New records of pseudoscorpions from the Juan Fernandez Islands (Chile), with the description of a new genus and three new species of Chernetidae (Arachnida: Pseudoscorpiones). - The new genus Selachochernes gen. n. with the type species S. allodentatus sp. n. (♂ only) is described from Masatierra. The new genus is characterized by a rallum of 4 setae, the absence of a tactile seta on tarsus of leg IV, the very unusual dentition of the chelal fingers and the presence of only 3 trichobothria on the movable chelal finger. Chelanops gracilipes sp. n. and Chelanops gracilipalpus sp. n. are described from Masatierra. Neocheiridium tenuisetosum Beier, 1959 is recorded from this archipelago for the first time, Lechytia kuscheli Beier, 1957 is briefly redescribed. Additional records are given for species previously recorded from the Juan Fernandez Islands.

Keywords: Selachochernes - Chelanops - Neocheiridium - taxonomy.

INTRODUCTION

The pseudoscorpion fauna of the Juan Fernandez Islands (Chile) has previously been known from Beier’s (1955, 1957) publications based on the collections constituted by Rev. Dr G. Kuschel. Eleven species were recorded from Masatierra (8 species) and from Masafuera (4 species), one of them being common to both islands. Most genera and species are endemic to the archipelago, only one species (Parazaona sp.) seems to be introduced (found in a house). The genus Stigmachernes Beier, 1957 was subsequently synonymized by Muchmore (1999) with Chelanops Gervais, 1849.

Years ago, Dr T. Kronestedt (Stockholm) sent me for study, together with other South American material, some specimens from Juan Fernandez Islands (Masatierra) collected by K. Bäckström during the Swedish Pacific Expedition of 1916/17, and by C. Skottsberg in 1955/56. Additionally, the late Prof. F. di Castri had sent to the Muséum d’histoire naturelle, Genève, the pseudoscorpion collection of the late Dr V. Vitali-di Castri with partly identified samples from different localities on mainland Chile. Amongst the unidentified pseudoscorpions, I came across a small collection made by Prof. H. Franz (Vienna) during his stay on Masatierra in 1968, which includes already recorded species, but also a new genus and two new species. The origin of these samples could be identified with the help of Ch. Hörweg (Vienna), who sent me copies of the hand-written lists of H. Franz.
The Vitali-di Castri collection also included material sent on loan to her by the National Museum of Natural History, Budapest, Hungary (type specimens and species from Argentina collected by Gy. Topal in 1961 and published by Beier, 1964b), which has now been returned to Budapest (Dr S. Mahunka). Type specimens collected by G. Kuschel in Chile (Beier, 1964a) and on Juan Fernandez Islands (Beier, 1955, 1957) have been returned to the Naturhistorisches Museum, Vienna (Austria) (Mag. Ch. Hörweg), whence it had probably been obtained on loan.

Unfortunately, most samples in the Vitali-di Castri collection do not have precise labels, only codes, without accompanying explanatory notes. Some codes concerning samples from mainland Chile could be deciphered, but the major part awaits such clarification, the codes corresponding probably to field numbers of ecological surveys carried out by F. di Castri in different regions of Chile.

The holo- and paratypes of the new species are deposited in the Muséum d’histoire naturelle Genève, Switzerland (MHNG, without registration number).

Terminology of the trichobothria follows Chamberlin (1931). Length/breadth ratio is given for pedipalpal segments in dorsal view, except for chelal hand and chela in Chthoniidae, where a length/depth ratio is given, because that was measured in lateral view.

**LIST OF IDENTIFIED SPECIES ALREADY KNOWN FROM THE ARCHIPELAGO**

**Lechytia kuscheli** Beier, 1957

**MATERIAL STUDIED:** MHNG, 1 ♂; Juan Fernandez Is., Masatierra, forest above Puerto Ingles, 14.XI.1968, leg. H. Franz (Sa 197-198). – MHNG, 1 P; Juan Fernandez Is., ex coll. V. Vitali-di Castri (OT-2).

