BARROW'S DUCK.
Clangula Barrovii, Swains. and Rich.

A fine male of this rare and beautiful species having been shot in Iceland by T. C. Atkinson, Esq. of Newcastle-upon-Tyne, when on a visit to that country, about two years since, we have much pleasure in figuring it as an occasional inhabitant of the European portion of the globe. Mr. Atkinson's specimen is now deposited in the Museum of the Newcastle Natural History Society. Although very nearly allied to the Golden Eye (Clangula vulgaris), it possesses, nevertheless, many characters by which it may be distinguished from that species. For our first knowledge of the Clangula Barrovii we are indebted to that highly interesting work the "Fauna Boreali-Americana" of Messrs. Swainson and Richardson; and as the observations of the latter gentleman were taken on the spot, we cannot do better than extract what he has recorded in the work above mentioned.

"Notwithstanding," says Dr. Richardson, "the general similarity in the form and markings of this bird and the Common Golden Eye, the difference in their bills evidently points them out to be distinct species. Exclusive of other specific characters," the Barrow's Duck "is distinguished by the purer colour of its dorsal plumage, and the smaller portion of white on its wings and scapulars. Its long flank feathers are also much more broadly bordered all round with black. The bases of the greater coverts in the Golden Eye are black; but they are concealed, and do not form the black band so conspicuous in Clangula Barrovii. The specific appellation is intended as a tribute to Mr. Barrow's varied talents, and his unwearied exertions for the promotion of science.

"Head and two inches of the neck bright pansi-purple, with a greenish reflection on the ears; forehead and chin brownish black. Dorsal plumage, wings, and broad tips of the long flank feathers mostly velvet black. Crescentic patch from the rictus to the sides of the forehead, lower part of the neck, shoulders, tips of the outer scapulars, lower row of lesser coverts, six secondaries, and under plumage pure white; space round the thighs, the tail, and its lateral under coverts broccoli-brown; bill blackish; legs orange; webs black.

"Bill shorter and narrower towards the point than that of the Golden Eye, and the feathers of the forehead, instead of running to a point on the ridge of the bill as in the latter, terminate with a semicircular outline. The plumage also of the occiput and nape is longer, forming a more decided crest than in that species. Wings two inches and a half shorter than the tail."

The female we have never seen, but have thought it best to append Dr. Richardson's description of that sex.

"Female—head and adjoining part of the neck umberr-brown, without a white mark; dorsal plumage pitch black; its anterior part, particularly the shoulders and the base of the neck all round, edged with ash grey. A white collar round the middle of the neck. Flanks clove-brown, edged with white. Intermediate coverts blotted with white and black; greater coverts white tipped with black secondaries as in the male. Both mandibles orange at the point, their tips and posterior parts black. Feet like the male."

Our Plate represents a male of the natural size.
