In one royal 12mo. vol. (*Now Ready.*)

It has been carefully revised throughout. Some small portions have been erased; much has been, I trust, amended; and a great deal of new matter has been added; so that, though fundamentally it is the same book, it is in many respects a new work.—*Preface.*

HORNER (WILLIAM E.), M. D.,

Professor of Anatomy in the University of Pennsylvania.

SPECIAL ANATOMY AND HISTOLOGY. Eighth edition. Extensively revised and modified. In two large octavo volumes, of more than one thousand pages, handsomely printed, with over three hundred illustrations.

This work has enjoyed a thorough and laborious revision on the part of the author, with the view of bringing it fully up to the existing state of knowledge on the subject of general and special anatomy. To adapt it more perfectly to the wants of the student, he has introduced a large number of additional wood-engravings, illustrative of the objects described, while the publishers have endeavored to render the mechanical execution of the work worthy of the extended reputation which it has acquired. The demand which has carried it to an EIGHTH EDITION is a sufficient evidence of the value of the work, and of its adaptation to the wants of the student and professional reader.

HOBLYN (RICHARD D.), A. M.

A DICTIONARY OF THE TERMS USED IN MEDICINE AND THE COLLATERAL SCIENCES. Second and Improved American Edition. Revised, with numerous Additions, from the second London edition, by ISAAC HAYS, M. D., &c. In one large royal 12mo. volume, of over four hundred pages, double columns. (*Nearly Ready.*)

In passing this work a second time through the press, the editor has subjected it to a very thorough revision, making such additions as the progress of science has rendered desirable, and supplying any omissions that may have previously existed. As a concise and convenient Dictionary of Medical Terms, at an exceedingly low price, it will therefore be found of great value to the student and practitioner.

HOPE (J.), M. D., F. R. S., &c.

A TREATISE ON THE DISEASES OF THE HEART AND GREAT VESSELS. Edited by PENNOCK. In one volume, octavo, with plates, 572 pages.

JONES (C. HANDFIELD), F. R. S., & EDWARD H. SIEVEKING, M.D.,
Assistant Physicians and Lecturers in St. Mary's Hospital, London.

A MANUAL OF PATHOLOGICAL ANATOMY. With 400 engravings on wood. In one large and handsome octavo volume, of about seven hundred pages. (*Now Ready.*)

This work will supply a want which has been felt of a volume which, within a reasonable size, should contain a clear and connected view of the present advanced state of pathological anatomy, embodying the numerous investigations and discoveries of recent observers, who, with the aid of the microscope, have so greatly enlarged the boundaries of pathological science. This has been the aim of the authors, and their reputation is sufficient guarantee that the object has been attained. The publishers have omitted nothing that is requisite to the full appreciation and understanding of the subject, and the very numerous illustrations with which the volume abounds, will, it is hoped, fully elucidate the details and descriptions.

JONES (T. WHARTON), F. R. S., &c.

THE PRINCIPLES AND PRACTICE OF OPHTHALMIC MEDICINE AND SURGERY. Edited by ISAAC HAYS, M. D., &c. In one very neat volume, large royal 12mo., of 529 pages, with four plates, plain or colored, and ninety-eight wood-cuts.

The work amply sustains, in every point the already high reputation of the author as an ophthalmic surgeon as well as a physiologist and pathologist. The book is evidently the result of much labor and research, and has been written with the greatest care and attention. We entertain little doubt that this book will become what its author hoped it

might become, a manual for daily reference and consultation by the student and the general practitioner. The work is marked by that correctness, clearness, and precision of style which distinguish all the productions of the learned author.—*British and Foreign Medical Review.*

KIRKES (WILLIAM SENHOUSE), M. D.,

Demonstrator of Morbid Anatomy at St. Bartholomew's Hospital, &c.; and

JAMES PAGET, F. R. S.,

Lecturer on General Anatomy and Physiology in St. Bartholomew's Hospital.

A MANUAL OF PHYSIOLOGY. Second American, from the second and improved London edition. With one hundred and sixty-five illustrations. In one large and handsome royal 12mo. volume. pp. 550. (*Just Issued.*)

In the present edition, the Manual of Physiology has been brought up to the actual condition of the science, and fully sustains the reputation which it has already so deservedly attained. We consider the work of MM. Kirkes and Paget to constitute one of the very best handbooks of Physiology we possess—presenting just such an outline of the science, comprising an account of its leading facts and generally admitted principles, as the student requires during his attendance upon a course of lectures, or for reference whilst preparing for examination. The text is fully and ably illustrated by a series of very superior wood-engravings, by which a comprehension of some of the more intricate of the subjects treated of is greatly facilitated.—*Am. Medical Journal.*

We need only say, that, without entering into discussions of unsettled questions, it contains all the recent improvements in this department of medical science. For the student beginning this study, and the practitioner who has but leisure to refresh his memory, this book is invaluable, as it contains all

that it is important to know, without special details, which are read with interest only by those who would make a specialty, or desire to possess a critical knowledge of the subject.—*Charleston Medical Journal.*

One of the best treatises that can be put into the hands of the student.—*London Medical Gazette.*

The general favor with which the first edition of this work was received, and its adoption as a favorite text-book by many of our colleges, will insure a large circulation to this improved edition. It will fully meet the wants of the student.—*Southern Med. and Surg. Journal.*

Particularly adapted to those who desire to possess a concise digest of the facts of Human Physiology.—*British and Foreign Med.-Chirurg. Review.*

We conscientiously recommend it as an admirable "Handbook of Physiology."—*London Journal of Medicine.*

KNAPP (F.), PH. D., &c.

TECHNOLOGY; or, Chemistry applied to the Arts and to Manufactures. Edited, with numerous Notes and Additions, by Dr. EDMUND RONALDS and Dr. THOMAS RICHARDSON. First American edition, with Notes and Additions, by Prof. WALTER R. JOHNSON. In two handsome octavo volumes, printed and illustrated in the highest style of art, with about five hundred wood-engravings.

LEHMANN.

PHYSIOLOGICAL CHEMISTRY. Translated by GEORGE E. DAY, M. D. (*Preparing.*)

LEE (ROBERT), M. D., F. R. S., &c.

CLINICAL MIDWIFERY; comprising the Histories of Five Hundred and Forty-five Cases of Difficult, Preternatural, and Complicated Labor, with Commentaries. From the second London edition. In one royal 12mo. volume, extra cloth, of 238 pages.

LA ROCHE (R.), M. D., &c.

PNEUMONIA; its Supposed Connection, Pathological and Etiological, with Autumnal Fevers, including an Inquiry into the Existence and Morbid Agency of Malaria. In one handsome octavo volume, extra cloth, of 500 pages.

A more simple, clear, and forcible exposition of the groundless nature and dangerous tendency of certain pathological and etiological heresies, has seldom been presented to our notice.—*N. Y. Journal of Medicine and Collateral Science*, March, 1854.

This work should be carefully studied by Southern physicians, embodying as it does the reflections of an original thinker and close observer on a subject peculiarly their own.—*Virginia Med. and Surgical Journal.*

The author had prepared us to expect a treatise from him, by his brief papers on kindred topics in

the periodical press, and yet in the work before us he has exhibited an amount of industry and learning, research and ability, beyond what we are accustomed to discover in modern medical writers; while his own extensive opportunities for observation and experience have been improved by the most laudable diligence, and display a familiarity with the whole subject in every aspect, which commands both our respect and confidence. As a corrective of prevalent and mischievous error, sought to be propagated by novices and innovators, we could wish that Dr. La Roche's book could be widely read.—*N. Y. Medical Gazette.*

BY THE SAME AUTHOR. (*In Press.*)

YELLOW FEVER, considered in its Historical, Pathological, and Etiological Relations. In one very large and handsome octavo volume.

LONGET (F. A.)

TREATISE ON PHYSIOLOGY. With numerous Illustrations. Translated from the French by F. G. SMITH, M. D., Professor of Institutes of Medicine in the Pennsylvania Medical College. (*Preparing.*)

LAWRENCE (W.), F. R. S., &c.

A TREATISE ON DISEASES OF THE EYE. A new edition, edited, with numerous additions, and 243 illustrations, by ISAAC HAYS, M. D., Surgeon to Wills Hospital, &c. In one very large and handsome octavo volume, of 950 pages, strongly bound in leather with raised bands. (*Now Ready.*)

This work is thoroughly revised and brought up to 1854.

This work is so universally recognized as the standard authority on the subject, that the publishers in presenting this new edition have only to remark that in its preparation the editor has carefully revised every portion, introducing additions and illustrations wherever the advance of science has rendered them necessary or desirable. In this manner it will be found to contain over one hundred pages more than the last edition, while the list of wood-engravings has been increased by sixty-seven figures, besides numerous improved illustrations substituted for such as were deemed imperfect or unsatisfactory. The various important contributions to ophthalmological science, recently made by Dalrymple, Jacob, Walton, Wilde, Cooper, &c., both in the form of separate treatises and contributions to periodicals, have been carefully examined by the editor, and, combined with the results of his own experience, have been freely introduced throughout the volume, rendering it a complete and thorough exponent of the most advanced state of the subject.

In a future number we shall notice more at length this admirable treatise—the safest guide and most comprehensive work of reference, which is within the reach of all classes of the profession.—*Stethoscope*, March, 1854.

This standard text-book on the department of which it treats, has not been superseded, by any or all of the numerous publications on the subject heretofore issued. Nor with the multiplied improvements of Dr. Hays, the American editor, is it at all likely that this great work will cease to merit the confidence and preference of students or practitioners. Its ample extent—nearly one thousand large

octavo pages—has enabled both author and editor to do justice to all the details of this subject, and condense in this single volume the present state of our knowledge of the whole science in this department, whereby its practical value cannot be excelled. We heartily commend it, especially as a book of reference, indispensable in every medical library. The additions of the American editor very greatly enhance the value of the work, exhibiting the learning and experience of Dr. Hays, in the light in which he ought to be held, as a standard authority on all subjects appertaining to this specialty, to which he has rendered so many valuable contributions.—*N. Y. Medical Gazette.*

BY THE SAME AUTHOR.

A TREATISE ON RUPTURES; from the fifth London edition. In one octavo volume, sheep, 480 pages.

LUDLOW (J. L.), M. D.,

Lecturer on Clinical Medicine at the Philadelphia Almshouse, &c.

A MANUAL OF EXAMINATIONS upon Anatomy and Physiology, Surgery, Practice of Medicine, Chemistry, Obstetrics, Materia Medica, Pharmacy, and Therapeutics. Designed for Students of Medicine throughout the United States. A new edition, revised and extensively improved. In one large royal 12mo. volume, with several hundred illustrations. (*Preparing.*)

LISTON (ROBERT), F. R. S., &c.