**REMARKS:** The species is known from different localities on Masatierra; the unique female is characterized as follows. Cephalothorax as long as broad (0.40 mm/0.40 mm); pedipalpal femur 4.3 times longer than broad (0.42 mm/0.10 mm) and 2.0 times longer than patella, which is 1.8 times longer than broad (0.21 mm/0.12 mm); hand 1.7 times longer than deep (0.27 mm/0.16 mm), chela 4.0 times longer than deep (length 0.63 mm); finger 1.5 times (length 0.39 mm) longer than hand. Chelal fingers with about 36 low and partly indistinct teeth (their canals still visible in tooth lamella); apical seta of pedipalpal coxa simple, apex sinoid; coxa of leg I with a pointed anterior projection.

Muchmore (1975) distinguished two groups in the genus *Lechytia* by the form of the apical seta on the pedipalpal coxa, which is either furecate (e.g. *L. sini* Muchmore, *arborea* Muchmore, *chthoniformis* Balzan) or simple (e.g. *L. hoffi* Muchmore, *L. kuscheli*, and *L. chilensis* Beier).
**Geogarypus bucculentus** Beier, 1955

Material studied: NRMS, 1 T; Masatierra, under bark, S.P.E. no. 443, 3.IV.1917, leg. K. Bäckström. – MHNG, 3♂ 2♀♀ 4T; Masatierra, forest above Juan Bautista, leg. H. Franz (SA 186).

**Neocheiridium tenuisetosum** Beier, 1959

Material studied: NRMS, 1 ♀; Masatierra, without date and exact locality, leg. K. Bäckström (S.P.E.).

Short description: Setae of carapace fine, acute and usually simple, those of tergites slightly longer, acute, curved, partly with a tiny tooth; cephalothorax broader than long (0.40 mm/0.51 mm); chelicerae: ralum with 4 setae, distal one large, velum-like; pedipalps: trochanter 1.55 times longer than broad (0.20 mm/0.13 mm), femur 5.15 times (0.46 mm/0.09 mm), patella 3.5 times (0.37 mm/0.11 mm), hand with pedicel 2.1 times longer than broad and 1.9 times longer than finger, length of finger 0.19 mm, chela with pedicel 3.2 times longer than broad (length 0.50 mm): 5 + 1 trichobothria on chelal fingers, each finger with 7 cusped teeth distally. Leg I: femur+patella 4.0 times longer than deep (0.27 mm/0.07 mm), tibia 3.1 times (0.18 mm/0.06 mm), tarsus 4.6 times longer than deep (0.19 mm/0.04 mm); leg IV: femur+patella 5.1 times longer than deep (0.37 mm/0.07 mm), tibia 4.7 times (0.26 mm/0.06 mm), tarsus 5.6 times (0.25 mm/0.04 mm) longer than deep.

This is the first record of this species since its description from Argentina (Bariloche, Rio Negro), hence it represents a new element for the fauna of the Juan Fernandez Islands.

**Asterochernes vittatus** Beier, 1955

Remark: No adult female of this species was available, I show therefore the spermatheca of *Asterochernes kuscheli* Beier from mainland Chile (Fig. 23).

**Chelanops insularis** Beier, 1955

**Chelanops kuscheli** Beier, 1955

**Pseudopilanus fernandezianus** Beier, 1957

Material studied: MHNG, 1 T; Juan Fernandez Islands, without data, ex coll. Vitali-di Castri (OT-27).
Remarks: The specimen fits well to the description given by Beier (1957). Examination of the holotype confirms the presence of a rallum composed of three setae (right chelicera; left chelicera is lacking), the trichobothrial pattern and the presence of spine-like setae on medial face of chelal hand; on the right chelal hand there is only one long spine-like seta near the finger base instead of three on the left one (Beier, 1957, fig. 2). There are 27 teeth on the fixed chelal finger, 30 teeth on the movable finger, the teeth are small, densely set, retrorse, with a small cusp. The venom duct in the movable finger is long, the nodus ramosus is situated halfway between t and st.

Descriptions

Selachochernes gen. n.

