NEW SPECIES OF FOSSIL WOOD (ARAUCARIOXYLON ARIZONICUM)
FROM ARIZONA AND NEW MEXICO.

BY F. H. KNOWLTON, ASS'T CURATOR, FOSSIL PLANTS.

(With Plate I.)

The material which furnished the basis of the following observations was selected from the large fossil trunks that have been on exhibition for several years past at the main entrance of the U. S. National Museum. These trees came originally from Arizona and New Mexico, in the vicinity of Fort Wingate. Their presence here is due to a suggestion made by General W. T. Sherman, while on a tour across the continent in the fall of 1878, to Lieut.-Col. P. T. Swaine, Fifteenth U. S. Infantry, then in command of the post of Fort Wingate, N. Mex. Acting upon this suggestion, an expedition was organized by Colonel Swaine early in the spring of 1879 for the purpose of procuring suitable specimens for the Smithsonian Institution. The outfit, in command of Second Lieut. J. T. C. Hegewald, consisted of a sergeant and twelve soldiers of the Fifteenth U. S. Infantry, with heavy wagons, suitable for hauling stone.

Following is an account of the expedition, as given by Lieutenant Hegewald:*

We made the usual drives, stopping at a forage agency each night, until we arrived at Navajo Springs, Ariz.

At Navajoe Springs we left the road, cutting diagonally across the country about 20 miles, arriving at Bear Spring, near the head of Lithodendron in the evening. We had to cross several arroyos, but, being in the dry season, we had nothing to fear from water or marshy soil. The country traversed was desolate and barren, sage-brush and piñon trees abounding, good grazing and water being very scarce. Here and

*Proc. U. S. Nat. Mus., v, 1882, pp. 1, 2.

there mountain peaks stood out in bold relief like great sign-posts to guide the traveler on his way. The water, when found, was in small quantities and alkaline.

Camping at Bear Spring, I turned the mules out to graze and left the men to prepare an early dinner while I rode down the valley to examine the thousands of specimens that lay scattered on each side of the valley along the slopes, which were perhaps 50 feet high, the valley of the *Lithodendron*, at its widest part, being scarcely half a mile. Along the slopes no vegetation whatever was to be seen, wood being very scarce. The soil was composed of clay and sand mostly, and these petrified broken into millions of pieces, lay scattered all adown these slopes. Some of the large fossil trees were well preserved, though the action of heat and cold had broken most of them in sections from 2 to 10 feet long, and some of these must have been immense trees. Measuring the exposed parts of several, they varied from 150 to 200 feet in length, and from 2 to $4\frac{1}{2}$ feet in diameter, the centers often containing most beautiful quartz crystals.

I encountered considerable difficulty in trying to procure two specimens answering to the General's description, and which I thought would please. After finding the larger of the two fossils sent, I could find no mate, the remainder being of a different species, and the exposed part broken in segments too short to answer. Finally I concluded to unearth part of the same specimen, which entered the ground at an angle of about twenty degrees.

Bringing back men and teams, I dug along some 30 feet, finding the second dark specimen, which made a good match, and which saw the light, perhaps, for the first time for ages, though both were parts of the same tree. This was on the right bank of *Lithodendron*, $1\frac{1}{4}$ miles from Bear Spring. I got both fossils loaded on the wagon and camped at the spring that night.

In Colonel Swaine's letter, which probably accompanied the specimens, the following additional information concerning these is given:

Only one of the two specimens obtained from the *Lithodendron* by Lieutenant Hegewald was forwarded to Washington. This is the large dark-colored one. In the place of the second one brought in from the locality of the *Lithodendron* a better specimen was found on the mesa to the north of and adjacent to Fort Wingate, about 2 miles from the flag-staff. This is the smaller and lighter-colored one.

From this it would appear that only two specimens were sent to Washington, but as there are two which, being darker colored, answer well to the description of those obtained at *Lithodendron*, and another lighter one, which is probably the one from the vicinity of Fort Wingate, we may suppose that it was afterwards decided to send all three specimens. Certain it is that there are three here now.

The light colored one, which presumably came from Fort Wingate, N. Mex., is about 11 feet long, and has a diameter at the larger end of $2\frac{1}{2}$ feet, and at the smaller end of about 2 feet. The segment under consideration came evidently from near the base of the trunk, as the large end is broken off just at the point where it begins to enlarge and spread out into the roots. The whole trunk has been subjected to considerable pressure, as is shown by the fact that it is slightly elliptical in cross section. This is further confirmed by the microscopical examination which shows the cells to be slightly compressed. It is perfectly silicified and exteriorly is light gray in color. The interior is very dark, nearly black, due to the presence of iron.

