## INTRODUCTION

Large collections of bird skins are found in many museums and in many countries, but far fewer institutions maintain collections preserved in alcohol or as skeletons, and fewer still attempt to expand these collections through field collecting. The anatomist wishing to study a particular group of birds often finds that specimens are unavailable, or, if available, unusable due to previous use or long storage. The avian anatomical collections of the Peabody Museum of Natural History have recently undergone considerable expansion in a number of geographic and taxonomic areas, and this expansion is likely to continue. The purpose of this paper is to list the birds represented in the alcohol and skeletal

collections, in order to encourage anatomists and others to make use of the specimens. The list represents holdings through the end of 1967.

#### ALCOHOL COLLECTION

##### HISTORICAL OUTLINE

The oldest specimens in the alcohol collection are nestling and adult Leach's Petrels (*Oceanodroma leucorhoa*) collected by A. E. Verrill in 1857. A century later the collection consisted of about 600 specimens. In 1959 the interest of Dr. Philip S. Humphrey, then Assistant Curator of Birds, and of the senior author resulted in a rapid increase in the size and scope of the collection. Dr. S. Dillon Ripley, as Curator of Birds, actively supported the expansion, encouraging field collectors to preserve whole birds and in a few cases making special purchases of specimens. The growth continued under the supervision of Dr. N. Philip Ashmole and has recently been further stimulated by Dr. Charles G. Sibley, the present Director of the Division of Vertebrate Zoology. As of this writing, the collection comprises over 7,000 specimens, of which about 5,000 are whole birds, the remainder being partial specimens.

##### GEOGRAPHIC AND TAXONOMIC REPRESENTATION

Most collections of preserved birds are richest in specimens from the geographical areas visited by the museums' skin collectors and in taxonomic groups of particular interest to the museums' research personnel. The Peabody Museum collections are no exceptions, but special efforts have been made to acquire specimens from areas not previously represented and to obtain a broad representation of the major bird groups. The collections also include specimens of nearly all local birds, migrant and resident. Particular attention has been paid to genera or species which, for one reason or another, are of more than usual anatomical interest. Collectors have been urged to duplicate specimens where possible, with the result that there is an average of 3.2 specimens per species and 6.0 per genus. The geographical regions best represented are North America (about 800 specimens); Mexico and Central America (500); South America (900); southern Europe (125); eastern Africa (1,300); and Madagascar (100).

## PRESERVATION, STORAGE AND RECORDS

Birds are preserved in the field by injection of 10 per cent formalin (4 per cent formaldehyde) into the body cavity and major muscle masses. On reaching the museum the specimens are washed, catalogued and transferred to 70 per cent ethyl alcohol, in which they are stored indefinitely. Most specimens are stored in glass jars of up to one gallon capacity, but fifty-gallon fiber-glass-lined vats and polyethylene tanks are used for the storage of large birds.

The locale and date of collecting are known for nearly all specimens, but weight, age and sex for very few (although sex can be determined by dissection when necessary). Data are maintained in a single master catalogue covering the alcohol collection only, and there is also a systematic card index covering both the alcohol and skeletal collections. The purpose of this index is to provide rapid information on the availability of a desired species and on the status of the specimens.

The philosophy behind an alcohol collection is quite different from that governing the management of skin and skeleton collections. Unlike the latter, which are not expended by proper use, the alcohol collection serves through a type of study which gradually destroys the specimens. With care, a single alcohol specimen may sometimes be used in many anatomical studies, some of which cause it little damage. In some other studies, however, a specimen may be nearly completely "consumed". The growth and use of the Peabody Museum avian anatomical collection has been directed toward making available to any competent anatomist the material which will be most useful to him. Loan requests should be made to the Division of Vertebrate Zoology, stating the genus and species desired and the type of specimen needed. It is undesirable to dissect a whole bird if a skinned "carcass" will do as well. If several species of a genus are useful, they should be listed in order of preference. When specimens of a particular sex, date or locale are of particular interest, order of preference should be stated here, too. Specimens are not normally loaned for dissection unless the borrower has described in some detail the extent and method of dissection and the length of time the specimen will be needed.

Decisions regarding loans are based primarily on the extent of

the proposed dissection and the rarity or replaceability of the specimen. If the dissection is extreme, the specimen is usually sent out on open exchange, or as an outright gift. To date, no request for the loan of specimens has been denied and the amount of material loaned is steadily increasing.