Diagnosis: Member of Chernetidae, Chernetinae. Tegument normally sclerotized, vestitural setae of cephalothorax, tergites and pedipalps short and strongly clavate. Cephalothorax with two eyespots, two indistinct transverse furrows, the subbasal one much nearer to posterior margin than to median furrow; most tergites divided, XI without tactile setae. Chelicera with 5 simple setae on hand; galea short, with 4 apical/subapical branchlets, rallum with 4 setae, the distal one dentate on anterior margin. Pedipalps heavily granulate, the strongly clavate setae of femur and patella inserted on coarser granula, distal setae on hand less clavate, fixed finger at base and on dorsal face with two long and stout setae; fixed chelal finger in distal half with acute, spaced teeth followed by lower, retrorse, cusped teeth, accessory teeth present on antialar face: the spaced marginal teeth and the accessory teeth forming two rows of teeth (like shark teeth); movable finger distally with slightly spaced teeth; long venom duct present in movable finger only. Trichobothria: 8 on fixed finger, est-ib-isb in middle of finger (near strong seta), ist forming a group with it-et; movable finger: 3 trichobothria (probably sb lacking). Leg IV: tarsus without tactile seta, arolia undivided, claws smooth.

Type species: Selachochernes allodentatus sp. n.

Distribution: Chile, Juan Fernandez Islands (Masatierra).

Etymology: From the Greek noun „selachos“ (cartilaginous fish, shark, ray), referring to the unusual, shark-like arrangement of teeth on the fixed chelal finger.

Affinities: Within the Chernetinae with a rallum of four setae, Selachochernes gen. n. is quite isolated and characterized at once by the particular trichobothrial pattern on the fixed finger (ib and isb distinctly distal of eb-esb opposite est) and the reduced number of trichobothria on the movable finger. By the presence of strongly clavate and a few long, stout setae on the chela it resembles Pseudopilanus Beier (type species fernandezianus Beier), but that genus differs in having a rallum of 3 setae, trichobothria ib-isb basal near eb-esb, and the chelal teeth numerous and closely set (27 on fixed, 30 on movable finger). For further evaluation of importance of some taxonomic characters see the following remarks. Since spermathecae of Pseudopilanus species from Chile are unrecorded, at least that of P. kuschelii from mainland Chile is shown (Fig. 22) as first step to a better knowledge of this genus.

Remarks: The presence of two superficially similar and not related genera in the Juan Fernandez archipelago might seem to be improbable, but the differences between P. fernandezianus and S. allodentatus sp. n. cannot be explained by possible
ontogenetic changes or variability of the one or the other taxonomic character (e.g. number of setae of rallum). Within a chernetid genus the number of setae of the rallum is relatively stable, variability is very unfrequent, the setae being frequently difficult to observe (particularly in case of a rallum with 4 setae, observation errors might therefore occur more frequently than natural variability); during ontogeny numbers of these setae are not changing from tritonymphs to adults, in Chernetidae at least. In the following species currently placed in *Pseudopilanus*, the rallum is composed of 3 setae (personal observations): *fernandezianus* (holotype), *kuscheli* (paratype), *chilensis* (syntype), *crassifemoratum* (holotype, paratype). Tooth morphology and arrangement on chelal finger are very similar (small, densely set, retrorse, cusped teeth) in *fernandezianus, chilensis* (syntypes: 39-41 teeth on fixed finger, 46 on movable finger), *kuscheli* (syntypes; 34-37 on fixed finger, 37-42 on movable finger), *crassifemoratum* (31 teeth on fixed, 32-33 teeth on movable finger). Tooth morphology is identical in tritonymph and adults (female, male) of *crassifemoratum*, an ontogenetic modification of tooth morphology from tritonymphal to adult stages in Chernetidae is unknown to me. Even in (slightly) sexual dimorphic species like *Pseudopilanus chilensis* (chelal finger of male in middle curved and therefore gaping when closed; those of female straight and not gaping) no difference in tooth morphology or arrangement is observable. This is also the case in strongly dimorphic species like *Parachernes melanolopygus* Beier or *Parachernes setiger* Mahnert (Chernetidae, both from Amazonia). Ontogenetic changes cannot explain the fundamental difference in trichobothrial pattern found in *allodentatus* (*ist* in distal third of fixed finger and close to *it*, *ib-ism-est* grouped together in middle of finger, *eb-esb* isolated near finger base) and *fernandezianus* (*ib-ism* grouped with *eb-esb* near finger base, *est* in middle of finger), since the position of the trichobothria *ib-ism* compared to that of *eb-esb* and of *est* does not change much from tritonymph to adult stage, as far as documented in the literature. This latter pattern (*ist* indistinctly distal of *est* in middle of finger, *ib-ism* near finger base and distinct basal of *est-ist*) is found in *P. chilensis*, and also in *kuscheli* and *crassifemoratum* (where *ist-est* are more basally placed), and it anticipates probably the pattern of adult *fernandezianus*. The presence of only three trichobothria in *S. allodentatus* might be variable and of importance on specific and not on generic level (e.g. in *Americhernes incertus* Mahnert from Amazonia). Furthermore, distribution of paraxial trichobothria on the fixed finger is considered of generic importance in Chernetidae (e.g. difference between the groups *Parachernes/Anaperochernes* and *Asterochernes/Parazaona*) (Beier, 1964a).

