BOTANICAL GAZETTE

AUGUST, 1894.

Descriptions of new species of Uredineæ and Ustilagineæ, with remarks on some other species. II.

P. DIETEL.

WITH PLATE XXIX.

Chrysomyxa Arctostaphyli, n. sp.—Sori hypophyllous on red brown spots of about 4^{mm} diameter, arranged into groups, flattened, of irregular outline. Depth of the layers 160–240 μ , spore cells oblong, about 18 μ in diameter.

On Arctostaphylos Uva Ursi. Wisconsin, leg. Davis (no.

921), comm. Ellis.

Chrysomyxa Chiogenis, n. sp.—Spots yellowish or none; sori hypophyllous, scattered. Uredo layers appearing, when fresh, honey colored; uredospores formed in chains, ovate, $^{22-29\times15-21}\mu$, with colorless, coarsely verrucose membranes. Teleutosori orange-red, waxy, $95-120\mu$ in depth, spores $8-12\mu$ in diameter.

On Chiogenes serpyllifolia. Wisconsin, June, 1893, leg.

Davis (no. 6,078), comm. Ellis.

By the dimensions of the spores this species is hardly distinguishable from Chrysomyxa Pyrolæ (DC.), but the uredospores on an average are smaller than in the last named species. Yet the sori do not occupy, as in this, uniformly the whole under surface of the leaves. Another difference, worthy of notice although small, consists in the structure of the membranes of the uredospores. In Chr. Chiogenis the tubercles, or, as DeBary has demonstrated, the prominent ends of the more dense staff-like portions of the membrane are thinner than in Chr. Pyrolæ. On the other hand the staff-like structure of the membrane is even more delicate in Chr. Ledi (Alb. et Schw.) and Chr. Rhododendri (DC.) than in our species under consideration.

23-Vol. XIX-No.8.

Puccinia vulpinoidis D. & H., n. sp.—Hypophyllous, sori small, elliptical to linear. Uredospores obovate or elliptical, pale brownish, echinulate. Teleutosori long covered by the epidermis, afterwards erumpent, black; teleutospores clavate or fusiform, somewhat constricted in the middle, upper cell truncate or attenuated, often obliquely, thickened at the summit, lower cell cuneiform, clear brown, the apex being darker colored, epispore smooth, 40-65×14-19µ. Pedicels persistent, about half the length of the spores.

On Carex vulpinoidea. Lafayette, Ind., Nov. 1888, leg.

H. L. Bolley.

Puccinia areolata D. & H., n. sp.—Aecidia and teleutosori hypophyllous on pale spots of I-2.5^{mm} diameter. Aecidia forming small irregular groups, pseudoperidia decaying, white, with torn edges, aecidiospores ovoid, about 25×21µ, with colorless minutely verrucose membranes. Teleutosori scattered, dark brown, punctiform to I^{mm} in diameter, soon naked, pulverulent. Teleutospores rather different in form and size, mostly elliptical to clavate, apex rounded, surmounted by a large hyaline papilla, lower cell with a similar papilla on the germ-pore beneath the septum, rounded at the base or somewhat narrowed toward it. Central constriction moderate. Epispore beset with minute warts, hardly visible in water, brown; 50-80×21-34µ. Pedicels deciduous, usually short.

On Caltha biflora. Skamania co., Wash., Aug. 1888, leg.

W. N. Suksdorf.

This is the fourth Puccinia on Caltha, all of which are said to occur in North America. Puccinia Treleasiana Pazschke on C. leptosepala and our species on C. biflora are exclusively American. Puccinia Zopfii Wint. and P. Calthæ Lk., both on C. palustris, have also a wide distribution in Europe. I have never seen the last named species from America. For comparison we give figures of all four species.—Plate XXIX, figs. 1-4.

Puccinia hyalomitra D. & H., n. sp.—Sori hypophyllous, oblong, $1-5^{mm}$ long, brown, pulverulent. Spores elliptical, slightly constricted at the septum, rounded at the base, apex with a flat conical hyaline thickening, lower cell provided with a similar lateral thickening, membrane thick $(5-6\mu)$, chestnut brown, smooth, $47-53 \times 32-37\mu$. Pedicels

colorless, easily detached at their bases with the spores, 100-120µ long.

On Chrysopsis villosa. Helena, Mont., April, 1889, leg.