LECTURES ON THE OPERATIONS OF SURGERY, and on Diseases and Accidents requiring Operations. Edited, with numerous Additions and Alterations, by T. D. MÜTTER, M. D. In one large and handsome octavo volume, of 566 pages, with 216 wood-cuts.

LALLEMAND (M.).

THE CAUSES, SYMPTOMS, AND TREATMENT OF SPERMATORRHEA. Translated and edited by HENRY J. McDOUGAL. In one volume, octavo, 320 pages. Second American edition. (*Now Ready.*)

LARDNER (DIONYSIUS), D. C. L., &c.

HANDBOOKS OF NATURAL PHILOSOPHY AND ASTRONOMY.

Revised, with numerous Additions, by the American editor. **FIRST COURSE**, containing Mechanics, Hydrostatics, Hydraulics, Pneumatics, Sound, and Optics. In one large royal 12mo. volume, of 750 pages, with 424 wood-cuts. **SECOND COURSE**, containing Heat, Electricity, Magnetism, and Galvanism, one volume, large royal 12mo., of 450 pages, with 250 illustrations. **THIRD COURSE** (*now ready*), containing Meteorology and Astronomy, in one large volume, royal 12mo. of nearly eight hundred pages, with thirty-seven plates and two hundred wood-cuts. The whole complete in three volumes, of about two thousand large pages, with over one thousand figures on steel and wood.

The various sciences treated in this work will be found brought thoroughly up to the latest period.

The work furnishes a very clear and satisfactory account of our knowledge in the important department of science of which it treats. Although the medical schools of this country do not include the study of physics in their course of instruction, yet no student or practitioner should be ignorant of its laws. Besides being of constant application in practice, such knowledge is of inestimable utility in facilitating the study of other branches of science. To students, then, and to those who, having already entered upon the active pursuits of business, are desirous to sustain and improve their knowledge of the general truths of natural philosophy, we can recommend this work as supplying in a clear and sat-

isfactory manner the information they desire.—*The Virginia Med. and Surg. Journal.*

The present treatise is a most complete digest of all that has been developed in relation to the great forces of nature, Heat, Magnetism, and Electricity. Their laws are elucidated in a manner both pleasing and familiar, and at the same time perfectly intelligible to the student. The illustrations are sufficiently numerous and appropriate, and altogether we can cordially recommend the work as well-deserving the notice both of the practising physician and the student of medicine.—*The Med. Examiner.*

MEIGS (CHARLES D.), M. D.,

Professor of Obstetrics, &c. in the Jefferson Medical College, Philadelphia.

ON THE NATURE, SIGNS, AND TREATMENT OF CHILDBED FEVER. In a Series of Letters addressed to the Students of his Class. In one handsome octavo volume, of three hundred and sixty-five pages. (*Now Ready.*)

BY THE SAME AUTHOR.

WOMAN: HER DISEASES AND THEIR REMEDIES. A Series of Lectures to his Class. Third and Improved edition. In one large and beautifully printed octavo volume. (*Just Issued. Revised and enlarged to 1854.*)

The gratifying appreciation of his labors, as evinced by the exhaustion of two large impressions of this work within a few years, has not been lost upon the author, who has endeavored in every way to render it worthy of the favor with which it has been received. The opportunity thus afforded for a second revision has been improved, and the work is now presented as in every way superior to its predecessors, additions and alterations having been made whenever the advance of science has rendered them desirable. The typographical execution of the work will also be found to have undergone a similar improvement and the work is now confidently presented as in every way worthy the position it has acquired as the standard American text-book on the Diseases of Females.

It contains a vast amount of practical knowledge, by one who has accurately observed and retained the experience of many years, and who tells the result in a free, familiar, and pleasant manner.—*Dublin Quarterly Journal.*

There is an off-hand fervor, a glow, and a warm-heartedness infecting the effort of Dr. Meigs, which is entirely captivating, and which absolutely hurries the reader through from beginning to end. Besides, the book teems with solid instruction, and it shows the very highest evidence of ability, viz., the clearness with which the information is presented. We know of no better test of one's understanding a subject than the evidence of the power of lucidly explaining it. The most elementary, as well as the obscurest subjects, under the pencil of Prof. Meigs, are isolated and made to stand out in such bold relief, as to produce distinct impressions upon the mind and memory of the reader.—*The Charleston Med. Journal.*

Professor Meigs has enlarged and amended this great work, for such it unquestionably is, having passed the ordeal of criticism at home and abroad, but been improved thereby; for in this new edition the author has introduced real improvements, and increased the value and utility of the book immeasurably. It presents so many novel, bright, and sparkling thoughts; such an exuberance of new ideas on almost every page, that we confess ourselves to have become enamored with the book and its author; and cannot withhold our congratulations from our Philadelphia conferees, that such a teacher is in their service. We regret that our limits will not allow of a more extended notice of this work, but must content ourselves with thus commending it as worthy of diligent perusal by physicians as well as students, who are seeking to be thoroughly instructed in the important practical subjects of which it treats.—*N. Y. Med. Gazette.*

BY THE SAME AUTHOR.

OBSTETRICS: THE SCIENCE AND THE ART. Second edition, revised and improved. With one hundred and thirty-one illustrations. In one beautifully printed octavo volume, of seven hundred and fifty-two large pages. (*Lately Published.*)

The rapid demand for a second edition of this work is a sufficient evidence that it has supplied a desideratum of the profession, notwithstanding the numerous treatises on the same subject which have appeared within the last few years. Adopting a system of his own, the author has combined the leading principles of his interesting and difficult subject, with a thorough exposition of its rules of practice, presenting the results of long and extensive experience and of familiar acquaintance with all the modern writers on this department of medicine. As an American Treatise on Midwifery, which has at once assumed the position of a classic, it possesses peculiar claims to the attention and study of the practitioner and student, while the numerous alterations and revisions which it has undergone in the present edition are shown by the great enlargement of the work, which is not only increased as to the size of the page, but also in the number. Among other additions may be mentioned

A NEW AND IMPORTANT CHAPTER ON "CHILDBED FEVER."

BY THE SAME AUTHOR. (*Now Ready.*)

A TREATISE ON ACUTE AND CHRONIC DISEASES OF THE NECK OF THE UTERUS. With numerous plates, drawn and colored from nature in the highest style of art. In one handsome octavo volume, extra cloth.

The object of the author in this work has been to present in a small compass the practical results of his long experience in this important and distressing class of diseases. The great changes introduced into practice, and the accessions to our knowledge on the subject, within the last few years, resulting from the use of the metroscope, brings within the ordinary practice of every physician numerous cases which were formerly regarded as incurable, and renders of great value a work like the present combining practical directions for diagnosis and treatment with an ample series of illustrations, copied accurately from colored drawings made by the author, after nature. No such accurate delineations of the pathology of the neck of the uterus have heretofore been given, requiring, as they do the rare combination of physician and artist, and their paramount importance to the physician in whose practice such cases are frequent, is too evident to be dwelt upon, while in artistic execution they are far in advance of anything of the kind as yet produced in this country.

BY THE SAME AUTHOR.

OBSERVATIONS ON CERTAIN OF THE DISEASES OF YOUNG CHILDREN. In one handsome octavo volume, of 214 pages.

MILLER (JAMES), F. R. S. E.,

Professor of Surgery in the University of Edinburgh, &c.

PRINCIPLES OF SURGERY. Third American, from the second and revised Edinburgh edition. Revised, with Additions, by F. W. SARGENT, M. D., author of "Minor Surgery," &c. In one large and very beautiful volume, of seven hundred and fifty-two pages, with two hundred and forty exquisite illustrations on wood.

The publishers have endeavored to render the present edition of this work, in every point of mechanical execution, worthy of its very high reputation, and they confidently present it to the profession as one of the handsomest volumes as yet issued in this country.

This edition is far superior, both in the abundance and quality of its material, to any of the preceding. We hope it will be extensively read, and the sound principles which are herein taught treasured up for future application. The work takes rank with Watson's Practice of Physic; it certainly does not fall behind that great work in soundness of principle or depth of reasoning and research. No physician who values his reputation, or seeks the interests of his clients, can acquit himself before his God and the world without making himself familiar with the sound and philosophical views developed in the foregoing book.—*New Orleans Medical and Surgical Journal*.

Without doubt the ablest exposition of the principles of that branch of the healing art in any lan-

guage. This opinion, deliberately formed after a careful study of the first edition, we have had no cause to change on examining the second. This edition has undergone thorough revision by the author; many expressions have been modified, and a mass of new matter introduced. The book is got up in the finest style, and is an evidence of the progress of typography in our country.—*Charleston Medical Journal and Review*.

We recommend it to both student and practitioner, feeling assured that as it now comes to us, it presents the most satisfactory exposition of the modern doctrines of the principles of surgery to be found in any volume in any language.—*N. Y. Journal of Medicine*.

BY THE SAME AUTHOR. (*Now Ready*.)

THE PRACTICE OF SURGERY. Third American from the second Edinburgh edition. Edited, with Additions, by F. W. SARGENT, M. D., one of the Surgeons to Will's Hospital, &c. Illustrated by three hundred and nineteen engravings on wood. In one large octavo volume, of over seven hundred pages.

This new edition will be found greatly improved and enlarged, as well by the addition of much new matter as by the introduction of a large and complete series of handsome illustrations. An equal improvement exists in the mechanical execution of the work, rendering it in every respect a companion volume to the "Principles."

No eulogium of ours could add to the popularity of Miller's Surgery. Its reputation in this country is unsurpassed by that of any other work, and, when taken in connection with the author's *Principles of Surgery*, constitutes a whole, without reference to which no conscientious surgeon would be willing to practice his art. The additions, by Dr. Sargent, have materially enhanced the value of the work.—*Southern Medical and Surgical Journal*.

It is seldom that two volumes have ever made so profound an impression in so short a time as the "Principles" and the "Practice" of Surgery by Mr. Miller—or so richly merited the reputation they have acquired. The author is an eminently sensible, practical, and well-informed man, who knows exactly what he is talking about and exactly how to talk it.—*Kentucky Medical Recorder*.

The two volumes together form a complete exposé of the present state of Surgery, and they ought to be on the shelves of every surgeon.—*N. J. Med. Reporter*.

By the almost unanimous voice of the profession, his works, both on the principles and practice of surgery have been assigned the highest rank. If we were limited to but one work on surgery, that one should be Miller's, as we regard it superior to all others.—*St. Louis Med. and Surg. Journal*.