**Selachochernes allodentatus** sp. n.  

**Material studied:** MHNG, holotype δ; Chile, Juan Fernandez Islands, Masatierra, forest above Puerto Ingles, 14.XI.1968, leg. H. Franz (Sa 197-198).

**Description:** Cephalothorax 0.86 times longer than broad, granulate (granula small and regular, separated by equivalent of own diameter from each another), eyespots indistinct, 4 anterior and 6 posterior strongly clavate setae. Tergites I/II indistinctly divided, XI undivided, III-X divided, all densely granulate, chaetotaxy of half-tergites: 3-3-3-5-5-5-5-5-5-5-10(total number; 2 medial discal setae), IV-X including an anterolateral seta; manducatory process with 3 marginal and 1 discal setae, suboral...
Selachochernes allodentatus gen. n., sp. n., δ holotype. (1-2) Left pedipalp. (3) Trichobothrial pattern, with sensillum proximal to st. Scale units 0.1 mm.

seta (see Judson, 1998) very short; pedipalpal coxa coarsely granulate, about 40 setae, coxa I 19, II 24, III 36, IV 42, all setae simple, acute; genital operculum with about 34 setae arranged in a semi-circle, the inner ones long and curved; genital entrance with 2/2 short simple and curved setae. Sternites divided, chaetotaxy of half-sternites III-XI: 6+4 discal setae (no suprastigmal seta)-6+1 suprastigmal seta-8-9-8-6-6-5-2 (2 short median setae); anal cone 2+2 setae. Pleural membrane granulate, intersegmental membrane striate.

Chelicera: 5 smooth setae on hand, fixed finger with 3 retrorse teeth and 3 sub-apical granula, lamina exterior well developed, movable finger with cone-like sub-apical tooth, subapical seta not reaching tip of galea, short galea with 4 subapical and apical branchlets; serrula exterior with 16 lamellae, rallum of 4 setae, only distal one dentate.

Pedipalps (Figs 1-2) coarsely granulate, the broadly clavate setae on coarser granula, setae on hand more slender; trochanter with rounded dorsal hump, 1.6 times longer than broad, femur abruptly enlarged, 2.4 times, patella 2.8 times longer than broad, club 2 times longer than broad and 2.5 times longer than pedicel, hand with pedicel 1.9 times longer than broad and as long as finger, chela with pedicel 3.6 times longer than broad; one long stout seta on paraxial face of fixed finger base, another long stout seta on dorsal face of fixed finger near trichobothria est/ist. Fixed finger with 5 spaced acute teeth followed (basal of est) by 9 low, retrorse, densely set teeth, 3 anti-axial accessory teeth (or 3 laterally displaced marginal teeth?), movable finger with 4 high, rounded and 10 low, mostly rounded teeth, no accessory teeth present; venom duct long, nodus ramosus near trichobothrium st. Trichobothria (Fig. 3): movable finger with 3 trichobothria only (probably sb lacking).
Leg I: femur 1.8 times longer than deep, patella 2.7 times longer than deep and 1.4 times longer than femur, tibia 3.7 times and tarsus 5.3 times longer than deep; leg IV: femur+patella 4.0 times longer than deep, tibia 4.9 times and tarsus 5.7 times longer than deep; undivided arolia as long as smooth claws.