The two remaining specimens, which probably came from *Lithodendron*, in Arizona, are black throughout. The larger is about 8 feet in length and decidedly elliptical in cross-section, the larger end measuring $20\frac{1}{2}$ inches in long and $13\frac{1}{2}$ inches in short diameter, the smaller end 17 inches in long and 12 inches in short diameter. The smaller specimen is 6 feet 4 inches long, and is also considerably compressed, the long and short diameter of the large end being respectively 24 by 16 inches and of the small end 17 by 12 inches.

In regard to the geological horizon to which these fossils belong, Prof. J. W. Powell, who has recently visited this section of the country, inclines to regard them as of Jurassic age. Other evidence points to their Cretaceous age, but until further and more definite knowledge is obtained these views must be regarded as uncertain.

A microscopical examination shows the internal structure of all to have been tolerably well preserved, the cells having suffered but little from the pressure to which the trunks had been subjected. They all belong to the genus *Araucarioxylon*, and probably are of the same species. The two from *Lithodendron* are absolutely identical in structure, but the one from Fort Wingate, as it lacks some of the essential characters, is referred provisionally to the same species. More abundant material may clear up all doubtful points.

The only material that has been examined microscopically from this part of the country, so far as I am able to learn, was that collected by Dr. Baldwin Möllhausen, a German traveler, in the valley of Rio Seco, New Mexico, about the year 1854. These specimens were submitted to Dr. H. R. Göppert, of Berlin, who reported upon them in Möllhausen's *Reise vom Mississippi nach den Küsten der Südsee*, p. 492. Among these specimens Göppert detected a new species, which, in honor of the discoverer, he named *Araucarites Möllhausianus*, but did not indicate any of the characters upon which it was founded, nor can I find that it was ever subsequently described. The specimens belonging to the National Museum represent an undescribed species of *Araucarioxylon* (*Araucarites* Presl.), which may possibly be the *Araucarites Möllhausianus* of Göppert, but it is manifestly impossible to decide this, except by an examination of the original specimen which Göppert says (*l. c.*) is deposited in the mineralogical cabinet of the University of Berlin. I have consequently decided to describe these species as new under the following name:

Araucarioxylon arizonicum, n. sp.

Araucarites möllhausianus? Göpp., in Möllhausen's "Reise," p. 492.

Diagnosis.—Annual ring not apparent to the naked eye, but under the microscope observed to be present, the yearly growths being separated by a layer of 2–5 tangentially compressed cells; tracheids with moderately thick walls, which are provided on the radial sides with a single row of large contiguous pores or rarely with two rows of alternating pores, and on the tangential sides with numerous, separated,

perfectly round, small pores; medullary rays numerous, composed of single series of 1-22 short, superimposed cells; resin ducts (Pl. I, figs. 1-5.)

Transverse section.—The cells in this section are observed to be indicated above, moderately thick walled, and to be separated by intercellular spaces. The largest cells observed have a diameter of $.055^{\text{mm}}$ and the smallest of about $.020^{\text{mm}}$, the average being about $.03^{\text{mm}}$.

Radial section.—As seen in this section the tracheids are observed to be long, and to be provided with numerous pores. These pores bordered pits are usually arranged in a single linear series, and number from 40 to 80 or more on each cell. (Fig. 4.) Usually they touch each other slightly, but sometimes, as indicated in Plate I, figure 4, they become a trifle compressed by actual contact. When these pores are arranged in two series, as illustrated in Plate I, figure 5, they alternate and are slightly, if at all, angled by mutual pressure. The pores are rather large, the average diameter for the outer circle being about $.02^{\text{mm}}$, that for the inner $.0040^{\text{mm}}$.

The medullary rays are composed of short, thin-walled cells, which in some instances, seem to have been provided with small oval pores. They are difficult of demonstration, and it is possible that the granular contents of the cells may give the appearance of exterior marking.

Tangential section.—This section demonstrates the presence of pores or bordered pits on the tangential walls, a circumstance of infrequent occurrence in the genus *Araucarioxylon*. They are much smaller than the pores on the radial walls, and are in a single or rarely in two series. The pores are always separated from each other, sometimes widely. The diameter of the outer circle is about $.0075^{\text{mm}}$, and that of the inner is about $.0027^{\text{mm}}$.

The medullary rays are numerous and range in height from 1 to 10 cells. It is possible that in some rare cases they may be in two series, but this is certainly not commonly the case.

No resin ducts have been detected in any of the sections, their absence being a well-known character of the genus.

An examination of the literature of the subject shows relationship between this and several described species. Thus *Araucarioxylon Eo- deanum* (Göpp.), Kraus (see Göppert, Monog. d. foss. Conif. p. 235, XLV, figs. 6, 7, and Foss. Fl. d. perm. Form. p. 256, Pl. LVII, figs. 1-3) is a well-known species from the Permian of Silesia, very much resembling it, yet there are minor points of difference in the histological elements as well as the great difference in the geological and geographical position. So also with *A. vogesiacum* Kraus, *A. Thuringicum* Kraus, *A. germanicum* Knowlton, MS., and others.