The author distinguished alike as a practitioner and writer, has in this and his "Principles," presented to the profession one of the most complete and reliable systems of Surgery extant. His style of writing is original, impressive, and engaging, energetic, concise, and lucid. Few have the faculty of condensing so much in small space, and at the same time so persistently holding the attention; indeed, he appears to make the very process of condensation a means of eliminating attractions. Whether as a text-book for students or a book of reference for practitioners, it cannot be too strongly recommended.—*Southern Journal of the Medical and Physical Sciences*.

MALGAIGNE (J. F.).

OPERATIVE SURGERY, based on Normal and Pathological Anatomy. Translated from the French, by FREDERICK BRITTON, A. B., M. D. With numerous illustrations on wood. In one handsome octavo volume, of nearly six hundred pages.

We have long been accustomed to refer to it as one of the most valuable text-books in our library.—*Buffalo Med. and Surg. Journal*.

Certainly one of the best books published on operative surgery.—*Edinburgh Medical Journal*.

To express in a few words our opinion of Malgaigne's work, we unhesitatingly pronounce it the very best guide in surgical operations that has come before the profession in any language.—*Charleston Med. and Surg. Journal*.

MOHR (FRANCIS), PH. D., AND REDWOOD (THEOPHILUS).

PRACTICAL PHARMACY. Comprising the Arrangements, Apparatus, and Manipulations of the Pharmaceutical Shop and Laboratory. Edited, with extensive Additions, by Prof. WILLIAM PROCTER, of the Philadelphia College of Pharmacy. In one handsomely printed octavo volume, of 570 pages, with over 500 engravings on wood.

It is a book, however, which will be in the hands of almost every one who is much interested in pharmaceutical operations, as we know of no other publication so well calculated to fill a void long felt.—*Medical Examiner*.

The book is strictly practical, and describes only manipulations or methods of performing the numerous processes the pharmacist has to go through, in the preparation and manufacture of medicines, together with all the apparatus and fixtures neces-

sary thereto. On these matters, this work is very full and complete, and details, in a style uncommonly clear and lucid, not only the more complicated and difficult processes, but those not less important ones, the most simple and common.—*Buffalo Medical Journal*.

The country practitioner who is obliged to dispense his own medicines, will find it a most valuable assistant.—*Monthly Journal and Retrospect*.

MACLISE (JOSEPH), SURGEON.

SURGICAL ANATOMY. Forming one volume, very large imperial quarto.

With sixty-eight large and splendid Plates, drawn in the best style and beautifully colored. Containing one hundred and ninety Figures, many of them the size of life. Together with copious and explanatory letter-press. Strongly and handsomely bound in extra cloth, being one of the cheapest and best executed Surgical works as yet issued in this country.

Copies can be sent by mail, in five parts, done up in stout covers.

This great work being now concluded, the publishers confidently present it to the attention of the profession as worthy in every respect of their approbation and patronage. No complete work of the kind has yet been published in the English language, and it therefore will supply a want long felt in this country of an accurate and comprehensive Atlas of Surgical Anatomy to which the student and practitioner can at all times refer, to ascertain the exact relative position of the various portions of the human frame towards each other and to the surface, as well as their abnormal deviations. The importance of such a work to the student in the absence of anatomical material, and to the practitioner when about attempting an operation, is evident, while the price of the book, notwithstanding the large size, beauty, and finish of the very numerous illustrations, is so low as to place it within the reach of every member of the profession. The publishers therefore confidently anticipate a very extended circulation for this magnificent work.

One of the greatest artistic triumphs of the age in Surgical Anatomy.—*British American Medical Journal*.

Too much cannot be said in its praise; indeed, we have not language to do it justice.—*Ohio Medical and Surgical Journal*.

The most admirable surgical atlas we have seen. To the practitioner deprived of demonstrative dissections upon the human subject, it is an invaluable companion.—*N. J. Medical Review*.

The most accurately engraved and beautifully colored plates we have ever seen in an American book—one of the best and cheapest surgical works ever published.—*Buffalo Medical Journal*.

It is very rare that so elegantly printed, so well illustrated, and so useful a work, is offered at so moderate a price.—*Charleston Medical Journal*.

Its plates can boast a superiority which places them almost beyond the reach of competition.—*Medical Examiner*.

Every practitioner, we think, should have a work of this kind within reach.—*Southern Medical and Surgical Journal*.

No such lithographic illustrations of surgical regions have hitherto, we think, been given.—*Boston Medical and Surgical Journal*.

As a surgical anatomist, Mr. MacLise has probably no superior.—*British and Foreign Medico-Chirurgical Review*.

Of great value to the student engaged in dissecting, and to the surgeon at a distance from the means

of keeping up his anatomical knowledge.—*Medical Times*.

The mechanical execution cannot be excelled.—*Transylvania Medical Journal*.

A work which has no parallel in point of accuracy and cheapness in the English language.—*N. Y. Journal of Medicine*.

To all engaged in the study or practice of their profession, such a work is almost indispensable.—*Dublin Quarterly Medical Journal*.

No practitioner whose means will admit should fail to possess it.—*Ranking's Abstract*.

Country practitioners will find these plates of immense value.—*N. Y. Medical Gazette*.

We are extremely gratified to announce to the profession the completion of this truly magnificent work, which, as a whole, certainly stands unrivalled, both for accuracy of drawing, beauty of coloring, and all the requisite explanations of the subject in hand.—*The New Orleans Medical and Surgical Journal*.

This is by far the ablest work on Surgical Anatomy that has come under our observation. We know of no other work that would justify a student, in any degree, for neglect of actual dissection. In those sudden emergencies that so often arise, and which require the instantaneous command of minute anatomical knowledge, a work of this kind keeps the details of the dissecting-room perpetually fresh in the memory.—*The Western Journal of Medicine and Surgery*.

☞ The very low price at which this work is furnished, and the beauty of its execution, require an extended sale to compensate the publishers for the heavy expenses incurred.

MULLER (PROFESSOR J.), M. D.

PRINCIPLES OF PHYSICS AND METEOROLOGY. Edited, with Additions, by R. EGLESFELD GRIFFITH, M. D. In one large and handsome octavo volume, extra cloth, with 550 wood-cuts, and two colored plates.

The Physics of Müller is a work superb, complete, unique: the greatest want known to English Science could not have been better supplied. The work is of surpassing interest. The value of this contribu-

tion to the scientific records of this country may be duly estimated by the fact that the cost of the original drawings and engravings alone has exceeded the sum of £2,900.—*Lancet*.

MAYNE (JOHN), M. D., M. R. C. S.

A DISPENSATORY AND THERAPEUTICAL REMEMBRANCER. Comprising the entire lists of Materia Medica, with every Practical Formula contained in the three British Pharmacopœias. With relative Tables subjoined, illustrating, by upwards of six hundred and sixty examples, the Extemporaneous Forms and Combinations suitable for the different Medicines. Edited, with the addition of the Formulæ of the United States Pharmacopœia, by R. EGLESFELD GRIFFITH, M. D. In one 12mo. volume, extra cloth, of over 300 large pages.

MATTEUCCI (CARLO).

LECTURES ON THE PHYSICAL PHENOMENA OF LIVING BEINGS.

Edited by J. PEREIRA, M. D. In one neat royal 12mo. volume, extra cloth, with cuts, 388 pages.

NEILL (JOHN), M. D.,

Surgeon to the Pennsylvania Hospital, &c.; and

FRANCIS GURNEY SMITH, M. D.,

Professor of Institutes of Medicine in the Pennsylvania Medical College.

AN ANALYTICAL COMPENDIUM OF THE VARIOUS BRANCHES OF MEDICAL SCIENCE; for the Use and Examination of Students. Second edition, revised and improved. In one very large and handsomely printed royal 12mo. volume, of over one thousand pages, with three hundred and fifty illustrations on wood. Strongly bound in leather, with raised bands.

The speedy sale of a large impression of this work has afforded to the authors gratifying evidence of the correctness of the views which actuated them in its preparation. In meeting the demand for a second edition, they have therefore been desirous to render it more worthy of the favor with which it has been received. To accomplish this, they have spared neither time nor labor in embodying in it such discoveries and improvements as have been made since its first appearance, and such alterations as have been suggested by its practical use in the class and examination-room. Considerable modifications have thus been introduced throughout all the departments treated of in the volume, but more especially in the portion devoted to the "Practice of Medicine," which has been entirely rearranged and rewritten. The authors therefore again submit their work to the profession, with the hope that their efforts may tend, however humbly, to advance the great cause of medical education.

Notwithstanding the enlarged size and improved execution of this work, the price has not been increased, and it is confidently presented as one of the cheapest volumes now before the profession.

In the rapid course of lectures, where work for the students is heavy, and review necessary for an examination, a compend is not only valuable, but it is almost a *sine qua non*. The one before us is, in most of the divisions, the most unexceptionable of all books of the kind that we know of. The newest and soundest doctrines and the latest improvements and discoveries are explicitly, though concisely, laid before the student. Of course it is useless for us to recommend it to all last course students, but there is a class to whom we very sincerely commend this cheap book as worth its weight in silver—that class is the graduates in medicine of more than ten years' standing, who have not studied medicine since. They will perhaps find out from it that the science is not exactly now what it was when they left it off.—*The Stethoscope*

Having made free use of this volume in our examinations of pupils, we can speak from experience in recommending it as an admirable compend for students, and as especially useful to preceptors who examine their pupils. It will save the teacher much labor by enabling him readily to recall all of the points upon which his pupils should be examined. A work of this sort should be in the hands of every one who takes pupils into his office with a view of examining them; and this is unquestionably the best of its class. Let every practitioner who has pupils provide himself with it, and he will find the labor of refreshing his knowledge so much facilitated that he will be able to do justice to his pupils at very little cost of time or trouble to himself.—*Transylvania Med. Journal*.

NELIGAN (J. MOORE), M. D., M. R. I. A., &c.

A PRACTICAL TREATISE ON DISEASES OF THE SKIN. In one neat royal 12mo. volume, of 334 pages.

OWEN (PROF. R.),

Author of "Lectures on Comparative Anatomy," "Archetype of the Skeleton," &c.

ON THE DIFFERENT FORMS OF THE SKELETON, AND OF THE TEETH. One vol. royal 12mo., with numerous illustrations. (*Now Ready*.)

The name of the distinguished author is a sufficient guarantee that this little volume will prove a satisfactory manual and guide to all students of Comparative Anatomy and Osteology. The importance of this subject in geological investigations will also render this work a most valuable assistant to those interested in that science.

PHILLIPS (BENJAMIN), F. R. S., &c.

SCROFULA; its Nature, its Prevalence, its Causes, and the Principles of its Treatment. In one volume, octavo, with a plate.