**Measurements** (in mm): Body length 1.8; cephalothorax 0.59/0.69; pedipalps: trochanter 0.33/0.21, femur 0.59/0.24, patella 0.51/0.18, hand with pedicel 0.41/0.22, pedicel length 0.06, finger length 0.42, chela length 0.78; leg I: femur 0.19/0.11, patella 0.26/0.10, tibia 0.27/0.07, tarsus 0.28/0.05; leg IV: femur+patella 0.50/0.12, tibia 0.38/0.08, tarsus 0.33/0.06.

**Chelanops gracilipes** sp. n.  

**Material studied:** MHNG holotype ?; Chile, Juan Fernandez Islands, Masatierra, forest above Puerto Ingles, 14 XI.1968, leg. H. Franz (Sa 197-198).

**Diagnosis:** The new species is characterized by its large size (length of palp femur 1.40 mm, length of chela 1.57 mm), by the chelal hand being only 1.3 times longer than finger, and the very slender legs (e.g. femur+patella of leg IV 5.2 times, tibia 6.7 times, tarsus 7.6 times longer than broad).

**Description:** Cephalothorax in anterior half reddish brown, basal half yellowish brown, pedipalps dark reddish brown, tergites brown. Cephalothorax 1.2 times longer than broad; no eyes or eyespots; laterally finely granulate, central part smooth; with two granulate transverse furrows, median furrow laterally curved forward, basal furrow narrower and situated halfway between median furrow and posterior margin; setae short, dentate and slightly clavate, 12 setae at posterior margin plus 17 in metazone; metazone with small central depression (groove). Tergites I-X distinctly divided, setae dentate and clavate, longer on posterior tergites, half-tergites with about 7 (6-9) setae on posterior margin, I-IV with 1 median, 1 lateral and 1 discal seta, V-X with 1 median seta, 1-2 lateral setae and 3-5 discal setae, XI with 16 setae (2 lateral tactile and 4 discal setae). Manducatory process with 3 marginal (suboral seta short) and 4 discal setae, coxae of legs with numerous setae. Spermatheca with paired tubes enlarged in distal two-thirds (Fig. 7); anterior genital operculum with about 40 smooth and acute setae; sternites divided, setae long, acute and finely dentate, chaetotaxy of half-sternites: III 11/12+3 suprastigmal setae, IV 7+1 suprastigmal seta, V-X 10+2 medial+1 lateral setae-12+2+1+2 discal setae-6+2+1+6-10+2+1+2-10+2+2+5+7+2+1+3; entire XI with 10 (2 lateral and 2 submedial tactile setae). Anal cone 2+2 setae.

Chelicera with 7 setae on hand, basal three dentate; fixed finger with 6 retorse teeth, movable finger with tooth-like subapical lobe; galea long, with 6 apical/subapical curved branchlets; serralia exterior with 26 lamellae; rallum with 4 setae, anterior one dentate.

Pedipalps (Figs 4-5) rugose but not granulate, setae short, dentate and weakly clavate; trochanter with high dorsal hump, 1.8 times longer than broad, femur increasing in breadth distally, 3.1 times longer than broad, patella 2.5 times, club 1.8 times longer than broad and 2.5 times longer than pedicel, hand with pedicel 1.7 times longer than broad and 1.3 times longer than finger, chela with pedicel 2.8 times,
Chelanops gracilipes sp. n., ♀ holotype. (4-5) Left pedipalp, setae of fingers omitted; with some vestitural setae at higher magnification. (6) Trichobothrial pattern. (7) Spermatheca with right cribrate plate (ventral view). (8) Left leg IV. Scale units 0.1 mm.

without pedicel 2.6 times longer than broad; finger 1.3 times longer than hand breadth, fingers not gaping when closed, fixed finger with 57 teeth plus 13 antiaxial (=lateral) and 6 paraxial (=medial) accessory teeth, movable finger with 60 teeth plus 11 antiaxial plus 6 paraxial accessory teeth; nodus ramosus in movable finger slightly
proximal to t. Trichobothria (Fig. 6): est opposite ist in middle of fixed finger, it proximal to et and nearer to finger tip than to ist; st on movable finger nearer to t than to sb.

Leg I: femur 1.65 times, patella 3.5 times longer than deep and 1.7 times longer than femur, tibia 5.4 times longer than deep and 1.1 times longer than tarsus, which is 7.15 times longer than deep; leg IV (Fig. 8): femur+patella 5.2 times, tibia 6.7 times longer than deep and 1.3 times longer than tarsus, tarsus 7.6 times longer than deep, tactile seta (length 0.19 mm) in distal half (TS=0.67); subterminal setae smooth, curved, claws smooth and longer than undivided arolia.