### SKELETON COLLECTION

#### HISTORICAL OUTLINE

The skeleton collection was instituted by O. C. Marsh in the 1870's, primarily as an aid in the identification and analysis of fossil material. Curatorial responsibility rested for many years with the Division of Vertebrate Paleontology, and until recently the growth of the collection has been due largely to the efforts of workers in that department. In recent years, however, many skeletons have been collected by ornithologists at the museum, with the result that a broader representation has been attained, particularly with regard to small birds. Responsibility for the avian skeleton collection is now vested in the Division of Vertebrate Zoology.

#### GEOGRAPHIC AND SYSTEMATIC REPRESENTATION

Having been initiated for the purpose of paleontological reference, the osteological collection is understandably strong in large birds, particularly the Ratites, Anseriformes, Falconiformes and larger members of all orders except the Coraciiformes, Piciformes and Passeriformes. The geographical distribution is broad, due to the purchase of many specimens from Europe (mostly from Gerhard in the 1880's) and the acquisition of much of R. W. Shufeldt's Australian collection. Over two hundred skeletons were obtained in Argentina in 1960-61 by Philip S. Humphrey.

Most of the specimens are accompanied by approximate geographical data, but date of collection, sex, weight and other data are available only for specimens acquired in the last few years.

#### PREPARATION, STORAGE AND RECORDS

Birds acquired in the field are identified, fleshed-off, sexed and dried, then returned to the museum for complete cleaning by

dermestid beetles (*Dermestes vulpinus*). After mild degreasing, when necessary, they are numbered and boxed. No disarticulation is performed, beyond that done by the beetles, nor are the skeletons wired. Fossil, subfossil and extinct birds are stored separately from the reference collection.

The catalogue of avian osteological material is separate from those of the skin and alcohol collections, but skeletons are carried in the systematic card index, along with alcohol specimens.

#### LOAN PROCEDURES

The curating of a skeletal collection is more like that of a skin collection than that of an alcohol collection, in that skeletons are not expended in normal use and it may be assumed that a skeleton will be returned in the same condition as it was in when borrowed. This collection, like most other avian collections, is available for general use, but the long time needed to prepare skeletons for shipment and the bulky nature of storage boxes make it desirable for workers needing large numbers of specimens to make every attempt to visit the museum or to arrange automobile transportation of the specimens.

Requests for loans should be directed to the Division of Vertebrate Zoology. They should state which parts of the skeletons are to be studied, since it is regrettably common for small bones to be missing or broken and these may be just the ones needed for the intended research.

#### SYSTEMATIC LIST

The following list enumerates the avian anatomical specimens, both preserved in alcohol and as skeletons, in the collections of the Peabody Museum of Natural History. The classification of orders and families is that of Wetmore (1960), with the following modifications among the Passeriformes: the Hypositidae are included in the Vangidae (cf. Dorst, 1960); the Chamaeidae are included in the Timaliidae; the Regulidae are included in the Sylviidae; and the Coerebidae are divided between the Thraupidae and the Parulidae, following Beecher (1951). With a few exceptions, the nomenclature employed below the family level is that of Peters' "Checklist of birds of the world" (Peters, 1931-1951;

Mayr and Greenway, eds., 1960, 1962; Mayr and Paynter, eds., 1964; Paynter, ed., 1967). Names used by Peters which are now obsolete have been updated, in most cases following the A.O.U. "Check-list of North American birds" (1957). The New World passerine families not yet covered by the Peters Checklist are treated according to the "Catalogue of birds of the Americas" (Cory and Hellmayr, 1924; Hellmayr, 1927-1938). In the few cases of families which are not covered by either of the above lists and for which no recent family revisions exist, the collections are arranged by a synthesis of regional works. The authority followed for each family is indicated under the family name in the list. Because the purpose of the list is merely to indicate which species are present in the collections, the genera and species are listed alphabetically within the families.

The following abbreviations designate the different types of specimens.

A — Complete alcohol specimen.

a — Skinned "carcass", ie., the portion remaining after the preparation of a study skin. The presence of carcasses is indicated only if there are no complete specimens of the species in the collection.

S — Complete skeleton.

k — Skull only.

‡ — Embryos

\* — Nestlings

† — Partial

The numbers preceding the letters in the list indicate the number of alcohol and skeletal specimens of the species in the collections; where no number is given only one specimen is on hand.