PANCOAST (J.), M. D.,

Professor of Anatomy in the Jefferson Medical College, Philadelphia, &c.

OPERATIVE SURGERY; or, A Description and Demonstration of the various Processes of the Art; including all the New Operations, and exhibiting the State of Surgical Science in its present advanced condition. Complete in one royal 4to. volume, of 380 pages of letter-press description and eighty large 4to. plates, comprising 486 illustrations. Second edition, improved.

Blanchard & Lea having become the publishers of this important book, have much pleasure in offering it to the profession.

This excellent work is constructed on the model of the French Surgical Works by Velpeau and Malgaigne; and, so far as the English language is concerned, we are proud as an American to say that, of ITS KIND IT HAS NO SUPERIOR.—*N. Y. Journal of Medicine*.

PARKER (LANGSTON),

Surgeon to the Queen's Hospital, Birmingham.

THE MODERN TREATMENT OF SYPHILITIC DISEASES, BOTH PRIMARY AND SECONDARY; comprising the Treatment of Constitutional and Confirmed Syphilis, by a safe and successful method. With numerous Cases, Formulæ, and Clinical Observations. From the Third and entirely rewritten London edition. In one neat octavo volume. (*Now Ready*.)

(Now Complete.)

PEREIRA (JONATHAN), M. D., F. R. S., AND L. S.

THE ELEMENTS OF MATERIA MEDICA AND THERAPEUTICS.

Third American edition, enlarged and improved by the author; including Notices of most of the Medicinal Substances in use in the civilized world, and forming an Encyclopædia of Materia Medica. Edited, with Additions, by JOSEPH CARSON, M. D., Professor of Materia Medica and Pharmacy in the University of Pennsylvania. In two very large octavo volumes of 2100 pages, on small type, with over four hundred and fifty illustrations.

VOLUME I.—Lately issued, containing the Inorganic Materia Medica, over 800 pages, with 145 illustrations.

VOLUME II.—Now ready, embraces the Organic Materia Medica, and forms a very large octavo volume of 1250 pages, with two plates and three hundred handsome wood-cuts.

The present edition of this valuable and standard work will enhance in every respect its well-deserved reputation. The care bestowed upon its revision by the author may be estimated by the fact that its size has been increased by about five hundred pages. These additions have extended to every portion of the work, and embrace not only the materials afforded by the recent editions of the pharmacopœias, but also all the important information accessible to the care and industry of the author in treatises, essays, memoirs, monographs, and from correspondents in various parts of the globe. In this manner the work comprises the most recent and reliable information respecting all the articles of the Materia Medica, their natural and commercial history, chemical and therapeutical properties, preparation, uses, doses, and modes of administration, brought up to the present time, with a completeness not to be met with elsewhere. A considerable portion of the work which preceded the remainder in London, has also enjoyed the advantage of a further revision by the author expressly for this country, and in addition to this the editor, Professor Carson, has made whatever additions appeared desirable to adapt it thoroughly to the U. S. Pharmacopœia, and to the wants of the American profession. An equal improvement will likewise be observable in every department of its mechanical execution. It is printed from new type, on good white paper, with a greatly extended and improved series of illustrations.

Gentlemen who have the first volume are recommended to complete their copies without delay. The first volume will no longer be sold separate.

When we remember that Philology, Natural History, Botany, Chemistry, Physics, and the Microscope, are all brought forward to elucidate the subject, one cannot fail to see that the reader has here a work worthy of the name of an encyclopædia of Materia Medica. Our own opinion of its merits is that of its editors, and also that of the whole profession, both of this and foreign countries—namely, "that in copiousness of details, in extent, variety, and accuracy of information, and in lucid explanation of difficult and recondite subjects, it surpasses all other works on Materia Medica hitherto published." We cannot close this notice without alluding to the special additions of the American editor, which pertain to the prominent vegetable productions of this country, and to the directions of the United States Pharmacopœia, in connection with all the articles contained in the volume which are referred to by it. The illustrations have been increased, and this edition by Dr. Carson cannot well be regarded in any other light than that of a treasure which should be found in the library of every physician.—*New York Journal of Medical and Collateral Science*, March, 1854.

The third edition of his "Elements of Materia

Medica, although completed under the supervision of others, is by far the most elaborate treatise in the English language, and will, while medical literature is cherished, continue a monument alike honorable to his genius, as to his learning and industry.—*American Journal of Pharmacy*, March, 1854.

The work, in its present shape, and so far as can be judged from the portion before the public, forms the most comprehensive and complete treatise on materia medica extant in the English language.—Dr. Pereira has been at great pains to introduce into his work, not only all the information on the natural, chemical, and commercial history of medicines, which might be serviceable to the physician and surgeon, but whatever might enable his readers to understand thoroughly the mode of preparing and manufacturing various articles employed either for preparing medicines, or for certain purposes in the arts connected with materia medica and the practice of medicine. The accounts of the physiological and therapeutic effects of remedies are given with great clearness and accuracy, and in a manner calculated to interest as well as instruct the reader.—*The Edinburgh Medical and Surgical Journal*.

PEASELEE (E. R.), M. D.,

Professor of Anatomy and Physiology in Dartmouth College, &c.

HUMAN HISTOLOGY, in its applications to Physiology and General Pathology; designed as a Text-Book for Medical Students. With numerous illustrations. In one handsome royal 12mo. volume. (*Preparing*.)

The subject of this work is one, the growing importance of which, as the basis of Anatomy and Physiology, demands for it a separate volume. The book will therefore supply an acknowledged deficiency in medical text-books, while the name of the author, and his experience as a teacher for the last thirteen years, is a guarantee that it will be thoroughly adapted to the use of the student.

PIRRIE (WILLIAM), F. R. S. E.,

Professor of Surgery in the University of Aberdeen.

THE PRINCIPLES AND PRACTICE OF SURGERY. Edited by JOHN

NEILL, M. D., Demonstrator of Anatomy in the University of Pennsylvania, Surgeon to the Pennsylvania Hospital, &c. In one very handsome octavo volume, of 780 pages, with 316 illustrations. (*Just Issued*.)

We know of no other surgical work of a reasonable size, wherein there is so much theory and practice, or where subjects are more soundly or clearly taught.—*The Stethoscope*.

There is scarcely a disease of the bone or soft parts, fracture, or dislocation, that is not illustrated by accurate wood-engravings. Then, again, every instrument employed by the surgeon is thus represented. These engravings are not only correct, but really beautiful, showing the astonishing degree of perfection to which the art of wood-engraving has

arrived. Prof. Pirrie, in the work before us, has elaborately discussed the principles of surgery, and a safe and effectual practice predicated upon them. Perhaps no work upon this subject heretofore issued is so full upon the science of the art of surgery.—*Nashville Journal of Medicine and Surgery*.

One of the best treatises on surgery in the English language.—*Canada Med. Journal*.

Our impression is, that, as a manual for students, Pirrie's is the best work extant.—*Western Med. and Surg. Journal*.

RAMSBOTHAM (FRANCIS H.), M. D.

THE PRINCIPLES AND PRACTICE OF OBSTETRIC MEDICINE AND SURGERY, in reference to the Process of Parturition. Sixth American, from the last London edition. Illustrated with one hundred and forty-eight Figures, on fifty-five Lithographic Plates. In one large and handsomely printed volume, imperial octavo, with 520 pages.

In this edition, the plates have all been redrawn, and the text carefully read and corrected. It is therefore presented as in every way worthy the favor with which it has so long been received.

From Prof. Hodge, of the University of Pa.

To the American public, it is most valuable, from its intrinsic undoubted excellence, and as being the best authorized exponent of British Midwifery. Its circulation will, I trust, be extensive throughout our country.

We recommend the student who desires to master this difficult subject with the least possible trouble, to possess himself at once of a copy of this work.—*American Journal of the Med. Sciences.*

It stands at the head of the long list of excellent obstetric works published in the last few years in Great Britain, Ireland, and the Continent of Europe. We consider this book indispensable to the library of every physician engaged in the practice of midwifery.—*Southern Med. and Surg. Journal.*

When the whole profession is thus unanimous in placing such a work in the very first rank as regards the extent and correctness of all the details of the theory and practice of so important a branch of learning, our commendation or condemnation would be of little consequence; but regarding it as the most useful of all works of the kind, we think it but an act of justice to urge its claims upon the profession.—*N. O. Med. Journal.*

RICORD (P.), M. D.,

Surgeon to the Hôpital du Midi, Paris, &c.

ILLUSTRATIONS OF SYPHILITIC DISEASE. Translated from the French, by THOMAS F. BETTON, M. D. With the addition of a History of Syphilis, and a complete Bibliography and Formulary of Remedies, collated and arranged, by PAUL B. GODDARD, M. D. With fifty large quarto plates, comprising one hundred and seventeen beautifully colored illustrations. In one large and handsome quarto volume.

Blanchard & Lea having purchased the remainder of this valuable work, which was originally sold as a subscription book, are now prepared to offer it to the profession. It is universally known as one of the handsomest volumes as yet presented in this country, and as containing the only extended and thorough series of illustrations on the subject.

BY THE SAME AUTHOR. (*Now Ready.*)

A TREATISE ON THE VENEREAL DISEASE. By JOHN HUNTER, F. R. S.

With copious Additions, by PH. RICORD, M. D. Edited, with Notes, by FREEMAN J. BUMSTEAD, M. D. In one handsome octavo volume, with plates.

From the Translator's Preface.

"M. Ricord's annotations to *Hunter's Treatise on the Venereal Disease* were first published at Paris, in 1840, in connection with Dr. G. Richelot's translation of the work, including the contributions of Sir Everard Home and Mr. Babington. In a second edition, which has recently appeared, M. Ricord has thoroughly revised his part of the work, bringing it up to the knowledge of the present day, and so materially increasing it that it now constitutes full one-third of the volume.

"This publication has been received with great favor by the French, both because it has placed within their reach an important work of Hunter, and also because it is the only recent practical work which M. Ricord has published, no edition of his *Traité des Maladies Vénériennes* having appeared for the last fifteen years."

Every one will recognize the attractiveness and value which this work derives from thus presenting the opinions of these two masters side by side. But, it must be admitted, what has made the fortune of the book, is the fact that it contains the "most complete embodiment of the veritable doctrines of the Hôpital du Midi," which has ever been made public. The doctrinal ideas of M. Ricord, ideas which, if not universally adopted, are incontestably dominant, have heretofore only been interpreted by more or less skillful secretaries, sometimes accredited and sometimes not.