Measurements (in mm): Body length 5.2; cephalothorax 1.35/1.16; pedipalps: trochanter 0.79/0.45, femur 1.40/0.45, patella 1.37/0.55, hand with pedicel 1.57/0.94, finger length 1.22, chela length with pedicel 2.58, without pedicel 2.41. Leg I: femur 0.42/0.25, patella 0.70/0.20, tibia 0.81/0.15, tarsus 0.73/0.10; leg IV: femur+patella 1.28/0.25, tibia 1.12/0.17, tarsus 0.87/0.11.

Etymology: Latin noun meaning „slender leg”, emphasizing the slender legs.

Affinities: The new species seems to be related to Chelanops kuscheli Beier, and differs from it by the more slender legs (e.g. femur+patella IV 5.2 vs 3.7-3.8 times, tibia 6.65 vs 4.7-5 times longer than deep) and relatively longer palpal fingers. Chelanops insularis Beier (Juan Fernandez Islands, Masatierra) has distinctly longer chelal fingers which are, furthermore, strongly curved and slightly gaping when closed. Chelanops atlanticus Beier (from Tristan da Cunha) has similar slender legs, but is notably smaller (length of palpal femur 0.90 mm vs 1.40 mm), has a more slender chela (ratio 3.1-3.2 vs 2.8 times), and has trichobothrium est distal of ist.

Chelanops gracilipalpus sp. n.

Material studied: MHNG, holotype ♂; Chile, Juan Fernandez Islands, Masatierra, forest above Puerto Ingles, 14.XI.1968, leg. H. Franz (Sa 197-198). – MHNG, paratypes 1♂ 3♀ 3 trito-, 5 protonymphs; same data. – NHMW; paratype 1 T; Masatierra, Bahia Cumberland, 200 m, 23.XII.1955, leg. Dr G. Kuschel (recorded by Beier, 1957 as Protowithius robustus Beier).

Diagnosis: The presence of accessory teeth on the chelal fingers, a rallum of four blades, the position of trichobothrium ist slightly proximal of est, and the presence of a short tactile seta in the distal third of tarsus IV places the species within the genus Chelanops. It is quite isolated within this genus by its very slender pedipalps (femur 4.5-5.0, patella 3.9-4.3, chela 4.5-4.9 times longer than broad).

Description: Cephalothorax and pedipalps brown, legs yellowish. Cephalothorax parallel-sided, 1.2 times longer than broad, finely granulate, prozone nearly smooth in central part; two transverse granulate furrows, subbasal one slightly closer to posterior margin than to median furrow; no eyes or eyespots; setae short, dentate and clavate, 7 on anterior margin, 14-18 setae on posterior margin and in metazone (Fig. 14). Tergites I-X divided, scaly sculptured, half-tergites mostly with 7-9 setae (Figs 15, 16) on posterior margin and 1 medial seta, from IV-X also with 1 lateral and 1 discal seta, XI with 12 setae (2 lateral tactile and 2 medial discal setae). Manducatory process with 3-4 marginal setae (suboral seta short) and 2 discal setae; pedipalpal
Chelanops gracilipalpus sp. n. (9) Left chelicera of holotype ♂, with galea of ♂ (left) and ♀ (right) (higher magnification). (10-11) Left pedipalp of holotype ♂, vestitural setae omitted, some setae shown at higher magnification. (12) Trichobothrial pattern of tritonymph. (13) Trichobothrial pattern of protonymph. (14-16) Setae (higher magnification) on posterior border of cephalothorax (14), on tergite I (15) and on tergite XI (16). (17) Spermatheca with right cribrate plate (ventral view). (18) Left leg IV. Scale units 0.1 mm.
coxae smooth except for a granulate mediiodistal zone, coxa I-IV with numerous acute, smooth setae. Male genital chamber with 4 acute setae on each side of entrance; female spermatheca (Fig. 17) with two sac-like tubules; anterior genital operculum of male with about 50 long, acute and curved setae in semi-circular arrangement, that of female with about 40 acute setae (Fig. 17); chaetotaxy of half-stermites: III 9 setae at posterior margin+13 discal setae+4 suprastigmata setae (♂: 14+4 suprastigmata setae), IV 6-8+1-2 suprastigmata setae, V-IX mostly 8-9 (-11) setae, 1 medial and 1 discal setae, X 6-7+2+1+4, entire XI 10 (2 lateral and 2 submedial tactile setae). Anal cone 2+2 (dorsal ones clavate, ventral ones dentate). Pleural membrane granulate.