F. D. Kelsey.

Puccinia Chloridis mihi in Hedwigia 31: 290, 1892, is apparently identical with the previously named Puccinia Chloridis

Phragmidium biloculare D. & H., n. sp. - Sori hypophyllous and on the pedicels and stems, on the leaves circular or oblong, often following the principal veins and confluent into long patches, soon naked, pulverulent. Uredosori orange yellow, teleutosori dark brown. Uredospores ovoid or elliptical, $22-30 \times 15-23\mu$, membranes colorless with minute distant papillæ. Teleutospores usually two-celled, seldom three-celled, elliptical, blunt or rounded at both ends, barely constricted or not at all, membranes yellow brown or dirty brown, so transparent as to make recognizable the orange red contents, covered with large tubercles which swell somewhat in water, sometimes nearly smooth, provided with three germ-pores in each cell, $30-44 \times 20-28\mu$, three-celled spores 45-54μ long. Pedicels colorless, to 60μ, detached with the spores.

On Potentilla gelida. Chiquash Mts., Skamania co., Wash.

Aug. 1892, leg. W. N. Suksdorf (no. 351).

It will seem contradictory that we have placed this fungus in the genus Phragmidium, for the three-celled spores are present only in a very small number, about one per cent. But in many other respects it accords so completely with the typical Phragmidia, that, in placing it in the genus Puccinia, one would separate this species from its nearest allies. shall discuss particularly this point on another occasion.

Tilletia Elymi D. & H., n. sp. - Spore masses black, destroying the ovaries. Spores globose, dark olive brown, 24-28 \mu in diameter. Epispore reticulated with ridges 2.6-4 \mu high and about 3 µ apart.

On Elymus spec. Skamania co., Wash., Aug. 1886, leg.

W. N. Suksdorf.

Tolyposporium Davidsonii D. & H., n. sp. - Spores produced in spherical firm walled galls of about 0.7mm diameter, on the outside and at the bases of the perigonial leaves and the leaslets within the inflorescence. Spore mass powdery, light chocolate brown, discharged by irregular ruptures of the

Spores aggregated in very different manner into balls of 2 to 7 cells or isolated, longish or isodiametric, flattened on the sides of contact, pale, densely verrucose. Dimensions

of the spore cells $12-15\times7-13\mu$.

On Atriplex spec. Los Angeles, Calif., Sept. 1893, leg. This is a very remarkable fungus on ac-Dr. A. Davidson. count of its peculiar appearance, represented in plate XXIX, fig. 5. The arrangement of the spore cells is a very variable one. In bicellular spores the cells touch each other by their longer sides, or the plane of separation is inclined (figs. 7a, 7b). In three-celled spores the cells are arranged into a triangle (7c) or into a straight line or in an intermediate manner (7d). If the spore ball is four-celled, the component cells are situated across in the same plane (7e), or may be arranged in a different manner (7f). Likewise in aggregates of more than four cells, these may lie in the same plane (7g) or form a nearly spherical body (7h). More than seven cells in one spore ball have not been observed; the most frequent cases are two to four cells. The spores are produced within small pisiform receptacles walled by a few layers of parenchymatous cells of the host plant. The formation of the spores begins in the center of the galls and gradually proceeds outwards. In the more advanced conditions the interior wall of the cavity is covered with a stratum of hyphæ whose innermost beds are transformed into a gelatinous mass forming the spores (see figs. 6 and 8).

Peronospora phlogina D. & H., n. sp.—Conidiophores erumpent in whitish afterwards dirty flocks from the under surfaces of the leaves, five to seven times bifurcated, the terminal branchlets slightly curved. Conidia ovoid, 26-29×16-20µ, nearly colorless, in masses appearing dirty brownish, smooth. Oospores spherical, 32-48 µ diam., coarsely verru-

cose, yellow brown.

On Phlox divaricata. Decorah, Iowa, June 1888, leg. Holway.

Leipzig, Germany.

EXPLANATION OF PLATE XXIX.

Fig. 1, Puccinia areolata.—Fig. 2, Puccinia Treleasiana.—Fig. 3, Puccinia Zopfii.—Fig. 4, Puccinia Calthæ. ×400.—Figs. 5–8, Tolyposporium Davidsonii.—Fig. 5, A diseased twig of Atriplex (with broken leaves)×2.—Fig. 6, Part of a section through a gall. ×250.—Fig. 7, Spores. ×500.—Fig. 8, Young spores.