In the notes to Hunter, the master substitutes himself for his interpreters, and gives his original thoughts to the world, in a summary form it is true, but in a lucid and perfectly intelligible manner. In conclusion we can say that this is incontestably the best treatise on syphilis with which we are acquainted, and, as we do not often employ the phrase, we may be excused for expressing the hope that it may find a place in the library of every physician.—*Virginia Med. and Surg. Journal.*

BY THE SAME AUTHOR.

LETTERS ON SYPHILIS, addressed to the Chief Editor of the Union Médicale.

With an Introduction, by Amédée Latour. Translated by W. P. Lattimore, M. D. In one neat octavo volume.

Blanchard & Lea are now the publishers of this valuable work.

From the Translator's Preface.

To those who have listened to the able and interesting lectures of our author at the Hôpital du Midi, this volume will need no commendation; while to those who have not had the pleasure to which we allude, the book will commend itself by the truths it contains, told as they are in the same inimitable style in which M. Ricord delivers his clinical lectures.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON VENEREAL DISEASES. With a Therapeutical Summary and Special Formulary. Translated by SIDNEY DOANE, M. D. Fourth edition. One volume, octavo, 340 pages.

RIGBY (EDWARD), M. D.,

Physician to the General Lying-in Hospital, &c.

A SYSTEM OF MIDWIFERY. With Notes and Additional Illustrations. Second American Edition. One volume octavo, 422 pages.

ROYLE (J. FORBES), M. D.

MATERIA MEDICA AND THERAPEUTICS; including the Preparations of the Pharmacopœias of London, Edinburgh, Dublin, and of the United States. With many new medicines. Edited by JOSEPH CARSON, M. D., Professor of Materia Medica and Pharmacy in the University of Pennsylvania. With ninety-eight illustrations. In one large octavo volume, of about seven hundred pages.

This work is, indeed, a most valuable one, and will fill up an important vacancy that existed between Dr. Pereira's most learned and complete system of Materia Medica, and the class of pro-

ductions on the other extreme, which are necessarily imperfect from their small extent.—*British and Foreign Medical Review.*

SKEY (FREDERICK C.), F. R. S., &c.

OPERATIVE SURGERY. In one very handsome octavo volume of over 650 pages, with about one hundred wood-cuts.

Its literary execution is superior to most surgical treatises. It abounds in excellent moral hints, and is replete with original surgical expedients and suggestions.—*Buffalo Med. and Surg. Journal.*

With high talents, extensive practice, and a long experience, Mr. Skey is perhaps competent to the task of writing a complete work on operative surgery.—*Charleston Med. Journal.*

We cannot withhold from this work our high commendation. Students and practitioners will find it an invaluable teacher and guide upon every topic connected with this department.—*N. Y. Medical Gazette.*

A work of the very highest importance—a work by itself.—*London Med. Gazette.*

SHARPEY (WILLIAM), M. D., JONES QUAIN, M. D., AND RICHARD QUAIN, F. R. S., &c.

HUMAN ANATOMY. Revised, with Notes and Additions, by JOSEPH LEIDY, M. D. Complete in two large octavo volumes, of about thirteen hundred pages. Beautifully illustrated with over five hundred engravings on wood.

It is indeed a work calculated to make an era in anatomical study, by placing before the student every department of his science, with a view to the relative importance of each; and so skilfully have the different parts been interwoven, that no one who makes this work the basis of his studies, will hereafter have any excuse for neglecting or undervaluing any important particulars connected with the structure of the human frame; and whether the bias of his mind lead him in a more especial manner to surgery, physis, or physiology, he will find here a work at once so comprehensive and practical as to defend him from exclusiveness on the one hand, and pedantry on the other.—*Monthly Journal and Retrospect of the Medical Sciences.*

We have no hesitation in recommending this treatise on anatomy as the most complete on that subject in the English language; and the only one, perhaps, in any language, which brings the state of knowledge forward to the most recent discoveries.—*The Edinburgh Med. and Surg. Journal.*

Admirably calculated to fulfil the object for which it is intended.—*Provincial Medical Journal.*

The most complete Treatise on Anatomy in the English language.—*Edinburgh Medical Journal.*

There is no work in the English language to be preferred to Dr. Quain's Elements of Anatomy.—*London Journal of Medicine.*

SMITH (HENRY H.), M. D., AND HORNER (WILLIAM E.), M. D.

AN ANATOMICAL ATLAS, illustrative of the Structure of the Human Body.

In one volume, large imperial octavo, with about six hundred and fifty beautiful figures.

These figures are well selected, and present a complete and accurate representation of that wonderful fabric, the human body. The plan of this Atlas, which renders it so peculiarly convenient for the student, and its superb artistical execution, have been already pointed out. We must congratulate

late the student upon the completion of this Atlas, as it is the most convenient work of the kind that has yet appeared; and we must add, the very beautiful manner in which it is "got up" is so creditable to the country as to be flattering to our national pride.—*American Medical Journal.*

SARGENT (F. W.), M. D.

ON BANDAGING AND OTHER POINTS OF MINOR SURGERY. In one handsome royal 12mo. volume of nearly 400 pages, with 128 wood-cuts.

The very best manual of Minor Surgery we have seen; an American volume, with nearly four hundred pages of good practical lessons, illustrated by about one hundred and thirty wood-cuts. In these days of "trial," when a doctor's reputation hangs upon a clove hitch, or the roll of a bandage, it would be well, perhaps, to carry such a volume as Mr. Sargent's always in our coat-pocket, or, at all events, to listen attentively to his instructions at home.—*Buffalo Med. Journal.*

We have carefully examined this work, and find it well executed and admirably adapted to the use of the student. Besides the subjects usually embraced in works on Minor Surgery, there is a short chapter on bathing, another on anæsthetic agents, and an appendix of formulæ. The author has given an excellent work on this subject, and his publishers have illustrated and printed it in most beautiful style.—*The Charleston Medical Journal.*

STANLEY (EDWARD).

A TREATISE ON DISEASES OF THE BONES. In one volume, octavo, extra cloth, 286 pages.

STILLÉ (ALFRED), M. D.

PRINCIPLES OF THERAPEUTICS. In one handsome volume. (*Preparing.*)

SIMON (JOHN), F. R. S.

GENERAL PATHOLOGY, as conducive to the Establishment of Rational Principles for the Prevention and Cure of Disease. A Course of Lectures delivered at St. Thomas's Hospital during the summer Session of 1850. In one neat octavo volume.

SMITH (TYLER W.), M. D.,

Lecturer on Obstetrics in the Hunterian School of Medicine.

ON PARTURITION, AND THE PRINCIPLES AND PRACTICE OF OBSTETRICS. In one large duodecimo volume, of 400 pages.

SIBSON (FRANCIS), M. D.,

Physician to St. Mary's Hospital.

MEDICAL ANATOMY. Illustrating the Form, Structure, and Position of the Internal Organs in Health and Disease. In large imperial quarto, with splendid colored plates. To match "Maclise's Surgical Anatomy." (*Preparing.*)

SOLLY (SAMUEL), F. R. S.

THE HUMAN BRAIN; its Structure, Physiology, and Diseases. With a Description of the Typical Forms of the Brain in the Animal Kingdom. From the Second and much enlarged London edition. In one octavo volume, with 120 wood-cuts.

SCHOEDLER (FRIEDRICH), PH. D.,

Professor of the Natural Sciences at Worms, &c.

THE BOOK OF NATURE; an Elementary Introduction to the Sciences of Physics, Astronomy, Chemistry, Mineralogy, Geology, Botany, Zoology, and Physiology. First American edition, with a Glossary and other Additions and Improvements; from the second English edition. Translated from the sixth German edition, by HENRY MEDLOCK, F. C. S., &c. In one thick volume, small octavo, of about seven hundred pages, with 679 illustrations on wood. Suitable for the higher Schools and private students. (*Now Ready.*)This volume, as its title shows, covers nearly all the sciences, and embodies a vast amount of information for instruction. No other work that we have seen presents the reader with so wide a range of elementary knowledge, with so full illustrations, at so cheap a rate.—*Silliman's Journal*, Nov. 1853.

TAYLOR (ALFRED S.), M. D., F. R. S.,

Lecturer on Medical Jurisprudence and Chemistry in Guy's Hospital.

MEDICAL JURISPRUDENCE. Third American, from the fourth and improved English Edition. With Notes and References to American Decisions, by EDWARD HARTSHORNE, M. D. In one large octavo volume, of about seven hundred pages. (*Just Issued.*)We know of no work on Medical Jurisprudence which contains in the same space anything like the same amount of valuable matter.—*N. Y. Journal of Medicine*.The American editor has appended several important facts, the whole constituting by far the best, most reliable, and interesting treatise on Medical Jurisprudence, and one that we cannot too strongly recommend to all who desire to become acquainted with the true and correct exposition of this department of medical literature.—*Northern Lancet*.

No work upon the subject can be put into the hands of students either of law or medicine which will engage them more closely or profitably; and none could be offered to the busy practitioner of either calling, for the purpose of casual or hasty

reference, that would be more likely to afford the aid desired. We therefore recommend it as the best and safest manual for daily use.—*American Journal of Medical Sciences*.We have heretofore had reason to refer to it in terms of commendation, and need now only state that, in the edition before us, the author has completely revised the whole work, making many additions and alterations, and brought it fully up to the present state of knowledge. The task of the American editor has been to present all the important facts and cases that have recently occurred in our own country, bearing on the subjects treated of. No better work can be placed in the hands of the physician or jurist.—*St. Louis Medical and Surgical Journal*.

BY THE SAME AUTHOR.

ON POISONS, IN RELATION TO MEDICAL JURISPRUDENCE AND MEDICINE. Edited, with Notes and Additions, by R. E. GRIFFITH, M. D. In one large octavo volume, of 688 pages.

The most elaborate work on the subject that our literature possesses.—*British and Foreign Medical-Chirurgical Review*.It contains a vast body of facts, which embrace all that is important in toxicology, all that is necessary to the guidance of the medical jurist, and all that can be desired by the lawyer.—*Medical-Chirurgical Review*.One of the most practical and trustworthy works on Poisons in our language.—*Western Journal of Medicine*.It is, so far as our knowledge extends, incomparably the best upon the subject; in the highest degree creditable to the author, entirely trustworthy, and indispensable to the student and practitioner.—*N. Y. Annalist*.

THOMSON (A. T.), M. D., F. R. S., &c.

DOMESTIC MANAGEMENT OF THE SICK ROOM, necessary in aid of Medical Treatment for the Cure of Diseases. Edited by R. E. GRIFFITH, M. D. In one large royal 12mo. volume, with wood-cuts, 360 pages.

TOMES (JOHN), F. R. S.