Chelicera (Fig. 9) with 7 (right chelicera with 6) setae, among them 3 internobasal setae with dentate apex, fixed finger with 6-7 retrorse teeth and 3 apical granules, movable finger with tooth-like subapical lobe; galea of male shorter than that of female, with 6 short branchlets, that of female slender, with six long branchlets in distal half; serrula exterior with 24-26 lamellae, rulum composed of 4 dentate setae of decreasing lengths.

Pedipalps (Figs 10-11): femur and hand finely granulate, patella rugose, nearly smooth; setae dentate and indistinctly clavate on paraxial side of femur; trochanter with large dorsal hump, 1.9-2.2 times longer than broad, femur club-shaped (distally broadest), 4.8-5.0 (♂)/4.5-4.8 (♀) times, patella 4.1-4.3 (♂)/3.9-4.2 (♀) times longer than broad, club 3.3-3.5 (♂)/3.0-3.1 (♀) times longer than broad, hand with pedicel 2.5 (♂)/2.2-2.5 (♀) times, chela with pedicel 4.9 (♂)/4.5-4.8 (♀) times, without pedicel 4.6 (♂)/4.2-4.5 (♀) times longer than broad, finger 1.1 times longer than hand with pedicel. Fixed finger with a large series of cone-like sensilla in paraxial basal third, with 90-96 small cusped marginal teeth, with 15-19 antiaxial and 3-6 paraxial accessory teeth; movable finger: 92-100 marginal teeth, 12-17 antiaxial and 1-3 paraxial accessory teeth; venom duct present in movable finger only, nodus ramulosus nearer to t than to st; trichobothria arrangement (Fig. 11) with a basal group (eb-esb-ib-isb), ist/est in distal half of fixed finger, ist slightly proximal of est, it/et near fingertip; st nearer to t than to sb.

Leg I: femur 1.8-1.9 times longer than deep, patella 3.9-4.4 times longer than deep and 1.8-1.9 times longer than femur, tibia 6.4-7.1 times and tarsus 7.6-8.5 times longer than deep; leg IV (Fig. 18): femur+patella 5.2-5.3 times, tibia 7.1-7.9 times and tarsus 7.3-9.1 times longer than deep, latter with a short tactile seta (length 0.16-0.19 mm) in distal third (TS=0.64-0.77), undivided arolia shorter than smooth claws, subterminal seta smooth, curved.

MEASUREMENTS (in mm): Body length 3.1-3.6 (♂)/4.3-4.6 (♀); cephalothorax 1.21-1.25/1.00-1.07 (♂) (♀ 1.34/1.07-1.11); pedipalps: trochanter 0.74-0.83/0.39-0.40 (♂) (♀ 0.82-0.90/0.40-0.43), femur 1.66-1.72/0.34-0.35 (♂) (♀ 1.69-1.71/0.35-0.39), patella 1.57-1.59/0.37-0.38 (♂) (♀ 1.60-1.62/0.39-0.41), hand with pedicel 1.40/0.56 (♂) (♀ 1.46-1.54/0.62-0.66), finger length 1.50-1.53 (♂) (♀ 1.59-1.67), chela length with pedicel 2.73-2.74 (♂) (♀ 2.91-2.96), without pedicel 2.56-2.58 (♂) (♀ 2.75-2.80). Leg I: femur 0.42-0.45/0.22-0.25, patella 0.76-0.82/0.18-0.19, tibia 0.84-0.85/0.13 (♂) (♀ 0.88-0.90/0.13), tarsus 0.78-0.85/0.10-0.11; leg IV: femur+patella 1.29-1.32/0.25 (♂) (♀ 1.36-1.37/0.26-0.27), tibia 1.11-1.14/0.15-0.16 (♂) (♀ 1.17-1.20/0.15-0.16), tarsus 0.95-0.99/0.11 (♂) (♀ 0.99-1.03/0.11-0.12)