A MANUAL OF DENTAL PRACTICE. Illustrated by numerous engravings on wood. In one handsome volume. (*Preparing.*)

TODD (R. B.), M. D., AND BOWMAN (WILLIAM), F. R. S.
PHYSIOLOGICAL ANATOMY AND PHYSIOLOGY OF MAN. With numerous handsome wood-cuts. Parts I, II, and III, in one octavo volume, 552 pages. Part IV will complete the work.

The distinguishing peculiarity of this work is, that the authors investigate for themselves every fact asserted; and it is the immense labor consequent upon the vast number of observations requisite to carry out this plan, which has so long delayed the appearance of its completion. The first portion of Part IV, with numerous original illustrations, was published in the Medical News and Library for 1853, and the completion will be issued immediately on its appearance in London. Those who have subscribed since the appearance of the preceding portion of the work can have the three parts by mail, on remittance of \$2 50 to the publishers.

TRANSACTIONS OF THE AMERICAN MEDICAL ASSOCIATION.
VOLUME VI, for 1853, large 8vo., of 870 pages, with numerous colored plates and wood-cuts.

Also to be had, a few sets of the Transactions from 1848 to 1853, in six large octavo volumes, price \$25. These volumes are all published by and sold on account of the Association.

WATSON (THOMAS), M. D., &c.

LECTURES ON THE PRINCIPLES AND PRACTICE OF PHYSIC.

Third American, from the last London edition. Revised, with Additions, by D. FRANCIS CONDIE, M. D., author of a "Treatise on the Diseases of Children," &c. In one octavo volume, of nearly eleven hundred large pages, strongly bound with raised bands.

To say that it is the very best work on the subject now extant, is but to echo the sentiment of the medical press throughout the country.—*N. O. Medical Journal.*

Of the text-books recently republished Watson is very justly the principal favorite.—*Holmes's Rep. to Nat. Med. Assoc.*

By universal consent the work ranks among the very best text-books in our language.—*Illinois and Indiana Med. Journal.*

Regarded on all hands as one of the very best, if not the very best, systematic treatise on practical medicine extant.—*St. Louis Med. Journal.*

Confessedly one of the very best works on the principles and practice of physic in the English or any other language.—*Med. Examiner.*

As a text-book it has no equal; as a compendium of pathology and practice no superior.—*New York Annalist.*

We know of no work better calculated for being placed in the hands of the student, and for a text-book; on every important point the author seems to have posted up his knowledge to the day.—*Amer. Med. Journal.*

One of the most practically useful books that ever was presented to the student.—*N. Y. Med. Journal.*

WALSHE (W. H.), M. D.,

Professor of the Principles and Practice of Medicine in University College, London.

DISEASES OF THE HEART, LUNGS, AND APPENDAGES; their Symptoms and Treatment. In one handsome volume, large royal 12mo., 512 pages.

We consider this as the ablest work in the English language, on the subject of which it treats; the author being the first stethoscopist of the day.—*Charleston Medical Journal.*

WHAT TO OBSERVE AT THE BEDSIDE AND AFTER DEATH, IN MEDICAL CASES.

Published under the authority of the London Society for Medical Observation. In one very handsome volume, royal 12mo., extra cloth. (*Just Issued.*)

We hail the appearance of this book as the grand desideratum.—*Charleston Medical Journal.*

This is truly a very capital book. The whole medical world will reap advantages from its publication. The medical journals will soon show its influence on the character of the "Reports of Cases" which they publish. Drs. Ballard and Walshe have

given to the world, through a small but useful medical organization, a cheap but invaluable book. We do advise every reader of this notice to buy it and use it. Unless he is so vain as to imagine himself superior to the ordinary human capacity, he will in six months see its inestimable advantages.—*Stethoscope.*

WILDE (W. R.),

Surgeon to St. Mark's Ophthalmic and Aural Hospital, Dublin.

AURAL SURGERY, AND THE NATURE AND TREATMENT OF DISEASES OF THE EAR. In one handsome octavo volume, with illustrations. (*Now Ready.*)

So little is generally known in this country concerning the causes, symptoms, and treatment of aural affections, that a practical and scientific work on that subject, from a practitioner of Mr. Wilde's great experience, cannot fail to be productive of much benefit, by attracting attention to this obscure class of diseases, which too frequently escape attention until past relief. The immense number of cases which have come under Mr. Wilde's observation for many years, have afforded him opportunities rarely enjoyed for investigating this branch of medical science, and his work may therefore be regarded as of the highest authority.

This work certainly contains more information on the subject to which it is devoted than any other with which we are acquainted. We feel grateful to the author for his manful effort to rescue this department of surgery from the hands of the empirics who nearly monopolize it. We think he has successfully shown that aural diseases are not beyond the resources of art; that they are governed by the same

laws, and amenable to the same general methods of treatment as other morbid processes. The work is not written to supply the cravings of popular patronage, but it is wholly addressed to the profession, and bears on every page the impress of the reflection of a sagacious and practical surgeon.—*Va. Surg. and Med. Journal.*

WILSON (ERASMUS), M. D., F. R. S.,
Lecturer on Anatomy, London.

A SYSTEM OF HUMAN ANATOMY, General and Special. Fourth American, from the last English edition. Edited by PAUL B. GODDARD, A. M., M. D. With two hundred and fifty illustrations. Beautifully printed, in one large octavo volume, of nearly six hundred pages.

In many, if not all the Colleges of the Union, it has become a standard text-book. This, of itself, is sufficiently expressive of its value. A work very desirable to the student; one, the possession of which will greatly facilitate his progress in the study of Practical Anatomy.—*New York Journal of Medicine*.

Its author ranks with the highest on Anatomy.—*Southern Medical and Surgical Journal*.

It offers to the student all the assistance that can be expected from such a work.—*Medical Examiner*.

The most complete and convenient manual for the student we possess.—*American Journal of Medical Science*.

In every respect, this work as an anatomical guide for the student and practitioner, merits our warmest and most decided praise.—*London Medical Gazette*.

BY THE SAME AUTHOR.

THE DISSECTOR; or, Practical and Surgical Anatomy. Modified and Rearranged, by PAUL BECK GODDARD, M. D. A new edition, with Revisions and Additions. In one large and handsome volume, royal 12mo., with one hundred and fifteen illustrations.

In passing this work again through the press, the editor has made such additions and improvements as the advance of anatomical knowledge has rendered necessary to maintain the work in the high reputation which it has acquired in the schools of the United States, as a complete and faithful guide to the student of practical anatomy. A number of new illustrations have been added, especially in the portion relating to the complicated anatomy of Hernia. In mechanical execution the work will be found superior to former editions.

BY THE SAME AUTHOR.

ON DISEASES OF THE SKIN. Third American, from the third London edition. In one neat octavo volume, of about five hundred pages, extra cloth. (*Just Issued*.) Also, to be had done up with fifteen beautiful steel plates, of which eight are exquisitely colored; representing the Normal and Pathological Anatomy of the Skin, together with accurately colored delineations of more than sixty varieties of disease, most of them the size of nature. The Plates are also for sale separate, done up in boards.

The increased size of this edition is sufficient evidence that the author has not been content with a mere republication, but has endeavored to maintain the high character of his work as the standard text-book on this interesting and difficult class of diseases. He has thus introduced such new matter as the experience of the last three or four years has suggested, and has made such alterations as the progress of scientific investigation has rendered expedient. The illustrations have also been materially augmented, the number of plates being increased from eight to sixteen.

The "Diseases of the Skin," by Mr. Erasmus Wilson, may now be regarded as the standard work in that department of medical literature. The plates by which this edition is accompanied leave nothing to be desired, so far as excellence of delineation and perfect accuracy of illustration are concerned.—*Medico-Chirurgical Review*.

Of these plates it is impossible to speak too highly. The representations of the various forms of cutaneous disease are singularly accurate, and the coloring exceeds almost anything we have met with in point of delicacy and finish.—*British and Foreign Medical Review*.

BY THE SAME AUTHOR.

ON CONSTITUTIONAL AND HEREDITARY SYPHILIS, AND ON SYPHILITIC ERUPTIONS. In one small octavo volume, beautifully printed, with four exquisite colored plates, presenting more than thirty varieties of syphilitic eruptions.

Dr. Wilson's views on the general subject of Syphilis appear to us in the main sound and judicious, and we commend the book as an excellent monograph on the subject. Dr. Wilson has presented us a very faithful and lucid description of Syphilis and has cleared up many obscure points in

connection with its transmissibility, pathology and sequelæ. His facts and references will, we are satisfied, be received as decisive, in regard to many questions vexatæ. They appear to us entitled to notice at some length.—*Medical Examiner*.

BY THE SAME AUTHOR. (*Now Ready*.)

HEALTHY SKIN; A Popular Treatise on the Skin and Hair, their Preservation and Management. Second American, from the fourth London edition. One neat volume, royal 12mo., with numerous illustrations.

Copies can be had done up in paper covers for mailing, price 75 cents.

WHITEHEAD (JAMES), F. R. C. S., &c.

THE CAUSES AND TREATMENT OF ABORTION AND STERILITY; being the Result of an Extended Practical Inquiry into the Physiological and Morbid Conditions of the Uterus. Second American Edition. In one volume, octavo, 368 pages. (*Now Ready*.)

The simple title of this work gives a very imperfect idea of its contents. The subject of sterility occupies a mere fraction of space, and upwards of one-half of the whole volume is taken up with an elaborate account of menstruation as a physiological process, and of the disorders which its deviations from health are apt to produce.—*Medical Chirurg. Review*.

Such are the advances made from year to year in

this department of our profession, that the practitioner who does not consult the recent works on the complaints of females, will soon find himself in the rear of his more studious brethren. This is one of the works which must be studied by those who would know what the present state of our knowledge is respecting the causes and treatment of abortion and sterility.—*The Western Journal of Medicine and Surgery*.

WEST (CHARLES), M. D.,

Physician to the Hospital for Sick Children, &c.

LECTURES ON THE DISEASES OF INFANCY AND CHILDHOOD.

Second American, from the Second and Enlarged London edition. In one volume, octavo, of nearly five hundred pages. (*Now Ready.*)

From the Preface to the Second Edition.

In the preparation of the second edition of these Lectures, the whole work has been carefully revised. A few formulæ have been introduced and a minute alphabetical index has been appended while additions amounting altogether to fifty pages, have been made, wherever I felt that more extended observation, or more careful reflection had enabled me to supply some of those deficiencies which I am well aware, are still far too numerous. The work now contains the result of 640 observations, and 199 post-mortem examinations, chiefly made among 16,276 children who came under my notice during the ten years of my connection with the Children's Infirmary in Lambeth.

We take leave of Dr. West with great respect for his attainments, a due appreciation of his acute powers of observation, and a deep sense of obligation for this valuable contribution to our professional literature. His book is undoubtedly in many respects the best we possess on diseases of children. The extracts we have given will, we hope, satisfy our readers of its value; and yet in all candor we must say that they are even inferior to some other parts, the length of which prohibited our entering upon them. That the book will shortly be in the hands of most of our readers we do not doubt, and it will give us much pleasure if our strong recommendation of it may contribute towards the result.—*The Dublin Quarterly Journal of Medical Science.*

Dr. West has placed the profession under deep obligation by this able, thorough, and finished work

upon a subject which almost daily taxes to the utmost the skill of the general practitioner. He has with singular felicity threaded his way through all the tortuous labyrinths of the difficult subject he has undertaken to elucidate, and has in many of the darkest corners left a light, for the benefit of succeeding travellers, which will never be extinguished. Not the least captivating feature in this admirable performance is its easy, conversational style, which acquires force from its very simplicity, and leaves an impression upon the memory, of the truths it conveys, as clear and refreshing as its own purity. The author's position secured him extraordinary facilities for the investigation of children's diseases, and his powers of observation and discrimination have enabled him to make the most of these great advantages.—*Nashville Medical Journal.*

BY THE SAME AUTHOR. (*Now Ready.*)

AN ENQUIRY INTO THE PATHOLOGICAL IMPORTANCE OF ULCERATION OF THE OS UTERI. Being the Croonian Lectures for the year 1854. In one neat octavo volume, extra cloth.

This work will appear in the "Medical News and Library" during the latter portion of 1854, and will be published in a separate form about December.

WILLIAMS (C. J. B.), M. D., F. R. S.,

Professor of Clinical Medicine in University College, London, &c.

PRINCIPLES OF MEDICINE; comprising General Pathology and Therapeutics, and a brief general view of Etiology, Nosology, Semeiology, Diagnosis, Prognosis, and Hygienics. Edited, with Additions, by MEREDITH CLYMER, M. D. Fourth American, from the last and enlarged London edition. In one octavo volume, of 476 pages. (*Now Ready.*)

This new edition has been materially enlarged and brought up by the editor.

It possesses the strongest claims to the attention of the medical student and practitioner, from the admirable manner in which the various inquiries in the different branches of pathology are investigated, combined, and generalized by an experienced practical physician, and directly applied to the investigation and treatment of disease.—**EDITOR'S PREFACE.**

The best exposition in our language, or, we believe, in any language, of rational medicine, in its present improved and rapidly improving state.—*British and Foreign Medico-Chirurg. Review.*

Few books have proved more useful, or met with a more ready sale than this, and no practitioner should regard his library as complete without it.—*Ohio Med. and Surg. Journal.*

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON DISEASES OF THE RESPIRATORY ORGANS; including Diseases of the Larynx, Trachea, Lungs, and Pleuræ. With numerous Additions and Notes, by M. CLYMER, M. D. With wood-cuts. In one octavo volume, pp. 508.

YOUATT (WILLIAM), V. S.

THE HORSE. A new edition, with numerous illustrations; together with a general history of the Horse; a Dissertation on the American Trotting Horse; how Trained and Jockeyed; an Account of his Remarkable Performances; and an Essay on the Ass and the Mule. By J. S. SKINNER, formerly Assistant Postmaster-General, and Editor of the Turf Register. One large octavo volume.

BY THE SAME AUTHOR.

THE DOG. Edited by E. J. LEWIS, M. D. With numerous and beautiful illustrations. In one very handsome volume, crown 8vo., crimson cloth, gilt.

B. & L. subjoin a condensed list of their publications in general and educational literature, of which more detailed catalogues will be furnished on application.

HISTORY AND BIOGRAPHY.

- BROWNING'S HISTORY OF THE HUGUENOTS.** 1 vol. 8vo.
- CAMPBELL'S (LORD) LIVES OF THE LORD CHANCELLORS OF ENGLAND,** from the earliest times to the Reign of George IV. In seven handsome crown octavo volumes, extra cloth or half morocco.

- GUIZOT'S LIFE OF CROMWELL.** Two large vols., royal 12mo. (Now ready.)
- HERVEY'S MEMOIRS OF GEORGE II.** 2 vols. royal 12mo., extra cloth.
- HUGHES'S OUTLINES OF SCRIPTURE GEOGRAPHY AND HISTORY,** 1 vol., royal 12mo., with colored maps. (Just issued.)
- INGERSOLL'S HISTORY OF THE LATE WAR.** 2 vols. 8vo.
- KENNEDY'S LIFE OF WILLIAM WIRT.** 2d edition, 2 vols. royal 12mo., extra cloth, with Portrait.
- Same work, library edition. 2 vols. 8vo.
- KAVANAGH'S WOMAN IN FRANCE IN THE EIGHTEENTH CENTURY.** 1 vol. royal 12mo., extra cloth.
- LOUIS BLANC'S FRANCE UNDER LOUIS PHILIPPE, 1830-1840.** 2 vols. crown 8vo., extra cloth.
- LOUIS BLANC'S FRENCH REVOLUTION.** 1 vol. crown 8vo., extra cloth.
- MARSH (MRS.) ROMANTIC HISTORY OF THE HUGUENOTS.** 2 vols. royal 12mo., extra cloth.
- NIEBUHR'S ANCIENT HISTORY.** By LEONHARD SCHMITZ. In three handsome crown octavo vols., (Lately Issued.)
- PARDOE'S FRANCIS THE FIRST.** 2 vols. royal 12mo., extra cloth.
- PALGRAVE'S NORMANDY AND ENGLAND.** In three vols. crown 8vo., (Preparing.)
- RUSH'S COURT OF LONDON.** 1 vol. 8vo.
- RANKE'S HISTORY OF THE REFORMATION IN GERMANY.** To be complete in 1 vol. 8vo.
- RANKE'S HISTORY OF THE OTTOMAN AND SPANISH EMPIRES.** 8vo. Price 50 cents.
- RUSSELL'S LIFE OF CHARLES JAMES FOX.** 2 vols., handsome royal 12mo. (Now ready.)
- Same Work, Second Series. (Preparing.)
- STRICKLAND'S LIVES OF THE QUEENS OF ENGLAND,** from the Norman Conquest. Complete in 6 handsome crown 8vo. volumes, various styles of binding.
- STRICKLAND'S LIVES OF THE QUEENS OF HENRY VIII.** In one handsome crown 8vo. vol., extra cloth, various styles.
- STRICKLAND'S LIFE OF QUEEN ELIZABETH.** In one handsome crown 8vo. volume, extra cloth, various styles.
- STEINMETZ'S HISTORY OF THE JESUITS.** 2 vols. crown 8vo., extra cloth.

MISCELLANEOUS.

- ACTON (MRS.) MODERN COOKERY.** Edited by Mrs. S. J. HALE. 1 handsome volume, royal 12mo., extra cloth, with illustrations.
- ADDISON ON CONTRACTS,** and on Parties to Actions, ex contractu. 1 large octavo volume, law sheep.
- BUFFUM'S SIX MONTHS IN THE GOLD MINES.** 1 vol. royal 12mo., extra cloth or paper, 50 cents.
- BAIRD'S WEST INDIES AND NORTH AMERICA.** 1 vol. royal 12mo., extra cloth.
- CLATER ON THE DISEASES OF HORSES.** By SKINNER. 1 vol. 12mo.
- CLATER'S CATTLE AND SHEEP DOCTOR.** 1 vol. 12mo., cuts.
- DON QUIXOTE.** With numerous illustrations by Johanna. 2 vols. 8vo. cloth, or half morocco.
- ENCYCLOPEDIA OF GEOGRAPHY.** In three octavo vols., many cuts and maps, various bindings.
- ENCYCLOPEDIA AMERICANA.** 14 vols. 8vo., various bindings.
- Vol. 14. bringing the work up to 1846, sold separate.
- EXPLORING EXPEDITION, NARRATIVE OF.** In six vols., imperial quarto, with several hundred plates, maps, and wood-cuts.
- EVANS'S SUGAR-PLANTER'S MANUAL.** 1 vol. 8vo., extra cloth, plates.
- ERMAN'S TRAVELS IN SIBERIA.** 2 vols. royal 12mo., extra cloth.
- FIELDING'S SELECT WORKS.** In one vol. 8vo. cloth, or 4 parts, paper.
- FLETCHER'S NOTES FROM NINEVEH.** 1 vol. royal 12mo., extra cloth.
- HAWKER ON SHOOTING.** Edited by PORTER. With plates and cuts. 1 vol. 8vo., beautiful extra cloth, new edition, (Just Issued.)
- HOLTHOUSE'S LAW DICTIONARY.** By PENNINGTON. 1 vol. large 12mo., law sheep.
- JOHNSON'S DICTIONARY OF GARDENING.** By LANDBRETH. 1 vol. large royal 12mo., 650 pages, many cuts.
- LANGUAGE OF FLOWERS.** 8th edition. 1 vol. 18mo., colored plates, crimson cloth, gilt.
- LEWIS'S HINTS TO SPORTSMEN.** 1 vol. royal 12mo., extra cloth, illustrated.
- LYNCH'S NARRATIVE OF THE U. S. EXPEDITION TO THE DEAD SEA AND RIVER JORDAN.** 1 large octavo volume, with numerous plates and maps.
- Same work, condensed edition, in neat royal 12mo.
- MACFARLANE'S TURKEY AND ITS DESTINY.** 2 vols. royal 12mo., extra cloth.
- MACKAY'S TRAVELS IN THE UNITED STATES.** 2 vols. royal 12mo., extra cloth.
- MARTINEAU'S EASTERN LIFE.** 1 vol. crown 8vo., extra cloth.
- MARTINEAU'S HOUSEHOLD EDUCATION.** 1 vol. royal 12mo., extra cloth.
- PAGET'S HUNGARY AND TRANSYLVANIA.** 2 vols. royal 12mo., extra cloth.
- PULSKY'S HUNGARIAN LADY.** 1 vol. royal 12mo., extra cloth.
- PICCIOLA—The Prisoner of Fenestrella.** Illustrated edition, with cuts, royal 12mo., beautiful crimson cloth.
- Same work, fancy paper, price 50 cents.
- READINGS FOR THE YOUNG FROM SIR WALTER SCOTT,** 2 vols. royal 18mo., extra crimson cloth, plates.
- SELECT WORKS OF TOBIAS SMOLLETT.** Cloth or paper.
- SHAW'S OUTLINES OF ENGLISH LITERATURE.** 1 large vol. royal 12mo., extra cloth.
- SMALL BOOKS ON GREAT SUBJECTS.** In three neat volumes, royal 18mo., extra cloth.
- SAM SLICK'S NEW WORK—WISE SAWS AND MODERN INSTANCES.** 1 vol. 12mo., (Now Ready.)