Tritonymph (1 specimen): Half-tergites with 6-7 setae on posterior margin, on posterior half-tergites also 1 medial, 1 lateral and 1 discal seta; chelicera with 6 setae on hand, two basal ones dentate, galea slender with 3 apical and 2 subapical branchlets. Chela 4.6 times longer than broad (1.99 mm/0.43 mm) (no other measurements taken), fixed finger with 71 cusped marginal teeth, 12 antiaxial and 2 paraxial accessory teeth, movable finger with 72 teeth, 5 antiaxial and 1 paraxial teeth; nodus ramosus proximal of trichobothrium t (Fig. 12).

Protonymph (1 specimen): Half-tergites with 3 setae on posterior margin; chelicera with 4 smooth setae on hand, galea long, with 2 apical and 1 subapical branchlets. Chela 4.2 times longer than broad (0.87 mm/0.21 mm), fixed finger with 29 marginal teeth (13 distal ones cusped, the following rounded) and 1 distal antiaxial accessory tooth; movable finger with 13 cusped teeth and 23 rounded ones; nodus ramosus distal of trichobothrium t (Fig. 13).

ETYMOLOGY: Latin noun, meaning „slender pedipalp“.

DISCUSSION: Chelanops gracilipalpus sp. n. is unique within the genus Chelanops by its very slender pedipalps. It might have affinities with Chelanops insularis (from Masatierra) and Chelanops skottsbergi (Beier) (from Masatierra and Masafuera) (see also Fig. 21: spermatheca), which also have a club-shaped palpal femur and relatively long chelal fingers. In spite of the very divergent proportions and measurement, I do not have any doubts concerning its generic placement, even if there are other discrepancies between the diagnosis of the genus Chelanops given by Muchmore (1999) and the new species (as well as the other Chelanops species from Juan Fernandez Islands): a long, erect tactile seta in the distal half of tarsus IV (here a short tactile seta, merely longer than depth of tarsus); spermatheca having 2 slender tubes of uniform diameter (here two sac-like distal parts with thin basal tubes). These differences do not allow, in my opinion, to place these species in a different genus.
Muchmore (1999) described the spermatheca of *C. coecus* as „occasionally seen as 2 slender tubes of uniform diameter“, and with a long erect tactile seta on tarsus IV. Several females which I identified as *C. coecus* from Argentina and Chile showed a spermatheca of the same form as that figured for *gracilipalpus* (and similar to those of *kuscheli* and *insularis*) (Figs 19, 20). Since the spermatheca is delicate and difficult to observe in the large abdomen, the description of the spermatheca given by Muchmore needs to be verified. The long tactile seta seems to break off easily, but I have never observed for *C. coecus* a short tactile seta as present in *gracilipalpus*, *gracilipes*, *insularis* and *kuscheli*.

The new species is superficially similar to *Protowithius robustus* Beier, and Beier (1957) himself confused a tritonymph of *C. gracilipalpus* sp. n. with *P. robustus*. Besides the major family differences between *Chernetidae* and *Withiidae*, *Chelanops gracilipalpus* sp. n. is distinguishable at once from *P. robustus* by its larger size (length of palpal femur 1.66-1.72 mm vs 1.27 mm), more slender pedipalpal patella (ratio 3.9-4.3 vs 2.8), more slender legs, and its trichobothrial pattern (*ist* proximal of *est*, *est* near finger tip, *ist* halfway between *it* and *isb*).

ACKNOWLEDGEMENTS

I express my thanks to Mag. Christoph Hörweg and Dr Jürgen Gruber (Naturhistorisches Museum Vienna) for their help in tracing localities concerning the collecting trips of Prof. Herbert Franz, and to Mr Gunvi Lindberg (Naturhistoriska Riksmuseet Stockholm) for information on the specimens collected by K. Bäckström. Deep thanks are addressed to Dr Torbjörn Kronestedt (Naturhistoriska Riksmuseet Stockholm) for his generous help and unlimited patience. I am also grateful to Dr Peter Schwendinger (Muséum d’histoire naturelle, Genève) and to an anonymous reviewer for their helpful comments and linguistic improvements.