- WHEATON'S INTERNATIONAL LAW.** 1 vol. large 8vo., law sheep, or extra cloth. 3d edition, much improved.
- YOUATT ON THE HORSE, &c.** By SKINNER. 1 vol. 8vo., many cuts.
- YOUATT ON THE DOG.** With plates. 1 vol. crown 8vo., beautiful crimson cloth.
- YOUATT ON THE FIG.** 1 vol. 12mo., extra cloth, with cuts.
- Same work in paper, price 50 cents.

NATURAL

SCIENCE.

- AMERICAN ORNITHOLOGY.** By PRINCE CHARLES BONAPARTE. In four handsome folio volumes, with beautiful colored plates.
- ARNOTT'S ELEMENTS OF PHYSICS.** New Edition. By ISAAC HAYS, M. D. In one octavo volume, with 200 illustrations.
- BRODERIP'S ZOOLOGICAL RECREATIONS.** 1 vol. royal 12mo., extra cloth.
- BOWMAN'S PRACTICAL CHEMISTRY.** 1 vol. royal 12mo., extra cloth; cuts.
- BIRD'S NATURAL PHILOSOPHY.** 1 vol. royal 12mo., with many cuts.

NATURAL SCIENCE.—Continued.

BEALE ON THE LAWS OF HEALTH IN RELATION TO MIND AND BODY. 1 vol. royal 12mo., extra cloth.

BREWSTER'S TREATISE ON OPTICS. 1 vol. 12mo., cuts.

CARPENTER'S GENERAL AND COMPARATIVE PHYSIOLOGY. With numerous wood-cuts. 1 vol. large 8vo., new edition. (Preparing.)

CARPENTER ON THE MICROSCOPE. Handsomely illustrated. (Preparing.)

DANA ON CORALS. 1 vol. royal 4to., extra cloth, with wood-cuts.

Atlas to do., large imperial folio, half morocco, with over 60 magnificent colored plates.

DE LA BECHE'S GEOLOGICAL OBSERVER. 1 large vol. 8vo. over 300 cuts. (Now Ready.)

FOWNES'S RECENT WORK ON CHEMISTRY. New edition. By BRIDGES. 1 vol. 12mo., many cuts, sheep or extra cloth.

GRAHAM'S ELEMENTS OF CHEMISTRY. Large 8vo., many cuts. (Part I, lately issued, Part II, preparing.)

GREGORY ON ANIMAL MAGNETISM. 1 vol. royal 12mo.

GRIFFITH'S CHEMISTRY OF THE FOUR SEASONS. 1 vol. 12mo., many cuts.

GRIFFITH'S MEDICAL BOTANY. 1 vol. large 8vo., extra cloth, nearly 400 cuts.

HERSCHEL'S OUTLINES OF ASTRONOMY. 1 vol. crown 8vo., ex. cl., with plates and wood-cuts.

HUMBOLDT'S ASPECTS OF NATURE. 2d edition. 1 large vol. royal 12mo., extra cloth.

HANDBOOKS OF NATURAL PHILOSOPHY AND ASTRONOMY. By DIONYSIUS LARDNER. 3 thick vols. royal 12mo., with 1000 wood-cuts.

HALE'S ETHNOLOGY AND PHILOLOGY OF THE U. S. EXPLORING EXPEDITION. 1 vol. royal 4to., extra cloth.

JOHNSTON'S PHYSICAL ATLAS OF NATURAL PHENOMENA. In one large and handsome imperial 4to. vol., half bound in morocco, with 26 maps, beautifully colored.

KNAPP'S TECHNOLOGY, OR CHEMISTRY APPLIED TO THE ARTS AND TO MANUFACTURES. Translated by RONALDS. Edited by JOHNSON. Vol. I., with 244 large wood engravings. Vol. II., large 8vo., with 250 wood engravings.

MULLER'S PHYSICS AND METEOROLOGY. 1 vol. large 8vo., 2 colored plates, and 550 wood-cuts.

MILLWRIGHT'S AND MILLER'S GUIDE. By OLIVER EVANS. In one vol. 8vo., sheep, many plates.

MATTEUCCI ON PHYSICAL PHENOMENA OF LIVING BEINGS. 1 vol. royal 12mo., ex. cl., cuts.

ORR'S CIRCLE OF THE SCIENCES, royal 12mo., with numerous illustrations, containing Animal and Vegetable Physiology, by Dr. Bushnan. The Different Forms of the Skeleton, by Prof. Owen. Physical Geography and Geology, by Prof. Ansted. Natural Philosophy, by Rev. W. Mitchell, &c. &c.

SOMERVILLE'S PHYSICAL GEOGRAPHY. New edition. 1 large vol. royal 12mo., extra cloth.

SCHOEDLER AND MEDLOCK'S BOOK OF NATURE. With Additions and Improvements. In one thick volume, crown 8vo., with over 679 illustrations.

WEISBACH'S PRINCIPLES OF THE MECHANICS OF MACHINERY AND ENGINEERING. 2 large octavo volumes, extra cloth, 900 beautiful wood engravings.

EDUCATIONAL WORKS.

ARNOTT'S ELEMENTS OF PHYSICS. New edition. Complete in 1 vol. 8vo., many illustrations.

BOLMAR'S FRENCH SERIES, consisting of:—

LEVIZAC'S FRENCH GRAMMAR, 1 volume, 12mo., sheep.

PERRIN'S FABLES, with Key. 1 vol. 12mo., half bound.

COLLOQUIAL PHRASES, 1 vol. 18mo., hf. bound.

ADVENTURES OF TELEMAQUE, 1 vol. 12mo., half bound.

KEY to do. do. do.

FRENCH VERBS, 1 vol. 12mo., half bound.

BAIRD'S CLASSICAL MANUAL. An Epitome of Ancient Geography, Mythology, Antiquities, and Chronology. 1 vol. royal 18mo., extra cloth.

Same work, half bound, embossed leather backs.

BUSHNAN'S PHYSIOLOGY OF ANIMAL AND VEGETABLE LIFE. A new and popular work. 1 vol. royal 12mo. with illustrations. (Just Ready.)

BIRD'S ELEMENTS OF NATURAL PHILOSOPHY. 1 vol. royal 12mo., sheep, or ext. cl. 372 cuts.

BUTLER'S ATLAS OF ANCIENT GEOGRAPHY. Revised edition. 1 vol. 8vo. half bound, 21 colored maps.

BUTLER'S GEOGRAPHIA CLASSICA. Revised edition; 1 vol. 12mo., half bound.

BREWSTER'S TREATISE ON OPTICS. With additions. By BACHE. 1 vol. 12mo., half bound, cuts.

BROWNE'S GREEK CLASSICAL LITERATURE. 1 vol. crown 8vo., extra cloth.

BROWNE'S ROMAN CLASSICAL LITERATURE. 1 vol. crown 8vo., ex. cloth. (Now Ready.)

FOSTER'S HANDBOOK OF MODERN EUROPEAN LITERATURE. 1 vol. royal 12mo., ex. cl.

FOWNE'S CHEMISTRY FOR STUDENTS. New edition. By BRIDGES. 1 vol. royal 12mo., many cuts, extra cloth, or sheep.

GRAHAM'S ELEMENTS OF CHEMISTRY. 2d edition, enlarged. Edited by BRIDGES. 8vo. many cuts. Part I, lately issued. Part II, preparing.

HERSCHEL'S OUTLINES OF ASTRONOMY. A new edition. With numerous plates and wood-cuts. 1 vol. crown 8vo., extra cloth.

HUGHES'S OUTLINES OF SCRIPTURE GEOGRAPHY AND HISTORY, 1 vol., royal 12mo., with colored maps. (Just issued.)

JOHNSTON'S ATLAS OF PHYSICAL GEOGRAPHY. 1 vol., with 26 colored plates, hf. bound.

LARDNER'S HANDBOOKS OF NATURAL PHILOSOPHY AND ASTRONOMY.

FIRST COURSE, containing Mechanics, Hydrostatics, Hydraulics, Pneumatics, Sound, and Optics. 1 very large vol., royal 12mo., sheep, 424 cuts.

SECOND COURSE, containing Heat, Electricity, Magnetism, and Galvanism. 1 vol. royal 12mo., sheep, 250 cuts.

THIRD COURSE, containing Astronomy and Meteorology. 1 very large vol., royal 12mo., 37 plates and 215 wood-cuts. (Now ready.)

MULLER'S PHYSICS AND METEOROLOGY. 1 vol. 8vo., over 500 beautiful cuts and two colored plates, extra cloth.

NATIONAL SCHOOL MANUAL. 4 parts. 12mo.

SOMERVILLE'S PHYSICAL GEOGRAPHY. 3d and enlarged edition, with American notes. 1 large vol. royal 12mo., extra cloth.

SHAW'S OUTLINES OF ENGLISH LITERATURE. 2d ed. With Sketch of American Literature. By TUCKERMAN. 1 vol. royal 12mo., ext. cl.

SCHOEDLER AND MEDLOCK'S BOOK OF NATURE. Edited and revised. 1 large vol., crown 8vo., with 679 wood cuts. (Now ready.)

SCHMITZ AND ZEUMPT'S CLASSICAL SERIES FOR SCHOOLS. In neat royal 18mo. volumes, as follows:—

KALTSCHMIDT'S LATIN DICTIONARY. Complete, handsome embossed leather.

SCHMITZ'S ELEMENTARY LATIN GRAMMAR AND EXERCISES.

SCHMITZ'S ADVANCED LATIN GRAMMAR.

ADVANCED LATIN EXERCISE BOOK, with Selections for Reading. (Now Ready.)

CÆSAR, extra cloth, with a Map.

SALLUST, extra cloth, with a Map.

VIRGIL, extra cloth.

OVID, extra cloth.

HORACE, extra cloth.

LIVY, extra cloth, two colored Maps.

CICERO, extra cloth.

QUINTUS CURTIUS, extra cloth, with a Map.

CORNELIUS NEPOS, now ready, extra cloth.

OTHER WORKS OF THE SERIES PREPARING.

ILLUSTRATED MEDICAL CATALOGUE.

BLANCHARD & LEA have now ready a Catalogue of their Medical, Surgical, and Scientific Publications, containing descriptions of the works, with Notices of the Press, and specimens of the Illustrations, making a pamphlet of sixty-four large octavo pages. It has been prepared with great care, and without regard to expense, forming one of the most beautiful specimens of typographical execution as yet issued in this country. Copies will be sent by mail, and the postage paid, on application to the Publishers, by inclosing two three cent postage stamps.
